If the handler action does not complete successfully, and an appropriate handler exists for the condition encountered in the handler action, that condition handler is activated. Otherwise, the condition encountered within the condition handler is unhandled.

**Unhandled conditions:** If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the compound statement containing the failing statement is terminated with an unhandled exception condition.
- If the unhandled condition is a warning or not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

**Considerations for using SIGNAL or RESIGNAL statements with nested compound statements:** If an SQL-procedure-statement specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound (dynamic) statement terminates with the specified exception. This happens even if this condition handler or another condition handler in the same compound (dynamic) statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If a compound-statement is nested in a compound (dynamic) statement, condition handlers in the compound (dynamic) statement may handle the exception from within the compound-statement because those condition handlers are within the scope of the exception.

**Null values in SQL variables:** If the value of an SQL variable is null and it is used in an SQL statement (such as CONNECT or DESCRIBE) that does not allow an indicator variable, an error is returned.

**Uncommitted changes:** Any uncommitted transactional work is scoped to the activation group of the connection in which the dynamic compound statement is run.

**Effect on open cursors:** Upon exit from the compound (dynamic) statement for any reason, all open cursors that are declared in that compound statement are closed.

**Considerations for SQLSTATE and SQLCODE SQL variables:** The compound (dynamic) statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within that compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE
variables were not changed within the compound (dynamic) statement, they contain the same values as when the compound (dynamic) statement was invoked.
CONNECT (type 1)

The CONNECT (type 1) statement connects an activation group within an application process to the identified application server using the rules for remote unit of work. This server is then the current server for the activation group. This type of CONNECT statement is used if RDBCNNMTH(*RUW) was specified on the CRTSQLxxx command.

Differences between the two types of statements are described in "CONNECT (type 1) and CONNECT (type 2) differences" on page 1735. Refer to "Application-directed distributed unit of work" on page 45 for more information about connection states.

Invocation

This statement can only be embedded within an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

CONNECT is not allowed in a trigger or function.

Authorization

The privileges held by the authorization ID of the statement must include communications-level security. (See the section about security in Distributed Database Programming).

If the application server is Db2 for i, the user profile of the person issuing the statement must also be a valid user profile on the application server system, UNLESS:

- User is specified. In this case, the USER clause must specify a valid user profile on the application server system.
- TCP/IP is used with a server authorization entry for the application server. In this case, the server authorization entry must specify a valid user profile on the application server system.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

\[
\text{CONNECT TO server-name variable authorization}\]

authorization:
Description

**TO server-name or variable**
Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

When the CONNECT statement is executed, the specified server name or the server name contained in the variable must identify an application server described in the local directory and the activation group must be in the connectable state.

If the server-name is a local relational database and an authorization-name is specified, it must be the user of the job. If the specified authorization-name is different than the user of the job, an error occurs and the application is left in the unconnected state.

**USER authorization-name or variable**
Identifies the authorization name that will be used to connect to the application server. It can be a global variable if it is qualified with schema name.

If a variable is specified,

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The authorization name must be left-justified within the variable and must conform to the rules of forming an authorization name.
- If the length of the authorization name is less than the length of the variable, it must be padded on the right with blanks.
- The value of the server name must not contain lowercase characters.

**USING password or variable**
Identifies the password that will be used to connect to the application server.

If password is specified as a literal, it must be a character string. The maximum length is 128 characters. It must be left justified. The literal form of the password is not allowed in static SQL or REXX.

If a variable is specified,

- It cannot be a global variable.
- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The password must be left-justified within the variable.
- If the length of the password is less than that of the variable, it must be padded on the right with blanks.
CONNECT (type 1)

RESET
CONNECT RESET is equivalent to CONNECT TO x where x is the local server name.

CONNECT with no operand
This form of the CONNECT statement returns information about the current server and has no effect on connection states, open cursors, prepared statements, or locks. The connection information is returned in the connection information items in the SQL Diagnostics Area (or the SQLCA).

Notes

Successful connection: If the CONNECT statement is successful:
- All open cursors are closed, all prepared statements are destroyed, and all locks are released from the current connection.
- The activation group is disconnected from all current and dormant connections, if any, and connected to the identified application server.
- The name of the application server is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the connection-information-items in the SQL Diagnostics Area.
- Information about the application server is also placed in the SQLERRP and SQLERRD(4) fields of the SQLCA. If the application server is an IBM relational database product, the information in the SQLERRP field has the form $ppp$v$v$rr$rr$mm, where:
  - $ppp$ identifies the product as follows:
    - ARI for Db2 for VM and VSE
    - DSN for Db2 for z/OS
    - QSQ for Db2 for i
    - SQL for all other Db2 products
  - $vv$ is a two-digit version identifier such as '09'
  - $rr$ is a two-digit release identifier such as '01'
  - $mm$ is a one-character modification level such as '0'
For example, if the application server is Version 9 of Db2 for z/OS, the value of SQLERRP is 'DSN09010'.
The SQLERRD(4) field of the SQLCA contains values indicating whether the application server allows committable updates to be performed. For a CONNECT (type 1) statement SQLERRD(4) will always contain the value 1. The value 1 indicates that committable updates can be performed, and the connection:
- Uses an unprotected conversation\(^88\), or
- Is a connection to an application requester driver program using the *RUW connection method, or
- Is a local connection using the *RUW connection method.
- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. Refer to Appendix C, “SQLCA (SQL communication area),” on page 1737.

88. To reduce the possibility of confusion between network connections and SQL connections, in this book the term ‘conversation’ will be used to apply to network connections over TCP/IP as well as over APPC, even though it formally applies only to APPC connections.
Unsuccessful connection: If the CONNECT statement is unsuccessful, the DB2_MODULE_DETECTING_ERROR condition information item in the SQL Diagnostics Area (or the SQLERRP field of the SQLCA) is set to the name of the module at the application requester that detected the error. Note that the first three characters of the module name identify the product. For example, if the application requester is Db2 LUW the first three characters are ‘SQL’.

If the CONNECT statement is unsuccessful because the activation group is not in the connectable state, the connection state of the activation group is unchanged.

If the CONNECT statement is unsuccessful for any other reason:
- The activation group remains in a connectable, but unconnected state
- All open cursors are closed, all prepared statements are destroyed, and all locks are released from all current and dormant connections.

An application in a connectable but unconnected state can only execute the CONNECT or SET CONNECTION statements.

Implicit connect:
- When running in the default activation group, the SQL program implicitly connects to a remote relational database when:
  - The activation group is in a connectable state.
  - The first SQL statement in the first SQL program on the program stack is executed.
- When running in a non-default activation group, the SQL program implicitly connects to a remote relational database when the first SQL statement in the first SQL program for that activation group is executed.

Note: It is a good practice for the first SQL statement executed by an activation group to be the CONNECT statement.

When APPC is used for connecting to an RDB, implicit connect always sends the authorization-name of the application requester job and does not send passwords. If the authorization-name of the application server job is different, or if a password must be sent, an explicit connect statement must be used.

When TCP/IP is used for connecting to an RDB, an implicit connect is not bound by the above restrictions. Use of the ADDSVRAUTE and other -SVRAUTE commands allows one to specify, for a given user under which the implicit (or explicit) CONNECT is done, the remote authorization-name and password to be used in connecting to a given RDB.

In order for the password to be stored with the ADDSVRAUTE or CHGSVRAUTE command, the QRETSVRSEC system value must be set to ‘1’ rather than the default of ‘0’. When using these commands for DRDA connection, it is very important to realize that the value of the RDB name entered into the SERVER parameter must be in UPPER CASE. For more information, see Example 2 under Type 2 CONNECT.

For more information about implicit connect, refer to the SQL Programming topic collection. Once a connection to a relational database for a user profile is established, the password, if specified, may not be validated again on subsequent connections to the same relational database with the same user profile.
Revalidation of the password depends on if the conversation is still active. See the Distributed Database Programming topic collection for more details.

**Connection states:** For a description of connection states, see "Remote unit of work connection management" on page 43. Consecutive CONNECT statements can be executed successfully because CONNECT does not remove the activation group from the connectable state.

A CONNECT to either a current or dormant connection in the application group is executed as follows:

- If the connection identified by the server-name was established using a CONNECT (type 1) statement, then no action is taken. Cursors are not closed, prepared statements are not destroyed, and locks are not released.
- If the connection identified by the server-name was established using a CONNECT (type 2) statement, then the CONNECT statement is executed like any other CONNECT statement.

CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT, COMMIT, DISCONNECT, SET CONNECTION, RELEASE, or ROLLBACK. To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

If any previous current or dormant connections were established using protected conversations, then the CONNECT (type 1) statement will fail. Either, a CONNECT (type 2) statement must be used, or the connections using protected conversations must be ended by releasing the connections and successfully committing.

For more information about connecting to a remote relational database and the local directory, see SQL Programming and the Distributed Database Programming.

**SET SESSION AUTHORIZATION:** If a SET SESSION AUTHORIZATION statement has been executed in the thread, a CONNECT to the local server will fail unless prior to the connect statement, the SYSTEM_USER value is the same as SESSION_USER.

This includes an implicit connect due to invoking a program that specifies ACTGRP(’NEW’).

**Examples**

**Example 1:** In a C program, connect to the application server TOROLAB.

```c
EXEC SQL CONNECT TO TOROLAB;
```

**Example 2:** In a C program, connect to an application server whose name is stored in the variable APP_SERVER (VARCHAR(18)). Following a successful connection, copy the product identifier of the application server to the variable PRODUCT.

```c
void main ()
{
    char product[9] = " ";
    EXEC SQL BEGIN DECLARE SECTION;
    char APP_SERVER[19];
    char username[11];
    char userpass[129];
    EXEC SQL END DECLARE SECTION;
    EXEC SQL INCLUDE SQLCA;
    strcpy(APP_SERVER,"TOROLAB");
    strcpy(username,"JOE");
```
strcpy(userpass,"XYZ1");
EXEC SQL CONNECT TO :APP_SERVER
    USER :username USING :userpass;
if (strncmp(SQLSTATE, "00000", 5) )
    { EXEC SQL GET DIAGNOSTICS CONDITION 1
    product = DB2_PRODUCT_ID; }
...
return;
CONNECT (type 2)

The CONNECT (type 2) statement connects an activation group within an application process to the identified application server using the rules for application directed distributed unit of work. This server is then the current server for the activation group. This type of CONNECT statement is used if RDBCNNMTH(*DUW) was specified on the CRTPSQLxxx command.

Differences between the two types of statements are described in "CONNECT (type 1) and CONNECT (type 2) differences" on page 1735. Refer to "Application-directed distributed unit of work" on page 45 for more information about connection states.

Invocation

This statement can only be embedded in an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

CONNECT is not allowed in a trigger or function.

Authorization

The privileges held by the authorization ID of the statement must include communications-level security. (See the section about security in the Distributed Database Programming topic collection.)

If the application server is Db2 for i, the profile ID of the person issuing the statement must also be a valid user profile on the application server system, UNLESS:

• USER is specified. If USER is specified, the USER clause must specify a valid user profile on the application server system.
• TCP/IP is used with a server authorization entry for the application server. If this is the case, the server authorization entry must specify a valid user profile on the application server system.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

• For the global variable identified in the statement,
  – The READ privilege on the global variable, and
  – The system authority *EXECUTE on the library containing the global variable
• Database administrator authority

Syntax

CONNECT

TO server-name

variable

authorization

RESET

authorization:
Description

**TO server-name or variable**

Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.
- The value of the server name must not contain lowercase characters.

When the CONNECT statement is executed, the specified server name or the server name contained in the variable must identify an application server described in the local directory.

Let S denote the specified server name or the server name contained in the variable. S must not identify an existing connection of the application process.

**USER authorization-name or variable**

Identifies the authorization name that will be used to connect to the application server. It can be a global variable if it is qualified with schema name.

If a variable is specified:

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable. The authorization name must be left-justified within the variable and must conform to the rules of forming an authorization name.
- If the length of the authorization name is less than the length of the variable, it must be padded on the right with blanks.

**USING password or variable**

Identifies the password that will be used to connect to the application server.

If password is specified as a literal, it must be a character string. The maximum length is 128 characters. It must be left justified. The literal form of the password is not allowed in static SQL or REXX.

If a variable is specified:

- It cannot be a global variable.
- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The password must be left-justified within the variable.
- If the length of the password is less than that of the variable, it must be padded on the right with blanks.

**RESET**

CONNECT RESET is equivalent to CONNECT TO x where x is the local server name.
CONNECT (type 2)

CONNECT with no operand

This form of the CONNECT statement returns information about the current server and has no effect on connection states, open cursors, prepared statements, or locks. The connection information is returned in the connection information items in the SQL Diagnostics Area (or the SQLCA).

In addition, the DB2_CONNECTION_STATUS connection information item in the SQL Diagnostics Area (or the SQLERRD(3) field of the SQLCA) will indicate the status of connection for this unit of work. It will have one of the following values:

- 1 - Committable updates can be performed on the connection for this unit of work.
- 2 - No committable updates can be performed on the connection for this unit of work.

Notes

Successful connection: If the CONNECT statement is successful:

- A connection to application server S is created and placed in the current and held states. The previous connection, if any, is placed in the dormant state.
- S is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the connection-information-items in the SQL Diagnostics Area.
- Information about application server S is also placed in the SQLERRP and SQLERRD(4) fields of the SQLCA. If the application server is an IBM relational database product, the information in the SQLERRP field has the form pppvvvrrm, where:
  - ppp identifies the product as follows:
    - ARI for Db2 for VM and VSE
    - DSN for Db2 for z/OS
    - QSQ for Db2 for i
    - SQL for all other Db2 products
  - vv is a two-digit version identifier such as '09'
  - rr is a two-digit release identifier such as '01'
  - m is a one-character modification level such as '0'

For example, if the application server is Version 9 of Db2 for z/OS, the value of SQLERRP is 'DSN09010'.

The SQLERRD(4) field of the SQLCA contains values indicating whether application server S allows committable updates to be performed. Following is a list of values and their meanings for the SQLERRD(4) field of the SQLCA on the CONNECT:

- 1 - committable updates can be performed. Conversation is unprotected.
- 2 - No committable updates can be performed. Conversation is unprotected.
- 3 - It is unknown if committable updates can be performed. Conversation is protected.
- 4 - It is unknown if committable updates can be performed. Conversation is unprotected.
- 5 - It is unknown if committable updates can be performed. The connection is either a local connection or a connection to an application requester driver program.
Additional information about the connection is placed in the SQLERRMC field of the SQLCA. Refer to Appendix C, “SQLCA (SQL communication area),” on page 1737.

Unsuccessful connection: If the CONNECT statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Implicit connect: Implicit connect will always send the authorization-name of the application requester job and will not send passwords. If the authorization-name of the application server job is different or if a password must be sent, an explicit connect statement must be used.

When TCP/IP is used for connecting to an RDB, an implicit connect is not bound by the above restrictions. Use of the ADDSVRAUTE and other -SVRAUTE commands allows one to specify, for a given user under which implicit (or explicit) CONNECT is done, the remote authorization-name and password to be used in connecting to a given RDB.

In order for the password to be stored with the ADDSVRAUTE or CHGSVRAUTE command, the QRETSVRSEC system value must be set to '1' rather than the default of '0'. When using these commands for DRDA connection, it is very important to realize that the value of the RDB name entered into the SERVER parameter must be in UPPER CASE. For more information, see Example 2 under Type 2 CONNECT.

For more information about implicit connect, refer to SQL Programming. Once a connection to a relational database for a user profile is established, the password, if specified, may not be validated again on subsequent connections to the same relational database with the same user profile. Revalidation of the password depends on if the conversation is still active. See Distributed Database Programming for more details.

SET SESSION AUTHORIZATION: If a SET SESSION AUTHORIZATION statement has been executed in the thread, a CONNECT to the local server will fail unless prior to the connect statement, the SYSTEM_USER value is the same as SESSION_USER.

This includes an implicit connect due to invoking a program that specifies ACTGRP(*NEW).

Examples

Example 1: Execute SQL statements at TOROLAB and SVLLAB. The first CONNECT statement creates the TOROLAB connection and the second CONNECT statement places it in the dormant state.

```sql
EXEC SQL CONNECT TO TOROLAB;

(execute statements referencing objects at TOROLAB)

EXEC SQL CONNECT TO SVLLAB;

(execute statements referencing objects at SVLLAB)
```

Example 2: Connect to a remote server specifying a userid and password, perform work for the user and then connect as another user to perform further work.
CONNECT (type 2)

EXEC SQL CONNECT TO SVLLAB USER :AUTHID USING :PASSWORD;

(execute SQL statements accessing data on the server)

EXEC SQL COMMIT;

(set AUTHID and PASSWORD to new values)

EXEC SQL CONNECT TO SVLLAB USER :AUTHID USING :PASSWORD;

(execute SQL statements accessing data on the server)

Example 3: User JOE wants to connect to TOROLAB3 and execute SQL statements under the user ID ANONYMOUS which has a password of SHIBBOLETH. The RDB directory entry for TOROLAB3 specifies *IP for the connection type.

Before running the application, some setup must be done.

This command will be required to allow server security information to be retained in the IBM i operating system, if it has not been previously run:

CHGSYSVAL SYSVAL(QRETSVRSEC) VALUE('1')

This command adds the required server authorization entry:

ADDSVRAUTE USRPRF(JOE) SERVER(TOROLAB3) USRID(ANONYMOUS) + PASSWORD(SHIBBOLETH)

This statement, run under JOE's user profile, will now make the wanted connection:

EXEC SQL CONNECT TO TOROLAB3;

(execute statements referencing objects at TOROLAB3)
The CREATE ALIAS statement defines an alias on a table, partition of a table, view, or member of a database file at the current or remote server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - *USE to the Create DDM File (CRTDDMF) command
  - Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the alias is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

To replace an existing alias, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the alias
  - All authorities needed to DROP the alias
- Database administrator authority

Syntax

```
CREATE OR REPLACE ALIAS alias-name

OR

FOR table-name

(view-name

(partition-name)

(member-name)
```

Description

**OR REPLACE**

Specifies to replace the definition for the alias if one exists at the current server. The existing definition is effectively dropped before the new definition is
CREATE ALIAS

replaced in the catalog with the exception that privileges that were granted on the alias are not affected. This option is ignored if a definition for the alias does not exist at the current server.

**alias-name**

Names the alias. The name, including the implicit or explicit qualifier, must not be the same as an index, table, view, alias or file that already exists at the current server.

If the *alias-name* is qualified, the name can be a two-part or three-part name. The schema name should not be a system schema. If a three-part name is used, the first part must identify a relational database name in the relational database directory.

For more information about connecting to a remote relational database and the local directory, see SQL Programming and the Distributed Database Programming.

If SQL names were specified, the alias will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the alias will be created in the schema that is specified by the qualifier. If not qualified, the alias will be created in the same schema as the table or view for which the alias was created. If the table is not qualified and does not exist at the time the alias is created:

- If the value of the CURRENT SCHEMA special register is *LIBL, the alias will be created in the current library (*CURLIB).
- Otherwise, the alias will be created in the current schema.

If the alias name is not a valid system name, Db2 for i will generate a system name. For information about the rules for generating a name, see “Rules for Table Name Generation” on page 1213.

**FOR table-name or view-name**

Identifies the table or view at the current or remote server for which the alias is to be defined. An alias name cannot be specified (an alias cannot refer to another alias), unless the name refers to an alias on a remote server.

The *table-name* or *view-name* need not identify a table or view that exists at the time the alias is created. If the table or view does not exist when the alias is created, a warning is returned. If the table or view does not exist when the alias is used, an error is returned.

If SQL names were specified and the *table-name* or *view-name* was not qualified, then the qualifier is the implicit qualifier. For more information, see “Naming conventions” on page 54.

If system names were specified and the *table-name* or *view-name* is not qualified and does not exist when the alias is created, the *table-name* or *view-name* is qualified by the library in which the alias is created.

**partition-name**

Identifies a partition of a partitioned table.

If a partition is specified, the alias cannot be used in SQL schema statements. If a partition is not specified, all partitions in the table are included in the alias.

If a partition name is specified, a three-part name should not be specified in the FOR clause. If a three-part name is specified and identifies a different relational database than the relational database of the alias, any attempt to use the alias will fail.
member-name

Identifies a member of a database file. If a member name is not specified and the table is not a partitioned table, "FIRST" is used. If a member name is not specified and the table is a partitioned table, all members (partitions) are used.

If a member is specified, the alias cannot be used in most SQL schema statements. It can be used in CREATE PROCEDURE, CREATE FUNCTION and in a CREATE TABLE with an as-result-table clause.

If a member name is specified, a three-part name should not be specified in the FOR clause. If a three-part name is specified and identifies a different relational database than the relational database of the alias, any attempt to use the alias will fail.

Notes

Alias references: An alias can be defined to reference either the system name or SQL name. Since system names are generated during create processing, it is generally recommended that the SQL name be specified.

However, if the alias specifies a reference to a three-part name and the alias will be used as a DDM file in native commands or native access, the name specified must be the system name.

The Override Database File (OVRDBF) CL command also allows the database manager to process individual members of a database file. Creating an alias over a partition of a table or member of a database file, however, is easier and performs better by eliminating the need to perform the override.

Alias attributes: An alias is created as a special form of a DDM file. Both an alias and a normal DDM file can be used in SQL, but if the alias or DDM file specifies a non-local relational database name, the specified table-name or view-name must be the same as the name of the alias.

An alias created over a distributed table is only created on the current server. For more information about distributed tables, see [DB2 Multisystem](#).

Alias ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the alias is created exists, the owner of the alias is that user profile.
- Otherwise, the owner of the alias is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the alias is the user profile or group user profile of the thread executing the statement.

Alias authority: If SQL names are used, aliases are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, aliases are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the alias is a member of a group profile (GRPPRF keyword) and group authority is specified (GPPAUT keyword), that group profile will also have authority to the alias.

REPLACE rules: When an alias is recreated by REPLACE:
**CREATE ALIAS**

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

**Packages and three-part aliases:** When an application uses three-part name aliases for remote objects and DRDA access, a package for the application program must exist at each location that is specified in the three-part names. A package can be explicitly created using the CRTSQLPKG CL command. If the three-part name alias is referenced and a package does not exist, the database manager will attempt to implicitly create the package.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword SYNONYM can be used as a synonym for ALIAS.

**Examples**

*Example 1:* Create an alias named CURRENT_PROJECTS for the PROJECT table.

```sql
CREATE ALIAS CURRENT_PROJECTS
    FOR PROJECT
```

*Example 2:* Create an alias named SALES_JANUARY on the JANUARY partition of the SALES table. The sales table has 12 partitions (one for each month of the year).

```sql
CREATE ALIAS SALES_JANUARY
    FOR SALES(JANUARY)
```

*Example 3:* Create an alias named REPORTS.SALES for the SALES table in schema REPORTS on relational database USARDB.

```sql
CREATE ALIAS REPORTS.SALES
    FOR USARDB.REPORTS.SALES
```
CREATE FUNCTION

The CREATE FUNCTION statement defines a user-defined function at the current server.

The following types of functions can be defined:

- **External Scalar**
  The function is written in a programming language such as C or Java and returns a scalar value. The external program is referenced by a function defined at the current server along with various attributes of the function. See “CREATE FUNCTION (external scalar)” on page 1012.

- **External Table**
  The function is written in a programming language such as C or Java and returns a set of rows. The external program is referenced by a function defined at the current server along with various attributes of the function. See “CREATE FUNCTION (external table)” on page 1033.

- **Sourced**
  The function is implemented by invoking another function (built-in, external, sourced, or SQL) that already exists at the current server. A sourced function can return a scalar result, or the result of an aggregate function. See “CREATE FUNCTION (sourced)” on page 1053. The function inherits attributes of the underlying source function.

- **SQL Scalar**
  The function is written exclusively in SQL and returns a scalar value. The function body is defined at the current server along with various attributes of the function. See “CREATE FUNCTION (SQL scalar)” on page 1064.

- **SQL Table**
  The function is written exclusively in SQL and returns a set of rows. The function body is defined at the current server along with various attributes of the function. See “CREATE FUNCTION (SQL table)” on page 1079.

**Notes**

**Choosing the schema and function name:** If a qualified function name is specified, the `schema-name` cannot be one of the system schemas (see “Schemas” on page 5). If `function-name` is not qualified, it is implicitly qualified with the default schema name.

The unqualified function name must not be one of the following names reserved for system use even if they are specified as delimited identifiers:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Delim</th>
<th>Delim</th>
<th>Delim</th>
<th>Delim</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>&lt;</td>
<td>&gt;</td>
<td>&gt;=</td>
<td></td>
</tr>
<tr>
<td>&lt;=</td>
<td>&lt;&gt;</td>
<td>~=</td>
<td>~&lt;</td>
<td></td>
</tr>
<tr>
<td>~&lt;</td>
<td>~=</td>
<td>!&lt;</td>
<td>!&gt;</td>
<td></td>
</tr>
<tr>
<td>ALL</td>
<td>FALSE</td>
<td>PERCENTILE_DISC</td>
<td>XMLAGG</td>
<td></td>
</tr>
<tr>
<td>AND</td>
<td>FOR</td>
<td>POSITION</td>
<td>XMLATTRIBUTES</td>
<td></td>
</tr>
<tr>
<td>ANY</td>
<td>FROM</td>
<td>RID</td>
<td>XMLCOMMENT</td>
<td></td>

<td>WHEN</td>
<td></td>
</tr>
</tbody>
</table>

**Defining the parameters:** The input parameters for the function are specified as a list within parenthesis.

The maximum number of parameters allowed in CREATE FUNCTION is 2000.

A function can have no input parameters. In this case, an empty set of parenthesis must be specified, for example:

```
CREATE FUNCTION WOOFER() 
```

The data type of the result of the function is specified in the RETURNS clause for the function.

**Choosing data types for parameters:** When choosing the data types of the input and result parameters for a function, the rules of promotion that can affect the values of the parameters need to be considered. See "Promotion of data types" on page 94. For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC

For portability of functions across platforms that are not Db2 for i, do not use the following data type names, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

**Specifying AS LOCATOR for a parameter:** Passing a locator instead of a value can result in fewer bytes being passed in or out of the function. This can be useful when the value of the parameter is very large. The AS LOCATOR clause specifies that a locator to the value of the parameter is passed instead of the actual value. Specify AS LOCATOR only for parameters that have a LOB or XML data type or a distinct type based on a LOB or XML data type and only when LANGUAGE JAVA is not in effect.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

AS LOCATOR cannot be specified for SQL functions.

**Determining the uniqueness of functions in a schema:** The same name can be used for more than one function in a schema if the function signature of each function is unique. The function signature is the qualified function name combined
with the number and data types of the input parameters. The combination of name, schema name, the number of parameters, and the data type each parameter (without regard for other attributes such as length, precision, scale, or CCSID) must not identify a user-defined function that exists at the current server. The return type has no impact on the determining uniqueness of a function. Two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a schema must not contain two functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, the database manager does not consider any length, precision, or scale attributes in the comparison. The database manager considers the synonyms of data types a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), and DECIMAL(4,3). Furthermore, the character and graphic types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

**Specifying a specific name for a function:** When defining multiple functions with the same name and schema (with different parameter lists), it is recommended that a specific name also be specified. The specific name can be used to uniquely identify the function such as when sourcing on this function, dropping the function, or commenting on the function. However, the function cannot be invoked by its specific name.

The specific name is implicitly or explicitly qualified with a schema name. If a schema name is not specified on CREATE FUNCTION, it is the same as the explicit or implicit schema name of the function name (function-name). If a schema name is specified, it must be the same as the explicit or implicit schema name of the function name. The name, including the schema name must not identify the specific name of another function or procedure that exists at the current server.

If a specific name is not specified, it is set to the function name. If a function or procedure with that specific name already exists, a unique name is generated similar to the rules used to generate unique table names.

**Extending or overriding a built-in function:**

Giving a user-defined function the same name as a built-in function is not a recommended practice unless the functionality of the built-in function needs to be extended or overridden.

- Extending the functionality of existing built-in functions:
CREATE FUNCTION

Create the new user-defined function with the same name as the built-in function, and a unique function signature. For example, a user-defined function similar to the built-in function ROUND that accepts the distinct type MONEY as input rather than the built-in numeric types might be necessary. In this case, the signature for the new user-defined function named ROUND is different from all the function signatures supported by the built-in ROUND function.

• Overriding a built-in function:
Create the new user-defined function with the same name and signature as an existing built-in function. The new function has the same name and data type as the corresponding parameters of the built-in function but implements different logic. For example, a user-defined function similar to the built-in function ROUND that uses different rules for rounding than the built-in ROUND function might be necessary. In this case, the signature for the new user-defined function named ROUND will be the same as a signature that is supported by the built-in ROUND function.

Once a built-in function has been overridden, if the schema for the new function appears in the SQL path before the system schemas, the database manager may choose a user-defined function rather than the built-in function. An application that uses the unqualified function name and was previously successful using the built-in function of that name might fail, or perhaps even worse, appear to run successfully but provide a different result if the user-defined function is chosen by the database manager rather than the built-in function.

The DISTINCT keyword can be passed on the invocation of a user-defined function that is sourced on one of the built-in aggregate functions. For example, assume that MY_AVG is a user-defined function that is sourced on the built-in AVG function. The user-defined function could be invoked with MY_AVG (DISTINCT expression). This results in the underlying built-in AVG function being invoked with the DISTINCT keyword.

Special registers in functions: The settings of the special registers of the invoker are inherited by the function on invocation and restored upon return to the invoker. Special registers may be changed in a function that can execute SQL statements, but these changes do not affect the caller.

Creating a secure function: Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all changes to the user-defined function. Db2 assume that such an audit control procedure is in place for all subsequent ALTER FUNCTION statements.

Invoking other user-defined functions in a secure function: When a secure user-defined function is referenced in an SQL statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, a user authorized who has security administrator authority i needs to ensure that those functions are allowed to access that data and should ensure that a change control audit procedure has been established for all changes to those functions.

MODIFIES SQL DATA and EXTERNAL ACTION functions: If a MODIFIES SQL DATA or EXTERNAL ACTION function is invoked in other than the outermost select list, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

Functions and adopted authority: Fenced functions run in separate threads. If ALLOW PARALLEL is specified for a NOT FENCED function, that function may
also run in a separate thread. Functions that run in separate threads will not run under any adopted authority that might be specified by the invoking application.

**Restore considerations:** When a function's associated program or service program is saved and subsequently restored and the object was updated with the function attributes when the function was created, the saved attributes will be processed and possibly changed during the restore.

If the 'Saved library' (SAVLIB) of the program or service program is different from the 'Restore to library' (RSTLIB), the function's schema name, specific schema name, and the external name may be changed as a result of the restore.

- If the saved function schema name and the library name of the saved object match, the function schema will be changed to the 'Restore to library' (RSTLIB). Otherwise, the function schema name is the saved function schema name.
- The specific schema name is always the same as function schema name.
- If the saved EXTERNAL NAME library and the library name of the saved object match, the EXTERNAL NAME library will be changed to the 'Restore to library' (RSTLIB). Otherwise, the EXTERNAL NAME library is the saved library name. If the saved EXTERNAL NAME library is *LIBL, it will not change.

If the same function signature already exists in the catalog:

- If the external program name or service program name is the same as the one that already exists in the catalog, the information in the catalog for that procedure will be replaced with the saved attributes (including the specific name).
- Otherwise, the saved attributes are not restored, and a warning (SQL9015) is issued.

If the same specific name already exists in the catalog, a warning is issued and a new specific name is generated. Otherwise, the specific name of the function is preserved.
CREATE FUNCTION (external scalar)

This CREATE FUNCTION (external scalar) statement defines an external scalar function at the current server. A user-defined external scalar function returns a single value each time it is invoked.

Invocation

This statement can be embedded in an application program, or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization id of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARAMS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If the external program or service program exists, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the external program or service program that is referenced in the SQL statement:
  - The system authority *EXECUTE on the library that contains the external program or service program.
  - The system authority *EXECUTE on the external program or service program, and
  - The system authority *CHANGE on the program or service program. The system needs this authority to update the program object to contain the information necessary to save/restore the function to another system. If user does not have this authority, the function is still created, but the program object is not updated.
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the function is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

---

89. The GRTOBJAUT CL command must be used to grant these privileges.
To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the service program object associated with the function
  - All authorities needed to DROP the function
  - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View and Corresponding System Authorities When Checking Privileges to a Distinct Type.

### Syntax

```
CREATE FUNCTION function-name
  OR REPLACE
  (
    ,
  )
  RETURNS data-type2 AS LOCATOR data-type3
    CAST FROM data-type4
    AS LOCATOR
    option-list
  SET OPTION-statement
```

**parameter-declaration:**

```
  parameter-name data-type1
    AS LOCATOR
    XML-cast-type
    default-clause
```

**data-type1, data-type2, data-type3, data-type4:**

```
built-in-type
  distinct-type-name
```

**XML-cast-type:**
CREATE FUNCTION (external scalar)

built-in-type:
Notes:

1. The `ccsid-clause` for XML is only allowed for `data-type2` and `data-type3`.

`ccsid-clause`:

```
| CCSID integer | normalize-clause |
```
CREATE FUNCTION (external scalar)

normalize-clause:

- NOT NORMALIZED
- NORMALIZED

default-clause:

- DEFAULT
- NULL
- constant
- special-register
- global-variable
- (expression)

option-list:

- LANGUAGE
  - C
  - C++
  - CL
  - COBOL
  - COBOLLE
  - JAVA
  - PLI
  - RPG
  - RPGLE

- PARAMETER STYLE
  - SQL
  - JAVA
  - GENERAL
  - GENERAL WITH NULLS
  - DB2GENERAL

- NOT DETERMINISTIC
- GLOBAL
- DETERMINISTIC
- STATEMENT

- READS SQL DATA
- CALLED ON NULL INPUT
- RETURNS NULL ON NULL INPUT

- NO SQL
- CONTAINS SQL
- MODIFIES SQL DATA

- INHERIT SPECIAL REGISTERS
- STATIC DISPATCH
- NO DBINFO
- DBINFO

- EXTERNAL ACTION
- FENCED
- NOT FENCED

- NO EXTERNAL ACTION
- NOT FENCED

- PROGRAM TYPE
  - MAIN
  - SUB

- NO FINAL CALL
- FINAL CALL
- ALLOW PARALLEL
- DISALLOW PARALLEL
- SCRATCHPAD
- 100
- integer
CREATE FUNCTION (external scalar)

Notes:
1. This clause and the clauses that follow in the option-list can be specified in any order. Each clause can be specified at most once.

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the function are not affected. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the specific-name and function-name of the new definition must be the same as the specific-name and function-name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

function-name

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in "CREATE FUNCTION" on page 1007.

(parameter-declaration,...)

Specifies the number of input parameters of the function and the data type of each parameter. Each parameter-declaration specifies an input parameter for the function.

The maximum number of parameters depends on the type of language:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs, the maximum is 90.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. In the case of JAVA, numeric parameters other than the DECIMAL and NUMERIC types are not nullable. A runtime error will
CREATE FUNCTION (external scalar)

occur if a null value is input to such a parameter for a CALLED ON NULL INPUT function. For more information, see Defining the parameters in "CREATE FUNCTION" on page 1007.

parameter-name
Names the parameter. Although not required, a parameter name can be specified for each parameter. The name cannot be the same as any other parameter-name in the parameter list.

data-type1
Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type. It cannot be an array type.

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type, see “CREATE TABLE” on page 1159. Some data types are not supported in all languages. For details on the mapping between the SQL data types and host language data types, see Embedded SQL Programming topic collection. Built-in data type specifications can be specified if they correspond to the language that is used to write the user-defined function.

distinct-type-name
Specifies a user-defined distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information on creating a distinct type, see “CREATE TYPE (distinct)” on page 1241.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

Date, time, and timestamp parameters are passed to the procedure as character strings in ISO format.

Any parameter that has an XML type must specify either the XML-cast-type clause or the AS LOCATOR clause.

AS LOCATOR
Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “CREATE FUNCTION” on page 1007.

AS XML-cast-type
Specifies the data type passed to the function for a parameter that is XML type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the function is created according to the
SQL_XML_DATA_CCSID QAQQINI option setting. The default CCSID is 1208. See “XML Values” on page 89 for a description of this option.

default-clause
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “Expressions” on page 174, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created. When the function is invoked, the default will be evaluated using the authority of the invoker.

A default cannot be specified for a parameter of type array.

RETURNS
Specifies the data type for the result of the function. Consider this clause in conjunction with the optional CAST FROM clause.

data-type2
Specifies the data type and attributes of the output.

You can specify any built-in data type (except LONG VARCHAR, LONG VARGRAPHIC, or DataLink) or a distinct type (that is not based on a DataLink). You cannot specify an array type.

If a CCSID is specified,
- If AS LOCATOR is not specified, the result returned is assumed to be encoded in that CCSID.
- If AS LOCATOR is specified and the CCSID of the data the locator points to is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified and the function is not referenced in the outermost select list of a view,
- If AS LOCATOR is not specified, the result returned is assumed to be encoded in the CCSID of the job (or associated graphic CCSID of the job for graphic string return values).
- If AS LOCATOR is specified, the data the locator points to is converted to the CCSID of the job, if the CCSID of the data the locator points to is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

If a CCSID is not specified and the function is referenced in the outermost select list of a view,
- If AS LOCATOR is not specified, the result returned is assumed to be encoded in the CCSID of the associated view column.
- If AS LOCATOR is specified, the data the locator points to is converted to the CCSID of the associated view column, if the CCSID of the data...
the locator points to is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. Specify AS LOCATOR only if the result of the function has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “CREATE FUNCTION” on page 1007.

**data-type3 CAST FROM data-type4**

Specifies the data type and attributes of the function (data-type4) and the data type in which that result is returned to the invoking statement (data-type3). The two data types can be different. For example, for the following definition, the function returns a DOUBLE value, which the database manager converts to a DECIMAL value and then passes to the statement that invoked the function:

```sql
CREATE FUNCTION SQRT (DECIMAL(15,0))
RETURNS DECIMAL(15,0)
CAST FROM DOUBLE
```

The value of data-type4 must not be XML or a distinct type and must be castable to data-type3. The value for data-type3 can be any built-in data type or distinct type. (For information on casting data types, see “Casting between data types” on page 96).

For CCSID information, see the preceding description of data-type2.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. Specify AS LOCATOR only if the result of the function has a LOB data type or a distinct type based on a LOB data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “CREATE FUNCTION” on page 1007.

**LANGUAGE**

Specifies the language interface convention to which the function body is written. All programs must be designed to run in the server’s environment.

If LANGUAGE is not specified, the LANGUAGE is determined from the program attribute information associated with the external program at the time the function is created. The language of the program is assumed to be C if:

- The program attribute information associated with the program does not identify a recognizable language
- The program cannot be found

C

The external program is written in C.
The external program is written in C++.

The external program is written in CL or ILE CL.

The external program is written in COBOL.

The external program is written in ILE COBOL.

The external program is written in JAVA. The database manager will call the user-defined function, which must be a public static method of the specified Java class.

When LANGUAGE JAVA is specified, specify the EXTERNAL NAME clause with a valid external-java-routine-name. Do not specify LANGUAGE JAVA when SCRATCHPAD, FINAL CALL, or DBINFO is specified.

The external program is written in PL/I.

The external program is written in RPG.

The external program is written in ILE RPG.

PARAMETER STYLE

Specifies the conventions used for passing parameters to and returning the values from functions:

SQL

All applicable parameters are passed. The parameters are defined to be in the following order:

• \( n \) parameters for the input parameters that are specified for the function.
• A parameter for the result of the function.
• \( n \) parameters for indicator variables for the input parameters.
• A parameter for the indicator variable for the result.
• A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the function. The SQLSTATE returned can either be:
  – the SQLSTATE from the last SQL statement executed in the external program,
  – an SQLSTATE that is assigned by the external program.

  The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the function.

• A VARCHAR(517) input parameter for the fully qualified function name.
• A VARCHAR(128) input parameter for the specific name.
• A VARCHAR(1000) output parameter for the message text.

When control is returned to the invoking program, the message text can be found in the 6th token of the SQLERRMC field of the SQLCA. Only a portion of the message text is available. For information on the layout of the message data in the SQLERRMC, see the replacement data descriptions for message SQL0443 in message file QSQLMSG. The
complete message text can be retrieved using the GET DIAGNOSTICS statement. For more information, see “GET DIAGNOSTICS” on page 1388.

- Zero to three optional parameters:
  - A structure (consisting of an INTEGER followed by a CHAR(n)) input and output parameter for the scratchpad, if SCRATCHPAD was specified on the CREATE FUNCTION statement.
  - An INTEGER input parameter for the call type, if FINAL CALL was specified on the CREATE FUNCTION statement.
  - A structure for the dbinfo structure, if DBINFO was specified on the CREATE FUNCTION statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

**DB2GENERAL**

This parameter style is used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a Java class. All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- A parameter for the result of the function.

DB2GENERAL is only allowed when the LANGUAGE is JAVA.

**GENERAL**

All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.

Note that the result is returned as a value of a C value returning function.

For example:

```java
return_val func(parameter-1, parameter-2, ...)
```

GENERAL is only allowed when EXTERNAL NAME identifies a service program.

**GENERAL WITH NULLS**

All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- An additional argument is passed for an indicator variable array.
- A parameter for the indicator variable for the result.

Note that the result is returned as a value of a C value returning function.

For example:

```java
return_val func(parameter-1, parameter-2, ...)
```

GENERAL WITH NULLS is only allowed when EXTERNAL NAME identifies a service program.
JAVA
Specifies that the function will use a parameter passing convention that conforms to the Java language and ISO/IEC FCD 9075-13:2003, Information technology - Database languages - SQL - Part 13: Java Routines and Types (SQL/JRT) specification. All applicable parameters are passed. The parameters are defined to be in the following order:
• The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.

Note that the result is returned as a value of a C value returning function. For example:
return_val func(parameter-1, parameter-2, ...)

JAVA is only allowed when the LANGUAGE is JAVA.

Note that the language of the external function determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NUL-terminated strings. For more information, see the SQL Programming topic collection. For Java routines, see the IBM Developer Kit for Java topic collection.

SPECIFIC specific-name
Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in "CREATE FUNCTION" on page 1007.

GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC
Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a function that is not deterministic is one that generates random numbers.

A function that is not deterministic might return incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

NOT DETERMINISTIC should be specified if the function contains a reference to a special register, a non-deterministic function, or a sequence.

GLOBAL DETERMINISTIC
Specifies that the function always returns the same result each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. The query optimizer may choose to cache global deterministic scalar function results. An example of a global deterministic function is a function that calculates the square root of the input argument.

90. If the result of the function contains sensitive data, consider using STATEMENT DETERMINISTIC or the DETERMINISTIC_UDF_SCOPE QAQQINI option or create the function NOT DETERMINISTIC to prevent inadvertent access to the result. For more information, see the Database Performance and Query Optimization topic collection.
CREATE FUNCTION (external scalar)

**STATEMENT DETERMINISTIC**
Specifies that the function might not return the same result each time that
the function is invoked with the same input arguments, but multiple
invocations of the function within a single SQL statement are considered
deterministic. The query optimizer will not cache statement deterministic
scalar function results. \(^1\) An example of a statement deterministic function
is a function that performs currency conversion.

**CONTAINS SQL, READS SQL DATA, MODIFIES SQL DATA, or NO SQL**
Specifies the classification of SQL statements and nested routines that the
function can execute. The database manager verifies that the SQL statements
issued by the function, and all routines locally invoked by the function, are
consistent with this specification. The verification is not performed when
nested remote routines are invoked. For the classification of each statement, see
Appendix B, “Characteristics of SQL statements,” on page 1725. The default is
READS SQL DATA. This option is ignored for parameter default expressions.

**READS SQL DATA**
Specifies that the function can execute statements with a data access
classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The
function cannot execute SQL statements that modify data.

**NO SQL**
Specifies that the function can execute only SQL statements with a data
access classification of NO SQL.

**CONTAINS SQL**
Specifies that the function can execute only SQL statements with a data
access classification of CONTAINS SQL or NO SQL. The function cannot
execute any SQL statements that read or modify data.

**MODIFIES SQL DATA**
The function can execute any SQL statement except those statements that
are not supported in any function.

**RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**
Specifies whether the function is called if any of the input arguments is null at
execution time. CALLED ON NULL INPUT is the default.

**RETURNS NULL ON INPUT**
Specifies that the function is not invoked if any of the input arguments is
null. The result is the null value.

**CALLED ON NULL INPUT**
Specifies that the function is to be invoked, if any, or all, argument values
are null. This specification means that the function must be coded to test
for null argument values. The function can return a null or nonnull value.

**INHERIT SPECIAL REGISTERS**
Specifies that existing values of special registers are inherited upon entry to the
function.

**STATIC DISPATCH**
Specifies that the function is dispatched statically. All functions are statically
dispatched.

\(^1\) The DETERMINISTIC, UDF SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC
function. For more information, see the Database Performance and Query Optimization topic collection.
**NO DBINFO or DBINFO**

Specifies whether additional status information is passed when the function is invoked. The default is NO DBINFO.

**NO DBINFO**

Specifies that no additional information is passed.

**DBINFO**

Specifies that the database manager should pass a structure containing status information to the function. Table 79 contains a description of the DBINFO structure. Detailed information about the DBINFO structure can be found in include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

DBINFO is only allowed with PARAMETER STYLE SQL or PARAMETER STYLE DB2GENERAL.

</tbody>
</table>
EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION
Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another function that has an external action.

NO EXTERNAL ACTION
The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

FENCED or NOT FENCED
Specifies whether the external function runs in an environment that is isolated from the database manager environment. FENCED is the default.

FENCED
The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to the function. However, the cursors in one thread are independent of the cursors in any other threads which reduces the possibility of cursor name conflicts.

NOT FENCED
The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls to the function. Since cursors can be kept open, the cursor position will also be preserved between calls to the function. However, cursor names may conflict since the UDF is now running in the same thread as the invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

PROGRAM TYPE MAIN or PROGRAM TYPE SUB
This parameter is allowed for compatibility with other products. It indicates whether the routine’s external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

PROGRAM TYPE MAIN
Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

PROGRAM TYPE SUB
Specifies that the routine executes as a procedure in a service program. The external program must be a *SRVPGM object.

NO FINAL CALL or FINAL CALL
Specifies whether a final call is made to the function. A final call enables the function to free any system resources that it has acquired. A final call is useful
when the function has been defined with the SCRATCHPAD keyword and the function acquires system resources and stores them in the scratchpad. The default is NO FINAL CALL.

**NO FINAL CALL**

Specifies that a final call is not made to the function. The function does not receive an additional argument that specifies the type of call.

**FINAL CALL**

Specifies that a final call is made to the function. To differentiate between final calls and other calls, the function receives an additional argument that specifies the type of call.

**FINAL CALL** is only allowed with PARAMETER STYLE SQL or PARAMETER STYLE DB2GENERAL.

The types of calls are:

**First Call**

Specifies the first call to the function for this reference to the function in this SQL statement. A first call is a normal call. SQL arguments are passed and the function is expected to return a result.

**Normal Call**

Specifies that SQL arguments are passed and the function is expected to return a result.

**Final Call**

Specifies the last call to the function to enable the function to free resources. A final call is not a normal call. If an error occurs, the database manager attempts to make the final call.

A final call occurs at these times:

- **End of statement:** When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- **End of a parallel task:** When the function is executed by parallel tasks.
- **End of transaction:** When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

Some functions that use a final call can receive incorrect results if parallel tasks execute the function. For example, if a function sends a note for each final call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that have inappropriate actions when executed in parallel.

If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends. If a commit occurs at the end of a parallel task, a final call is made regardless of whether a cursor defined as WITH HOLD is open.

Commitable operations should not be performed during a FINAL CALL, because the FINAL CALL may occur during a close that is invoked as part of a COMMIT operation.

**ALLOW PARALLEL or DISALLOW PARALLEL**

Specifies whether the function can be run in parallel.
CREATE FUNCTION (external scalar)

The default is DISALLOW PARALLEL if one or more of the following clauses are specified: NOT DETERMINISTIC, EXTERNAL ACTION, FINAL CALL, MODIFIES SQL DATA, or SCRATCHPAD. Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL
Specifies that the database manager can consider parallelism for the function. The database manager is not required to use parallelism on the SQL statement that invokes the function or on any SQL statement issued from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, MODIFIES SQL DATA, SCRATCHPAD, and FINAL CALL for considerations that apply to specification of ALLOW PARALLEL.

DISALLOW PARALLEL
Specifies that the database manager must not use parallelism for the function.

NO SCRATCHPAD or SCRATCHPAD
Specifies whether the function requires a static memory area.

NO SCRATCHPAD
Specifies that the function does not require a persistent memory area.

SCRATCHPAD integer
Specifies that the function requires a persistent memory area of length integer. The integer can range from 1 to 16,000,000. If the memory area is not specified, the size of the area is 100 bytes. If parameter style SQL is specified, a pointer is passed following the required parameters that points to a static storage area. If ALLOW PARALLEL is specified, a memory area is allocated for each user-defined function reference in the statement. If DISALLOW PARALLEL is specified, only 1 memory area will be allocated for the function.

The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```
SELECT A, UDFX(A)
FROM TABLEB
WHERE UDFX(A) > 103 OR UDFX(A) < 19
```

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the DISALLOW PARALLEL clause for functions that will not work correctly with parallelism.

SCRATCHPAD is only allowed with PARAMETER STYLE SQL or PARAMETER STYLE DB2GENERAL.

EXTERNAL
Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.
If *external-program-name* is not specified, the external program name is assumed to be the same as the function name.

**NAME external-program-name**

Specifies the program, service program, or Java class that will be executed when the function is invoked in an SQL statement. The name must identify a program, service program, or Java class that exists at the application server at the time the function is invoked. If the naming option is *SYS and the name is not qualified:

- The current path will be used to search for the program at the time the function is invoked.
- *LIBL will be used to search for the program or service program at the time COMMENT, GRANT, LABEL, or REVOKE operations are performed on the function.

The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

The program, service program, or Java class need not exist at the time the function is created, but it must exist at the time the function is invoked.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statements are not allowed in the external program of the function.

**NOT SECURED or SECURED**

Specifies whether the function is considered secure for row access control and column access control.

**NOT SECURED**

Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

**SECURED**

Specifies that the function is considered secure for row access control and column access control. This option can be used for an external function that is written in C, C++, ILE RPG, ILE COBOL, ILE CL, or Java. The program or service program must exist when the CREATE FUNCTION statement is executed.

A function must be defined as secure when it is referenced in a row permission or a column mask.

**SET OPTION-statement**

Specifies the options that will be used for parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see [“SET OPTION” on page 1575](#).

The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. Other options are accepted but will be ignored.
CREATE FUNCTION (external scalar)

Notes

General considerations for defining user-defined functions: See "CREATE FUNCTION" on page 1007 for general information on defining user-defined functions.

REPLACE rules: When an external function is recreated by REPLACE:
- Any existing comment or label is discarded.
- If a different external program is specified:
  - Authorized users are not copied to the new program.
  - Journal auditing is not changed.
- Otherwise:
  - Authorized users are maintained. The object owner will not change.
  - Current journal auditing is not changed.

Creating the function: When an external function associated with an ILE external program or service program is created, an attempt is made to save the function's attributes in the associated program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The attributes can be saved for external functions subject to the following restrictions:
- The external program library must not be QSYS.
- The external program must exist when the CREATE FUNCTION statement is issued.
  If system naming is specified and the external program name is not qualified, the external program must be found in the library list.
- The external program must be an ILE *PGM or *SRVPGM object.
- The external program must not already contain attributes for 32 routines.

If the object cannot be updated, the function will still be created.

Invoking the function: When an external function is invoked, it runs in whatever activation group was specified when the external program or service program was created. However, ACTGRP(*CALLER) should normally be used so that the function runs in the same activation group as the calling program. ACTGRP(*NEW) is not allowed.

LANGUAGE JAVA functions always run in the default activation group (*DFACTGRP). Caution should be used when writing MODIFIES SQL DATA Java functions. Since changes performed by the Java function are performed in the default activation group, transaction problems may occur if the invoker runs in a new activation group (*NEW).

Notes for Java functions: To be able to run Java functions, you must have the IBM IBM Developer Kit for Java (5770-JV1) installed on your system. Otherwise, an SQLCODE of -443 will be returned and a CPDB521 message will be placed in the job log.

If an error occurs while running a Java function, an SQLCODE of -443 will be returned. Depending on the error, other messages may exist in the job log of the job where the function was run.
Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords SIMPLE CALL can be used as a synonym for GENERAL.
- The keyword DB2GENRL may be used as a synonym for DB2GENERAL.
- The value DB2SQL may be used as a synonym for SQL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Examples

Example 1: Assume an external function program in C is needed that implements the following logic:

\[
\text{result} = 2 \times \text{input} - 4
\]

The function should return a null value if and only if one of the input arguments is null. The simplest way to avoid a function call and get a null result when an input value is null is to specify RETURNS NULL ON NULL INPUT on the CREATE FUNCTION statement. The following statement defines the function, using the specific name MINENULL1.

```
CREATE FUNCTION NTEST1 (SMALLINT)
RETURNS SMALLINT
EXTERNAL NAME NTESTMOD
SPECIFIC MINENULL1
LANGUAGE C
DETERMINISTIC
NO SQL
FENCED
PARAMETER STYLE SQL
RETURNS NULL ON NULL INPUT
NO EXTERNAL ACTION
```

The program code:

```
void nudf1
(int *input, /* ptr to input argument */
 int *output, /* ptr to output argument */
 short *input_ind, /* ptr to input indicator */
 short *output_ind, /* ptr to output indicator */
 char sqlstate[6], /* sqlstate */
 char fname[140], /* fully qualified function name */
 char finst[129], /* function specific name */
 char msgtext[71]) /* msg text buffer */
{
 if (*input_ind == -1)
  *output_ind = -1;
 else
  *output = 2{*input}-4;
  *output_ind = 0;
}
return;
```
CREATE FUNCTION (external scalar)

Example 2: Assume that a user wants to define an external function named CENTER. The function program will be written in C. The following statement defines the function, and lets the database manager generate a specific name for the function. The name of the program containing the function body is the same as the name of the function, so the EXTERNAL clause does not include 'NAME external-program-name'.

```
CREATE FUNCTION CENTER (INTEGER, FLOAT)
    RETURNS FLOAT
    LANGUAGE C
    DETERMINISTIC
    NO SQL
    PARAMETER STYLE SQL
    NO EXTERNAL ACTION
```

Example 3: Assume that user McBride (who has database administrator authority) wants to define an external function named CENTER in the SMITH schema. McBride plans to give the function specific name FOCUS98. The function program uses a scratchpad to perform some one-time only initialization and save the results. The function program returns a value with a DOUBLE data type. The following statement written by user McBride defines the function and ensures that when the function is invoked, it returns a value with a data type of DECIMAL(8,4).

```
CREATE FUNCTION SMITH.CENTER (DOUBLE, DOUBLE, DOUBLE)
    RETURNS DECIMAL
    CAST FROM DOUBLE
    EXTERNAL NAME CMOD
    SPECIFIC FOCUS98
    LANGUAGE C
    DETERMINISTIC
    NO SQL
    FENCED
    PARAMETER STYLE SQL
    NO EXTERNAL ACTION
    SCRATCHPAD
    NO FINAL CALL
```

Example 4: The following example defines a Java user-defined function that returns the position of the first vowel in a string. The user-defined function is written in Java, is to be run fenced, and is the FINDVWL method of class JAVAUDFS.

```
CREATE FUNCTION FINDV (VARCHAR(32000))
    RETURNS INTEGER
    FENCED
    LANGUAGE JAVA
    PARAMETER STYLE JAVA
    EXTERNAL NAME 'JAVAUDFS.FINDVWL'
    NO EXTERNAL ACTION
    CALLED ON NULL INPUT
    DETERMINISTIC
    NO SQL
```
CREATE FUNCTION (external table)

This CREATE FUNCTION (external table) statement defines an external table function at the current server. The function returns a result table.

An external user-defined table function may be used in the FROM clause of a subselect, and returns a table to the subselect by returning one row each time it is invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization id of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If the external program or service program exists, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the external program or service program that is referenced in the SQL statement:
  - The system authority *EXECUTE on the library that contains the external program or service program.
  - The system authority *EXECUTE on the external program or service program, and
  - The system authority *CHANGE on the program or service program. The system needs this authority to update the program object to contain the information necessary to save/restore the function to another system. If user does not have this authority, the function is still created, but the program object is not updated.
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the function is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority
CREATE FUNCTION (external table)

To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the service program object associated with the function
  - All authorities needed to DROP the function
  - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View and Corresponding System Authorities When Checking Privileges to a Distinct Type.

**Syntax**

```sql
CREATE FUNCTION function-name
  OR REPLACE
  (
    parameter-declaration
  )
  RETURNS TABLE
  (column-name data-type AS LOCATOR) AS LOCATOR
  option-list
  SET OPTION-statement
```

**parameter-declaration:**

```sql
parameter-name data-type1 AS LOCATOR default-clause
```

**data-type1, data-type2:**

```sql
built-in-type
```

**XML-cast-type:**
CREATE FUNCTION (external table)

built-in-type:
## CREATE FUNCTION (external table)

- NOT SECURED
- SECURED
```

Notes:
1. This clause and the clauses that follow in the option-list can be specified in any order. Each clause can be specified at most once.

Description

**OR REPLACE**

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the function are not affected. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the **specific-name** and **function-name** of the new definition must be the same as the **specific-name** and **function-name** of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

**function-name**

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is "LIBL, the function will be created in the current library ("CURLIB).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the Schema and Function Name in CREATE FUNCTION on page 1007.

**(parameter-declaration,...)**

Specifies the number of input parameters of the function and the data type of each parameter. Each **parameter-declaration** specifies an input parameter for the function.

The maximum number of parameters depends on the type of language:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs, the maximum is 90.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language. A function can have zero or more input parameters. There must be one entry in the list for each parameter.
that the function expects to receive. All the parameters for a function are input parameters and are nullable. In the case of JAVA, numeric parameters other than the DECIMAL and NUMERIC types are not nullable. A runtime error will occur if a null value is input to such a parameter for a CALLED ON NULL INPUT function. For more information, see Defining the parameters in "CREATE FUNCTION" on page 1007.

**parameter-name**

Names the parameter. Although not required, a parameter name can be specified for each parameter. The name cannot be the same as any other parameter-name in the parameter list.

**data-type**

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type. It cannot be an array type.

**built-in-type**

Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE" on page 1159. Some data types are not supported in all languages. For details on the mapping between the SQL data types and host language data types, see Embedded SQL Programming topic collection. Built-in data type specifications can be specified if they correspond to the language that is used to write the user-defined function.

**distinct-type-name**

Specifies a user-defined distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information about creating a distinct type, see "CREATE TYPE (distinct)" on page 1241.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

Parameters with a large object (LOB) data type are not supported when PARAMETER STYLE JAVA is specified.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

Date, time, and timestamp parameters are passed to the procedure as character strings in ISO format.

Any parameter that has an XML type must specify either the XML-cast-type clause or the AS LOCATOR clause.

**AS LOCATOR**

Specifies that the input parameter is a locator to the value rather than the actual value. You can specify AS LOCATOR only if the input parameter has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in "CREATE FUNCTION" on page 1007.

**AS XML-cast-type**

Specifies the data type passed to the function for a parameter that is XML
CREATE FUNCTION (external table)

Type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the function is created according to the SQL_XML_DATA_CCSID QAQQINI option setting. The default CCSID is 1208. See "XML Values" on page 89 for a description of this option.

**default-clause**

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in "Expressions" on page 174 that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created. When the function is invoked, the default will be evaluated using the authority of the invoker.

A default cannot be specified for a parameter of type array.

**RETURNS TABLE**

Specifies that the output of the function is a table. The parenthesis that follow this clause enclose a list of names and the data types of the columns of the result table.

The maximum number of result columns depends on the type of language. Assume that the number of parameters is \( N \).

- For JAVA and ILE programs and service programs, there must be no more than 8000 - \( N \) columns.
- For OPM programs, there must be no more than 125 - \( N \) columns.

**column-name**

Specifies the name of a column of the output table. Do not specify the same name more than once.

**data-type2**

Specifies the data type of the column. The column is nullable.

You can specify any built-in data type (except LONG VARCHAR, LONG VARGRAPHIC, or DataLink) or a distinct type (that is not based on a DataLink). You cannot specify an array type.

If a DATE or TIME is specified, the table function must return the date or time in ISO format.

If a CCSID is specified,
- If AS LOCATOR is not specified, the result returned is assumed to be encoded in that CCSID.
- If AS LOCATOR is specified and the CCSID of the data the locator points to is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified,
CREATE FUNCTION (external table)

- If AS LOCATOR is not specified, the result returned is assumed to be encoded in the CCSID of the job (or associated graphic CCSID of the job for graphic string return values).
- If AS LOCATOR is specified, the data the locator points to is converted to the CCSID of the job, if the CCSID of the data the locator points to is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

AS LOCATOR
Specifies that the function returns a locator to the value for the column rather than the actual value. You can specify AS LOCATOR only for a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “CREATE FUNCTION” on page 1007.

LANGUAGE
The language clause specifies the language of the external program.

If LANGUAGE is not specified, the LANGUAGE is determined from the program attribute information associated with the external program at the time the function is created. The language of the program is assumed to be C if:
- The program attribute information associated with the program does not identify a recognizable language
- The program cannot be found

C
The external program is written in C.

C++
The external program is written in C++.

CL
The external program is written in CL or ILE CL.

COBOL
The external program is written in COBOL.

COBOLLE
The external program is written in ILE COBOL.

JAVA
The external program is written in JAVA. The database manager will call the user-defined function as a method in a Java class.

PL/I
The external program is written in PL/I.

RPG
The external program is written in RPG.

RPGLE
The external program is written in ILE RPG.

PARAMETER STYLE
Specifies the conventions used for passing parameters to and returning the values from functions:
CREATE FUNCTION (external table)

DB2GENERAL
This parameter style is used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a Java class. All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- The next M parameters are the result columns of the function that are specified on the RETURNS TABLE clause.

DB2GENERAL is only allowed when the LANGUAGE is JAVA.

SQL
All applicable parameters are passed. The parameters are defined to be in the following order:

- The first N parameters are the input parameters that are specified on the CREATE FUNCTION statement.
- The next M parameters are the result columns of the function that are specified on the RETURNS TABLE clause.
- N parameters for indicator variables for the input parameters.
- M parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause.
- A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the function. The SQLSTATE returned either be:
  - the SQLSTATE from the last SQL statement executed in the external program,
  - an SQLSTATE that is assigned by the external program.
    The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the function.
- A VARCHAR(517) input parameter for the fully qualified function name.
- A VARCHAR(128) input parameter for the specific name.
- A VARCHAR(1000) output parameter for the message text.
- A structure (consisting of an INTEGER followed by a CHAR(n)) input and output parameter for the scratchpad, if SCRATCHPAD was specified on the CREATE FUNCTION statement.
- An INTEGER input parameter for the call type.
- A structure for the dbinfo structure, if DBINFO was specified on the CREATE FUNCTION statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

Note that the language of the external function determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NUL-terminated strings. For more information, see the SQL Programming topic collection. For Java routines, see the IBM Developer Kit for Java topic collection.
**SPECIFIC specific-name**

Specifies a unique name for the function. For more information on specific names, see “Creating a specific name for a function in CREATE FUNCTION” on page 1007.

**GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

**NOT DETERMINISTIC**

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a table function that is not deterministic is one that references special registers, non-deterministic functions, or a sequence in a way that affects the table function result table.

**GLOBAL DETERMINISTIC**

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. The query optimizer may choose to cache global deterministic function results.

**STATEMENT DETERMINISTIC**

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments, but multiple invocations of the function within a single SQL statement are considered deterministic. The query optimizer will not cache statement deterministic function results.

**CONTAINS SQL, READS SQL DATA, MODIFIES SQL DATA, or NO SQL**

Specifies the classification of SQL statements and nested routines that the function can execute. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the function, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see Appendix B, “Characteristics of SQL statements,” on page 1725. The default is READS SQL DATA. This option is ignored for parameter default expressions.

**READS SQL DATA**

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

**NO SQL**

Specifies that the function can execute only SQL statements with a data access classification of NO SQL.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute any SQL statements that read or modify data.

---

92. The DETERMINISTIC_UDF_SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC function. For more information, see the Database Performance and Query Optimization topic collection.
### CREATE FUNCTION (external table)

**MODIFIES SQL DATA**

The function can execute any SQL statement except those statements that are not supported in any function.

**RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**

Specifies whether the function is called if any of the input arguments is null at execution time. CALLED ON NULL INPUT is the default.

**RETURNS NULL ON NULL INPUT**

Specifies that the function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows.

**CALLED ON NULL INPUT**

Specifies that the function is to be invoked, if any argument values are null. This specification means that the function must be coded to test for null argument values. The function can return an empty table, depending on its logic.

**INHERIT SPECIAL REGISTERS**

Specifies that existing values of special registers are inherited upon entry to the function.

**STATIC DISPATCH**

Specifies that the function is dispatched statically. All functions are statically dispatched.

**NO DBINFO or DBINFO**

Specifies whether additional status information is passed when the function is invoked. The default is NO DBINFO.

**NO DBINFO**

Specifies that no additional information is passed.

**DBINFO**

Specifies that the database manager should pass a structure containing status information to the function. Table 80 contains a description of the DBINFO structure. Detailed information about the DBINFO structure can be found in sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

#### Table 80. DBINFO fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relational database</td>
<td>VARCHAR(128)</td>
<td>The name of the current server.</td>
</tr>
<tr>
<td>Authorization ID</td>
<td>VARCHAR(128)</td>
<td>The run-time authorization ID.</td>
</tr>
</tbody>
</table>
### Table 80. DBINFO fields (continued)

<table>
<thead>

<td>VARCHAR(128)</td>
<td>• Base table name</td>
</tr>
<tr>
<td></td>
<td>VARCHAR(128)</td>
<td>• Column name</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If the user-defined function is not on the right-hand side of a SET clause in an UPDATE statement, these fields are blank.</td>
</tr>
<tr>
<td>Version and release</td>
<td>CHAR(8)</td>
<td>The version, release, and modification level of the database manager.</td>
</tr>
<tr>
<td>Platform</td>
<td>INTEGER</td>
<td>The server’s platform type.</td>
</tr>
<tr>
<td>Number of table function column list entries</td>
<td>SMALLINT</td>
<td>The number of non-zero entries in the table function column list specified in the &quot;Table function column list&quot; field below.</td>
</tr>
<tr>
<td>Reserved</td>
<td>CHAR(24)</td>
<td>Reserved for future use.</td>
</tr>
</tbody>
</table>
## CREATE FUNCTION (external table)

### Table 80. DBINFO fields (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table function column list</td>
<td>Pointer (16 Bytes)</td>
<td>This field is a pointer to an array of short integers which is dynamically allocated by the database manager. Only the first ( n ) entries, where ( n ) is specified in the “Number of table function column list entries” field, are of interest, ( n ) may be equal to 0, and is less than or equal to the number of result columns defined for the function in the RETURNS TABLE clause. The values correspond to the ordinal numbers of the columns which this statement needs from the table function. A value of 1 means the first defined result column, 2 means the second defined result column, and so on. The values may be in any order. Note that ( n ) could be equal to zero for a statement that is similar to SELECT COUNT(*) FROM TABLE(TF(...)) AS QQ, where no actual column values are needed by the query. This array represents an opportunity for optimization. The function need not return all values for all the result columns of the table function. Only a subset of the values may be needed in a particular context, and these are the columns identified (by number) in the array. Since this optimization may complicate the function logic, the function can choose to return every defined column.</td>
</tr>
</tbody>
</table>

### EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

### EXTERNAL ACTION

Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another function that has an external action.

### NO EXTERNAL ACTION

The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

### FENCED or NOT FENCED

Specifies whether the external function runs in an environment that is isolated from the database manager environment. FENCED is the default.

### FENCED

The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to the function. However, the cursors in one thread are independent of the cursors in any other threads which reduces the possibility of cursor name conflicts.

### NOT FENCED

The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls to the function. Since cursors can be kept open, the cursor position will
also be preserved between calls to the function. However, cursor names may conflict since the UDF is now running in the same thread as the invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

**PROGRAM TYPE MAIN or PROGRAM TYPE SUB**

This parameter is allowed for compatibility with other products. It indicates whether the routine’s external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

**PROGRAM TYPE MAIN**

Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

**PROGRAM TYPE SUB**

Specifies that the routine executes as a procedure in a service program. The external program must be a *SRVPGM object.

**NO FINAL CALL or FINAL CALL**

Specifies whether a separate first call and final call are made to the function. To differentiate between types of calls, the function receives an additional argument that specifies the type of call. For table functions, the call-type argument is always present (regardless of whether FINAL CALL or NO FINAL CALL is in effect), and it indicates first call, open call, fetch call, close call, or final call.

With NO FINAL CALL, the database manager will only make three types of calls to the table function: open, fetch and close. However, if FINAL CALL is specified, then in addition to open, fetch and close, a first call and a final call can be made to the table function.

A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the SCRATCHPAD keyword and the function acquires system resources and stores them in the scratchpad. The default is NO FINAL CALL.

**NO FINAL CALL**

Specifies that separate first and final calls are not made to the function. However, the open, fetch, and close calls are still made to the function, and the table function always receives an additional argument that specifies the type of call.

**FINAL CALL**

Specifies that separate first and final calls are made to the function. It also controls when the scratchpad is re-initialized.

The types of calls are:

**First Call**

Specifies the first call to the function for this reference to the function in this SQL statement.

**Open Call**

Specifies a call to open the table function result in this SQL statement.

**Fetch Call**

Specifies a call to fetch a row from the table function in this SQL statement.
CREATE FUNCTION (external table)

Close Call
Specifies a call to close the table function result in this SQL statement.

Final Call
Specifies the last call to the function to enable the function to free resources. If an error occurs, the database manager attempts to make the final call.

A final call occurs at these times:
- *End of statement*: When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- *End of transaction*: When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends.

Committable operations should not be performed during a FINAL CALL, because the FINAL CALL may occur during a close invoked as part of a COMMIT operation.

ALLOW PARALLEL or DISALLOW PARALLEL
Specifies whether the function can be run in parallel.

The default is DISALLOW PARALLEL if one or more of the following clauses are specified: NOT DETERMINISTIC, EXTERNAL ACTION, FINAL CALL, MODIFIES SQL DATA, or SCRATCHPAD. Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL
Specifies that the database manager can consider parallelism for the function. The database manager is not required to use parallelism on the SQL statement that invokes the function or on any SQL statement issued from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, MODIFIES SQL DATA, SCRATCHPAD, and FINAL CALL for considerations that apply to specification of ALLOW PARALLEL.

DISALLOW PARALLEL
Specifies that the database manager must not use parallelism for the function.

NO SCRATCHPAD or SCRATCHPAD
Specifies whether the function requires a static memory area.

NO SCRATCHPAD
Specifies that the function does not require a persistent memory area.

SCRATCHPAD integer
Specifies that the function requires a persistent memory area of length integer. The integer can range from 1 to 16,000,000. If the memory area is not specified, the size of the area is 100 bytes. If parameter style SQL is specified, a pointer is passed following the required parameters that points to a static storage area. Only 1 memory area will be allocated for the function.

The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example,
assuming that function UDFX was defined with the SCRATCHPAD keyword, two scratchpads are allocated for the two references to UDFX in the following SQL statement:

```sql
SELECT A.C1, B.C1
FROM TABLE(UDFX(:hv1)) AS A, TABLE(UDFX(:hv1)) AS B
```

**EXTERNAL**

Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.

If `external-program-name` is not specified, the external program name is assumed to be the same as the function name.

**NAME** `external-program-name`

Specifies the program, service program, or Java class that will be executed when the function is invoked in an SQL statement. The name must identify a program, service program, or Java class that exists at the application server at the time the function is invoked. If the naming option is `*SYS and the name is not qualified:

- The current path will be used to search for the program at the time the function is invoked.
- `*LIBL will be used to search for the program or service program at the time COMMENT, GRANT, LABEL, or REVOKE operations are performed on the function.

The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

The program, service program, or Java class need not exist at the time the function is created, but it must exist at the time the function is invoked.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statements are not allowed in the external program of the function.

**CARDINALITY** `bigint`

Specifies an estimate of the expected number of rows to be returned by the function for the database manager to use during optimization. `bigint` must be in the range from 0 to 9,223,372,036,854,775,807 inclusive. The database manager assumes a finite value if CARDINALITY is not specified.

A table function that returns a row every time it is called and never returns the end-of-table condition has infinite cardinality. A query that invokes such a function and requires an eventual end-of-table condition before it can return any data will not return unless interrupted. Table functions that never return the end-of-table condition should not be used in queries involving DISTINCT, GROUP BY, or ORDER BY.

**NOT SECURED or SECURED**

Specifies whether the function is considered secure for row access control and column access control.

**NOT SECURED**

Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.
**SECURED**

Specifies that the function is considered secure for row access control and column access control. This option can be used for an external function that is written in C, C++, ILE RPG, ILE COBOL, ILE CL, or Java. The program or service program must exist when the CREATE FUNCTION statement is executed.

A function must be defined as secure when it is referenced in a row permission or a column mask.

**SET OPTION**-statement

Specifies the options that will be used parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see [“SET OPTION” on page 1575](#).

The following options are used when processing default value expressions: ALWCPYCTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. Other options are accepted but will be ignored.

**Notes**

**General considerations for defining user-defined functions:** See [“CREATE FUNCTION” on page 1007](#) for general information about defining user-defined functions.

**REPLACE rules:** When an external function is recreated by REPLACE:

- Any existing comment or label is discarded.
- If a different external program is specified:
  - Authorized users are not copied to the new program.
  - Journal auditing is not changed.
- Otherwise:
  - Authorized users are maintained. The object owner will not change.
  - Current journal auditing is not changed.

**Creating the function:** When an external function associated with an ILE external program or service program is created, an attempt is made to save the function’s attributes in the associated program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The attributes can be saved for external functions subject to the following restrictions:

- The external program library must not be SYSIBM, QSYS, or QSYS2.
- The external program must exist when the CREATE FUNCTION statement is issued.
  - If system naming is specified and the external program name is not qualified, the external program must be found in the library list.
- The external program must be an ILE *PGM or *SRVPGM object.
- The external program must not already contain attributes for 32 routines.
If the object cannot be updated, the function will still be created.

**Invoking the function:** When an external function is invoked, it runs in whatever activation group was specified when the external program or service program was created. However, ACTGRP(*CALLER) should normally be used so that the function runs in the same activation group as the calling program. ACTGRP(*NEW) is not allowed.

LANGUAGE JAVA functions always run in the default activation group (*DFTACTGRP). Caution should be used when writing MODIFIES SQL DATA Java functions. Since changes performed by the Java function are performed in the default activation group, transaction problems may occur if the invoker runs in a new activation group (*NEW).

**Notes for Java functions:** To be able to run Java functions, you must have the IBM IBM Developer Kit for Java (5770-JV1) installed on your system. Otherwise, an SQLCODE of -443 will be returned and a CPDB521 message will be placed in the job log.

If an error occurs while running a Java function, an SQLCODE of -443 will be returned. Depending on the error, other messages may exist in the job log of the job where the function was run.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The value DB2GENRL may be used as a synonym for DB2GENERAL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.
- The keywords PARAMETER STYLE DB2SQL may be used as a synonym for PARAMETER STYLE SQL.

**Example**

The following creates a table function written to return a row consisting of a single document identifier column for each known document in a text management system. The first parameter matches a given subject area and the second parameter contains a given string.

Within the context of a single session, the UDF will always return the same table, and therefore it is defined as DETERMINISTIC. Note the RETURNS clause which defines the output from DOCMATCH. FINAL CALL must be specified for each table function. Although the size of the output for DOCMATCH is highly variable, CARDINALITY 20 is a representative value, and is specified to help the optimizer.

```
CREATE FUNCTION DOCMATCH (VARCHAR(30), VARCHAR(255))
    RETURNS TABLE (DOCID CHAR(16))
    EXTERNAL NAME 'MYLIB/RAJIV(UDFMATCH)'
    LANGUAGE C
    PARAMETER STYLE SQL
```
CREATE FUNCTION (external table)

NO SQL
DETERMINISTIC
NO EXTERNAL ACTION
NOT FENCED
SCRATCHPAD
FINAL CALL
DISALLOW PARALLEL
CARDINALITY 20
This CREATE FUNCTION (sourced) statement defines a user-defined function, based on another existing scalar or aggregate function, at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If the source function is a user-defined function, the authorization ID of the statement must include at least one of the following for the source function:

- The EXECUTE privilege on the function
- Database administrator authority

To create a sourced function, the privileges held by the authorization ID of the statement must also include at least one of the following:

- The following system authorities:
  - *USE to the Create Service Program (CRTSRVPGM) command or
  - *USE to the Create Program (CRTPGM) command
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the function is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority
CREATE FUNCTION (sourced)

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View, Corresponding System Authorities When Checking Privileges to a Function or Procedure, and Corresponding System Authorities When Checking Privileges to a Distinct Type.

Syntax

```
CREATE FUNCTION function-name (parameter-declaration) [
  RETURNS data-type2 AS LOCATOR SPECIFIC qualified-specific-name
  SOURCE function-name (parameter-type SPECIFIC qualified-specific-name
    SET OPTION-statement

parameter-declaration:
  parameter-name data-type1 AS LOCATOR default-clause

data-type1, data-type2, data-type3:
  built-in-type distinct-type-name
```

Notes:
1. The RETURNS, SPECIFIC, and SOURCE clauses can be specified in any order.

built-in-type:
**CREATE FUNCTION (sourced)**

**normalize-clause:**

```
NOT NORMALIZED
NORMALIZED
```

**default-clause:**

```
DEFAULT NULL
```

- `constant`
- `special-register`
- `global-variable`
- `(expression)`

**parameter-type:**

```
data-type3 AS LOCATOR
```

**Description**

**function-name**

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

If the function is sourced on an existing function to enable the use of the existing function with a distinct type, the name can be the same name as the existing function. In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in “CREATE FUNCTION” on page 1007.

**(parameter-declaration,...)**

Specifies the number of input parameters of the function and the data type of each parameter. Each parameter-declaration specifies an input parameter for the function. A maximum of 2000 parameters can be specified. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. In the case of JAVA, numeric parameters other than the DECIMAL and NUMERIC types are not nullable. A runtime error will occur if a null value is input to such a parameter for a CALLED ON NULL INPUT function. For more information, see Defining the parameters in “CREATE FUNCTION” on page 1007.
parameter-name
Names the parameter. Although not required, a parameter name can be specified for each parameter. The name cannot be the same as any other parameter-name in the parameter list.

data-type
Specifies the data type of the parameter. The data type can be a built-in data type or a distinct data type. It cannot be an array type.

Any valid SQL data type may be used, provided that it is castable to the type of the corresponding parameter of the function identified in the SOURCE clause (for information, see “Casting between data types” on page 96). However, this checking does not guarantee that an error will not occur when the function is invoked. For more information, see Considerations for invoking a sourced user-defined function.

built-in-type
The data type of the input parameter is a built-in data type. See “CREATE TABLE” on page 1159 for a more complete description of each built-in data type.

distinct-type-name
The data type of the input parameter is a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). See “CREATE TYPE (distinct)” on page 1241 for more information.

If the name of the distinct type is specified without a schema name, the database manager resolves the schema name by searching the schemas in the SQL path.

DataLinks are not allowed for functions sourced on external functions.

If a CCSID is specified, the parameter is converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

AS LOCATOR
Specifies that the input parameter is a locator to the value rather than the actual value. You can specify AS LOCATOR only if the input parameter has a LOB data type or a distinct type based on a LOB data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “CREATE FUNCTION” on page 1007.

default-clause
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “Expressions” on page 174 that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.
CREATE FUNCTION (sourced)

All objects referenced in a default expression must exist when the function is created.

A default cannot be specified for a parameter of type array.

RETURNS
Specifies the result of the function.

data-type2
Specifies the data type of the column. The column is nullable. The data type can be a built-in data type (except LONG VARCHAR, LONG VARGRAPHIC, or a DataLink) or distinct type (that is not based on a DataLink). It cannot be an array type.

Any valid SQL data type can be used provided it is castable from the result type of the source function. (For information about casting data types, see “Casting between data types” on page 96) However, this checking does not guarantee that an error will not occur when this new function is invoked. For more information, see Considerations for invoking a sourced user-defined function.

AS LOCATOR
Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified. The AS LOCATOR clause is not allowed for functions sourced on SQL functions.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “CREATE FUNCTION” on page 1007.

SPECIFIC qualified-specific-name
Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in “CREATE FUNCTION” on page 1007.

SOURCE
Specifies that the new function is being defined as a sourced function. A sourced function is implemented by another function (the source function). The function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function. The source function must not be any of the following built-in functions (If a particular syntax is shown, only the indicated form cannot be specified.):

- ARRAY_AGG
- BINARY when more than one argument is specified
- BLOB when more than one argument is specified
- CARDINALITY
- CHAR when more than one argument is specified
- CLOB when more than one argument is specified
CREATE FUNCTION (sourced)

- COALESCE
- CONTAINS
- DATAPARTITIONNAME
- DATAPARTITIONNUM
- DBCLOB when more than one argument is specified
- DBPARTITIONNAME
- DBPARTITIONNUM
- DECFLOAT when more than one argument is specified
- DECIMAL when more than one argument is specified
- DECRYPT_BIN when more than one argument is specified
- DECRYPT_BINARY when more than one argument is specified
- DECRYPT_BIT when more than one argument is specified
- DECRYPT_CHAR when more than one argument is specified
- DECRYPT_DB when more than one argument is specified
- EXTRACT
- GRAPHIC when more than one argument is specified
- HASH
- HASHED_VALUE
- LAND
- LOR
- MAX
- MAX_CARDINALITY
- MIN
- NODENAME
- NODENUMBER
- PARTITION
- PERCENTILE_CONT
- PERCENTILE_DISC
- POSITION
- RAISE_ERROR
- RID
- RRN
- SCORE
- SECOND when more than one argument is specified
- STRIP
- SUBSTRING
- TIMESTAMP when the second argument is an integer
- TIMESTAMP_FORMAT when more than two arguments are specified
- TRANSLATE when more than one argument is specified
- TRIM
- TRIM_ARRAY
- VALUE
- VARBINARY when more than one argument is specified
- VARCHAR when more than one argument is specified
- VARGRAPHIC when more than one argument is specified
CREATE FUNCTION (sourced)

- VERIFY_GROUP_FOR_USER when more than two arguments are specified
- XMLAGG
- XMLATTRIBUTES
- XMLCOMMENT
- XMLCONCAT
- XMLDOCUMENT
- XMLELEMENT
- XMLFOREST
- XMLGROUP
- XMLNAMESPACES
- XMPARSE
- XMLPI
- XMLROW
- XMLSERIALIZE
- XMLTEXT
- XMLVALIDATE
- XOR
- XSLTRANSFORM
- ZONED when more than one argument is specified

`function-name`
Identifies the function to be used as the source function by its function name. The source function can be defined with any number of parameters. If more than one function is defined with the specified name in the specified or implicit schema, an error is returned.

If an unqualified `function-name` is specified, the SQL path is used to locate the function. The database manager selects the first schema that has only one function with this name on which the user has EXECUTE authority. An error is returned if a function is not found, or if the database manager encounters a schema that has more than one function with this name.

`function-name (parameter-type, ...)`
Identifies the function to be used as the source function by its function signature, which uniquely identifies the function. The `function-name (parameter-type,...)` must identify a function with the specified signature at the current server. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If `function-name()` is specified, the function identified must have zero parameters.

To use a built-in function as the source function, this syntax variation must be used.

`function-name`
Identifies the name of the source function. If an unqualified name is specified, the schemas of the SQL path are searched. Otherwise, the database manager searches for the function in the specified schema.
**parameter-type,...**

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

Empty parentheses are allowed for some data types that are specified in this context. For data types that have a length, precision or scale attribute, use one of the following specifications:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or CCSID attribute, specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified. If AS LOCATOR is specified and a length is explicitly specified, the data type length is ignored.

For more information on the AS LOCATOR clause, see Specifying AS LOCATOR for a parameter in “CREATE FUNCTION” on page 1007.

**SPECIFIC qualified-specific-name**

Identifies the function to be used as the source function by its specific name. The qualified-specific-name must identify a specific function that exists in the specified schema.

**SET OPTION-statement**

Specifies the options that will be used for parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see SET OPTION” on page 1575. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMP, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. Other options are accepted but will be ignored.
The number of input parameters in the function that is being created must be the same as the number of parameters in the source function. If the data type of each input parameter is not the same as or castable to the corresponding parameter of the source function, an error occurs. The data type of the final result of the source function must match or be castable to the result of the sourced function.

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

Notes

General considerations for defining user-defined functions: See "CREATE FUNCTION" on page 1007 for general information about defining user-defined functions.

Function ownership: If SQL names were specified:
- If a user profile with the same name as the schema into which the function is created exists, the owner of the function is that user profile.
- Otherwise, the owner of the function is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the function is the user profile or group user profile of the thread executing the statement.

Function authority: If SQL names are used, functions are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, functions are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the function is a member of a group profile (GRPPRF keyword) and group authority is specified (GRP AUT keyword), that group profile will also have authority to the function.

Considerations for invoking a sourced user-defined function: When a sourced function is invoked, each argument to the function is assigned to the associated parameter defined for the function. The values are then cast (if necessary) to the data type of the corresponding parameters of the underlying function. An error can occur either in the assignment or in the cast. For example: an argument passed on input to a function that matches the data type and length or precision attributes of the parameter for the function might not be castable if the corresponding parameter of the underlying source function has a shorter length or less precision. It is recommended that the data types of the parameters of a sourced function be defined with attributes that are less than or equal to the attributes of the corresponding parameters of the underlying function.

The result of the underlying function is assigned to the RETURNS data type of the sourced function. The RETURNS data type of the underlying function might not be
castable to the RETURNS data type of the source function. This can occur when
the RETURNS data type of this new source function has a shorter length or less
precision than the RETURNS data type of the underlying function. For example, an
error would occur when function A is invoked assuming the following functions
exist. Function A returns an INTEGER. Function B is a sourced function, is defined
to return a SMALLINT, and the definition references function A in the SOURCE
clause. It is recommended that the RETURNS data type of a sourced function be
defined with attributes that are the same or greater than the attributes defined for
the RETURNS data type of the underlying function.

Considerations when the function is based on a user-defined function: If the
sourced function is based directly or indirectly on an external scalar function, the
sourced function inherits the attributes of the external scalar function. This can
involve several layers of sourced functions. For example, assume that function A is
sourced on function B, which in turn is sourced on function C. Function C is an
external scalar function. Functions A and B inherit all of the attributes for function
C.

The sourced function inherits the secure attribute from the user-defined function is
it directly based on. A sourced function based on a built-in function is always
secure.

Creating the function: When a sourced function is created, a small service
program object is created that represents the function. When this service program
is saved and restored to another system, the attributes from the CREATE
FUNCTION statement are automatically added to the catalog on that system.

Examples

Example 1: Assume that distinct type HATSIZE is defined and is based on the
built-in data type INTEGER. An AVG function could be defined to compute the
average hat size of different departments. Create a sourced function that is based
on built-in function AVG.

```
CREATE FUNCTION AVG (HATSIZE)
RETURNS HATSIZE
SOURCE AVG (INTEGER)
```

The syntax of the SOURCE clause includes an explicit parameter list because the source function is a built-in function.

When distinct type HATSIZE was created, two cast functions were generated,
which allow HATSIZE to be cast to INTEGER for the argument and INTEGER to
be cast to HATSIZE for the result of the function.

Example 2: After Smith created the external scalar function CENTER in his schema,
there is a need to use this function, function, but the invocation of the function
needs to accept two INTEGER arguments instead of one INTEGER argument and
one DOUBLE argument. Create a sourced function that is based on CENTER.

```
CREATE FUNCTION MYCENTER (INTEGER, INTEGER)
RETURNS DOUBLE
SOURCE SMITH.CENTER (INTEGER, DOUBLE);
```
CREATE FUNCTION (SQL scalar)

This CREATE FUNCTION (SQL scalar) statement creates an SQL function at the current server. The function returns a single result.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see Privileges necessary to create in a schema.
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

If the SECURED attribute is specified, or the function is secure and OR REPLACE is specified:

- The authorization ID of the statement must have security administrator authority. See Administrative authority” on page 18.

To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the service program object associated with the function
  - All authorities needed to DROP the function
  - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
• Database administrator authority

For information about the system authorities corresponding to SQL privileges, see

Corresponding System Authorities When Checking Privileges to a Table or View

and

Corresponding System Authorities When Checking Privileges to a Distinct Type

CREATE FUNCTION (SQL scalar)

SQL-routine-body

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the function are not affected. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the specific-name and function-name of the new definition must be the same as the specific-name and function-name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

function-name

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the function will be created in the current library (*CURLIB).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in “CREATE FUNCTION” on page 1007.

(parameter-declaration,...)

Specifies the number of input parameters of the function and the data type of each parameter. Each parameter-declaration specifies an input parameter for the function. A maximum of 2000 parameters can be specified. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. For more information, see Defining the parameters in “CREATE FUNCTION” on page 1007.

parameter-name

Names the parameter. The name is used to refer to the parameter within the body of the function. The name cannot be the same as any other parameter-name in the parameter list.

data-type1

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct data type.
built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE" on page 1159.

distinct-type-name
Specifies a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information about creating a distinct type, see "CREATE TYPE (distinct)" on page 1241.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

array-type-name
Specifies an array type.

If the name of the array type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter is converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

A parameter that is an array of XML or LOB type is read only.

default-clause
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in "Expressions" on page 174, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created.

A default cannot be specified for a parameter of type array.

RETURNS
Specifies the result of the function.

data-type
Specifies the expression that is to be returned for the function. The result data type of the expression must be assignable (using storage assignment rules) to the data type that is defined in the RETURNS clause. For more information, see "Assignments and comparisons" on page 99.

You can specify any built-in data type (except LONG VARCHAR, or LONG VARGRAPHIC), a distinct type, or an array type.

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified, the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is encoded in a different CCSID. To
avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

**LANGUAGE SQL**

Specifies that this is an SQL function.

**SPECIFIC specific-name**

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in [“CREATE FUNCTION” on page 1007](#).

**GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

**NOT DETERMINISTIC**

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a function that is not deterministic is one that generates random numbers.

A function that is not deterministic might return incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

NOT DETERMINISTIC should be specified if the function contains a reference to a special register, a non-deterministic function, or a sequence.

**GLOBAL DETERMINISTIC**

Specifies that the function always returns the same result each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. The query optimizer may choose to cache global deterministic scalar function results. An example of a global deterministic function is a function that calculates the square root of the input argument.

**STATEMENT DETERMINISTIC**

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments, but multiple invocations of the function within a single SQL statement are considered deterministic. The query optimizer will not cache statement deterministic scalar function results. An example of a statement deterministic function is a function that performs currency conversion.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an

---

93. If the result of the function contains sensitive data, consider using STATEMENT DETERMINISTIC or the DETERMINISTIC_UDF_SCOPE QAQQINI option or create the function NOT DETERMINISTIC to prevent inadvertent access to the result. For more information, see the [Database Performance and Query Optimization](#) topic collection.

94. The DETERMINISTIC_UDF_SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC function. For more information, see the [Database Performance and Query Optimization](#) topic collection.
object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

EXTERNAL ACTION
Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another function that has an external action.

NO EXTERNAL ACTION
The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

CONTAINS SQL, READS SQL DATA, or MODIFIES SQL DATA
Specifies the classification of SQL statements and nested routines that the function can execute. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the function, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see Appendix B, “Characteristics of SQL statements,” on page 1725. The default is READS SQL DATA. This option applies to any parameter default expressions.

READS SQL DATA
Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

CONTAINS SQL
Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute any SQL statements that read or modify data.

MODIFIES SQL DATA
The function can execute any SQL statement except those statements that are not supported in any function.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT
Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON INPUT
Specifies that the function is not invoked if any of the input arguments is null. The result is the null value.

CALLED ON NULL INPUT
Specifies that the function is to be invoked if any or all argument values are null. This specification means that the function must be coded to test for null argument values. The function can return a null or nonnull value.

INHERIT SPECIAL REGISTERS
Specifies that existing values of special registers are inherited upon entry to the function.

STATIC DISPATCH
Specifies that the function is dispatched statically. All functions are statically dispatched.
CREATE FUNCTION (SQL scalar)

DISALLOW DEBUG MODE, ALLOW DEBUG MODE, or DISABLE DEBUG MODE
Indicates whether the function is created so it can be debugged by the Unified Debugger. If DEBUG MODE is specified, a DBGVIEW option in the SET OPTION statement must not be specified.

DISALLOW DEBUG MODE
The function cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the function is DISALLOW, the function can be subsequently altered to change the debug mode attribute.

ALLOW DEBUG MODE
The function can be debugged by the Unified Debugger. When the DEBUG MODE attribute of the function is ALLOW, the function can be subsequently altered to change the debug mode attribute.

DISABLE DEBUG MODE
The function cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the function is DISABLE, the function cannot be subsequently altered to change the debug mode attribute.

If FENCED or ALLOW PARALLEL is specified for the function, the DEBUG MODE option will be ignored. DISALLOW DEBUG MODE will be used.

If DEBUG MODE is not specified, but a DBGVIEW option in the SET OPTION statement is specified, the function cannot be debugged by the Unified Debugger, but may be debugged by the system debug facilities. If neither DEBUG MODE nor a DBGVIEW option is specified, the debug mode used is from the CURRENT DEBUG MODE special register.

FENCED or NOT FENCED
Specifies whether the SQL function runs in an environment that is isolated from the database manager environment. FENCED is the default.

FENCED
The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to the function. However, the cursors in one thread are independent of the cursors in any other threads which reduces the possibility of cursor name conflicts.

NOT FENCED
The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls to the function. Since cursors can be kept open, the cursor position will also be preserved between calls to the function. However, cursor names may conflict since the UDF is now running in the same thread as the invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

ALLOW PARALLEL or DISALLOW PARALLEL
Specifies whether the function can be run in parallel.

The default is DISALLOW PARALLEL if one or more of the following clauses are specified: NOT DETERMINISTIC, EXTERNAL ACTION, or MODIFIES SQL DATA. Otherwise, ALLOW PARALLEL is the default.

ALLOW PARALLEL
Specifies that the database manager can consider parallelism for the
function. The database manager is not required to use parallelism on the SQL statement that invokes the function or on any SQL statement issued from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, and MODIFIES SQL DATA for considerations that apply to specification of ALLOW PARALLEL.

**DISALLOW PARALLEL**
Specifies that the database manager must not use parallelism for the function.

**CONCURRENT ACCESS RESOLUTION**
Specifies whether the database manager should wait for data that is in the process of being updated. DEFAULT is the default.

**DEFAULT**
Specifies that the concurrent access resolution is not explicitly set for this function. The value that is in effect when the function is invoked will be used.

**WAIT FOR OUTCOME**
Specifies that the database manager is to wait for the commit or rollback of data in the process of being updated.

**USE CURRENTLY COMMITTED**
Specifies that the database manager is to use the currently committed version of the data when encountering data that is in the process of being updated.

When the lock contention is between a read transaction and a delete or update transaction, the clause is applicable to scans with isolation level CS (but not for CS KEEP LOCKS).

**SYSTEM_TIME SENSITIVE**
Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default.

**YES**
References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**NO**
References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**NOT SECURED or SECURED**
Specifies whether the function is considered secure for row access control and column access control.

**NOT SECURED**
Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

**SECURED**
Specifies that the function is considered secure for row access control and column access control.
CREATE FUNCTION (SQL scalar)

A function must be defined as secure when it is referenced in a row permission or a column mask.

WRAPPED obfuscated-statement-text

Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

SET OPTION-statement

Specifies the options that will be used to create the function. These options also apply to any default value expressions. For example, to create a debuggable function, the following statement could be included:

```
SET OPTION DBGVIEW = +SOURCE
```

The default values for the options depend on the options in effect at create time. For information about the , see "SET OPTION" on page 1575.

The options CNULRQD, CNULIGN, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMP, DECRESULT, DFTRDCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLSS, TIMFMT, and TIMSEP.

SQL-routine-body

Specifies a single SQL-procedure-statement, including a compound statement. See Chapter 8, “SQL control statements,” on page 1645 for more information about defining SQL functions.

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statement is not allowed in a function.

If the SQL-routine-body is a compound statement, it must contain at least one RETURN statement and a RETURN statement must be executed when the function is called.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL table) with a REPLACE keyword are not allowed in an SQL-routine-body.

Notes

General considerations for defining user-defined functions: For general information about defining user-defined functions, see "CREATE FUNCTION" on page 1007.

SQL path and function resolution: Resolution of function invocations inside the function body is done according to the SQL path that is in effect for the CREATE FUNCTION statement and does not change after the function is created.

Function ownership: If SQL names were specified:

- If a user profile with the same name as the schema into which the function is created exists, the owner of the function is that user profile.
- Otherwise, the owner of the function is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the function is the user profile or group user profile of the thread executing the statement.
**Function authority:** If SQL names are used, functions are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, functions are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the function is a member of a group profile (GRPPRF keyword) and group authority is specified (GRP AUT keyword), that group profile will also have authority to the function.

**REPLACE rules:** When a function is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

If the function is replaced and the function signature or result data type is altered, the results from any function, materialized query table, procedure, trigger, or view that references the function may be unpredictable. Any referenced objects should be recreated.

**Creating the function:** When an SQL function is created, the database manager creates a temporary source file that will contain C source code with embedded SQL statements. A *SRVPGM object is then created using the CRTSRVPGM command. The SQL options used to create the service program are the options that are in effect at the time the CREATE FUNCTION statement is executed. The service program is created with ACTGRP(*CALLER).

When an SQL function is created, the function's attributes are stored in the created service program object. If the *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The specific name is used to determine the name of the source file member and *SRVPGM object. If the specific name is a valid system name, it will used as the name of member and program. If the member already exists, it will be overlaid. If a program already exists in the specified library, a unique name is generated using the rules for generating system table names. If the specific name is not a valid system name, a unique name is generated using the rules for generating system table names.

**Invoking the function:** When an SQL function is invoked, it runs in the activation group of the calling program.

If a function is specified in the select-list of a select-statement and if the function specifies EXTERNAL ACTION or MODIFIES SQL DATA, the function will only be invoked for each row returned. Otherwise, the UDF may be invoked for rows that are not selected.

**Inline functions:** When an SQL scalar function is inlined, instead of invoking the function as part of a query, the expression in the RETURN statement of the function may be copied (inlined) into the query itself. Such a function is called an *inline function*. A scalar function is an *inline function* if:

- The SQL function is global deterministic.
- The SQL-routine-body contains only a RETURN statement.
- No input parameter is an array type.
- The data type of the result is not XML or an array type.
CREATE FUNCTION (SQL scalar)

- All objects referenced in the function exist when the function is created.
- The SQL-routine-body does not contain a common table expression that references an input parameter.
- The SQL-routine-body does not contain a nested table expression without a preceding LATERAL keyword that references an input parameter.

An inline function is only copied (inlined) into a query if:
- The query is eligible for the SQL Query Engine (SQE).
- The function references an object and the authority attributes of the function and the query are compatible based on one of the following conditions:
  - The function is defined to run under the user’s authority (*USER).
  - The query is running under the owner's authority (*OWNER) and the owner of the query is the same as the owner of the function.
  - The query is running under the user's authority (*USER), and the user or the user’s group profile is the same as the owner of the function.

Note: If the function is defined as FENCED, the query must not use adopted authority. If the query runs under the owner’s authority (*OWNER) and the function runs under the user’s authority (*USER), the owner of the query must be the same as the user or the user's group profile.

When a function is inlined, some of the options specified when the function was created are ignored:
- PARALLEL or NOT PARALLEL
- MODIFIES SQL DATA
- Commitment control level
- CONCURRENT ACCESS RESOLUTION
- ALWCPYDTA
- ATOMIC or NOT ATOMIC

If a function is inlined and it contains a reference to a special register, the value of the special register will be the same as other references to the same special register in the query.

Returning an array from a function: If the return type of a function is an array type, the function can only be invoked from within an SQL function or SQL procedure routine body in one of the following contexts:
- the select-list of a SELECT INTO
- the select-list of a DECLARE CURSOR
- the select-list of a scalar subselect on the right side of a SET statement

A select-list that contains a function that returns an array type cannot use the DISTINCT keyword. A query that contains this select list cannot use UNION, EXCEPT, or INTERSECT.

Obfuscated statements: A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name and parameters are readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the function is created from an obfuscated statement are ignored.
function that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

**Setting of the default value:** Parameters of a function that are defined with a default value are set to their default value when the function is invoked, but only if a value is not supplied for the corresponding argument, or the argument is specified as DEFAULT.

**Dependent objects:** An SQL routine is dependent on objects that are referenced in the SQL-routine-body. The names of the dependent objects are stored in catalog view SYSROUTINEDEP. If the object reference in the SQL-routine-body is a fully qualified name or, in SQL naming, if an unqualified name is qualified by the current schema, then the schema name of the object in SYSROUTINEDEP will be set to the specified name or the value of the current schema. Otherwise, the schema name is not set to a specific schema name. Unqualified function names, variable names, and type names will have a schema name of CURRENT PATH. If the name is not set to an actual schema name, then DROP and ALTER statements will not be able to determine whether the routine is dependent on the object being altered or dropped.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

**Example**

*Example 1:* Define a scalar function that returns the tangent of a value using the existing SIN and COS built-in functions.

```sql
CREATE FUNCTION TAN
    (X DOUBLE)
RETURNS DOUBLE
LANGUAGE SQL
CONTAINS SQL
NO EXTERNAL ACTION
DETERMINISTIC
RETURN SIN(X)/COS(X)
```

Notice that a parameter name (X) is specified for the input parameter to function TAN. The parameter name is used within the body of the function to refer to the input parameter. The invocations of the SIN and COS functions, within the body of the TAN user-defined function, pass the parameter X as input.

*Example 2:* Define a scalar function that returns a date formatted as mm/dd/yyyy followed by a string of up to 3 characters:

```sql
CREATE FUNCTION BADPARM
    (INP1 DATE,
     USA VARCHAR(3))
RETURNS VARCHAR(20)
LANGUAGE SQL
CONTAINS SQL
```
CREATE FUNCTION (SQL scalar)

NO EXTERNAL ACTION
DETERMINISTIC
RETURN CHAR(INP1,USA) CONCAT USA

Assume that the function is invoked as in the following statement:

```sql
SELECT BADPARM(BIRTHDATE,'ISO')
FROM EMPLOYEE WHERE EMPNO='000010'
```

The result is '08/24/1933ISO'. Notice that parameter names (INP1 and USA) are specified for the input parameters to function BADPARM. Although there is an input parameter named USA, the instance of USA in the parameter list for the CHAR function is taken as the keyword parameter for the built-in CHAR function and not the parameter named USA.
CREATE FUNCTION (SQL table)

This CREATE FUNCTION (SQL table) statement creates an SQL table function at the current server. The function returns a single result table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSFUNCS catalog view and SYSPARMS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

- The following system authorities:
  - *USE to the Create Service Program (CRTSRVPGM) command or
  - Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

If the SECURED attribute is specified, or the function is secure and OR REPLACE is specified:

- The authorization ID of the statement must have security administrator authority. See "Administrative authority" on page 18.

To replace an existing function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the service program object associated with the function
  - All authorities needed to DROP the function
  - The system authority *READ to the SYSFUNCS catalog view and SYSPARMS catalog table
CREATE FUNCTION (SQL table)

- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#)

**Syntax**

\[
\text{CREATE FUNCTION} \quad \text{function-name} \quad \text{OR REPLACE} \quad (, \ldots) \quad \text{function-definition} \quad \text{WRAPPED—obfuscated-statement-text}
\]

**function-definition:**

\[
\text{RETURNS TABLE}(\quad \text{column-name—data-type2} \quad ) \quad \text{option-list} \quad \text{SQL-routine-body} \quad \text{SET OPTION-statement}
\]

**parameter-declaration:**

\[
\text{parameter-name—data-type1—default-clause}
\]

**data-type1, data-type2:**

\[
\text{built-in-type—distinct-type-name}
\]

**built-in-type:**
CREATE FUNCTION (SQL table)

ccsid-clause:

- CCSID integer
- normalize-clause
CREATE FUNCTION (SQL table)

normalize-clause:

default-clause:

option-list:

Notes:

1. This clause and the clauses that follow in the option-list can be specified in any order. Each clause can be specified at most once.
SQL-routine-body:

---SQL-control-statement---

### Description

**OR REPLACE**

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the function are not affected. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the `specific-name` and `function-name` of the new definition must be the same as the `specific-name` and `function-name` of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

**function-name**

Names the user-defined function. The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, or CCSID attributes of the data type) must not identify a user-defined function that exists at the current server.

For SQL naming, the function will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the function will be created in the schema that is specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is `*LIBL`, the function will be created in the current library (`*CURLIB`).
- Otherwise, the function will be created in the current schema.

In general, more than one function can have the same name if the function signature of each function is unique.

Certain function names are reserved for system use. For more information see Choosing the schema and function name in "CREATE FUNCTION" on page 1007.

**parameter-declaration,...)**

Specifies the number of input parameters of the function and the data type of each parameter. Each `parameter-declaration` specifies an input parameter for the function. A maximum of 2000 parameters can be specified. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All the parameters for a function are input parameters and are nullable. For more information, see Defining the parameters in "CREATE FUNCTION" on page 1007.

**parameter-name**

Names the parameter. The name is used to refer to the parameter within the body of the function. The name cannot be the same as any other `parameter-name` in the parameter list.

**data-type1**

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct data type.
CREATE FUNCTION (SQL table)

**built-in-type**
Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE" on page 1159.

**distinct-type-name**
Specifies a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information about creating a distinct type, see "CREATE TYPE (distinct)" on page 1241.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

**default-clause**
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in "Expressions" on page 174, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

All objects referenced in a default expression must exist when the function is created.

**RETURNS TABLE**
Specifies the output table of the function.

Assume the number of parameters is N. There must be no more than 8000-N columns.

**column-name**
Specifies the name of a column of the output table. Do not specify the same name more than once.

**data-type2**
Specifies the data type and attributes of the output.

You can specify any built-in data type (except LONG VARCHAR, or LONG VARGRAPHIC) or a distinct type. When the function is invoked the results are assigned to these data types (using storage assignment rules).

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified and the function is not referenced in a view, the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function.
This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

If a CCSID is not specified and the function is referenced in a view, the return data is converted to the CCSID of the associated view column. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

**LANGUAGE SQL**

Specifies that this is an SQL function.

**SPECIFIC specific-name**

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a function in "CREATE FUNCTION" on page 1007.

**GLOBAL DETERMINISTIC or STATEMENT DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. The default is NOT DETERMINISTIC.

**NOT DETERMINISTIC**

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a table function that is not deterministic is one that references special registers, non-deterministic functions, or a sequence in a way that affects the table function result table.

**GLOBAL DETERMINISTIC**

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. The query optimizer may choose to cache global deterministic function results.

**STATEMENT DETERMINISTIC**

Specifies that the function might not return the same result each time that the function is invoked with the same input arguments, but multiple invocations of the function within a single SQL statement are considered deterministic. The query optimizer will not cache statement deterministic function results.95

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a stream file. The default is EXTERNAL ACTION.

**EXTERNAL ACTION**

Specifies that the function can take an action that changes the state of an object that the database manager does not manage. Thus, the function

---

95. The DETERMINISTIC_UDF_SCOPE QAQQINI option can be used to get this same behavior for a GLOBAL DETERMINISTIC function. For more information, see the Database Performance and Query Optimization topic collection.
must be invoked with each successive function invocation. EXTERNAL ACTION should be specified if the function contains a reference to another function that has an external action.

**NO EXTERNAL ACTION**
The function does not perform an external action. It need not be called with each successive function invocation.

NO EXTERNAL ACTION functions might perform better than EXTERNAL ACTION functions because they might not be invoked for each successive function invocation.

**CONTAINS SQL, READS SQL DATA, or MODIFIES SQL DATA**
Specifies the classification of SQL statements and nested routines that the function can execute. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the function, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see [Appendix B, “Characteristics of SQL statements,” on page 1725](#). The default is READS SQL DATA. This option applies to any parameter default expressions.

**READS SQL DATA**
Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

**CONTAINS SQL**
Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute any SQL statements that read or modify data.

**MODIFIES SQL DATA**
The function can execute any SQL statement except those statements that are not supported in any function.

**RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**
Specifies whether the function is called if any of the input arguments is null at execution time.

**RETURNS NULL ON NULL INPUT**
Specifies that the function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows. RETURNS NULL ON NULL INPUT is the default.

**CALLED ON NULL INPUT**
Specifies that the function is to be invoked if any argument values are null. This specification means that the function must be coded to test for null argument values. The function can return an empty table, depending on its logic.

**INHERIT SPECIAL REGISTERS**
Specifies that existing values of special registers are inherited upon entry to the function.

**STATIC DISPATCH**
Specifies that the function is dispatched statically. All functions are statically dispatched.

**FENCED or NOT FENCED**
Specifies whether the SQL function runs in an environment that is isolated from the database manager environment. FENCED is the default.
FENCED

The function will run in a separate thread.

FENCED functions cannot keep SQL cursors open across individual calls to
the function. However, the cursors in one thread are independent of the
cursors in any other threads which reduces the possibility of cursor name
conflicts.

NOT FENCED

The function may run in the same thread as the invoking SQL statement.

NOT FENCED functions can keep SQL cursors open across individual calls
to the function. Since cursors can be kept open, the cursor position will
also be preserved between calls to the function. However, cursor names
may conflict since the UDF is now running in the same thread as the
invoking SQL statement and other NOT FENCED UDFs.

NOT FENCED functions usually perform better than FENCED functions.

ALLOW PARALLEL or DISALLOW PARALLEL

Specifies whether the function can be run in parallel.

The default is DISALLOW PARALLEL if one or more of the following clauses
are specified: NOT DETERMINISTIC, EXTERNAL ACTION, or MODIFIES SQL
DATA, or if this is a pipelined table function. Otherwise, ALLOW PARALLEL
is the default.

ALLOW PARALLEL

Specifies that the database manager can consider parallelism for the
function. The database manager is not required to use parallelism on the
SQL statement that invokes the function or on any SQL statement issued
from within the function.

See the descriptions of NOT DETERMINISTIC, EXTERNAL ACTION, and
MODIFIES SQL DATA for considerations that apply to specification of
ALLOW PARALLEL.

DISALLOW PARALLEL

Specifies that the database manager must not use parallelism for the
function.

CONCURRENT ACCESS RESOLUTION

Specifies whether the database manager should wait for data that is in the
process of being updated. DEFAULT is the default.

DEFAULT

Specifies that the concurrent access resolution is not explicitly set for this
function. The value that is in effect when the function is invoked will be
used.

WAIT FOR OUTCOME

Specifies that the database manager is to wait for the commit or rollback of
data in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that the database manager is to use the currently committed
version of the data when encountering data that is in the process of being
updated.

When the lock contention is between a read transaction and a delete or
update transaction, the clause is applicable to scans with isolation level CS
(but not for CS KEEP LOCKS).
CREATE FUNCTION (SQL table)

**SYSTEM_TIME SENSITIVE**
Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default.

**YES**
References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**NO**
References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**NOT SECURED or SECURED**
Specifies whether the function is considered secure for row access control and column access control.

**NOT SECURED**
Specifies that the function is considered not secure for row access control and column access control. This is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

**SECURED**
Specifies that the function is considered secure for row access control and column access control.

A function must be defined as secure when it is referenced in a row permission or a column mask.

**WRAPPED obfuscated-statement-text**
Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

**CARDINALITY bigint**
This optional clause provides an estimate of the expected number of rows to be returned by the function for optimization purposes. Valid values for integer range from 0 to 9 223 372 036 854 775 807 inclusive.

If the CARDINALITY clause is not specified for a table function, the database manager will assume a finite value as a default.

A table function that returns a row every time it is called and never returns the end-of-table condition has infinite cardinality. A query that invokes such a function and requires an eventual end-of-table condition before it can return any data will not return unless interrupted.

**SET OPTION-statement**
Specifies the options that will be used to create the function. These options also apply to any default value expressions. For example, to create a debuggable function, the following statement could be included:

**SET OPTION DBGVIEW = *SOURCE**

The default values for the options depend on the options in effect at create time. For more information, see "SET OPTION" on page 1575.

The options CNULRQD, CNULIGN, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE FUNCTION statement. CLOSQLCSR(*ENDACTGRP) is always used for SQL table functions. The following options are used when processing default value expressions:
CREATE FUNCTION (SQL table)

ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPRT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP.

**SQL-routine-body**

Specifies a single SQL statement, including a compound statement. See [Chapter 8, “SQL control statements,” on page 1645](#) for more information about defining SQL functions.

A non-pipelined table function must contain exactly one RETURN statement. A pipelined table function must contain at least one RETURN statement. The RETURN statement must be executed when the function is invoked.

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK and SET TRANSACTION statement is not allowed in a function.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL table) with a REPLACE keyword are not allowed in an SQL-routine-body.

**Notes**

**General considerations for defining user-defined functions:** See [Chapter 8, “SQL control statements,” on page 1645](#) for general information about defining user-defined functions.

**Function ownership:** If SQL names were specified:

- If a user profile with the same name as the schema into which the function is created exists, the *owner* of the function is that user profile.
- Otherwise, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the function is the user profile or group user profile of the thread executing the statement.

**Function authority:** If SQL names are used, functions are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, functions are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the function is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the function.

**Pipelined and non-pipelined functions:** There are two types of SQL table functions. A table function which does not contain any PIPE statements within the SQL-routine-body is a non-pipelined table function. It contains one RETURN statement which returns a table. A pipelined table function is a table function which contains one or more RETURN statements with no return values and zero or more PIPE statements within the SQL-routine-body. It returns a table a row at a time. The two types of table functions are invoked in exactly the same way.

A PIPE statement returns a result row from the table function. To get the next row, control returns in the SQL-routine-body to the statement following the PIPE statement.
**CREATE FUNCTION (SQL table)**

**REPLACE rules:** When a function is recreated by REPLACE:
- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

If the function is replaced and the function signature or result data types are altered, the results from any function, materialized query table, procedure, trigger, or view that references the function may be unpredictable. Any referenced objects should be recreated.

**Creating the function:** When an SQL function is created, the database manager creates a temporary source file that will contain C source code with embedded SQL statements. A *SRVPGM object is then created using the CRTSRVPGM command. The SQL options used to create the service program are the options that are in effect at the time the CREATE FUNCTION statement is executed. The service program is created with ACTGRP(*CALLER).

When an SQL function is created, the function’s attributes are stored in the created service program object. If the *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The specific name is used to determine the name of the source file member and *SRVPGM object. If the specific name is a valid system name, it will used as the name of member and program. If the member already exists, it will be overlaid. If a program already exists in the specified library, a unique name is generated using the rules for generating system table names. If the specific name is not a valid system name, a unique name is generated using the rules for generating system table names.

**Invoking the function:** When an SQL function is invoked, it runs in the activation group of the calling program.

**Inline functions:** When an SQL table function is inlined, instead of invoking the function as part of a query, the fullselect in the RETURN statement of the function may be copied (inlined) into the query itself. Such a function is called an inline function. A table function is an inline function if:
- The SQL function is defined as NO EXTERNAL ACTION.
- The SQL-routine-body contains only a RETURN statement.
- No column in the result table is the XML data type.
- All objects referenced in the function exist when the function is created.
- The SQL-routine-body does not contain a common table expression that references an input parameter.

An inline function is only copied (inlined) into a query if:
- The query is eligible for the SQL Query Engine (SQE).
- The function does not reference a table on a different server.
- The function references an object and the authority attributes of the function and the query are compatible based on one of the following conditions:
  - The function is defined to run under the user’s authority (*USER).
  - The query is running under the owner’s authority (*OWNER) and the owner of the query is the same as the owner of the function.
– The query is running under the user’s authority (*USER), and the user or the user’s group profile is the same as the owner of the function.

Note: If the function is defined as FENCED, the query must not use adopted authority. If the query runs under the owner’s authority (*OWNER) and the function runs under the user’s authority (*USER), the owner of the query must be the same as the user or the user’s group profile.

When a function is inlined, some of the options specified when the function was created are ignored:

• PARALLEL or NOT PARALLEL
• MODIFIES SQL DATA
• Commitment control level
• CONCURRENT ACCESS RESOLUTION
• ALWCPYDTA
• ATOMIC or NOT ATOMIC

If a function is inlined and it contains a reference to a special register, the value of the special register will be the same as other references to the same special register in the query.

Obfuscated statements: A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name and parameters are readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the function is created from an obfuscated statement are ignored. A function that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

Dependent objects: An SQL routine is dependent on objects that are referenced in the SQL-routine-body. The names of the dependent objects are stored in catalog view SYSROUTINEDEP. If the object reference in the SQL-routine-body is a fully qualified name or, in SQL naming, if an unqualified name is qualified by the current schema, then the schema name of the object in SYSROUTINEDEP will be set to the specified name or the value of the current schema. Otherwise, the schema name is not set to a specific schema name. Unqualified function names, variable names, and type names will have a schema name of CURRENT PATH. If the name is not set to an actual schema name, then DROP and ALTER statements will not be able to determine whether the routine is dependent on the object being altered or dropped.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

• The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
• The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
• The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.
CREATE FUNCTION (SQL table)

Example

Define a table function that returns the employees in a specified department number.

```
CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
  RETURNS TABLE (EMPNO CHAR(6),
                  LASTNAME VARCHAR(15),
                  FIRSTNAME VARCHAR(12))
  LANGUAGE SQL
  READS SQL DATA
  NO EXTERNAL ACTION
  DETERMINISTIC
  DISALLOW PARALLEL
  RETURN
    SELECT EMPNO, LASTNAME, FIRSTNAME
         FROM EMPLOYEE
         WHERE EMPLOYEE.WORKDEPT = DEPTEMPLOYEES.DEPTNO
```
The CREATE INDEX statement creates an index on a table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see Privileges necessary to create in a schema.
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

- The following system authorities:
  - *USE to the Create Logical File (CRTL) command
  - *CHANGE to the data dictionary if the library into which the index is created is an SQL schema with a data dictionary
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the table is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.
CREATE INDEX

Syntax

CREATE UNIQUE WHERE NOT NULL ENCODED VECTOR

INDEX index-name FOR SYSTEM NAME system-object-identifier

ON table-name (key-expression ASC DESC)

WHERE search-condition index-options

key-expression:

expression AS column-name COLUMN FOR system-column-name

index-options:

DISTINCT WITH integer VALUES NOT PARTITIONED PARTITIONED

INCLUDE (aggregate-function-name (expression))

PAGESIZE 64 8 16 32 128 256 512

ADD ALL COLUMNS

ADD KEYS ONLY

ADD column-name

ADD rename-index-columns
CREATE INDEX

```
(1)

media-preference

memory-preference

rename-index-columns:

RENAME (table-system-column-name) TO

(RENAMESYSTEM-COLUMN-NAMEFORCOLUMNINDEX-SYSTEM-COLUMN-NAME)

media-preference:

UNIT ANY

UNIT SSD

memory-preference:

KEEP IN MEMORY

NO

YES

Notes:

1 The index-options may be specified in any order.

Description

UNIQUE

Prevents the table from containing two or more rows with the same value of the index key. When UNIQUE is used, all null values for a column are considered equal. For example, if the key is a single column that can contain null values, that column can contain only one null value. The constraint is enforced when rows of the table are updated or new rows are inserted.

The constraint is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

UNIQUE WHERE NOT NULL

Prevents the table from containing two or more rows with the same value of the index key, where all null values for a column are not considered equal. Multiple null values in a column are allowed. Otherwise, this is identical to UNIQUE.

ENCODED VECTOR

Specifies that the resulting index will be an encoded vector index (EVI).```
CREATE INDEX

An encoded vector index cannot be used to ensure an ordering of rows. It is used by the database manager to improve the performance of queries. For more information, see the Database Performance and Query Optimization topic collection.

index-name
Names the index. The name, including the implicit or explicit qualifier, must not be the same as an index, table, view, alias, or file that already exists at the current server.

If SQL names were specified, the index will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the index name will be created in the schema that is specified by the qualifier. If not qualified, the index name will be created in the same schema as the table over which the index is created.

If the index name is not a valid system name and the FOR SYSTEM NAME clause is not used, Db2 for i will generate a system name. For information about the rules for generating a name, see “Rules for Table Name Generation” on page 1213.

FOR SYSTEM NAME system-object-identifier
Identifies the system-object-identifier of the index. system-object-identifier must not be the same as a table, view, alias, or index that already exists at the current server. The system-object-identifier must be an unqualified system identifier.

When system-object-identifier is specified, index-name must not be a valid system object name.

ON table-name
Identifies the table on which the index is to be created. The table-name must identify a base table (not a view) that exists at the current server.

If the table is a partitioned table, an alias may be specified which identifies a single partition. The created index will then only be created over the specified partition.

key-expression
Identifies a column or expression that will be part of the index key.

The number of keys defined for the index must not exceed 120, and the sum of their byte lengths must not exceed 32766-n, where n is the number of keys specified that allow nulls.

expression
If expression contains only a column-name, it must be an unqualified name that identifies a column of the table. expression must contain a column reference. The same column-name cannot be specified more than once if:

• a WHERE clause, INCLUDE clause, or RCDFMT clause is specified,
• an expression is defined as part of an index key, or
• a column is renamed using the AS clause.

If the expression is not a column name, the expression must not reference a column that contains a field procedure.

A column-name must not identify a LOB, XML, or DATALINK column, or a distinct type based on a LOB, XML, or DATALINK column. If the expression is not a column name, any intermediate result expression and the final result expression must not be a DATALINK, LOB, or XML data type.

It must not contain any of the following:
CREATE INDEX

- Subqueries
- Aggregate functions
- Variables
- Global variables
- Parameter markers
- Special registers
- Sequence references
- OLAP specifications
- ROW CHANGE expressions
- REGEXP_LIKE predicate
- User-defined functions other than functions that were implicitly generated with the creation of a distinct type
- Any function that is not deterministic
- The following built-in scalar functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN2</td>
<td>DLURLPATHONLY</td>

<tr>
<td>DLURLPATH</td>
<td>LOCATE_IN_STRING</td>
</tr>
</tbody>
</table>

1 For DataLinks with an attribute of FILE LINK CONTROL and READ PERMISSION DB.

**column-name**

Names a column of the index. Do not use the same name for more than one column of the index or for a system-column-name of the index.

If the expression is not a column name and is not named, a name will be generated for the index key column. The name will be SQLIXxxxxx, where xxxx is a number that makes the column name unique for the index.

**FOR COLUMN system-column-name**

Provides an IBM i name for the column. Do not use the same name for more than one column of the index or for a column-name of the index.

If the system-column-name is not specified, and the column-name is not a valid system-column-name, a system column name is generated. The name will be SQLIXxxxxx, where xxxx is a number that makes the column name unique for the index.

**ASC**

Specifies that the index entries are to be kept in ascending order of the column values. ASC is the default.
CREATE INDEX

DESC
   Specifies that the index entries are to be kept in descending order of the column values.

Ordering is performed in accordance with the comparison rules described in "Assignments and comparisons" on page 99. The null value is higher than all other values.

WHERE search-condition
   Specifies the condition to apply for a row to be included in the index. The search-condition cannot contain a predicate with a subquery. It must not contain any of the items listed as restrictions for key-expression.

WITH integer DISTINCT VALUES
   Specifies the estimated number of distinct key values. This clause may be specified for any type of index.

   For encoded vector indexes this is used to determine the initial size of the codes assigned to each distinct key value. Only 1, 2, and 4 byte codes are used. If the INCLUDE clause is not specified, the default value is 255 (a 1-byte code). Otherwise, a 4-byte code is used. During the create or rebuild of the index if the number of distinct values exceeds the maximum supported by the size of the code, the size of the code is increased.

   For non-encoded vector indexes, this clause is ignored.

PARTITIONED
   Specifies that an index partition should be created for each data partition defined for the table using the specified columns. The table-name must identify a partitioned table. If the index is unique, the columns of the index must be the same or a superset of the columns of the data partition key. PARTITIONED is the default if the index is not unique and the table is partitioned.

NOT PARTITIONED
   Specifies that a single index should be created that spans all of the data partitions defined for the table. The table-name must identify a partitioned table. NOT PARTITIONED is the default if the index is unique and the table is partitioned. An index on a table that is not partitioned is also by default not partitioned.

   If an encoded vector index is specified, NOT PARTITIONED is not allowed.

PAGESIZE
   Specifies the logical page used for the index in kilobytes. Indexes with larger logical page sizes are typically more efficient when scanned during query processing. Indexes with smaller logical page sizes are typically more efficient for simple index probes and individual key look ups.

   The default value for PAGESIZE is determined by the length of the key and has a minimum value of 64.

   If an encoded vector index is specified, PAGESIZE is not allowed.

INCLUDE
   Specifies aggregate function expressions to be included in the index. These aggregates make it possible for the index to be used directly to return aggregate results for a query. INCLUDE is only allowed for an encoded vector index.

aggregate-function-name ( expression )

   The aggregate function name must be one of the built-in functions AVG, COUNT, COUNT_BIG, SUM, STDDEV, STDDEV_SAMP, VARIANCE, or
VARIANCE_SAMP. The DISTINCT keyword must not be specified. The expression argument of the aggregate function must not contain any of the items listed as restrictions for key-expression.

**RCDFT** format-name
An unqualified name that designates the IBM i record format name of the index. A format-name is a system identifier.

If the INCLUDE keyword is specified, RCDFT is not allowed.

**ADD ALL COLUMNS**
Specifies that all non-hidden columns of table-name will be added to the format for the index. All the columns will be defined in the same order as they appear in the format of table-name and will precede any expressions defined as index keys.

**ADD KEYS ONLY**
Specifies that only the columns specified as index key columns will be added to the format for the index. Other columns from table-name will not be added.

**ADD column-name**
Specifies that the listed columns will be added to the format for the index. The index key columns will be first, followed by the added columns.

**RENAME**
Specifies the columns from table-name that will be included in the format for the index. The order of the columns in the index format will be the same as the order of the columns in the list. The columns in the index can also be renamed.

  * table-system-column-name
    Identifies the system column name of a column in table-name.

  * index-system-column-name
    Provides the system column name for the corresponding column in the index.

  * index-column-name
    Provides the column name for the corresponding column in the index.

When this clause is used, the following rules apply:

- Each key-expression must contain only a column-name. It can be either the column name or the system column name of a column in table-name. The key-expression cannot include an AS clause to rename the column.
- If a list of table-system-column-names is specified, it must contain the same number of names as are provided in the index column name list.
- If a list of table-system-column-names is not specified, every index-system-column-name must be the system column name for a column in table-name.
- Each index-column-name and index-system-column-name must be unique and unqualified.
- Every column in key-expression must be included in the RENAME clause.

**media-preference**

Specifies the preferred storage media for the index.
CREATE INDEX

UNIT ANY
No storage media is preferred. Storage for the index will be allocated from any available storage media.

UNIT SSD
Solid state disk storage media is preferred. Storage for the index may be allocated from solid state disk storage media, if available.

memory-preference

KEEP IN MEMORY
Specifies whether the data for the index should be brought into a main storage pool when the data is used for a query.

NO  The data will not be brought into a main storage pool.

YES  The data will be brought into a main storage pool.

Notes

Effects of the statement: CREATE INDEX creates a description of the index. If the named table already contains data, CREATE INDEX creates the index entries for it. If the table does not yet contain data, the index entries are created when data is inserted into the table.

Collating sequence: Any index created over columns containing SBCS or mixed data is created with the collating sequence in effect at the time the statement is executed. For collating sequences other than *HEX, the key for SBCS data or mixed data is the weighted value of the key based on the collating sequence.

Index attributes: An index is created as a keyed logical file. When an index is created, the file wait time and record wait time attributes are set to the default that is specified on the WAITFILE and WAITRCD keywords of the Create Logical File (CRTLF) command.

The date and time format used for date and time result columns is ISO.

An index created over a distributed table is created on all of the servers across which the table is distributed. For more information about distributed tables, see DB2 Multisystem.

Index ownership: If SQL names were specified:
• If a user profile with the same name as the schema into which the index is created exists, the owner of the index is that user profile.
• Otherwise, the owner of the index is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the index is the user profile or group user profile of the thread executing the statement.

Index authority: If SQL names are used, indexes are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, indexes are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.
If the owner of the index is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the index.

**Record format sharing:** An index that defines a key column as an expression or that specifies the RCDFMT, WHERE, INCLUDE, or AS clauses does not share the format of table-name. Otherwise, the index will share the format of table-name and its format-name will be the same as the system-object-name of the index.

**Examples**

*Example 1:* Create an index named UNIQUE_NAM on the PROJECT table. The purpose of the index is to ensure that there are not two entries in the table with the same value for project name (PROJNAME). The index entries are to be in ascending order.

```sql
CREATE UNIQUE INDEX UNIQUE_NAM
ON PROJECT(PROJNAME)
```

*Example 2:* Create an index named JOB_BY_DPT on the EMPLOYEE table. Arrange the index entries in ascending order by job title (JOB) within each department (WORKDEPT).

```sql
CREATE INDEX JOB_BY_DPT
ON EMPLOYEE (WORKDEPT, JOB)
```

*Example 3:* Create an index named DEPT_TYPE on the DEPARTMENT table. Arrange the index entries in ascending order by type of department, which is determined by the second and third characters of the department number (DEPTNO).

```sql
CREATE INDEX DEPT_TYPE
ON DEPARTMENT (SUBSTR(DEPTNO,2,2))
```
The CREATE MASK statement creates a column mask for column access control at
the current server. A column mask specifies what value should be returned for the
specified column.

Invocation

This statement can be embedded in an application program or issued interactively.
It is an executable statement that can be dynamically prepared.

Authorization

The authorization ID of the statement must have security administrator authority.
See "Administrative authority" on page 18.

Syntax

```
CREATE MASK mask-name ON table-name
    OR REPLACE
    AS correlation-name
    FOR COLUMN column-name
    RETURN case-expression
    DISABLE
    ENABLE
```

Description

**OR REPLACE**

Specifies to replace the definition for the column mask if one exists at the
current server. The existing definition is effectively dropped before the new
definition is replaced in the catalog.

**mask-name**

Names the column mask for column access control. The name, including the
implicit or explicit qualifier, must not be the same as a column mask or a row
permission that already exists at the current server. The *mask-name* cannot start
with QIBM.

If SQL names were specified, the mask will be created in the schema specified
by the implicit or explicit qualifier.

If system names were specified, the mask will be created in the schema that is
specified by the qualifier. If not qualified and there is no default schema, the
mask will be created in the same schema as the *table-name*.

The schema name for the *mask-name* must be the same as the schema name for
*table-name*.

**table-name**

Identifies the table on which the column mask is created. The name must
identify a table that exists at the current server. It must not identify a declared
temporary table, table in QTEMP, distributed table, view, logical file, member
alias, file with read triggers, or catalog table.

**correlation-name**

Specifies a correlation name that can be used within *case-expression* to designate
the table.
FOR COLUMN column-name
Identifies the column to which the mask applies. It must be an unqualified name that identifies a column of the table. A mask must not already exist for the column.

RETURN case-expression
Specifies a CASE expression to be evaluated to determine the value to return for the column. The result of the CASE expression is returned in place of the column value in a row. The result data type, length, null attribute, and CCSID of the CASE expression must be compatible with the data type of the column. If the column does not allow the null value, the result of the CASE expression cannot be the NULL value. For more information about the compatibility of data types see [Assignments and comparisons" on page 99]. If the data type of column-name is a user defined data type, the result data type of the CASE expression must be the same user defined type. Any objects referenced in the case expression must exist at the current server. The case expression must not reference any of the following:
- The table for which the column mask is being defined
- A declared global temporary table
- A variable (host variable, SQL variable, SQL parameter, or trigger transition variable)
- A parameter marker
- A user-defined function that is defined as NOT SECURED
- A function that is not deterministic or has an external action
- An RRN, RID, HASHED_VALUE, DATAPARTITIONNAME, DATAPARTITIONNUM, DBPARTITIONNAME, or DBPARTITIONNUM
- function that references the table for which the column mask is being defined
- An OLAP specification
- A ROW CHANGE expression
- A sequence reference
- A * or name.* in a select clause
- A table in QTEMP
- A member alias
- A distributed table
- A file with read triggers
- A multi-format logical file
- A remote object
- A view that contains any of the above

ENABLE or DISABLE
Specifies that the column mask is to be initially enabled or disabled for column access control.

DISABLE
Specifies that the column mask is to be disabled for column access control. The column mask will remain ineffective regardless of whether column access control is activated for the table or not. This is the default.

ENABLE
Specifies that the column mask is to be enabled for column access control.

---

96. STATEMENT DETERMINISTIC functions are allowed but are not recommended.
If column access control is not currently activated for this table, the column mask will become effective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes effective immediately.

Notes

Prerequisites: In order to create a mask, IBM Advanced Data Security must be installed.

How column masks affect queries: The application of enabled column masks does not interfere with the operations of other clauses within the statement such as WHERE, GROUP BY, HAVING, SELECT DISTINCT, or ORDER BY. The rows that are returned in the final result table remain the same, except that the values in the resulting rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY clause with a sort-key expression, the order is based on the original values of the column and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT statement. If the masked column is embedded in an expression, the result of the expression might become different because the column mask is applied on the column before the expression evaluation can take place. For example, a column mask on column SSN might change the result of the aggregate function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the masked values. However, if the expression in the query is the same as the expression that is used to mask the column value in the definition of the column mask, the result of the expression might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression appears in the definition of the column mask. In this particular example, you can remove the expression from the query to avoid the same expression being evaluated twice.

Conflicts between the definition of a column mask and SQL: A column mask is created as a stand alone object, without knowing all of the contexts in which it might be used. To mask the value of a column in the final result table, the definition of the column mask is merged into a query by Db2. When the definition of the column mask is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of the column mask can return an error. When this happens, either the statement needs to be modified or the column mask must be dropped or recreated with a different definition.

Column masks and null columns: If the column is not nullable, the definition of its column mask will not, most likely, consider a null value for the column. After the column access control is activated for the table, if the table is the null-padded table in an outer join, the value of the column in the final result table might be a null. To ensure that the column mask can mask a null value, if the table is the null-padded table in an outer join, Db2 will add "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition. This forces a null value to always be masked as a null value. For a nullable column, this removes the ability to mask a null value as something else. Example 4 shows this added WHEN clause.

Column mask values for SQL data change statements: For INSERT, UPDATE, and MERGE, when a column is referenced while deriving the values of a new row, if that column has an enabled column mask, the masked value is used to derive the new values. If the object table also has column access control activated, the column
mask that is applied to derive the new values must return the column itself, not a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert or update and an error is returned. The rules that are used to apply column masks in order to derive the new values follow the same rules for the final result table of a query. See the data change statements for how the column masks are used to affect the insertability and updatability.

**Column masks and trigger transition variables**: Values for OLD ROW and OLD TABLE transition variables will never contain masked values.

A SET transition-variable assignment statement can assign masked data to the variable. If a violation check constraint does not exist for the column, the masked data will be inserted or updated in the table’s column and no error will be issued.

**Column masks that are created before column access control is activated**: The CREATE MASK statement is an independent statement that can be used to create a column access control mask before column access control is activated for a table. The only requirement is that the table and the columns exist before the mask is created. Multiple column masks can be created for a table but a column can have only one mask. The definition of a mask is stored in the Db2 catalog. Dependency on the table for which the mask is being created and dependencies on other objects referenced in the definition are recorded. A column mask can be created as enabled or disabled for column access control. An enabled column mask does not take effect until the ALTER TABLE statement with the ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for the table. A disabled column mask remains ineffective even when column access control is activated for the table. The ALTER MASK statement can be used to alter between ENABLE and DISABLE. After column access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are implicitly applied by Db2 to mask the values returned for the columns referenced in the final result table of the queries or to determine the new values used in the data change statements.

**Column masks that are created after column access control is activated**: The enabled column masks become effective as soon as they are committed. Thereafter, when the table is referenced in a data manipulation statement, all enabled column masks are implicitly applied by Db2 to the statement. Any disabled column mask remains ineffective even when column access control is activated for the table.

**No cascaded effect when column or row access control enforced tables are referenced in column mask definitions**: A column mask definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables and columns is ignored when the table for which the column mask is being created is referenced in a data manipulation statement.

**Examples**

**Example 1**: After column access control is activated for table EMPLOYEE, Paul from the payroll department can see the social security number of the employee whose employee number is 123456. Mary who is a manager can see only the last four characters of the social security number. Peter who is neither cannot see the social security number.

```
CREATE MASK SSN_MASK ON EMPLOYEE
   FOR COLUMN SSN
   RETURN CASE
```
CREATE MASK

WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'PAYROLL') = 1) THEN SSN
WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR') = 1) THEN 'XXX-XX- ' || SUBSTR(SSN,8,4)
ELSE NULL
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SSN FROM EMPLOYEE
WHERE EMPNO = 123456;

Example 2: In the SELECT statement, column SSN is embedded in an expression that is the same as the expression used in the column mask SSN_MASK. After column access control is activated for table EMPLOYEE, the column mask SSN_MASK is applied to column SSN in the SELECT statement. For this particular expression, the SELECT statement produces the same result as before column access control is activated for all users. The user can replace the expression in the SELECT statement with column SSN to avoid the same expression getting evaluated twice.

CREATE MASK SSN_MASK ON EMPLOYEE
FOR COLUMN SSN RETURN
CASE
WHEN (1 = 1)
THEN 'XXX-XX- ' || SUBSTR(SSN,8,4)
ELSE NULL
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT 'XXX-XX- ' || SUBSTR(SSN,8,4) FROM EMPLOYEE
WHERE EMPNO = 123456;

Example 3: Employee with EMPNO 123456 earns bonus $8000 and salary $80000 in May. When the manager retrieves his salary, the manager receives his salary, not the null value. This is because of no cascaded effect when column mask SALARY_MASK references column BONUS for which column mask BONUS_MASK is defined.

CREATE MASK SALARY_MASK ON EMPLOYEE
FOR COLUMN SALARY RETURN
CASE
WHEN (BONUS < 10000)
THEN SALARY
ELSE NULL
END
ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
FOR COLUMN BONUS RETURN
CASE
    WHEN (BONUS > 5000)
    THEN NULL
    ELSE BONUS
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
    WHERE EMPNO = 123456;

Example 4: This example shows Db2 adds "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition then merges the column mask definition into the statement.

CREATE TABLE EMPLOYEE (EMPID INT,
    DEPTID CHAR(8),
    SALARY DEC(9,2) NOT NULL,
    BONUS DEC(9,2));

CREATE MASK SALARY_MASK ON EMPLOYEE
    FOR COLUMN SALARY RETURN
    CASE
        WHEN SALARY < 10000
            THEN CAST(SALARY*2 AS DEC(9,2))
        ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
    END
    ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
    FOR COLUMN BONUS RETURN
    CASE
        WHEN BONUS > 10000
            THEN BONUS
        ELSE NULL
    END
    ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM DEPT
    LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;

/* When SALARY_MASK is effectively merged into the above statement,
* 'WHEN SALARY IS NULL THEN NULL' is added by Db2 as the
* first WHEN clause, as follows:
*/

SELECT CASE WHEN SALARY IS NULL THEN NULL
    WHEN SALARY < 10000 THEN CAST(SALARY*2 AS DEC(9,2))
    ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
END SALARY
    FROM DEPT
    LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;
CREATE PERMISSION

The CREATE PERMISSION statement creates a row permission for row access control at the current server. It determines the rows within a table that are available based on the result of the search-condition.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The authorization ID of the statement must have security administrator authority. See “Administrative authority” on page 18.

Syntax

```
CREATE PERMISSION permission-name ON table-name 
OR REPLACE
AS correlation-name

FOR ROWS WHERE search-condition ENFORCED FOR ALL ACCESS
DISABLE
ENABLE
```

Description

OR REPLACE

Specifies to replace the definition for the row permission if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog.

permission-name

Names the row permission for row access control. The name, including the implicit or explicit qualifier, must not be the same as a column mask or a row permission that already exists at the current server. The permission-name cannot start with QIBM.

If SQL names were specified, the permission will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the permission will be created in the schema that is specified by the qualifier. If not qualified and there is no default schema, the permission will be created in the same schema as the table-name.

The schema name for the permission-name must be the same as the schema name for table-name.

table-name

Identifies the table on which the column permission is created. The name must identify a table that exists at the current server. It must not identify a declared temporary table, table in QTEMP, distributed table, view, logical file, member alias, file with read triggers, or catalog table.

correlation-name

Specifies a correlation name that can be used within search-condition to designate the table.
FOR ROWS WHERE
Indicates that a row permission is created. A row permission specifies a search
condition under which rows of the table can be accessed.

search-condition
Specifies a condition that can be true, false, or unknown for a row of the
table.

The search-condition follows the same rules used by the search condition in
a WHERE clause. In addition, it must not reference any of the following:
• The table for which the row permission is being defined
• A declared global temporary table
• A variable (host variable, SQL variable, SQL parameter, or trigger
  transition variable)
• A parameter marker
• A user-defined function that is defined as NOT SECURED
• A function that is not deterministic or has an external action
  97
• An RRN, RID, HASHED_VALUE, DATAPARTITIONNAME,
  DATAPARTITIONNUM, DBPARTITIONNAME, or DBPARTITIONNUM
  function that references the table for which the row permission is being
  defined
• An OLAP specification
• A ROW CHANGE expression
• A sequence reference
• A * or name.* in a select clause
• A table in QTEMP
• A member alias
• A distributed table
• A file with read triggers
• A multi-format logical file
• A remote object
• A view that contains any of the above

ENFORCED FOR ALL ACCESS
Specifies that the row permission applies to all references of the table. If row
access control is activated for the table, when the table is referenced in a data
manipulation statement, Db2 implicitly applies the row permission to control
the access of the table. If the reference of the table is for a fetch operation such
as SELECT, the application of the row permission determines what set of rows
can be retrieved by the user who requested the fetch operation. If the reference
of the table is for a data change operation such as INSERT, the application of
the row permission determines whether all rows to be changed are insertable
or updatable by the user who requested the data change operation.

ENABLE or DISABLE
Specifies that the row permission is to be initially enabled or disabled for row
access control.

DISABLE
Specifies that the row permission is to be disabled for row access control.

---

97. STATEMENT DETERMINISTIC functions are allowed but are not recommended.
CREATE PERMISSION

The row permission will remain ineffective regardless of whether row access control is activated for the table or not. This is the default.

**ENABLE**

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for this table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately.

**Notes**

**Prerequisites:** In order to create a permission, IBM Advanced Data Security must be installed.

**How row permissions are applied and how they affect certain statements:** See the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause for information on how to activate row access control and how row permissions are applied. See the description of subselect for information on how the application of row permissions affects the fetch operation. See the data change statements for information on how the application of row permissions affects the data change operation.

**Row permissions that are created before row access control is activated for a table:** The CREATE PERMISSION statement is an independent statement that can be used to create a row permission before row access control is activated for a table. The only requirement is that the table and the columns exist before the permission is created. Multiple row permissions can be created for a table.

The definition of the row permission is stored in the Db2 catalog. Dependency on the table for which the permission is being created and dependencies on other objects referenced in the definition are recorded. A row permission can be created as enabled or disabled for row access control. An enabled row permission does not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for the table. A disabled row permission remains ineffective even when row access control is activated for the table. The ALTER PERMISSION statement can be used to alter between ENABLE and DISABLE.

After row access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled row permissions that are defined for the table are implicitly applied by Db2 to control access to the table.

**Row permissions that are created after row access control is activated for a table:** An enabled row permission becomes effective as soon as it is committed. Thereafter, when the table is referenced in a data manipulation statement, all enabled row permissions are implicitly applied to the statement. Any disabled row permission remains ineffective even when row access control is activated for the table.

**No cascaded effect when row or column access control enforced tables are referenced in row permission definitions:** A row permission definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables is ignored when the table for which the row permission is being created is referenced in a data manipulation statement.
DECRESULT option for permissions: The DECRESULT option for permissions will always use maximum precision of 63, maximum scale of 63, and minimum divide scale of 0.

Examples

Example 1: Secure user-defined function ACCOUNTING_UDF in row permission SALARY_ROW_ACCESS processes the sensitive data in column SALARY. After row access control is activated for table EMPLOYEE, Accountant Paul retrieves the salary of employee with EMPNO 123456 who is making $100,000 a year. Paul may or may not see the row depending on the output value from user-defined function ACCOUNTING_UDF.

```
CREATE PERMISSION SALARY_ROW_ACCESS ON EMPLOYEE
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR','ACCOUNTING') = 1
    AND ACCOUNTING_UDF(SALARY) < 120000
  ENFORCED FOR ALL ACCESS
  ENABLE;
COMMIT;

ALTER TABLE EMPLOYEE
  ACTIVATE ROW ACCESS CONTROL;

CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'TELLER') = 1
    AND BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
      WHERE EMP_ID = SESSION_USER)
  ENFORCED FOR ALL ACCESS
  ENABLE;
COMMIT;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'CSR') = 1
  ENFORCED FOR ALL ACCESS
  ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
  ACTIVATE ROW ACCESS CONTROL;

SELECT * FROM CUSTOMER;
```

Example 2: The tellers in a bank can only access customers from their branch. All tellers have secondary authorization ID TELLER. The customer service representatives are allowed to access all customers of the bank. All customer service representatives have secondary authorization ID CSR. A row permission is created for each group of personnel in the bank according to the access rules defined by someone with security administrator authority. After row access control is activated for table CUSTOMER, in a SELECT statement the search conditions of both row permissions are merged into the statement and they are combined with the logical OR operator to control the set of rows accessible by each group.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'TELLER') = 1
    AND BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
      WHERE EMP_ID = SESSION_USER)
  ENFORCED FOR ALL ACCESS
  ENABLE;
COMMIT;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'CSR') = 1
  ENFORCED FOR ALL ACCESS
  ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
  ACTIVATE ROW ACCESS CONTROL;

SELECT * FROM CUSTOMER;
```
The CREATE PROCEDURE statement defines a procedure at the current server.

The following types of procedures can be defined:

- **External**
  The procedure program or service program is written in a programming language such as C, COBOL, or Java. The external executable is referenced by a procedure defined at the current server along with various attributes of the procedure. See "CREATE PROCEDURE (external)" on page 1113.

- **SQL**
  The procedure is written exclusively in SQL. The procedure body is defined at the current server along with various attributes of the procedure. See "CREATE PROCEDURE (SQL)" on page 1130.

**Notes**

**Choosing data types for parameters:** For portability of procedures across platforms that are not Db2 for i, do not use the following data types, which might have different representations on different platforms:

- **FLOAT.** Use DOUBLE or REAL instead.
- **NUMERIC.** Use DECIMAL instead.

**Specifying AS LOCATOR for a parameter:** Passing a locator instead of a value can result in fewer bytes being passed in or out of the procedure. This can be useful when the value of the parameter is very large. The AS LOCATOR clause specifies that a locator to the value of the parameter is passed instead of the actual value. Specify AS LOCATOR only for parameters with a LOB or XML data type or a distinct type based on a LOB or XML data type.

AS LOCATOR cannot be specified for SQL procedures.

**Determining the uniqueness of procedures in a schema:** At the current server, each procedure signature must be unique. The signature of a procedure is the qualified procedure name combined with the number of the parameters (the data types of the parameters are not part of a procedure's signature). This means that two different schemas can each contain a procedure with the same name that have the same number of parameters. However, a schema must not contain two procedures with the same name that have the same number of parameters.

**The specific name for a procedure:** When defining multiple procedures with the same name and schema (with different number of parameters), it is recommended that a specific name also be specified. The specific name can be used to uniquely identify the procedure when dropping, granting to, revoking from, or commenting on the procedure.

If specific-name is not specified, it is the same as the procedure name. If a function or procedure with that specific name already exists, a unique name is generated similar to the rules used to generate unique table names.

**Special registers in procedures:** The settings of the special registers of the caller are inherited by the procedure when called and restored upon return to the caller. Special registers may be changed within a procedure, but these changes do not affect the caller.
CREATE PROCEDURE (external)

The CREATE PROCEDURE (external) statement defines an external procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS catalog view and SYSPARMS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If the external program or service program exists, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the external program or service program that is referenced in the SQL statement:
  - The system authority *EXECUTE on the library that contains the external program or service program.
  - The system authority *EXECUTE on the external program or service program, and
  - The system authority *CHANGE on the program or service program. The system needs this authority to update the program or service program object to contain the information necessary to save/restore the procedure to another system. If user does not have this authority, the procedure is still created, but the program or service program object is not updated.
- Database administrator authority

If a distinct type or array type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type or array type identified in the statement:
  - The USAGE privilege on the type, and
  - The system authority *EXECUTE on the library containing the distinct type or array type
- Database administrator authority

To replace an existing procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the program object associated with the procedure
  - All authorities needed to DROP the procedure
  - The system authority *READ to the SYSPROCS catalog view and SYSPARMS catalog table
- Database administrator authority
CREATE PROCEDURE (external)

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Function or Procedure and Corresponding System Authorities When Checking Privileges to a Distinct Type.

built-in-type:
CREATE PROCEDURE (external)

ccsid-clause:

  |CCSID integer normalize-clause
normalize-clause:

Description

OR REPLACE

Specifies to replace the definition for the procedure if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the procedure are not affected. This option is ignored if a definition for the procedure does not exist at the current server. To replace an existing procedure, the specific-name and procedure-name of the new definition must be the same as the specific-name and procedure-name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new procedure is created.

procedure-name

Names the procedure. The combination of name, schema name, the number of parameters must not identify a procedure that exists at the current server.

For SQL naming, the procedure will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the procedure will be created in the schema specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the procedure will be created in the current library (*CURLIB).
- Otherwise, the procedure will be created in the current schema.

(parameter-declaration,...)

Specifies the number of parameters of the procedure and the data type of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. All parameters are nullable. Although not required, you can give each parameter a name.

The maximum number of parameters allowed in CREATE PROCEDURE depends on the type of language and the parameter style:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs and REXX,
  - If PARAMETER STYLE GENERAL is specified the maximum is 255.
  - If PARAMETER STYLE GENERAL WITH NULLS is specified the maximum is 254.
  - If PARAMETER STYLE SQL is specified the maximum is 254.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language.

IN Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned.98 The default is IN.

---

98. When the language type is REXX, all parameters must be input parameters.
OUT
Identifies the parameter as an output parameter that is returned by the procedure.

A DataLink or a distinct type based on a DataLink cannot be specified as an output parameter.

INOUT
Identifies the parameter as both an input and output parameter for the procedure. If an INOUT parameter is defined with a default and the default is used when calling the procedure, no value for the parameter is returned.

A DataLink or a distinct type based on a DataLink cannot be specified as an input and output parameter.

parameter-name
Names the parameter. The name cannot be the same as any other parameter-name for the procedure.

data-type
Specifies the data type of the parameter.

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE" on page 1159.

distinct-type-name
Specifies a distinct type. Any length, precision, scale, or encoding scheme attributes for the parameter are those of the source type of the distinct type as specified using "CREATE TYPE (distinct)" on page 1241.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

array-type-name
Specifies an array type. Array types are only supported for LANGUAGE JAVA. To use an array type as a parameter for a Java stored procedure, the parameter style must be JAVA.

If the name of the array type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID before passing it to the procedure. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the procedure is invoked.

Date, time, and timestamp parameters are passed to the procedure as character strings in ISO format.

Some data types are not supported in all languages. For details on the mapping between the SQL data types and host language data types, see Embedded SQL Programming topic collection. Built-in data type specifications can be specified if they correspond to the language that is used to write the procedure.

Any parameter that has an XML type must specify either the XML-cast-type clause or the AS LOCATOR clause.

AS LOCATOR
Specifies that the parameter is a locator to the value rather than the actual
value. You can specify AS LOCATOR only if the parameter has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

**AS XML-cast-type**

Specifies the data type passed to the procedure for a parameter that is XML type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the procedure is created according to the SQL_XML_DATA_CCSID QAQQINI option setting. The default CCSID is 1208. See "XML Values" on page 89 for a description of this option.

**default**

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in "Expressions" on page 174, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation of the procedure. The maximum length of the expression string is 64K.

The default expression must not modify SQL data. The expression must be assignment compatible to the parameter data type. All objects referenced in a default expression must exist when the procedure is created. When the procedure is called, the default will be evaluated using the authority of the invoker.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

A default cannot be specified:

- for an OUT parameter.
- for a parameter of type array.

**LANGUAGE**

Specifies the language that the external program or service program is written in. The language clause is required if the external program is a REXX procedure.

If LANGUAGE is not specified, the LANGUAGE is determined from the attribute information associated with the external program or service program at the time the procedure is created. If the attribute information associated with the program or service program does not identify a recognizable language or the program or service program cannot be found, then the language is assumed to be C.

C The external program is written in C.

C++

The external program is written in C++.

CL The external program is written in CL.

COBOL The external program is written in COBOL.

COBOLLE The external program is written in ILE COBOL.
**JAVA**
The external program is written in JAVA.

**PLI**
The external program is written in PL/I.

**REXX**
The external program is a REXX procedure.

**RPG**
The external program is written in RPG.

**RPGLE**
The external program is written in ILE RPG.

**PARAMETER STYLE**
Specifies the conventions used to pass parameters to and returning the values from procedures:

**SQL**
Specifies that in addition to the parameters on the CALL statement, several additional parameters are passed to the procedure. The parameters are defined to be in the following order:

- The first $n$ parameters are the parameters that are specified on the CREATE PROCEDURE statement.
- $n$ parameters for indicator variables for the parameters.
- A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the procedure. The SQLSTATE returned is assigned by the external program.
  The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the procedure.
- A VARCHAR(517) input parameter for the fully qualified procedure name.
- A VARCHAR(128) input parameter for the specific name.
- A VARCHAR(1000) output parameter for the message text.

The following additional parameter may be passed as the last parameter:

- A parameter for the dbinfo structure, if DBINFO was specified on the CREATE PROCEDURE statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqldf in the appropriate source file in library QSYSINC. For example, for C, sqldf can be found in QSYSINC/H.

PARAMETER STYLE SQL cannot be used with LANGUAGE JAVA.

**DB2GENERAL**
Specifies that the procedure will use a parameter passing convention that is defined for use with Java methods.

PARAMETER STYLE DB2GENERAL can only be specified with LANGUAGE JAVA. For details on passing parameters in JAVA, see the [IBM Developer Kit for Java](#).

**GENERAL**
Specifies that the procedure will use a parameter passing mechanism
where the procedure receives the parameters specified on the CALL. Additional arguments are not passed for indicator variables.

PARAMETER STYLE GENERAL cannot be used with LANGUAGE JAVA.

**GENERAL WITH NULLS**

Specifies that in addition to the parameters on the CALL statement as specified in GENERAL, another argument is passed to the procedure. This additional argument contains an indicator array with an element for each of the parameters of the CALL statement. In C, this would be an array of short INTs. For more information about how the indicators are handled, see the [SQL Programming](#) topic collection.

PARAMETER STYLE GENERAL WITH NULLS cannot be used with LANGUAGE JAVA.

**JAVA**

Specifies that the procedure will use a parameter passing convention that conforms to the Java language and ISO/IEC FCD 9075-13:2003, *Information technology - Database languages - SQL - Part 13: Java Routines and Types (SQL/JRT)* specification. INOUT and OUT parameters will be passed as single entry arrays to facilitate returning values.

PARAMETER STYLE JAVA can only be specified with LANGUAGE JAVA. For increased portability, you should write Java procedures that use the PARAMETER STYLE JAVA conventions. For details on passing parameters in JAVA, see the [IBM Developer Kit for Java](#) topic collection.

Note that the language of the external procedure determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NUL-terminated strings. For more information, see the [SQL Programming](#) topic collection. For Java routines, see the [IBM Developer Kit for Java](#) topic collection.

**DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments. The default is NOT DETERMINISTIC.

**NOT DETERMINISTIC**

The procedure may not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

**DETERMINISTIC**

The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, provided the referenced data in the database has not changed.

**MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies the classification of SQL statements and nested routines that this procedure can execute. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the procedure, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see [Appendix B, “Characteristics of SQL statements,” on page 1725](#). The default is MODIFIES SQL DATA. This option is ignored for parameter default expressions.
MODIFIES SQL DATA
Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA
Specifies that the procedure can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL.

CONTAINS SQL
Specifies that the procedure can only execute statements with a data access classification of CONTAINS SQL or NO SQL.

NO SQL
Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL.

CALLED ON NULL INPUT
Specifies that the procedure is to be called if any or all argument values are null. This specification means that the procedure must be coded to test for null argument values.

INHERIT SPECIAL REGISTERS
Specifies that existing values of special registers are inherited upon entry to the procedure.

FENCED or NOT FENCED
This parameter is allowed for compatibility with other products and is not used by Db2 for i.

DYNAMIC RESULT SETS integer
Specifies the maximum number of result sets that can be returned from the procedure. The minimum value for integer is zero and the maximum value is 32767.

If no DYNAMIC RESULT SETS clause is specified, result sets are returned for all cursors that remain open when the procedure ends.

Result sets are returned in the order in which the corresponding cursors are opened, unless a SET RESULT SETS statement is executed in the procedure. If the number of cursors that are still open for result sets when the procedure ends exceeds the maximum number specified on the DYNAMIC RESULT SETS clause, a warning is returned on the CALL statement and the number of result sets specified on the DYNAMIC RESULT SETS clause is returned.

If the SET RESULT SETS statement is issued, the number of results returned is the minimum of the number of result sets specified on this keyword and the SET RESULT SETS statement. If the SET RESULT SETS statement specifies a number larger than the maximum number of result sets, a warning is returned. Note that any result sets from cursors that have a RETURN TO CLIENT attribute are included in the number of result sets of the outermost procedure.

The result sets are scrollable if a cursor is used to return a result set and the cursor is scrollable. If a cursor is used to return a result set, the result set starts with the current position. Thus, if 5 FETCH NEXT operations have been performed before returning from the procedure, the result set starts with the 6th row of the result set.

Cursor result sets are only returned if the external program does not have an attribute of ACTGRP(*NEW).

For more information about result sets, see “SET RESULT SETS” on page 1598.
CREATE PROCEDURE (external)

**DISALLOW DEBUG MODE, ALLOW DEBUG MODE, or DISABLE DEBUG MODE**
Indicates whether the procedure is created so it can be debugged by the Unified Debugger. If DEBUG MODE is not specified, the procedure will be created with the debug mode specified by the CURRENT DEBUG MODE special register.

DEBUG MODE can only be specified with LANGUAGE JAVA.

**DISALLOW DEBUG MODE**
The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISALLOW, the procedure can be subsequently altered to change the debug mode attribute.

**ALLOW DEBUG MODE**
The procedure can be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is ALLOW, the procedure can be subsequently altered to change the debug mode attribute.

**DISABLE DEBUG MODE**
The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISABLE, the procedure cannot be subsequently altered to change the debug mode attribute.

**PROGRAM TYPE**
This parameter is allowed for compatibility with other products. It indicates whether the routine’s external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

**SUB**
Specifies that the procedure executes as a procedure in a service program. The external program must be a *SRVPGM object.

**MAIN**
Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

**DBINFO**
Specifies whether additional status information is passed to the procedure when it is called. The default is NO DBINFO.

**NO DBINFO**
Additional information is not passed.

**DBINFO**
An additional argument is passed when the procedure is called.

The argument is a structure that contains information such as the name of the current server, the application run-time authorization ID, and identification of the version and release of the database manager that called the procedure. See [Table 81] for further details. Detailed information about the DBINFO structure can be found in include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

DBINFO is only allowed with PARAMETER STYLE SQL.

**Table 81. DBINFO fields**

<table>
<thead>
<tr>

<td>Platform</td>
<td>INTEGER</td>
<td>The server’s platform type.</td>
</tr>
</tbody>
</table>

**EXTERNAL**

Specifies that the CREATE PROCEDURE statement is being used to define a new procedure based on code written in an external programming language.

If NAME clause is not specified, "NAME procedure-name" is assumed. In this case, procedure-name must not be longer than 8 characters. The NAME clause is required for a LANGUAGE JAVA procedure since the default name is not valid for a Java procedure.

**NAME external-program-name**

Specifies the program or service program that will be executed when the procedure is called by the CALL statement. The program name must identify a program or service program that exists at the application server at the time the procedure is called. If the naming option is *SYS and the name is not qualified:

- The current path will be used to search for the program at the time the procedure is called.
- *LIBL will be used to search for the program or service program at the time COMMENT, GRANT, LABEL, or REVOKE operations are performed on the procedure.
The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

The external program or service program need not exist at the time the procedure is created, but it must exist at the time the procedure is called.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, and SET TRANSACTION statements are not allowed in a procedure that is running on a remote application server. COMMIT and ROLLBACK statements are not allowed in an ATOMIC SQL procedure or in a procedure that is running on a connection to a remote application server.

**SPECIFIC specific-name**

Specifies a unique name for the function. For more information on specific names, see Specifying a specific name for a procedure in CREATE PROCEDURE on page 1112.

**OLD SAVEPOINT LEVEL or NEW SAVEPOINT LEVEL**

Specifies whether a new savepoint level is to be created on entry to the procedure.

**OLD SAVEPOINT LEVEL**

A new savepoint level is not created. Any SAVEPOINT statements issued within the procedure with OLD SAVEPOINT LEVEL implicitly or explicitly specified on the SAVEPOINT statement are created at the same savepoint level as the caller of the procedure. This is the default.

**NEW SAVEPOINT LEVEL**

A new savepoint level is created on entry to the procedure. Any savepoints set within the procedure are created at a savepoint level that is nested deeper than the level at which this procedure was invoked. Therefore, the name of any new savepoint set within the procedure will not conflict with any existing savepoints set in higher savepoint levels (such as the savepoint level of the calling program or service program) with the same name.

**COMMIT ON RETURN**

Specifies whether the database manager commits the transaction immediately on return from the procedure.

**NO**

The database manager does not issue a commit when the procedure returns. NO is the default.

**YES**

The database manager issues a commit if the procedure returns successfully. If the procedure returns with an error, a commit is not issued.

The commit operation includes the work that is performed by the calling application process and the procedure.99

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**AUTONOMOUS**

Specifies that the procedure is executed in a unit of work that is independent from the calling application. When this option is specified the database always commits or rolls back the autonomous procedure's transactional work based on the SQLSTATE that is returned from the procedure. A SQLSTATE indication of

---

99. If the external program or service program was created with ACTGRP(*NEW) and the job commitment definition is not used, the work that is performed in the procedure will be committed or rolled back as a result of the activation group ending.
unqualified success or warning will cause the transaction to be committed. All other SQLSTATEs will cause the autonomous procedure's unit of work to be rolled back.

The invocation of any trigger, function, or procedure from within the autonomous procedure will be part of the autonomous procedure's unit of work unless the trigger, function, or procedure was explicitly created to run under a different activation group.

An autonomous procedure cannot be called directly or indirectly from another autonomous procedure.

If AUTONOMOUS is specified, DYNAMIC RESULT SETS 0 must be specified.

**SET OPTION-statement**

Specifies the options that will be used for parameter defaults. The default values for the options depend on the options in effect at create time. For more information, see "SET OPTION" on page 1575.

The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP. The options CNULRQD, CNULIGN, COMPILEOPT, EXTIND, NAMING, and SQLCA are not allowed in the CREATE PROCEDURE statement. Other options are accepted but will be ignored.

**Notes**

**General considerations for defining procedures:** See "CREATE PROCEDURE" on page 1112 for general information about defining procedures.

**Language considerations:** For information needed to create the programs for a procedure, see [Embedded SQL Programming](#).

**REPLACE rules:** When an external procedure is recreated by REPLACE:

- Any existing comment or label is discarded.
- If a different external program is specified:
  - Authorized users are not copied to the new program.
  - Journal auditing is not changed.
- Otherwise:
  - Authorized users are maintained. The object owner will not change.
  - Current journal auditing is not changed.

**Error handling considerations:** Values of arguments passed to a procedure which correspond to OUT parameters are undefined and those which correspond to INOUT parameters are unchanged when an error is returned by the procedure.

**Creating the procedure:** When an external procedure associated with an ILE external program or service program is created, an attempt is made to save the procedure's attributes in the associated program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The attributes can be saved for external procedures subject to the following restrictions:
CREATE PROCEDURE (external)

- The external program library must not be QSYS.
- The external program must exist when the CREATE PROCEDURE statement is issued.
  If system naming is specified and the external program name is not qualified, the external program must be found in the library list.
- The external program must be an ILE *PGM or *SRVPGM object.
- The external program must not already contain attributes for 32 routines.

If the object cannot be updated, the procedure will still be created.

**Calling the procedure:** If a DECLARE PROCEDURE statement defines a procedure with the same name as a created procedure, and a static CALL statement where the procedure name is not identified by a variable is executed from the same source program, the attributes from the DECLARE PROCEDURE statement will be used rather than the attributes from the CREATE PROCEDURE statement.

The CREATE PROCEDURE statement applies to static and dynamic CALL statements as well as to a CALL statement where the procedure name is identified by a variable.

When an external procedure is invoked, it runs in whatever activation group was specified when the external program or service program was created. However, ACTGRP(*CALLER) should normally be used so that the procedure runs in the same activation group as the calling program.

The external program or service program for a procedure with the AUTONOMOUS attribute must be defined to run in activation group QSQAUTOAG. When an autonomous procedure is invoked in a job, every procedure that runs in the QSQAUTOAG activation group must have been created with the same storage model. They must all be *TERASPACE or all be *SNGLVL.

**Setting of the default value:** Parameters of a procedure that are defined with a default value are set to their default value when the procedure is invoked, but only if a value is not supplied for the corresponding argument, or the argument is specified as DEFAULT.

**Notes for Java procedures:** To be able to run Java procedures, you must have the IBM Developer Kit for Java installed on your system. Otherwise, an SQLCODE of -443 will be returned and a CPDB521 message will be placed in the job log.

If an error occurs while running a Java procedure, an SQLCODE of -443 will be returned. Depending on the error, other messages may exist in the job log of the job where the procedure was run.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:
- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL can be used as synonyms for CALLED ON NULL INPUT.
- The keywords SIMPLE CALL can be used as a synonym for GENERAL.
- The value DB2GENRL may be used as a synonym for DB2GENERAL.
• DYNAMIC RESULT SET, RESULT SETS, and RESULT SET may be used as synonyms for DYNAMIC RESULT SETS.
• The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
• The keywords PARAMETER STYLE DB2SQL can be used as a synonym for PARAMETER STYLE SQL.

Example

Example 1: Create the procedure definition for a procedure, written in Java, that is passed a part number and returns the cost of the part and the quantity that are currently available.

```
CREATE PROCEDURE PARTS_ON_HAND (IN PARTNUM INTEGER,
                                  OUT COST DECIMAL(7,2),
                                  OUT QUANTITY INTEGER)
LANGUAGE JAVA
PARAMETER STYLE JAVA
EXTERNAL NAME 'parts.onhand'
```

Example 2: Create the procedure definition for a procedure, written in C, that is passed an assembly number and returns the number of parts that make up the assembly, total part cost and a result set that lists the part numbers, quantity and unit cost of each part.

```
CREATE PROCEDURE ASSEMBLY_PARTS (IN ASSEMBLY_NUM INTEGER,
                                  OUT NUM_PARTS INTEGER,
                                  OUT COST DOUBLE)
LANGUAGE C
PARAMETER STYLE GENERAL
DYNAMIC RESULT SETS 1
FENCED
EXTERNAL NAME ASSEMBLY
```
The CREATE PROCEDURE (SQL) statement creates an SQL procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS catalog view and SYSPARMS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - *USE on the Create Program (CRTPGM) command, and
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the procedure is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

If a distinct type or array type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type or array type identified in the statement:
  - The USAGE privilege on the type, and
  - The system authority *EXECUTE on the library containing the distinct type or array type
- Database administrator authority

To replace an existing procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the program or service program object associated with the procedure
CREATE PROCEDURE (SQL)

- All authorities needed to DROP the procedure
- The system authority *READ to the SYSPROCS catalog view and SYSPARMS catalog table

- Database administrator authority

For information on the system authorities corresponding to SQL privileges, see "Corresponding System Authorities When Checking Privileges to a Function or Procedure" and "Corresponding System Authorities When Checking Privileges to a Distinct Type".

normalize-clause:

Description

OR REPLACE

Specifies to replace the definition for the procedure if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the procedure are not affected. This option is ignored if a definition for the procedure does not exist at the current server. To replace an existing procedure, the specific-name and procedure-name of the new definition must be the same as the specific-name and procedure-name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new procedure is created.

procedure-name

Names the procedure. The combination of name, schema name, the number of parameters must not identify a procedure that exists at the current server.

For SQL naming, the procedure will be created in the schema specified by the implicit or explicit qualifier.

For system naming, the procedure will be created in the schema specified by the qualifier. If no qualifier is specified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the procedure will be created in the current library (*CURLIB).
- Otherwise, the procedure will be created in the current schema.

The schema-name cannot be QSYS2, QSYS, QTEMP, or SYSIBM.

(parameter-declaration,...)

Specifies the number of parameters of the procedure and the data type of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. All parameters are nullable.

The maximum number of parameters allowed in an SQL procedure is 2000.

IN Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned. The default is IN.

A parameter that is an array of XML or LOB type is read only.

OUT Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned. If an INOUT parameter is defined with a default and the default is used when calling the procedure, no value for the parameter is returned.
**parameter-name**
Names the parameter. The name cannot be the same as any other parameter-name for the procedure.

**data-type**
Specifies the data type of the parameter. The data type can be a built-in data type or a distinct data type.

**built-in-type**
Specifies a built-in data type. For a more complete description of each built-in data type, see “CREATE TABLE” on page 1159.

**distinct-type-name**
Specifies a distinct type. The length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). For more information on creating a distinct type, see “CREATE TYPE (distinct)” on page 1241.

If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

**array-type-name**
Specifies an array type.

If the name of the array type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the procedure. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the procedure is called.

**default**
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in “Expressions” on page 174, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation of the procedure. The maximum length of the expression string is 64K.

The default expression must not modify SQL data. The expression must be assignment compatible to the parameter data type. All objects referenced in a default expression must exist when the procedure is created.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

A default cannot be specified:
• for an OUT parameter.
• for a parameter of type array.

**LANGUAGE SQL**
Specifies that this procedure is written exclusively in SQL.

**SPECIFIC specific-name**
Specifies a unique name for the procedure. For more information on specific names, see “Specifying a specific name for a procedure in CREATE PROCEDURE” on page 1112.
**CREATE PROCEDURE (SQL)**

**DETERMINISTIC or NOT DETERMINISTIC**
Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments. The default is NOT DETERMINISTIC.

**NOT DETERMINISTIC**
The procedure may not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

**DETERMINISTIC**
The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, provided the referenced data in the database has not changed.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**
Specifies the classification of SQL statements and nested routines that this procedure can execute. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the procedure, are consistent with this specification. The verification is not performed when nested remote routines are invoked. For the classification of each statement, see Appendix B, “Characteristics of SQL statements,” on page 1725. The default is MODIFIES SQL DATA. This option applies to any parameter default expressions.

**MODIFIES SQL DATA**
Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

**READS SQL DATA**
Specifies that the procedure can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL.

**CONTAINS SQL**
Specifies that the procedure can only execute statements with a data access classification of CONTAINS SQL or NO SQL.

**CALLED ON NULL INPUT**
Specifies that the procedure is to be called if any or all argument values are null. This specification means that the procedure must be coded to test for null argument values.

**INHERIT SPECIAL REGISTERS**
Specifies that existing values of special registers are inherited upon entry to the procedure.

**DYNAMIC RESULT SETS** *integer*
Specifies the maximum number of result sets that can be returned from the procedure. The minimum value for *integer* is zero and the maximum value is 32767. The default is DYNAMIC RESULT SETS 0.

Result sets are returned in the order in which the corresponding cursors are opened, unless a SET RESULT SETS statement is executed in the procedure. If the number of cursors still open for result sets when the procedure ends exceeds the maximum number specified on the DYNAMIC RESULT SETS clause, a warning is returned on the CALL statement and the number of result sets specified on the DYNAMIC RESULT SETS clause is returned.

If the SET RESULT SETS statement is issued, the number of results returned is the minimum of the number of result sets specified on this keyword and the SET RESULT SETS statement. If the SET RESULT SETS statement specifies a
number larger than the maximum number of result sets, a warning is returned. Note that any result sets from cursors that have a RETURN TO CLIENT attribute are included in the number of result sets of the outermost procedure.

The result sets are scrollable if the cursor is used to return a result set and the cursor is scrollable. If a cursor is used to return a result set, the result set starts with the current position. Thus, if 5 FETCH NEXT operations have been performed prior to returning from the procedure, the result set will start with the 6th row of the result set.

For more information about result sets, see “SET RESULT SETS” on page 1598.

**DISALLOW DEBUG MODE, ALLOW DEBUG MODE, or DISABLE DEBUG MODE**

Indicates whether the procedure is created so it can be debugged by the Unified Debugger. If DEBUG MODE is specified, a DBGVIEW option in the SET OPTION statement must not be specified.

**DISALLOW DEBUG MODE**

The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISALLOW, the procedure can be subsequently altered to change the debug mode attribute.

**ALLOW DEBUG MODE**

The procedure can be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is ALLOW, the procedure can be subsequently altered to change the debug mode attribute.

**DISABLE DEBUG MODE**

The procedure cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of the procedure is DISABLE, the procedure cannot be subsequently altered to change the debug mode attribute.

If DEBUG MODE is not specified, but a DBGVIEW option in the SET OPTION statement is specified, the procedure cannot be debugged by the Unified Debugger, but may be debugged by the system debug facilities. If neither DEBUG MODE nor a DBGVIEW option is specified, the debug mode used is from the CURRENT DEBUG MODE special register.

**FENCED or NOT FENCED**

This parameter is allowed for compatibility with other products and is not used by Db2 for i.

**PROGRAM TYPE MAIN or PROGRAM TYPE SUB**

Specifies whether the procedure is created as a program (*PGM) or a procedure in a service program (*SRVPGM).

**PROGRAM TYPE MAIN**

Specifies that the procedure is created as a program (*PGM).

**PROGRAM TYPE SUB**

Specifies that the procedure is created as a procedure in a service program (*SRVPGM).

PROGRAM TYPE SUB procedures usually perform slightly better than PROGRAM TYPE MAIN procedures.

**OLD SAVEPOINT LEVEL or NEW SAVEPOINT LEVEL**

Specifies whether a new savepoint level is to be created on entry to the procedure.

**OLD SAVEPOINT LEVEL**

A new savepoint level is not created. Any SAVEPOINT statements issued
within the procedure with OLD SAVEPOINT LEVEL implicitly or explicitly specified on the SAVEPOINT statement are created at the same savepoint level as the caller of the procedure. This is the default.

**NEW SAVEPOINT LEVEL**
A new savepoint level is created on entry to the procedure. Any savepoints set within the procedure are created at a savepoint level that is nested deeper than the level at which this procedure was invoked. Therefore, the name of any new savepoint set within the procedure will not conflict with any existing savepoints set in higher savepoint levels (such as the savepoint level of the calling program) with the same name.

**COMMIT ON RETURN**
Specifies whether the database manager commits the transaction immediately on return from the procedure.

**NO**
The database manager does not issue a commit when the procedure returns. NO is the default.

**YES**
The database manager issues a commit if the procedure returns successfully. If the procedure returns with an error, a commit is not issued.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**AUTONOMOUS**
Specifies that the procedure is executed in a unit of work that is independent from the calling application. When this option is specified the database always commits or rolls back the autonomous procedure's transactional work based on the SQLSTATE that is returned from the procedure. A SQLSTATE indication of unqualified success or warning will cause the transaction to be committed. All other SQLSTATEs will cause the autonomous procedure's unit of work to be rolled back.

The invocation of any trigger, function, or procedure from within the autonomous procedure will be part of the autonomous procedure's unit of work unless the trigger, function, or procedure was explicitly created to run under a different activation group.

An autonomous procedure cannot be called directly or indirectly from another autonomous procedure.

If AUTONOMOUS is specified, DYNAMIC RESULT SETS 0 must be specified.

**CONCURRENT ACCESS RESOLUTION**
Specifies whether the database manager should wait for data that is in the process of being updated. DEFAULT is the default.

**DEFAULT**
Specifies that the concurrent access resolution is not explicitly set for this procedure. The value that is in effect when the procedure is called will be used.

**WAIT FOR OUTCOME**
Specifies that the database manager is to wait for the commit or rollback of data in the process of being updated.
USE CURRENTLY COMMITTED
Specifies that the database manager is to use the currently committed version of the data when encountering data that is in the process of being updated.

When the lock contention is between a read transaction and a delete or update transaction, the clause is applicable to scans with isolation level CS (but not for CS KEEP LOCKS).

SYSTEM_TIME SENSITIVE
Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default.

YES
References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

NO
References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

WRAPPED obfuscated-statement-text
Specifies the encoded definition of the procedure. A CREATE PROCEDURE statement can be encoded using the WRAP scalar function.

SET OPTION-statement
Specifies the options that will be used to create the procedure. These options also apply to any default value expressions. For example, to create a debuggable procedure, the following statement could be included:

SET OPTION DBGVIEW = +SOURCE

The default values for the options depend on the options in effect at create time. For more information, see "SET OPTION" on page 1575.

The options CLOSQLCSR, CNULRQD, CNULIGN, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE PROCEDURE statement. The following options are used when processing default value expressions: ALWCOPYDATA, CONACC, DATFMT, DATSEP, DECFLTRND, DECRIPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP.

SQL-routine-body
Specifies a single SQL-procedure-statement, including a compound statement. See Chapter 8, "SQL control statements," on page 1645 for more information about defining SQL procedures.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, and SET TRANSACTION statements are not allowed in a procedure that is running on a remote application server. COMMIT and ROLLBACK statements are not allowed in an ATOMIC SQL procedure or in a procedure that is running on a connection to a remote application server.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL Table) with a REPLACE keyword are not allowed in an SQL-routine-body.

Notes

General considerations for defining procedures: See "CREATE PROCEDURE" on page 1112 for general information on defining procedures.
**CREATE PROCEDURE (SQL)**

**Procedure ownership:** If SQL names were specified:
- If a user profile with the same name as the schema into which the procedure is created exists, the owner of the procedure is that user profile.
- Otherwise, the owner of the procedure is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the procedure is the user profile or group user profile of the thread executing the statement.

**Procedure authority:** If SQL names are used, procedures are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, procedures are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the procedure is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the procedure.

**REPLACE rules:** When a procedure is recreated by REPLACE:
- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

**Error handling in procedures:** Consideration should be given to possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception SQLSTATE that is not handled within the procedure using a handler within a compound statement results in the exception SQLSTATE being returned to the caller of the procedure. Values of arguments passed to a procedure that correspond to OUT parameters are undefined and those that correspond to INOUT parameters are unchanged when an error is returned by the procedure.

**Creating the procedure:** When an SQL procedure is created, SQL creates a temporary source file that will contain C source code with embedded SQL statements. A program or service program object is then created using the CRTPGM or CRTSRVPGM command. The SQL options used to create the program are the options that are in effect at the time the CREATE PROCEDURE statement is executed. If AUTONOMOUS is specified, the program or service program is created with ACTGRP(QSQAUTOAG). Otherwise, the program is created with ACTGRP(*CALLER).

When an SQL procedure is created, the procedure's attributes are stored in the created program or service program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the attributes are used to update the catalogs.

The specific procedure name is used as the name of the member in the source file and the name of the program object, if it is a valid system name. If the procedure name is not a valid system name, a unique name is generated. If a source file member with the same name already exists, the member is overlaid. If a module or a program with the same name already exists, the objects are not overlaid, and a unique name is generated. The unique names are generated according to the rules for generating system table names.

**Invoking the procedure:** If a DECLARE PROCEDURE statement defines a procedure with the same name as a created procedure, and a static CALL
statement where the procedure name is not identified by a variable is executed from the same source program, the attributes from the DECLARE PROCEDURE statement will be used rather than the attributes from the CREATE PROCEDURE statement.

The CREATE PROCEDURE statement applies to static and dynamic CALL statements as well as to a CALL statement where the procedure name is identified by a variable.

SQL procedures must be called using the SQL CALL statement. When called, the SQL procedure runs in the activation group of the calling program.

SQL procedures are built with the *TERASPACE storage model. When an autonomous SQL procedure is invoked in a job, every procedure that runs in the QSQAUTOAG activation group must use the *TERASPACE storage model.

**Obfuscated statements**: A CREATE PROCEDURE statement can be executed in obfuscated form. In an obfuscated statement, only the procedure name and parameters are readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the procedure is created from an obfuscated statement are ignored. A procedure that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

**Setting of the default value**: Parameters of a procedure that are defined with a default value are set to their default value when the procedure is invoked, but only if a value is not supplied for the corresponding argument, or the argument is specified as DEFAULT.

**Dependent objects**: An SQL routine is dependent on objects that are referenced in the SQL-routine-body. The names of the dependent objects are stored in catalog view SYSROUTINEDEP. If the object reference in the SQL-routine-body is a fully qualified name or, in SQL naming, if an unqualified name is qualified by the current schema, then the schema name of the object in SYSROUTINEDEP will be set to the specified name or the value of the current schema. Otherwise, the schema name is not set to a specific schema name. Unqualified function names, variable names, and type names will have a schema name of CURRENT PATH. If the name is not set to an actual schema name, then DROP and ALTER statements will not be able to determine whether the routine is dependent on the object being altered or dropped.

**Syntax alternatives**: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL can be used as synonyms for CALLED ON NULL INPUT.
- DYNAMIC RESULT SET, RESULT SETS, and RESULT SET may be used as synonyms for DYNAMIC RESULT SETS.
Example

Create an SQL procedure that returns the median staff salary. Return a result set containing the name, position, and salary of all employees who earn more than the median salary.

```sql
CREATE PROCEDURE MEDIAN_RESULT_SET (OUT medianSalary DECIMAL(7,2))
LANGUAGE SQL
DYNAMIC RESULT SETS 1
BEGIN
    DECLARE v_numRecords INTEGER DEFAULT 1;
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE c1 CURSOR FOR
        SELECT salary
        FROM staff
        ORDER BY salary;
    DECLARE c2 CURSOR WITH RETURN FOR
        SELECT name, job, salary
        FROM staff
        WHERE salary > medianSalary
        ORDER BY salary;
    DECLARE EXIT HANDLER FOR NOT FOUND
        SET medianSalary = 6666;
    SET medianSalary = 0;
    SELECT COUNT(*) INTO v_numRecords FROM STAFF;
    OPEN c1;
    WHILE v_counter < (v_numRecords / 2 + 1)
        DO FETCH c1 INTO medianSalary;
        SET v_counter = v_counter + 1;
    END WHILE;
    CLOSE c1;
    OPEN c2;
END
```
The CREATE SCHEMA statement defines a schema at the current server and optionally creates tables, views, aliases, indexes, sequences, and distinct types. Comments and labels may be added in the catalog description of these objects, and privileges can be granted to users.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The *USE system authority to the following CL commands:
  - Create Library (CRTLIB)
  - If WITH DATA DICTIONARY is specified, Create Data Dictionary (CRTDTADCT)
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privileges defined for each SQL statement included in the CREATE SCHEMA statement
- Database administrator authority

If the AUTHORIZATION clause is specified, the privileges held by the authorization ID of the statement must also include at least one of the following:

- The system authority *ADD to the user profile identified by authorization-name
- Database administrator authority

Syntax
CREATE SCHEMA

<table>
<thead>
<tr>
<th>COMMENT statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE ALIAS statement</td>
</tr>
<tr>
<td>CREATE INDEX statement</td>
</tr>
<tr>
<td>CREATE SEQUENCE statement</td>
</tr>
<tr>
<td>CREATE TABLE statement</td>
</tr>
<tr>
<td>CREATE TYPE (Array) statement</td>
</tr>
<tr>
<td>CREATE TYPE (Distinct) statement</td>
</tr>
<tr>
<td>CREATE VIEW statement</td>
</tr>
<tr>
<td>GRANT (Sequence Privileges) statement</td>
</tr>
<tr>
<td>GRANT (Table or View Privileges) statement</td>
</tr>
<tr>
<td>GRANT (Type Privileges) statement</td>
</tr>
<tr>
<td>LABEL statement</td>
</tr>
</tbody>
</table>

Notes:

1. Only labels and comments on object types created in the schema are supported in the CREATE SCHEMA statement.

Description

schema-name

Names the schema. A schema is created using this name. If schema-name is specified, the authorization ID of the statement is the run-time authorization ID. The name must not be the same as the name of an existing schema at the current server. The name should not begin with 'SYS' or 'Q'. Such schema names indicate that the schema is a system schema.

If the schema-name is not a valid system name and a system-schema-name is not specified, SQL will generate a system name. For information about the rules for generating the name, see "Rules for Schema Name Generation" on page 1149.

FOR SCHEMA system-schema-name

Identifies the system name of the schema. system-schema-name must not be the same as a schema that already exists at the current server. The system-schema-name must be an unqualified system identifier that is a valid system name.

If both schema-name and system-schema-name are specified, they cannot both be valid system names.

authorization-name

Identifies the authorization ID of the statement. This authorization name is also the schema-name. The name must not be the same as the name of an existing schema at the current server.

IN ASP

Specifies the auxiliary storage pool (ASP) in which to create the schema.

integer

The integer must be between 1 and 32. If 1 is specified, the schema is created on the system ASP.

ASP-name

The name must identify an auxiliary storage pool that exists at the current server.
If this clause is omitted,

- If the name space of the invoking thread is set to an independent auxiliary storage pool (IASP), the schema will be created in the IASP name space.
- Otherwise, an ASP of 1 is assumed.

**COMMENT statement**

Adds or replaces comments in the catalog descriptions of an object created in the schema. Only comments on objects created in the schema are allowed. See the COMMENT statement “COMMENT” on page 968.

**CREATE ALIAS statement**

Creates an alias into the schema. See the CREATE ALIAS statement “CREATE ALIAS” on page 1003.

**CREATE INDEX statement**

Creates an index into the schema. See the CREATE INDEX statement “CREATE INDEX” on page 1093.

**CREATE SEQUENCE statement**

Creates a sequence into the schema. See the CREATE SEQUENCE statement “CREATE SEQUENCE” on page 1151.

**CREATE TABLE statement**

Creates a table into the schema. See the CREATE TABLE statement “CREATE TABLE” on page 1159.

**CREATE TYPE (Array) statement**

Creates an array type into the schema. See the CREATE TYPE (Array) statement “CREATE TYPE (array)” on page 1236.

**CREATE TYPE (Distinct) statement**

Creates a user-defined distinct type into the schema. See the CREATE TYPE (Distinct) statement “CREATE TYPE (distinct)” on page 1241.

**CREATE VIEW statement**

Creates a view into the schema. See the CREATE VIEW statement “CREATE VIEW” on page 1255.

**GRANT (Sequence Privileges) statement**

Grants privileges for sequences in the schema. See the GRANT statement “GRANT (sequence privileges)” on page 1427.

**GRANT (Table or View Privileges) statement**

Grants privileges for tables and views in the schema. See the GRANT statement “GRANT (table or view privileges)” on page 1430.

**GRANT (Type Privileges) statement**

Grants privileges for types in the schema. See the GRANT statement “GRANT (type privileges)” on page 1436.

**LABEL statement**

Adds or replaces labels in the catalog descriptions of an object created in the schema. Only labels on objects created in the schema are allowed. See the LABEL statement “LABEL” on page 1463.

**Notes**

**Schema attributes:** A schema is created as:

- A library: A library groups related objects, and allows you to find objects by name.
CREATE SCHEMA

- A catalog: A catalog contains descriptions of the tables, views, indexes, and other objects in the schema. A catalog consists of a set of views. For more information, see SQL Programming.
- A journal and journal receiver: A journal QSQJRN and journal receiver QSQJRN0001 is created in the schema, and is used to record changes to all tables subsequently created in the schema. For more information, see Journal Management.

An index created over a distributed table is created on all of the servers across which the table is distributed. For more information about distributed tables, see DB2 Multisystem.

Object ownership: The owner of the schema and created objects is determined as follows:

- If an AUTHORIZATION clause is specified, the specified authorization ID owns the schema and all objects created by the statement.
- Otherwise, the owner of the schema and all objects created by the statement is the user profile or the group user profile of the thread executing the statement.

Object authority: If SQL names are used, the schema and any other objects are created with the system authority of *EXCLUDE on *PUBLIC and the library is created with the create authority parameter CRTAUT(*EXCLUDE). The owner is the only user having any authority to the schema. If other users require authority to the schema, the owner can grant authority to the objects created; using the CL command Grant Object Authority (GRTOBJAUT).

If system names are used, the schema and any other objects are created with the system authority given to *PUBLIC is determined by the system value QCRTAUT, and the library is created with CRTAUT(*SYSVAL). For more information about system security, see Security Reference and SQL Programming.

If the owner of the schema is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the schema.

Object names: If a CREATE TABLE, CREATE INDEX, CREATE ALIAS, CREATE TYPE, CREATE SEQUENCE, or CREATE VIEW statement contains a qualified name for the table, index, alias, distinct type, sequence, or view being created, the schema name specified in that qualified name must be the same as the name of the schema being created. Any other object names referenced within the schema definition may be qualified by any schema name. Unqualified table, index, alias, distinct type, sequence, or view names in any SQL statement are implicitly qualified with the name of the created schema.

Delimiters are not used between the SQL statements.

SQL statement length: If the CREATE SCHEMA statement is executed via the RUNSQLSTM command, the maximum length of any individual CREATE TABLE, CREATE INDEX, CREATE TYPE, CREATE ALIAS, CREATE SEQUENCE, CREATE VIEW, COMMENT, LABEL, or GRANT statements within the CREATE SCHEMA statement is 2 097 152. Otherwise, the entire CREATE SCHEMA statement is limited to 2 097 152.

Name resolution performance: The name of the schema can affect the performance of statements that reference objects in the schema. If the length of a schema name
is greater than 30, the performance of finding objects in the schema will be worse than schemas whose name length is less than or equal to 30. To minimize the performance impact, ensure that the first 5 characters of the system name and the schema name are the same.

Syntax alternatives: The COLLECTION keyword can be used as a synonym for SCHEMA for compatibility to prior releases. This keyword is non-standard and should not be used.

Deprecated features: The WITH DATA DICTIONARY clause causes an IDDU data dictionary to be created in the schema. While the clause can still be specified at the end of the CREATE SCHEMA statement and is still supported; it is not recommended.

A schema created with a data dictionary cannot contain tables with LOB, XML, or DATALINK columns. The clause has no effect on the creation of catalog views.

Rules for Schema Name Generation

A system name will be generated if a schema is created with a name that is longer than 10 characters.

The SQL name or its corresponding system name may both be used in SQL statements to access the schema once it is created. However, the SQL name is only recognized by Db2 for i and the system name must be used in other environments.

If the schema-name is an ordinary identifier and longer than 10 characters, a 10-character system-schema-name will be generated as:

- The first 5 characters of the name
- A 5 digit unique number

For example:
The system-schema-name for LONGSCHEMANAME would be LONGS00001

If the schema-name is a delimited identifier and longer than 10 characters, a 10-character system-schema-name will be generated as:

- The first 4 characters from within the delimiters will be used as the first characters of the system-schema-name.
- If the first 4 characters are all uppercase letters, digits, or underscores, an underscore and a 5 digit unique number is appended.
- Otherwise, a 4 digit unique number is appended.

For example:
The system name for "longschemaname" would be "long0001"
The system name for "LONGSchemaName" would be LONG_00001

Examples

Example 1: Create a schema that has an inventory part table and an index over the part number. Give authority to the schema to the user profile JONES.

```
CREATE SCHEMA INVENTORY

CREATE TABLE PART (PARTNO SMALLINT NOT NULL,
DESCR VARCHAR(24),
QUANTITY INT)
```
CREATE INDEX PARTIND ON PART (PARTNO)

GRANT ALL ON PART TO JONES

Example 2: Create a schema using the authorization ID of SMITH. Create a student table that has a comment on the student number column.

CREATE SCHEMA AUTHORIZATION SMITH

CREATE TABLE SMITH.STUDENT (STUDNBR SMALLINT NOT NULL UNIQUE,
   LASTNAME CHAR(20),
   FIRSTNAME CHAR(20),
   ADDRESS CHAR(50))

COMMENT ON STUDENT (STUDNBR IS 'THIS IS A UNIQUE ID#')
The CREATE SEQUENCE statement creates a sequence at the application server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - *USE to the Create Data Area (CRTDTAARA) command
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSSEQOBJECTS catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

To replace an existing sequence, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the data area associated with the sequence
  - All authorities needed to DROP the sequence
  - The system authority *READ to the SYSSEQOBJECTS catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Sequence](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).
CREATE SEQUENCE

Syntax

```
CREATE OR REPLACE SEQUENCE sequence-name
```

Notes:
1. The same clause must not be specified more than once.

**data-type:**

```
built-in-type
distinct-type-name
```

**built-in-type:**

```
SMALLINT
INTEGER
INT
BIGINT
DECIMAL
DEC
NUMERIC
NUM
```

**Description**

**OR REPLACE**

Specifies to replace the definition for the sequence if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the sequence are not affected. This option is ignored if a definition for the sequence does not exist at the current server.
sequence-name
Names the sequence. The name, including the implicit or explicit qualifier, must not identify a sequence or data area that already exists at the current server. If a qualified sequence name is specified, the schema-name cannot be QSYS2, QSYS, or SYSIBM.

If SQL names were specified, the sequence will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the sequence will be created in the schema that is specified by the qualifier. If not qualified:
- If the value of the CURRENT SCHEMA special register is *LIBL, the sequence will be created in the current library (*CURLIB).
- Otherwise, the sequence will be created in the current schema.

AS data-type
Specifies the data type to be used for the sequence value. The data type can be any exact numeric type (SMALLINT, INTEGER, BIGINT, DECIMAL, or NUMERIC) with a scale of zero, or a user-defined distinct type for which the source type is an exact numeric type with a scale of zero. The default is INTEGER.

built-in-type
Specifies the built-in data type used as the basis for the internal representation of the sequence. If the data type is DECIMAL or NUMERIC, the precision must be less than or equal to 63 and the scale must be 0. See "CREATE TABLE" on page 1159 for a more complete description of each built-in data type.

For portability of applications across platforms, use DECIMAL instead of a NUMERIC data type.

distinct-type-name
Specifies that the data type of the sequence is a distinct type (a user-defined data type). If the source type is DECIMAL or NUMERIC, the precision of the sequence is the precision of the source type of the distinct type. The precision of the source type must be less than or equal to 63 and the scale must be 0. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

START WITH numeric-constant
Specifies the first value that is generated for the sequence. The value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence, without non-zero digits to the right of the decimal point.

If a value is not explicitly specified when the sequence is defined, the default is the MINVALUE for an ascending sequence and the MAXVALUE for a descending sequence.

This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY numeric-constant
Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value that could be assigned to a column of the
CREATE SEQUENCE

data type associated with the sequence, and does not exceed the value of a
large integer constant, without nonzero digits existing to the right of the
decimal point.

If the value is 0 or positive, this is an ascending sequence. If the value is
negative, this is a descending sequence. The default is 1.

**NO MINVALUE or MINVALUE**
Specifies the minimum value at which a descending sequence either cycles or
stops generating values, or an ascending sequence cycles to after reaching the
maximum value. The default is NO MINVALUE.

**NO MINVALUE**
For an ascending sequence, the value is the START WITH value, or 1 if
START WITH is not specified. For a descending sequence, the value is the
minimum value of the data type (and precision, if DECIMAL or
NUMERIC) associated with the sequence.

**MINVALUE numeric-constant**
Specifies the numeric constant that is the minimum value. This value can
be any positive or negative value that could be assigned to a column of the
data type associated with the sequence and without non-zero digits to the
right of the decimal point. The value must be less than or equal to the
maximum value.

**NO MAXVALUE or MAXVALUE**
Specifies the maximum value at which an ascending sequence either cycles or
stops generating values, or a descending sequence cycles to after reaching the
minimum value. The default is NO MAXVALUE.

**NO MAXVALUE**
For an ascending sequence, the value is the maximum value of the data
type (and precision, if DECIMAL or NUMERIC) associated with the
sequence. For a descending sequence, the value is the START WITH value,
or -1 if START WITH is not specified.

**MAXVALUE numeric-constant**
Specifies the numeric constant that is the maximum value. This value can
be any positive or negative value that could be assigned to a column of the
data type associated with the sequence and without non-zero digits to the
right of the decimal point. The value must be greater than or equal to the
minimum value.

**NO CYCLE or CYCLE**
Specifies whether this sequence should continue to generate values once the
maximum or minimum value of the sequence has been reached. The default is
NO CYCLE.

**NO CYCLE**
Specifies that values will not be generated for the sequence once the
maximum or minimum value for the sequence has been reached.

**CYCLE**
Specifies that values continue to be generated for this sequence after the
maximum or minimum value has been reached. If this option is used, after
an ascending sequence reaches the maximum value of the sequence, it
generates its minimum value. After a descending sequence reaches its
minimum value of the sequence, it generates its maximum value. The
maximum and minimum values for the column determine the range that is
used for cycling.
When CYCLE is in effect, then duplicate values can be generated for the sequence.

**CACHE or NO CACHE**

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of the NEXT VALUE sequence expression. The default is CACHE 20.

**CACHE integer-constant**

Specifies the maximum number of sequence values that are preallocated and kept in memory. Preallocating and storing values in the cache improves performance.

In certain situations, such as system failure, all cached sequence values that have not been used in committed statements are lost, and thus, will never be used. The value specified for the CACHE option is the maximum number of sequence values that could be lost in these situations.

The minimum value that can be specified is 2.

**NO CACHE**

Specifies that values for the sequence are not preallocated. If NO CACHE is specified, the performance of the NEXT VALUE sequence expression will be worse than if CACHE is specified.

**ORDER or NO ORDER**

Specifies whether the sequence values must be generated in order of request. The default is NO ORDER.

**NO ORDER**

Specifies that the sequence numbers do not need to be generated in order of request.

**ORDER**

Specifies that the sequence numbers are generated in order of request. If ORDER is specified, the performance of the NEXT VALUE sequence expression will be worse than if NO ORDER is specified.

**Notes**

**Sequence attributes:** A sequence is created as a *DTAARA object. The *DTAARA objects should not be changed with the Change Data Area (*CHGDTAARA) or any other similar interface because doing so may cause unexpected failures or unexpected results when attempting to use the SQL sequence through SQL.

**Sequence ownership:** The owner of the sequence is the user profile or group user profile of the thread executing the statement.

**Sequence authority:** If SQL names are used, sequences are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, sequences are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the sequence is a member of a group profile (GRPPRF keyword) and group authority is specified (GRP AUT keyword), that group profile will also have authority to the sequence.

**REPLACE rules:** When a sequence is recreated by REPLACE:

- Any existing comment or label is discarded.
• Authorized users are maintained. The object owner could change.
• Current journal auditing is preserved.

Relationship of MINVALUE and MAXVALUE: Typically, MINVALUE will be less than MAXVALUE, but this is not required. MINVALUE could be equal to MAXVALUE. If START WITH was the same value as MINVALUE and MAXVALUE, and CYCLE is implicitly or explicitly specified, this would be a constant sequence. In this case a request for the next value appears to have no effect because all the values generated by the sequence are in fact the same.

MINVALUE must not be greater than MAXVALUE

Defining constant sequences: It is possible to define a sequence that would always return a constant value. This could be done by specifying an INCREMENT value of zero and a START WITH value that does not exceed MAXVALUE, or by specifying the same value for START WITH, MINVALUE and MAXVALUE. For a constant sequence, each time a NEXT VALUE expression is processed the same value is returned. A constant sequence can be used as a numeric global variable. ALTER SEQUENCE can be used to adjust the values that will be generated for a constant sequence.

Defining sequences that cycle: A sequence can be cycled manually by using the ALTER SEQUENCE statement. If NO CYCLE is implicitly or explicitly specified, the sequence can be restarted or extended using the ALTER SEQUENCE statement to cause values to continue to be generated once the maximum or minimum value for the sequence has been reached.

A sequence can be explicitly defined to cycle by specifying the CYCLE keyword. Use the CYCLE option when defining a sequence to indicate that the generated values should cycle once the boundary is reached. When a sequence is defined to automatically cycle (for example CYCLE was explicitly specified), then the maximum or minimum value generated for a sequence may not be the actual MAXVALUE or MINVALUE specified, if the increment is a value other than 1 or -1. For example, the sequence defined with START WITH=1, INCREMENT=2, MAXVALUE=10 will generate a maximum value of 9, and will not generate the value 10.

When defining a sequence with CYCLE, then any application conversion tools (for converting applications from other vendor platforms to Db2) should also explicitly specify MINVALUE, MAXVALUE and START WITH.

Caching sequence numbers: A range of sequence numbers can be kept in memory for fast access. When an application accesses a sequence that can allocate the next sequence number from the cache, the sequence number allocation can happen quickly. However, if an application accesses a sequence that cannot allocate the next sequence number from the cache, the sequence number allocation will require an update to the *DTAARA object.

Choosing a high value for CACHE allows faster access to more successive sequence numbers. However, in the event of a failure, all sequence values in the cache are lost. If the NO CACHE option is used, the values of the sequence are not stored in the sequence cache. In this case every access to the sequence requires an update to the *DTAARA object. The choice of the value for CACHE should be made keeping the trade-off between performance and application requirements in mind.
Persistence of the most recently generated sequence value: The database manager remembers the most recently generated value for a sequence within the SQL-session, and returns this value for a PREVIOUS VALUE expression specifying the sequence name. The value persists until either the next value is generated for the sequence, the sequence is dropped, altered, or replaced, or until the end of the application session. The value is unaffected by COMMIT and ROLLBACK statements.

PREVIOUS VALUE is defined to have a linear scope within the application session. Therefore, in a nested application:

- on entry to a nested function, procedure, or trigger, the nested application inherits the most recently generated value for a sequence. That is, specifying an invocation of a PREVIOUS VALUE expression in a nested application will reflect sequence activity done in the invoking application, routine, or trigger before entering the nested application. An invocation of PREVIOUS VALUE expression in a nested application results in an error if a NEXT VALUE expression for the specified sequence had not yet been done in the invoking application, routine, or trigger.

- on return from a function, procedure, or trigger, the invoking application, routine or trigger will be affected by any sequence activity in the function, procedure, or trigger. That is, an invocation of PREVIOUS VALUE in the invoking application, routine, or trigger after returning from the nested application will reflect any sequence activity that occurred in the lower level applications.

Sequence journaling: When a sequence is created, journaling may be automatically started.

- If a data area called QDFTJRN exists in the same schema that the sequence is created into and the user is authorized to the data area, journaling will be started to the journal named in the data area if all the following are true:
  - The identified schema for the table must not be QSYS, QSYS2, QRECOVERY, QSPL, QRCL, QRPLOBJ, QGPL, QTEMP, SYSIBM, or any of the IASP equivalents to these libraries.
  - The journal specified in the data area must exist and the user must be authorized to start journaling to the journal.
  - The first 10 bytes of the data area must contain the name of the schema in which to find the journal.
  - The second 10 bytes must contain the name of the journal.
  - The remaining bytes contain the object types being implicitly journaled and the options that affect when implicit journaling is performed. The object type must include the value *DTAARA or *ALL. The value *NONE can be used to prevent journaling from being started.

For more information, see the [Journal Management] topic collection.

- If the sequence is created into a schema that has specified (using the STRJRNLIB command) that journaling should implicitly be started.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases of other Db2 products. These keywords are non-standard and should not be used:

- The keywords NOMINVALUE, NOMAXVALUE, NOCYCLE, NOCACHE, and NOORDER can be used as synonyms for NO MINVALUE, NO MAXVALUE, NO CYCLE, NO CACHE, and NO ORDER.

- A comma can be used to separate multiple sequence options.
CREATE SEQUENCE

Examples

Create a sequence called ORG_SEQ that starts at 1, increments by 1, does not cycle, and caches 24 values at a time:

```
CREATE SEQUENCE ORG_SEQ
    START WITH 1
    INCREMENT BY 1
    NO MAXVALUE
    NO CYCLE
    CACHE 24
```

The options START WITH 1, INCREMENT 1, NO MAXVALUE, and NO CYCLE are the values that would have been used if they had not been explicitly specified.
CREATE TABLE

The CREATE TABLE statement defines a table at the current server. The definition must include its name and the names and attributes of its columns. The definition may include other attributes of the table such as primary key.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see Privileges necessary to create in a schema
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - *USE to the Create Physical File (CRTPF) command
  - *CHANGE to the data dictionary if the library into which the table is created is an SQL schema with a data dictionary
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the table is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

To define a foreign key, the privileges held by the authorization ID of the statement must include at least one of the following on the parent table:

- The REFERENCES privilege or object management authority for the table
- The REFERENCES privilege on each column of the specified parent key
- Ownership of the table
- Database administrator authority

If a field procedure is defined, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority *EXECUTE on the program, and
  - The system authority *EXECUTE on the library containing the program
- Database administrator authority

If the LIKE clause or select-statement is specified, the privileges held by the authorization ID of the statement must include at least one of the following on the tables or views specified in these clauses:

- The SELECT privilege for the table or view
CREATE TABLE

- Ownership of the table or view
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:
- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

To replace an existing table, the privileges held by the authorization ID of the statement must include at least one of the following:
- The following system authorities:
  - The system authority of *OBJMGT on the table
  - All authorities needed to DROP the table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).
Syntax

Description

OR REPLACE

Specifies to replace the definition for the table if one exists at the current server. The existing definition is effectively altered before the new definition is replaced in the catalog.

A definition for the table exists if:

- FOR SYSTEM NAME is specified and the system-object-identifier matches the system-object-identifier of an existing table.
- FOR SYSTEM NAME is not specified and table-name is a system object name that matches the system-object-identifier of an existing table.

If a definition for the table exists and table-name is not a system object name, table-name can be changed to provide a new name for the table.

This option is ignored if a definition for the table does not exist at the current server.
CREATE TABLE

table-name
Names the table. The name, including the implicit or explicit qualifier, must not identify an alias, file, index, table, or view that already exists at the current server.

If SQL names were specified, the table will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the table will be created in the schema that is specified by the qualifier. If not qualified:

• If the value of the CURRENT SCHEMA special register is *LIBL, the table will be created in the current library (*CURLIB).
• Otherwise, the table will be created in the current schema.

FOR SYSTEM NAME system-object-identifier
Identifies the system-object-identifier of the table. system-object-identifier must not be the same as a table, view, alias, or index that already exists at the current server. The system-object-identifier must be an unqualified system identifier.

When system-object-identifier is specified, table-name must not be a valid system object name.

column-definition
Defines the attributes of a column. There must be at least one column definition and no more than 8000 column definitions.

The sum of the row buffer byte counts of the columns must not be greater than 32766 or, if a VARCHAR, VARGRAPHIC, or VARBINARY column is specified, 32740. Additionally, if a LOB or XML column is specified, the sum of the row data byte counts of the columns must not be greater than 3 758 096 383 at the time of insert or update. For information about the byte counts of columns according to data type, see "Maximum row sizes" on page 1210.

column-name
Names a column of the table. Do not qualify column-name and do not use the same name for more than one column of the table or for a system-column-name of the table.

FOR COLUMN system-column-name
Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the system-column-name is not specified, and the column-name is not a valid system-column-name, a system column name is generated. For more information about how system column names are generated, see "Rules for Column Name Generation" on page 1213.

data-type
Specifies the data type of the column.

built-in-type
For built-in-types, use:

SMALLINT
For a small integer.

INTEGER or INT
For a large integer.
BIGINT
For a big integer.

DECIMAL(integer, integer) or DEC(integer, integer)
DECIMAL(integer) or DEC(integer)
DECIMAL or DEC
For a packed decimal number. The first integer is the precision of the number; that is, the total number of digits; it can range from 1 to 63. The second integer is the scale of the number (the number of digits to the right of the decimal point). It can range from 0 to the precision of the number.

You can use DECIMAL(p) for DECIMAL(p,0), and DECIMAL for DECIMAL(5,0).

NUMERIC(integer, integer) or NUM(integer, integer)
NUMERIC(integer) or NUM(integer)
NUMERIC or NUM
For a zoned decimal number. The first integer is the precision of the number, that is, the total number of digits; it may range from 1 to 63. The second integer is the scale of the number, (the number of digits to the right of the decimal point). It may range from 0 to the precision of the number.

You can use NUMERIC(p) for NUMERIC(p,0), and NUMERIC for NUMERIC(5,0).

FLOAT
For a double-precision floating-point number.

FLOAT(integer)
For a single- or double-precision floating-point number, depending on the value of integer. The value of integer must be in the range 1 through 53. The values 1 through 24 indicate single-precision, the values 25 through 53 indicate double-precision. The default is 53.

REAL
For single-precision floating point.

DOUBLE PRECISION or DOUBLE
For double-precision floating point.

DECFlOAT(integer)
DECFLoAT
For a IEEE decimal floating-point number. The value of integer must be either 16 or 34 and represents the number of significant digits that can be stored. If integer is omitted, then the DECFLoAT column will be capable of representing 34 significant digits.

CHARACTER(integer) or CHAR(integer)
CHARACTER or CHAR
For a fixed-length character string of length integer bytes. The integer can range from 1 through 32766 (32765 if null capable). If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 32766 (32765 if null capable). If the length specification is omitted, a length of 1 is assumed.

CHARACTER VARYING (integer) or CHAR VARYING (integer) or VARCHAR (integer)
For a varying-length character string of maximum length integer bytes, which can range from 1 through 32740 (32739 if null capable). If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 32740 (32739 if null capable).
CHARACTER LARGE OBJECT (integer[K|M|G]) or CHAR LARGE OBJECT (integer[K|M|G]) or CLOB (integer[K|M|G])

For a character large object string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2 147 483 647. If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 2 147 483 647. If the length specification is omitted, a length of 1 megabyte is assumed. A CLOB is not allowed in a distributed table.

integer
  The maximum value for integer is 2 147 483 647. The maximum length of the string is integer.

integer K
  The maximum value for integer is 2 097 152. The maximum length of the string is 1024 times integer.

integer M
  The maximum value for integer is 2 048. The maximum length of the string is 1 048 576 times integer.

integer G
  The maximum value for integer is 2. The maximum length of the string is 1 073 741 824 times integer.

GRAPHIC(integer)

For a fixed-length graphic string of length integer, which can range from 1 through 16383 (16382 if null capable). If the length specification is omitted, a length of 1 is assumed.

VARGRAPHIC(integer) or GRAPHIC VARYING(integer)

For a varying-length graphic string of maximum length integer, which can range from 1 through 16370 (16369 if null capable).

DBCLOB(integer[K|M|G])

For a double-byte character large object string of the specified maximum length.

The maximum length must be in the range of 1 through 1 073 741 823. If the length specification is omitted, a length of 1 megabyte is assumed. A DBCLOB is not allowed in a distributed table.

integer
  The maximum value for integer is 1 073 741 823. The maximum length of the string is integer.

integer K
  The maximum value for integer is 1 028 576. The maximum length of the string is 1024 times integer.

integer M
  The maximum value for integer is 1 024. The maximum length of the string is 1 048 576 times integer.

integer G
  The maximum value for integer is 1. The maximum length of the string is 1 073 741 824 times integer.
NATIONAL CHARACTER or NATIONAL CHAR or NCHAR

For a fixed-length Unicode graphic string of length integer, which can range from 1 through 16383 (16382 if null capable). If the length specification is omitted, a length of 1 is assumed. The CCSID is 1200.

NATIONAL CHARACTER VARYING (integer) or NATIONAL CHAR VARYING (integer) or NVARCHAR (integer)

For a varying-length Unicode graphic string of maximum length integer, which can range from 1 through 16370 (16369 if null capable). The CCSID is 1200.

NATIONAL CHARACTER LARGE OBJECT (integer[K|M|G]) or NCHAR LARGE OBJECT (integer[K|M|G]) or NCLOB (integer[K|M|G])

For a Unicode double-byte character large object string of the specified maximum length.

The maximum length must be in the range of 1 through 1 073 741 823. If the length specification is omitted, a length of 1 megabyte is assumed. The CCSID is 1200. An NCLOB is not allowed in a distributed table.

integer

The maximum value for integer is 1 073 741 823. The maximum length of the string is integer.

integer K

The maximum value for integer is 1 028 576. The maximum length of the string is 1024 times integer.

integer M

The maximum value for integer is 1 024. The maximum length of the string is 1 048 576 times integer.

integer G

The maximum value for integer is 1. The maximum length of the string is 1 073 741 823 times integer.

BINARY(integer)

BINARY

For a fixed-length binary string of length integer. The integer can range from 1 through 32766 (32765 if null capable). If the length specification is omitted, a length of 1 is assumed.

BINARY VARYING (integer) or VARBINARY (integer)

For a varying-length binary string of maximum length integer, which can range from 1 through 32740 (32739 if null capable).

BLOB(integer[K|M|G]) or BINARY LARGE OBJECT (integer[K|M|G])

BLOB or BINARY LARGE OBJECT

For a binary large object string of the specified maximum length. The maximum length must be in the range of 1 through 2 147 483 647. If the length specification is omitted, a length of 1 megabyte is assumed. A BLOB is not allowed in a distributed table.

integer

The maximum value for integer is 2 147 483 647. The maximum length of the string is integer.

integer K

The maximum value for integer is 2 097 152. The maximum length of the string is 1024 times integer.
integer \texttt{M}

The maximum value for integer is 2,048. The maximum length of the string is 1,048,576 times integer.

integer \texttt{G}

The maximum value for integer is 2. The maximum length of the string is 1,073,741,824 times integer.

\textbf{DATE}

For a date.

\textbf{TIME}

For a time.

\textbf{TIMESTAMP(\textit{integer}) or TIMESTAMP}

For a timestamp. The integer must be between 0 and 12 and specifies the precision of fractional seconds from 0 (seconds) to 12 (picoseconds). The default is 6 (microseconds).

\textbf{DATALINK(\textit{integer}) or DATALINK}

For a DataLink of the specified maximum length. The maximum length must be in the range of 1 through 32717. If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 through 32717. The specified length must be sufficient to contain both the largest expected URL and any DataLink comment. If the length specification is omitted, a length of 200 is assumed. A DATALINK is not allowed in a distributed table.

A DATALINK value is an encapsulated value with a set of built-in scalar functions. The DLVALUE function creates a DATALINK value. The following functions can be used to extract attributes from a DATALINK value.

- DLCOMMENT
- DLINKTYPE
- DLURLCOMPLETE
- DLURLPATH
- DLURLPATHONLY
- DLURLSCHEME
- DLURLSERVER

A DataLink cannot be part of any index. Therefore, it cannot be included as a column of a primary key, foreign key, or unique constraint.

\textbf{ROWID}

For a row ID. Only one ROWID column is allowed in a table. A ROWID is not allowed in a partitioned table.

\textbf{XML}

For an XML document. Only well-formed documents can be inserted into an XML column. The CCSID for the column cannot be 65535. The maximum length of the column is always 2,147,483,647 bytes.

An XML column has the following restrictions:

- The column cannot be part of any index.
- The column cannot be part of a primary, unique, or foreign key.
- The column cannot be used in a check constraint.
- A default value (WITH DEFAULT) cannot be specified for the column. If the column is nullable, the default for the column is the null value.
CREATE TABLE

- The column cannot be specified in the distribution clause of a distributed table.
- The column cannot be specified in the partitioning clause of a partitioned table.

distinct-type-name
Specifies that the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

ALLOCATE(integer)
Specifies for VARCHAR, VARGRAPHIC, VARBINARY, XML, and LOB types the space to be reserved for the column in each row. Column values with lengths less than or equal to the allocated value are stored in the fixed-length portion of the row. Column values with lengths greater than the allocated value are stored in the variable-length portion of the row and require additional input/output operations to retrieve. The allocated value may range from 1 to maximum length of the string, subject to the maximum row buffer size limit. For information about the maximum row buffer size, see "Maximum row sizes" on page 1210. If FOR MIXED DATA or a mixed data CCSID is specified, the range is 4 to the maximum length of the string. If the allocated length specification is omitted, an allocated length of 0 is assumed. For VARGRAPHIC, the integer is the number of DBCS or Unicode graphic characters. If a constant is specified for the default value and the ALLOCATE length is less than the length of the default value, the ALLOCATE length is assumed to be the length of the default value.

FOR BIT DATA
Specifies that the values of the column are not associated with a coded character set and are never converted. FOR BIT DATA is only valid for CHARACTER or VARCHAR columns. The CCSID of a FOR BIT DATA column is 65535. FOR BIT DATA is not allowed for CLOB columns.

FOR SBCS DATA
Specifies that the values of the column contain SBCS (single-byte character set) data. FOR SBCS DATA is the default for CHAR, VARCHAR, and CLOB columns if the default CCSID at the current server at the time the table is created is not DBCS-capable or if the length of the column is less than 4. FOR SBCS DATA is only valid for CHARACTER, VARCHAR, or CLOB columns. The CCSID of FOR SBCS DATA is determined by the default CCSID at the current server at the time the table is created.

FOR MIXED DATA
Specifies that the values of the column contain both SBCS data and DBCS data. FOR MIXED DATA is the default for CHAR, VARCHAR, and CLOB columns if the default CCSID at the current server at the time the table is created is DBCS-capable and the length of the column is greater than 3. Every FOR MIXED DATA column is a DBCS-open application server field. FOR MIXED DATA is only valid for CHARACTER, VARCHAR, or CLOB columns. The CCSID of FOR MIXED DATA is determined by the default CCSID at the current server at the time the table is created.

CCSID integer
Specifies that the values of the column contain data of CCSID integer. If the integer is an SBCS CCSID, the column is SBCS data. If the integer is a mixed data CCSID, the column is mixed data and the length of the column...
must be greater than 3. For character columns, the CCSID must be an SBCS
CCSID or a mixed data CCSID. For graphic columns, the CCSID must be a
DBCS, UTF-16, or UCS-2 CCSID. If a CCSID is not specified for a graphic
column, the CCSID is determined by the default CCSID at the current
server at the time the table is created. For XML columns, the CCSID must
not be 65535. If a CCSID is not specified for an XML column, the CCSID is
established at the time the CREATE TABLE is executed according to the
SQL.XML.DAT.A.CCSID QAQQINI option setting. The default CCSID is
1208. See “XML Values” on page 89 for a description of this option. For a
list of valid CCSIDs, see Appendix E, “CCSID values,” on page 1765.

CCSID 1208 (UTF-8) or 1200 (UTF-16) data can contain combining characters.
Combining character support allows a resulting character to be comprised
of more than one character. After the first character, up to 300 different
non-spacing accent characters (umlauts, accent, etc.) can follow in the data
string. If the resulting character is one that is already defined in the
character set, that character has more than one representation.
Normalization replaces the string of combining characters with the hex
value of the defined character. This ensures that the same character is
represented in a single consistent way. If normalization is not performed,
two strings that look identical will not compare equal.

NOT NORMALIZED
The data should not be normalized when passed from the application.

NORMALIZED
The data should be normalized when passed from the application.

DEFAULT
Specifies a default value for the column. This clause cannot be specified more
than once in a column-definition. DEFAULT cannot be specified for the
following types of columns because Db2 generates default values:

• a ROWID column
• an identity column (a column that is defined AS IDENTITY)
• a row change timestamp column
• a row-begin column
• a row-end column
• a transaction-start-ID column
• a generated expression column

For an XML column, the default is NULL unless NOT NULL is specified; in
that case there is no default.

If a value is not specified following the DEFAULT keyword, then:

• if the column is nullable, the default value is the null value.
• if the column is not nullable, the default depends on the data type of the
column:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character or graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string length of 0</td>
</tr>
<tr>
<td>Date</td>
<td>The current date at the time of INSERT</td>
</tr>
</tbody>
</table>
### CREATE TABLE

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>The current time at the time of INSERT</td>
</tr>
<tr>
<td>Timestamp</td>
<td>The current timestamp at the time of INSERT</td>
</tr>
<tr>
<td>Datalink</td>
<td>A value corresponding to DLVALUE('URL', '')</td>
</tr>
<tr>
<td>distinct-type</td>
<td>The default value of the corresponding source type of the distinct type.</td>
</tr>
</tbody>
</table>

Omission of NOT NULL and DEFAULT from a column-definition is an implicit specification of DEFAULT NULL.

- **constant**
  Specifies the constant as the default for the column. The specified constant must represent a value that could be assigned to the column in accordance with the rules of assignment as described in “Assignments and comparisons” on page 99. A floating-point constant or decimal floating-point constant must not be used for a SMALLINT, INTEGER, DECIMAL, or NUMERIC column. A decimal constant must not contain more digits to the right of the decimal point than the specified scale of the column.

- **USER**
  Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value of the column. The data type of the column must be CHAR or VARCHAR with a length attribute that is greater than or equal to the length attribute of the USER special register.

- **NULL**
  Specifies null as the default for the column. If NOT NULL is specified, DEFAULT NULL must not be specified within the same column-definition. NULL is the only default value allowed for a datalink column.

- **CURRENT_DATE**
  Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the column must be DATE or a distinct type based on a DATE.

- **CURRENT_TIME**
  Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the column must be TIME or a distinct type based on a TIME.

- **CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(integer)**
  Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the column must be TIMESTAMP or a distinct type based on a TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

- **cast-function-name**
  This form of a default value can only be used with columns defined as a distinct type, BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME or TIMESTAMP data types. The following table describes the allowed uses of these cast-functions.
<table>
<thead>
<tr>
<th>Data Type</th>
<th>Cast Function Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distinct type N based on a BINARY, VARBINARY, BLOB, CLOB,</td>
<td>BINAR, VARBINARY, BLOB, CLOB, or DBCLOB *</td>
</tr>
<tr>
<td>or DBCLOB</td>
<td></td>
</tr>
<tr>
<td>Distinct type N based on a DATE, TIME, or TIMESTAMP</td>
<td>N (the user-defined cast function that was generated when N was created) **</td>
</tr>
<tr>
<td></td>
<td>or</td>
</tr>
<tr>
<td></td>
<td>DATE, TIME, or TIMESTAMP *</td>
</tr>
<tr>
<td>Distinct type N based on other data types</td>
<td>N (the user-defined cast function that was generated when N was created) **</td>
</tr>
<tr>
<td>BINARY, VARBINARY, BLOB, CLOB, or DBCLOB</td>
<td>BINAR, VARBINARY, BLOB, CLOB, or DBCLOB *</td>
</tr>
<tr>
<td>DATE, TIME, or TIMESTAMP</td>
<td>DATE, TIME, or TIMESTAMP *</td>
</tr>
</tbody>
</table>

**Notes:**

* The name of the function must match the name of the data type (or the source type of the distinct type) with an implicit or explicit schema name of QSYS2.

** The name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type.

---

**constant**

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. For BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME, and TIMESTAMP functions, the constant must be a string constant.

**USER**

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value for the column. The data type of the source type of the distinct type of the column must be CHAR or VARCHAR with a length attribute greater than or equal to the length attribute of the USER special register.

**CURRENT_DATE**

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the source type of the distinct type of the column must be DATE.

**CURRENT_TIME**

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the source type of the distinct type of the column must be TIME.

**CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(integer)**

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the source type of the distinct type of the column must be TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

If the value specified is not valid, an error is returned.
**CREATE TABLE**

**GENERATED**
- Specifies that the database manager generates values for the column.
- **GENERATED** may be specified if the column is to be considered one of the following types of columns:
  - an identity column
  - a row change timestamp column

**GENERATED** must be specified if the column is to be considered one of the following types of columns:
- a row-begin column
- a row-end column
- a transaction-start-ID column
- a generated expression column

It may also be specified if the data type of the column is a ROWID (or a distinct type that is based on a ROWID). Otherwise, it must not be specified. **GENERATED** must not be specified with **default-clause** in a column definition.

**ALWAYS**
- Specifies that the database manager will always generate a value for the column when a row is inserted or updated and a default value must be generated. **ALWAYS** is the recommended value.

**BY DEFAULT**
- Specifies that the database manager will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For a ROWID column, the database manager uses a specified value, but it must be a valid unique row ID value that was previously generated by the database manager or Db2 for i.

For an identity column or row change timestamp column, the database manager inserts or updates a specified value but does not verify that it is a unique value for the column unless the identity column or row change timestamp column has a unique constraint or a unique index that solely specifies the identity column or row change timestamp column.

**AS IDENTITY**
- Specifies that the column is an identity column for the table. A table can have only one identity column. An identity column is not allowed in a distributed table. **AS IDENTITY** can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL, or NUMERIC with a scale of zero, or a distinct type based on one of these data types). If a DECIMAL or NUMERIC data type is specified, the precision must not be greater than 31.

An identity column is implicitly NOT NULL.

**START WITH numeric-constant**
- Specifies the first value that is generated for the identity column. The value can be any positive or negative value that could be assigned to the column without non-zero digits existing to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending sequence and the MAXVALUE for a descending sequence. This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The **START WITH** clause can be used to
start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

**INCREMENT BY numeric-constant**

Specifies the interval between consecutive values of the identity column. The value must not exceed the value of a large integer constant without any non-zero digits existing to the right of the decimal point. The value must be assignable to the column. The default is 1.

If the value is zero or positive, the sequence of values for the identity column ascends. If the value is negative, the sequence of values descends.

**MAXVALUE or MINVALUE**

Specifies the maximum value at which an ascending identity column either cycles or stops generating values, or a descending identity column cycles to after reaching the minimum value.

**MAXVALUE numeric-constant**

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column, but the value must be greater than the minimum value.

If a value is not explicitly specified when the identity column is defined, this is the maximum value of the data type for an ascending sequence; or the START WITH value, or -1 if START WITH was not specified, for a descending sequence.

**MINVALUE numeric-constant**

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column, but the value must be less than the maximum value.

If a value is not explicitly specified when the identity column is defined, this is the START WITH value, or 1 if START WITH was not specified, for an ascending sequence; or the minimum value of the data type (and precision, if DECIMAL) for a descending sequence.

**CACHE or NO CACHE**

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table.

**CACHE integer**

Specifies the number of values of the identity column sequence that the database manager preallocates and keeps in memory. The minimum value that can be specified is 2, and the maximum is the largest value that can be represented as an integer. The default is 20.

In certain situations, such as system failure, all cached identity column values that have not been used in committed statements are lost, and thus, will never be used. The value specified for the CACHE option is the maximum number of identity column values that could be lost in these situations.

**NO CACHE**

Specifies that values for the identity column are not preallocated.

**CYCLE or NO CYCLE**

Specifies whether this identity column should continue to generate values after reaching either the maximum or minimum value of the sequence.
**CYCLE**
Specifies that values continue to be generated for this column after the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches the maximum value of the sequence, it generates its minimum value. After a descending sequence reaches its minimum value of the sequence, it generates its maximum value. The maximum and minimum values for the column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the database manager for an identity column. If a unique constraint or unique index exists on the identity column, and a non-unique value is generated for it, an error occurs.

**NO CYCLE**
Specifies that values will not be generated for the identity column once the maximum or minimum value for the sequence has been reached. This is the default.

**ORDER or NO ORDER**
Specifies whether the identity values must be generated in order of request.

**ORDER**
Specifies that the values are generated in order of request.

**NO ORDER**
Specifies that the values do not need to be generated in order of request. This is the default.

**FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP**
Specifies that the column is a timestamp and the values will be generated by the database manager. The database manager generates a value for the column for each row as a row is inserted, and for every row in which any column is updated. The value generated for a row change timestamp column is a timestamp corresponding to the time of the insert or update of the row. If multiple rows are inserted with a single SQL statement, the value for the row change timestamp column may be different for each row to reflect when each row was inserted. The generated value is not guaranteed to be unique.

A table can have only one row change timestamp column. If data-type is specified, it must be a TIMESTAMP with a precision of 6 or a distinct type based on a TIMESTAMP with a precision of 6. A row change timestamp column cannot have a DEFAULT clause and must be NOT NULL.

**AS ROW BEGIN**
Specifies that the column contains timestamp data and that the values are generated by the database manager. The database manager generates a value for the column for each row as the row is inserted, and for every row in which any column is updated. The generated value is a timestamp that corresponds to the start time that is associated with the most recent transaction. If multiple rows are inserted with a single SQL statement, the values for the transaction start timestamp column are the same for each row.

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value. This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The
SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this
adjustment to the timestamp value to occur. If multiple rows are inserted or
updated within a single SQL transaction and an adjustment is not needed, the
values for the row-begin column are the same for all the rows and are unique
from the values generated for the column for another transaction.

A row-begin column is intended to be used for a system-period temporal table
and is required as the first column of a SYSTEM_TIME period. A table can
have only one row-begin column. If data-type is not specified, the column is
defined as a TIMESTAMP(12). If data-type is specified, it must be
TIMESTAMP(12). The column cannot have a DEFAULT clause and must be
defined as NOT NULL. A row-begin column is not updatable.

AS ROW END

Specifies that a value for the data type of the column is assigned by the
database manager whenever a row is inserted or any column in the row is
updated. The assigned value is TIMESTAMP '9999-12-30-0.00.00.0000000000000'.
For a system-period temporal table, when a row is deleted, the value of the
row-end column in the historical row reflects when the row was deleted. If
multiple rows are deleted with a single SQL statement, the values for the
column in the historical rows are the same.

A row-end column is intended to be used for a system-period temporal table
and is required as the second column of a SYSTEM_TIME period. A table can
have only one row-end column. If data-type is not specified, the column is
defined as TIMESTAMP(12). If data-type is specified, it must be
TIMESTAMP(12). The column cannot have a DEFAULT clause and must be
defined as NOT NULL. A row-end column is not updatable.

AS TRANSACTION START ID

Specifies that the value is assigned by the database manager whenever a row is
inserted into the table or any column in the row is updated. The database
manager assigns a unique timestamp value per transaction or the null value.
The null value is assigned to the transaction-start-ID column if the column is
nullable and if there is a row-begin column in the table for which the value
did not need to be adjusted. Otherwise the value is generated using a reading
of the time-of-day clock during execution of the first data change statement in
the transaction that requires a value to be assigned to a row-begin column or
transaction-start-ID column in the table, or a row in a system-period temporal
table is deleted. If multiple rows are inserted or updated within a single SQL
transaction, the values for the transaction-start-ID column are the same for all
the rows and are unique from the values generated for the column for another
transaction.

A transaction-start-ID column is intended to be used for a system-period
temporal table and is required for a system-period temporal table. A table can
have only one transaction-start-ID column. If data-type is not specified, the
column is defined as TIMESTAMP(12). If data-type is specified it must be
TIMESTAMP(12). A transaction-start-ID column cannot have a DEFAULT
clause. A transaction-start-ID column is not updatable.

DATA CHANGE OPERATION

Specifies that the database manager generates a value for each row that is
inserted, for every row in which any column is updated, and for all rows
deleted from a system-period temporal table when the history table is defined
with ON DELETE ADD EXTRA ROW. The column will contain one of the
following values:

I insert operation
CREATE TABLE

U  update operation
D  delete operation

If data-type is not specified, the column is defined as CHAR(1). If data-type is specified it must be CHAR(1). The column cannot have a DEFAULT clause or a field procedure.

special-register

Specifies that the value of a special register is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the special register at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table:

<table>
<thead>
<tr>
<th>Special register</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT CLIENT_ACCTNG</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_APPLNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_PROGRAMID</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_USERID</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_WRKSTNNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT SERVER</td>
<td>VARCHAR(18)</td>
</tr>
<tr>
<td>SESSION_USER</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>USER</td>
<td>VARCHAR(18)</td>
</tr>
</tbody>
</table>

The column cannot have a DEFAULT clause or a field procedure.

built-in-global-variable

Specifies that the value of a built-in global variable is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the built-in global variable at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table:

<table>
<thead>
<tr>
<th>Built-in global variable</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>QSYS2.JOB_NAME</td>
<td>VARCHAR(28)</td>
</tr>
<tr>
<td>QSYS2.SERVER_MODE_JOB_NAME</td>
<td>VARCHAR(28)</td>
</tr>
<tr>
<td>SYSIBM.CLIENT_HOST</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>SYSIBM.CLIENT_IPADDR</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM.CLIENT_PORT</td>
<td>INTEGER</td>
</tr>
<tr>
<td>SYSIBM PACKAGE_NAME</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM PACKAGE_SCHEMA</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM PACKAGE_VERSION</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SYSIBM ROUTINE_SCHEMA</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM ROUTINE_SPECIFIC_NAME</td>
<td>VARCHAR(128)</td>
</tr>
</tbody>
</table>
The column cannot have a DEFAULT clause or a field procedure.

**NOT NULL**
Prevents the column from containing null values. Omission of NOT NULL implies that the column can be null. NOT NULL is required for a row change timestamp column, a row-begin column, and a row-end column.

**NOT HIDDEN**
Indicates the column is included in implicit references to the table in SQL statements. This is the default.

**IMPICITLY HIDDEN**
Indicates the column is not visible in SQL statements unless it is referred to explicitly by name. For example, SELECT * does not include any hidden columns in the result. A table must contain at least one column that is not IMPICITLY HIDDEN.

**period-definition**

**PERIOD FOR**
Defines a period for the table.

**SYSTEM_TIME (begin-column-name, end-column-name)**
Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME. A table can have only one SYSTEM_TIME period.

**begin-column-name**
Identifies the column that records the beginning of the period of time in which a row is valid. The name must identify a column that exists in the table. begin-column-name must not be the same as end-column-name. begin-column-name must be defined as AS ROW BEGIN.

**end-column-name**
Identifies the column that records the end of the period of time in which a row is valid. In the history table that is associated with a system-period temporal table, the history table column that corresponds to end-column-name in the system-period temporal table is set to reflect the deletion of the row. The name must identify a column that exists in the table. end-column-name must be defined as AS ROW END.

**column-constraint**

**CONSTRAINT constraint-name**
Names the constraint. A constraint-name must not identify a constraint that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

**PRIMARY KEY**
Provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

This clause must not be specified in more than one column definition and must not be specified at all if the UNIQUE clause is specified in the
column definition. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure.

When a primary key is added, a CHECK constraint is implicitly added to enforce the rule that the NULL value is not allowed in the column that makes up the primary key.

**UNIQUE**

Provides a shorthand method of defining a unique constraint composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE (C) clause is specified as a separate clause.

This clause cannot be specified more than once in a column definition and must not be specified if PRIMARY KEY is specified in the column definition. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure.

**references-clause**

The references-clause of a column-definition provides a shorthand method of defining a foreign key composed of a single column. Thus, if a references-clause is specified in the definition of column C, the effect is the same as if references-clause were specified as part of a FOREIGN KEY clause in which C is the only identified column. The references-clause is not allowed if the table is a declared global temporary table, a distributed table, or a history table. The column cannot be a row change timestamp column.

**CHECK(check-condition)**

The CHECK(check-condition) of a column-definition provides a shorthand method of defining a check constraint whose check-condition only references a single column. Thus, if CHECK is specified in the column definition of column C, no columns other than C can be referenced in the check-condition of the check constraint. The effect is the same as if the check constraint were specified as a separate clause.

If ON INSERT VIOLATION or ON UPDATE VIOLATION is specified, column C must be referenced in these clauses.

ROWID, XML, and DATALINK with FILE LINK CONTROL columns cannot be referenced in a CHECK constraint. For additional restrictions, see “check-constraint” on page 1195.

**FIELDPROC**

Designates an external-program-name as the field procedure exit routine for the column. It must be an ILE program that does not contain SQL. It cannot be a service program.

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used, it is passed to the field procedure for decoding.

The field procedure is also invoked during the processing of the CREATE TABLE statement. When so invoked, the procedure provides Db2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information supplied for the column in the CREATE TABLE statement defines the data characteristics of the decoded values.
constant
   Specifies a parameter that is passed to the field procedure when it is
   invoked. A parameter list is optional.

A field procedure cannot be defined for a column that is a ROWID or
DATALINK or a distinct type based on a ROWID or DATALINK. The column
must not be an identity column, a row change timestamp column, a row-begin
column, a row-end column, a transaction-start-ID column, or a generated
expression column. The column must not have a default value of CURRENT
DATE, CURRENT TIME, CURRENT TIMESTAMP, or USER. The nullability
attribute of the encoded and decoded form of the field must match. The
column cannot be referenced in a check condition, unless it is referenced in a
NULL predicate. If it is part of a foreign key, the corresponding parent key
column must use the same field procedure. See [SQL Programming] for more
details on how to create a field procedure.

datalink-options
   Specifies the options associated with a DATALINK data type.

   LINKTYPE URL
       Defines the type of link as a Uniform Resource Locator (URL).

   NO LINK CONTROL
       Specifies that there will not be any check made to determine that the
       linked files exist. Only the syntax of the URL will be checked. There is no
database manager control over the linked files.

   FILE LINK CONTROL
       Specifies that a check should be made for the existence of the linked files.
       Additional options may be used to give the database manager further
control over the linked files.

       If FILE LINK CONTROL is specified, each file can only be linked once.
       That is, its URL can only be specified in a single FILE LINK CONTROL
       column in a single table.

file-link-options
   Additional options to define the level of database manager control of the
linked files.

   INTEGRITY
       Specifies the level of integrity of the link between a DATALINK value
       and the actual file.

       ALL
           Any file specified as a DATALINK value is under the control of the
database manager and may NOT be deleted or renamed using
standard file system programming interfaces.

   READ PERMISSION
       Specifies how permission to read the file specified in a DATALINK
value is determined.

       FS
           The read access permission is determined by the file system
permissions. Such files can be accessed without retrieving the file
name from the column.

       DB
           The read access permission is determined by the database. Access
to the file will only be allowed by passing a valid file access token,
returned on retrieval of the DATALINK value from the table, in the
open operation. If READ PERMISSION DB is specified, WRITE
PERMISSION BLOCKED must be specified.
CREATE TABLE

WRITE PERMISSION
Specifies how permission to write to the file specified in a DATALINK value is determined.

FS
The write access permission is determined by the file system permissions. Such files can be accessed without retrieving the file name from the column.

BLOCKED
Write access is blocked. The file cannot be directly updated through any interface. An alternative mechanism must be used to perform updates to the information. For example, the file is copied, the copy updated, and then the DATALINK value updated to point to the new copy of the file.

RECOVERY
Specifies whether the database manager will support point in time recovery of files referenced by values in this column.

NO
Specifies that point in time recovery will not be supported.

ON UNLINK
Specifies the action taken on a file when a DATALINK value is changed or deleted (unlinked). Note that this is not applicable when WRITE PERMISSION FS is used.

RESTORE
Specifies that when a file is unlinked, the DataLink File Manager will attempt to return the file to the owner with the permissions that existed at the time the file was linked. In the case where the user is no longer registered with the file server, the result depends on the file system that contains the files. If the files are in the AIX® file system, the owner is "dfmunknown". If the files are in IFS, the owner is QDLFM. This can only be specified when INTEGRITY ALL and WRITE PERMISSION BLOCKED are also specified.

DELETE
Specifies that the file will be deleted when it is unlinked. This can only be specified when READ PERMISSION DB and WRITE PERMISSION BLOCKED are also specified.

MODE DB2OPTIONS
This mode defines a set of default file link options. The defaults defined by DB2OPTIONS are:
- INTEGRITY ALL
- READ PERMISSION FS
- WRITE PERMISSION FS
- RECOVERY NO

LIKE

$table-name$ or $view-name$
Specifies that the columns of the table have exactly the same name and description as the columns of the identified table ($table-name$) or view ($view-name$). The name must identify a table or view that exists at the current server.

The use of LIKE is an implicit definition of $n$ columns, where $n$ is the number of columns in the identified table or view. The implicit definition includes the following attributes of the $n$ columns (if applicable to the data type):
• Column name (and system column name)
• Data type, length, precision, and scale
• CCSID
• FIELDPROC (only copied for table-name)

If the LIKE clause is specified immediately following the table-name and not enclosed in parenthesis, the following column attributes are also included, otherwise they are not included (the default value, identity, row change timestamp, and hidden attributes can also be controlled by using the copy-options):

• Default value, if a table-name is specified (view-name is not specified)
• Nullability
• Hidden attributes
• Column heading and text (see “LABEL” on page 146)

Any REFFLD information for the column will be copied to the new column definition.

If table-name contains a row change timestamp column, row-begin column, row-end column, transaction-start-ID column, or a generated expression column, the corresponding column of the new table inherits only the data type of the source column. The new column is not considered a generated column.

The implicit definition does not include any other optional attributes of the identified table or view. For example, the new table does not automatically include primary keys, foreign keys, triggers, or a period. The new table has these and other optional attributes only if the optional clauses are explicitly specified.

If the specified table or view is a non-SQL created physical file or logical file, any non-SQL attributes are removed. For example, the date and time format will be changed to ISO.

**copy-options**

**INCLUDING IDENTITY COLUMN ATTRIBUTES or EXCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies whether identity column attributes are inherited.

**INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that the table inherits the identity attribute, if any, of the columns resulting from select-statement, table-name, or view-name. In general, the identity attribute is copied if the element of the corresponding column in the table, view, or select-statement is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with the identity attribute. If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS select-statement clause, the columns of the new table do not inherit the identity attribute in the following cases:

• The select list of the select-statement includes multiple instances of an identity column name (that is, selecting the same column more than once).
• The select list of the select-statement includes multiple identity columns (that is, a join returned more than one identity column).
• The identity column is included in an expression in the select list.
• The select-statement includes a set operation (UNION or INTERSECT).
CREATE TABLE

If INCLUDING IDENTITY is not specified, the table will not have an identity column.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES**
Specifies that the table does not inherit the identity attribute, if any, of the columns resulting from the full select, table-name, or view-name.

**EXCLUDING COLUMN DEFAULTS or INCLUDING COLUMN DEFAULTS or USING TYPE DEFAULTS**
Specifies whether column defaults are inherited.

**EXCLUDING COLUMN DEFAULTS**
Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on INSERT for the new table.

**INCLUDING COLUMN DEFAULTS**
Specifies that the table inherits the default values of the columns resulting from the select-statement, table-name, or view-name. In general, the default values are copied if the element of the corresponding column in the table, view, or select-statement is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with a default value. A default value is the value assigned to a column when a value is not specified on an INSERT.

Do not specify INCLUDING COLUMN DEFAULTS if you specify USING TYPE DEFAULTS.

If INCLUDING COLUMN DEFAULTS is not specified, the default values are not inherited.

**USING TYPE DEFAULTS**
Specifies that the default values for the table depend on the data type of the columns that result from the select-statement, table-name, or view-name. If the column is nullable, then the default value is the null value. Otherwise, the default value is as follows:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character or graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string length of 0</td>
</tr>
<tr>
<td>Date</td>
<td>The current date at the time of INSERT</td>
</tr>
<tr>
<td>Time</td>
<td>The current time at the time of INSERT</td>
</tr>
<tr>
<td>Timestamp</td>
<td>The current timestamp at the time of INSERT</td>
</tr>
<tr>
<td>Datalink</td>
<td>A value corresponding to DLVALUE(”,URL,”)</td>
</tr>
<tr>
<td>XML</td>
<td>There is no default value</td>
</tr>
<tr>
<td>distinct-type</td>
<td>The default value of the corresponding source type of the distinct type.</td>
</tr>
</tbody>
</table>

Do not specify USING TYPE DEFAULTS if INCLUDING COLUMN DEFAULTS is specified.
INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES or EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies whether implicitly hidden columns are inherited.

INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies that the table inherits implicitly hidden columns from select-statement, table-name, or view-name and those columns will be defined with the implicitly hidden attribute in the new table.

If INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES is not specified, the table will not have any implicitly hidden columns.

EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies that the table does not inherit implicitly hidden columns from fullselect, table-name, or view-name.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies whether the row change timestamp attribute is inherited.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that the table inherits the row change timestamp attribute, if any, of the columns resulting from select-statement, table-name, or view-name. In general, the row change timestamp attribute is copied if the element of the corresponding column in the table, view, or select-statement is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with the row change timestamp attribute. If the INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES clause is specified with the AS select-statement clause, the columns of the new table do not inherit the row change timestamp in the following cases:

- The select list of the select-statement includes multiple instances of a row change timestamp column name (that is, selecting the same column more than once).
- The select list of the select-statement includes multiple row change timestamp columns (that is, a join returned more than one row change timestamp column).
- The row change timestamp column is included in an expression in the select list.
- The select-statement includes a set operation (UNION or INTERSECT).

If INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES is not specified, the table will not have a row change timestamp column.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that the table does not inherit the row change timestamp attribute, if any, of the columns resulting from fullselect, table-name, or view-name.

as-result-table

column-name

Names a column in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the select-statement. Each column-name must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the select-statement.
A list of column names must be specified if the result table of the select-statement has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation (UNION or INTERSECT) that is not named using the AS clause of the select list.

**FOR COLUMN system-column-name**

Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the system-column-name is not specified, and the column-name is not a valid system-column-name, a system column name is generated. For more information about how system column names are generated, see “Rules for Table Name Generation” on page 1213.

**select-statement**

Specifies that the columns of the table have the same name and description as the columns that would appear in the derived result table of the select-statement if the select-statement were to be executed. The use of AS (select-statement) is an implicit definition of n columns for the table, where n is the number of columns that would result from the select-statement.

The implicit definition includes the following attributes of the n columns (if applicable to the data type):
- Column name (and system column name)
- Data type, length, precision, and scale
- CCSID
- Nullability
- FIELDPROC
- Column heading and text (see "LABEL" on page 1463)

The following attributes are not included (some attributes can be included by using the copy-options):
- Default value
- Hidden attribute
- Identity attributes
- Row change timestamp attribute
- Row-begin, row-end, and transaction-start-ID
- Generated expression

The implicit definition does not include any other optional attributes of the identified table or view. For example, the new table does not automatically include a primary key or foreign key from a table. The new table has these and other optional attributes only if the optional clauses are explicitly specified.

Any column in the select-clause that is either a direct reference to a column in another table or view or uses only a CAST to change the result attributes will have REFFLD information generated for the definition in the file object.

The select-statement must not reference variables, but may reference global variables.

The select-statement must not contain a PREVIOUS VALUE or a NEXT VALUE expression. The UPDATE, SKIP LOCKED DATA, and USE AND KEEP EXCLUSIVE LOCKS clauses may not be specified.

If the select-statement contains an isolation-clause the isolation level specified in the isolation-clause applies to the entire SQL statement.
**WITH DATA**

Specifies that the select-statement is executed. After the table is created, the result table rows of the select-statement are automatically inserted into the table.

**WITH NO DATA**

Specifies that the select-statement is used only to define the attributes of the new table. The table is not populated using the results of the select-statement.

**unique-constraint**

**CONSTRAINT constraint-name**

Names the constraint. A constraint-name must not identify a constraint that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

**PRIMARY KEY(column-name,...)**

Defines a primary key composed of the identified columns. A table can only have one primary key. Thus, this clause cannot be specified more than once and cannot be specified at all if the shorthand form has been used to define a primary key for the table. The identified columns cannot be the same as the columns specified in another UNIQUE constraint specified earlier in the CREATE TABLE statement. For example, PRIMARY KEY(A,B) would not be allowed if UNIQUE (B,A) had already been specified.

Each column-name must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their byte counts must not exceed 32766-n, where n is the number of columns specified that allow nulls. For information about byte-counts see Table 82 on page 1211.

The unique index is created as part of the system physical file, not a separate system logical file. When a primary key is added, a CHECK constraint is implicitly added to enforce the rule that the NULL value is not allowed in any of the columns that make up the primary key.

**UNIQUE (column-name,...)**

Defines a unique constraint composed of the identified columns. The UNIQUE clause can be specified more than once. The identified columns cannot be the same as the columns specified in another UNIQUE constraint or PRIMARY KEY that was specified earlier in the CREATE TABLE statement. For determining if a unique constraint is the same as another constraint specification, the column lists are compared. For example, UNIQUE (A,B) is the same as UNIQUE (B,A).

Each column-name must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their byte counts must not exceed 32766-n, where n is the number of columns specified that allows nulls. For information about byte-counts see Table 82 on page 1211.

A unique index on the identified column is created during the execution of the CREATE TABLE statement. The unique index is created as part of the system physical file, not as a separate system logical file.
**CREATE TABLE**

**referential-constraint**

**CONSTRAINT** *constraint-name*

Names the constraint. A *constraint-name* must not identify a constraint that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

**FOREIGN KEY**

Each specification of the FOREIGN KEY clause defines a referential constraint. FOREIGN KEY is not allowed if the table is a declared global temporary table or a distributed table.

(*column-name,...*)

The foreign key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column and must not be a row change timestamp column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their lengths must not exceed 32766–n, where n is the number of columns specified that allow nulls.

**REFERENCES** *table-name*

The *table-name* specified in a REFERENCES clause must identify the table being created or a base table that already exists at the application server, but it must not identify a catalog table, a declared temporary table, a distributed table, or a history table. If the parent is a partitioned table, the unique index that enforces the parent unique constraint must be non-partitioned.

A referential constraint is a duplicate if its foreign key, parent key, and parent table are the same as the foreign key, parent key, and parent table of a previously specified referential constraint. Duplicate referential constraints are allowed, but not recommended.

Let T2 denote the identified parent table and let T1 denote the table being created.

The specified foreign key must have the same number of columns as the parent key of T2. The description of the nth column of the foreign key and the description of the nth column of that parent key must have identical data types, lengths, CCSIDs, and FIELDPROCs.

(*column-name,...*)

The parent key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T2. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column and must not be a row change timestamp column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their byte counts must not exceed 32766–n, where n is the number of columns specified that allow nulls. For information about byte-counts see [Table 82 on page 1211](#).

The list of column names must be identical to the list of column names in the primary key of T2 or a UNIQUE constraint that exists on T2.
The names need not be specified in the same order as in the primary key; however, they must be specified in corresponding order to the list of columns in the foreign key clause. If a column name list is not specified, then T2 must have a primary key. Omission of the column name list is an implicit specification of the columns of that primary key.

The referential constraint specified by a FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent.

**ON DELETE**
Specifies what action is to take place on the dependent tables when a row of the parent table is deleted. There are five possible actions:

- NO ACTION (default)
- RESTRICT
- CASCADE
- SET NULL
- SET DEFAULT

SET NULL must not be specified unless some column of the foreign key allows null values.

CASCADE must not be specified if T1 contains a DataLink column with FILE LINK CONTROL.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let \( p \) denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of \( p \) in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of \( p \) in T1 is set to null. SET NULL is not allowed if the dependent table is a partitioned table and a foreign key column is also a partitioning key.
- If SET DEFAULT is specified, each column of the foreign key of each dependent of \( p \) in T1 is set to its default value. SET DEFAULT is not allowed if the dependent table is a partitioned table and a foreign key column is also a partitioning key unless the default keeps the row in the same partition.

**ON UPDATE**
Specifies what action is to take place on the dependent tables when a row of the parent table is updated.

The update rule applies when a row of T2 is the object of an UPDATE or propagated update operation and that row has dependents in T1. Let \( p \) denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are updated.

**check-constraint**

**CONSTRAINT** *constraint-name*
Names the check constraint. A *constraint-name* must not identify a constraint
that was previously specified in the CREATE TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

**CHECK** *(check-condition)*

Defines a check constraint. At any time, the *check-condition* must be true or unknown for every row of the table.

The *check-condition* is a search-condition except:

- It can only refer to columns of the table
- The result of any expression in the *check-condition* cannot be a ROWID, XML, or DATALINK with FILE LINK CONTROL data type.
- It must not contain any of the following:
  - Subqueries
  - Aggregate functions
  - Variables
  - Global variables
  - Parameter markers
  - Sequence-references
  - Complex expressions that contain LOBs (such as concatenation)
  - OLAP specifications
  - ROW CHANGE expressions
  - IS JSON, JSON_EXISTS, or REGEXP_LIKE predicates
  - Special registers
  - User-defined functions other than functions that were implicitly generated with the creation of a distinct type
  - The following built-in scalar functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Function</th>
<th>Function</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN2</td>
<td>DLURLPATHONLY</td>
<td>LPAD</td>
<td>RPAD</td>
</tr>
<tr>
<td>BSON_TO_JSON</td>
<td>DLURLSCHEME</td>
<td>MAX_CARDINALITY</td>
<td>SCORE</td>
</tr>
<tr>
<td>CARDINALITY</td>

<td>LOCATE_IN_STRING</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1 For DataLinks with an attribute of FILE LINK CONTROL and READ PERMISSION DB.

**ON INSERT VIOLATION**

Specifies the action to take if the *check-condition* is false for a row being inserted. If this clause is not specified, an error will occur if the *check-condition* is false for an insert.
**SET column-name = DEFAULT**

The default value for `column-name` is inserted into the table instead of the value provided by the insert operation.

`column-name` must be referenced in the `check-condition`.

**ON UPDATE VIOLATION**

Specifies the action to take if the `check-condition` is false for a row being updated. If this clause is not specified, an error will occur if the `check-condition` is false for an update.

**PRESERVE column-name**

The current value for `column-name` remains in the table rather than being replaced by the value provided by the update operation.

`column-name` must be referenced in the `check-condition`.

For more information about `search-condition`, see [“Search conditions” on page 249](#).

For more information about `check constraints` involving LOB data types and expressions, see the [Database Programming](#) topic collection.

**NOT LOGGED INITIALLY**

Any changes made to the table by INSERT, DELETE, or UPDATE statements in the same unit of work after the table is created by this statement are not logged (journaled).

At the completion of the current unit of work, the NOT LOGGED INITIALLY attribute is deactivated and all operations that are done on the table in subsequent units of work are logged (journaled).

The NOT LOGGED INITIALLY option is useful for situations where a large result set needs to be created with data from an alternate source (another table or a file) and recovery of the table is not necessary. Using this option will save the overhead of logging (journaling) the data.

ACTIVATE NOT LOGGED INITIALLY is ignored if the table has a DATALINK column with FILE LINK CONTROL.

**VOLATILE or NOT VOLATILE**

Indicates to the optimizer whether the cardinality of table `table-name` can vary significantly at run time. Volatility applies to the number of rows in the table, not to the table itself. The default is NOT VOLATILE.

**VOLATILE**

Specifies that the cardinality of `table-name` can vary significantly at run time, from empty to large. To access the table, the optimizer will typically use an index, if possible.

**NOT VOLATILE**

Specifies that the cardinality of `table-name` is not volatile. Access plans that reference this table will be based on the cardinality of the table at the time the access plan is built. NOT VOLATILE is the default.

**RCDFMT**

Indicates the record format name of the table.
CREATE TABLE

**RCDfmt format-name**

An unqualified name that designates the IBM i record format name of the table. A format-name is a system identifier.

If a record format name is not specified, the format-name is the same as the system-object-name of the table.

**media-preference**

Specifies the preferred storage media for the table or partition.

**UNIT ANY**

No storage media is preferred. Storage for the table or partition will be allocated from any available storage media. If UNIT ANY is specified on the table, any media-preference that is specified on a partition is used.

**UNIT SSD**

Solid state disk storage media is preferred. Storage for the table or partition may be allocated from solid state disk storage media, if available. If UNIT SSD is specified on the table, any media-preference specified on a partition is ignored.

**memory-preference**

**KEEP IN MEMORY**

Specifies whether the data for the table should be brought into a main storage pool when the data is used in a query.

**NO** The data will not be brought into a main storage pool.

**YES** The data will be brought into a main storage pool.

**ON REPLACE**

Specifies the action to take when replacing a table that exists at the current server. This option is ignored if an existing table is not being replaced.

**PRESERVE ALL ROWS**

Current rows of the specified table will be preserved. PRESERVE ALL ROWS is not allowed if WITH DATA is specified with result-table-as.

All rows of all partitions in a partitioned table are preserved. If the new table definition is a range partitioned table, the defined ranges must be able to contain all the rows from the existing partitions.

If a column is dropped, the column values will not be preserved. If a column is altered, the column values may be modified.

If the table is not a partitioned table or is a hash partitioned table, PRESERVE ALL ROWS and PRESERVE ROWS are equivalent.

**PRESERVE ROWS**

Current rows of the specified table will be preserved. PRESERVE ROWS is not allowed if WITH DATA is specified with result-table-as.

If a partition of a range partitioned table is dropped, the rows of that partition will be deleted without processing any delete triggers. To determine if a partition of a range partitioned table is dropped, the range definitions and the partition names (if any) of the partitions in the new table definition are compared to the partitions in the existing table definition. If either the specified range or the name of a partition matches, it is preserved. If a partition does not have a partition-name, its boundary-spec must match an existing partition.
If a partition of a hash partition table is dropped, the rows of that partition will be preserved.

If a column is dropped, the column values will not be preserved. If a column is altered, the column values may be modified.

**DELETE ROWS**

Current rows of the specified table will be deleted. Any existing DELETE triggers are not fired.

DELETE ROWS is not allowed if the table is a system-period temporal table or a history table.

**distribution-clause**

**IN NODEGROUP nodegroup-name**

Specifies the nodegroup across which the data in the table will be distributed. The name must identify a nodegroup that exists at the current server. If this clause is specified, the table is created as a distributed table across all the systems in the nodegroup.

A LOB, DATALINK, XML, or IDENTITY column is not allowed in a distributed table.

The DB2 Multisystem product must be installed to create a distributed table. For more information about distributed tables, see the [Db2 Multisystem topic collection](#).

**DISTRIBUTE BY HASH (column-name,...)**

Specifies the partitioning key. The partitioning key is used to determine on which node in the nodegroup a row will be placed. Each column-name must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. If the DISTRIBUTE BY clause is not specified, the first column of the primary key is used as the partitioning key. If there is no primary key, the first column of the table that is not floating point, date, time, or timestamp is used as the partitioning key.

The columns that make up the partitioning key must be a subset of the columns that make up any unique constraints over the table. Floating point, date, time, timestamp, LOB, XML, DataLink, ROWID, and columns that have a field procedure cannot be used in a partitioning key.

**partitioning-clause**

**PARTITION BY RANGE**

Specifies that ranges of column values are used to determine the target data partition when inserting a row into the table. The number of partitions must not exceed 256.

**partition-expression**

Specifies the key data over which the range is defined to determine the target data partition of the data.

**column-name**

Identifies a column in the data partitioning key. The partitioning key is used to determine into which partition in the table a row will be placed. The column-name must be an unqualified name that identifies a column of the table. The same column must not be identified more than once.
CREATE TABLE

LOB, XML, DataLink, ROWID, row change timestamp columns, identity columns, and any column with a field procedure cannot be used in a partitioning key.

The number of identified columns must not exceed 120. The sum of length attributes of the columns must not be greater than 2000.

**NULLS LAST**
Indicates that null values compare high.

**NULLS FIRST**
Indicates that null values compare low.

**partition-element**
Specifies ranges for a data partitioning key.

**PARTITION partition-name**
Names the data partition. The name must not be the same as any other data partition for the table.

If the clause is not specified, a unique partition name is generated by the database manager.

**boundary-spec**
Specifies the boundaries of a range partition. If more than one partition key is specified, the boundaries must be specified in ascending sequence. The ranges must not overlap.

**starting-clause**
Specifies the low end of the range for a data partition. The number of specified starting values must be the same as the number of columns in the partitioning key. If a starting-clause is not specified for the first boundary-spec, the default is MINVALUE INCLUSIVE for each column of the partitioning key. If a starting-clause is not specified for a subsequent boundary-spec, the previous adjacent boundary-spec must contain an ending-clause. The default is the same as that ending-clause except that the INCLUSIVE or EXCLUSIVE attribute is reversed.

**STARTING FROM**
Introduces the starting-clause.

**constant**
Specifies a constant that must conform to the rules of a constant for the data type of the corresponding column of the partition key. If the corresponding column of the partition key is a distinct type, the constant must conform to the rules of the source type of the distinct type. The value must not be in the range of any other boundary-spec for the table.

**MINVALUE**
Specifies a value that is lower than the lowest possible value for the data type of the column-name to which it corresponds. If MINVALUE is specified, all subsequent values in the starting-clause must also be MINVALUE.

**MAXVALUE**
Specifies a value that is greater than the greatest possible value for the data type of the column-name to which it corresponds. If MAXVALUE is specified, all subsequent values in the ending-clause must also be MAXVALUE.
INCLUSIVE
Indicates that the specified range values are included in the data partition.

EXCLUSIVE
Indicates that the specified range values are excluded from the data partition. This specification is ignored when MINVALUE or MAXVALUE is specified.

ending-clause
Specifies the high end of the range for a data partition. The number of specified ending values must be the same as the number of columns in the data partitioning key. An ending-clause must be specified for the last boundary-spec. If an ending-clause is not specified for a previous boundary-spec, the next adjacent boundary-spec must contain a starting-clause. The default is the same as that starting-clause except that the INCLUSIVE or EXCLUSIVE attribute is reversed.

ENDING AT
Introduces the ending-clause.

constant
Specifies a constant that must conform to the rules of a constant for the data type of the corresponding column of the partition key. If the corresponding column of the partition key is a distinct type, the constant must conform to the rules of the source type of the distinct type. The value must not be in the range of any other boundary-spec for the table.

MINVALUE
Specifies a value that is lower than the lowest possible value for the data type of the column-name to which it corresponds. If MINVALUE is specified, all subsequent values in the starting-clause must also be MINVALUE.

MAXVALUE
Specifies a value that is greater than the greatest possible value for the data type of the column-name to which it corresponds. If MAXVALUE is specified, all subsequent values in the ending-clause must also be MAXVALUE.

INCLUSIVE
Indicates that the specified range values are included in the data partition.

EXCLUSIVE
Indicates that the specified range values are excluded from the data partition. This specification is ignored when MINVALUE or MAXVALUE is specified.

EVERY integer-constant
Specifies that multiple data partitions will be added where integer-constant specifies the width of each data partition range. If EVERY is specified, only a single SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, DATE, or TIMESTAMP column can be specified for the partition key.

The starting value of the first data partition is the specified STARTING value. The starting value of each subsequent partition is the starting...
value of the previous partition + integer-constant. If the starting-clause specified EXCLUSIVE, the starting value of every partition is EXCLUSIVE. Otherwise, the starting value of every partition is INCLUSIVE.

The ending value of every partition of the range is (the partition’s start value + integer-constant). If the ending-clause specified EXCLUSIVE, the ending value of the last partition is EXCLUSIVE. Otherwise, the ending value of the last partition is INCLUSIVE. The ending values of the other partitions is EXCLUSIVE if the starting value is INCLUSIVE. Otherwise, the ending values of the other partitions is INCLUSIVE.

The number of partitions added is determined by adding integer-constant repeatedly to the STARTING value until the ENDING value is reached. For example:

```
CREATE TABLE FOO
(A INT)
PARTITION BY RANGE(A)
 (STARTING(1) ENDING(10) EVERY(2))
```

is equivalent to the following CREATE TABLE statement:

```
CREATE TABLE FOO
(A INT)
PARTITION BY RANGE(A)
 (STARTING(1) ENDING(2),
 STARTING(3) ENDING(4),
 STARTING(5) ENDING(6),
 STARTING(7) ENDING(8),
 STARTING(9) ENDING(10))
```

In the case of dates and timestamps, the EVERY value must be a labeled duration. For example:

```
CREATE TABLE FOO
(A DATE)
PARTITION BY RANGE(A)
 (STARTING('2001-01-01') ENDING('2010-01-01') EVERY(3 MONTHS))
```

**PARTITION BY HASH**

Specifies that the hash function is used to determine the target data partition when inserting a row into the table.

```
(column-name,...)
```

Specifies the partitioning key. The partitioning key is used to determine into which partition in the table a row will be placed. Each column-name must be an unqualified name that identifies a column of the table. The same column must not be identified more than once.

Floating point, LOB, XML, date, time, timestamp, DataLink, ROWID, identity columns, and columns with a field procedure cannot be used in a partitioning key.

**INTO integer PARTITIONS**

Specifies the number of partitions. The number of partitions must not exceed 256.

**materialized-query-definition**

```
column-name
```

Names a column in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the select-statement. Each column-name must be unique and unqualified. If a list of
column names is not specified, the columns of the table inherit the names of the columns of the result table of the `select-statement`.

A list of column names must be specified if the result table of the `select-statement` has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation (UNION or INTERSECT) that is not named using the AS clause of the select list.

**FOR COLUMN** `system-column-name`

Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the `system-column-name` is not specified, and the column-name is not a valid `system-column-name`, a system column name is generated. For more information about how system column names are generated, see "Rules for Table Name Generation" on page 1213.

**select-statement**

Specifies that the columns of the table have the same name and description as the columns that would appear in the derived result table of the `select-statement` if the `select-statement` were to be executed. The use of AS (select-statement) is an implicit definition of `n` columns for the table, where `n` is the number of columns that would result from the `select-statement`.

The implicit definition includes the following attributes of the `n` columns (if applicable to the data type):

- Column name (and system column name)
- Data type, length, precision, and scale
- CCSID
- Nullability
- FIELDPROC
- Column heading and text (see "LABEL" on page 1463)

The following attributes are not included:

- Default value
- Hidden attribute
- Identity attributes
- Row change timestamp attribute
- Row-begin, row-end, and transaction-start-ID
- Generated expression

The implicit definition does not include any other optional attributes of the identified table or view. For example, the new table does not automatically include a primary key or foreign key from a table. The new table has these and other optional attributes only if the optional clauses are explicitly specified.

The `select-statement` must not refer to variables or global variables, or include parameter markers. If an expression in the SELECT clause of the `select-statement` is not a column name, then the expression must not reference a column with a field procedure.

The `select-statement` must not contain a PREVIOUS VALUE or a NEXT VALUE expression. The UPDATE, SKIP LOCKED DATA, and USE AND KEEP EXCLUSIVE LOCKS clauses may not be specified.
refreshable-table-options

Specifies that the table is a materialized query table and the REFRESH TABLE statement can be used to populate the table with the results of the select-statement.

A materialized query table whose select-statement contains a GROUP BY clause is summarizing data from the tables referenced in the select-statement. Such a materialized query table is also known as a summary table. A summary table is a specialized type of materialized query table.

When a materialized query table is defined, the following select-statement restrictions apply:

- The select-statement cannot contain a reference to another materialized query table or to a view that refers to a materialized query table.
- The select-statement cannot contain a reference to a declared temporary table, a table in QTEMP, a program-described file, or a non-SQL logical file in the FROM clause.
- The select-statement cannot contain a reference to a view that references another materialized query table or a declared temporary table. When a materialized query table is defined with ENABLE QUERY OPTIMIZATION, the select-statement cannot contain a reference to a view that contains one of the restrictions from the following paragraph.
- The select-statement cannot contain an expression with a DataLink or a distinct type based on a DataLink where the DataLink is FILE LINK CONTROL.
- The select-statement cannot contain a result column that is not an SQL data type, such as binary with precision, DBCS-ONLY, or DBCS-EITHER.

When a materialized query table is defined with ENABLE QUERY OPTIMIZATION, the following additional select-statement restrictions apply:

- Must not include any special registers.
- Must not include any non-deterministic functions.
- The ORDER BY clause is allowed, but is only used by REFRESH. It may improve locality of reference of data in the materialized query table.
- If the subselect references a view, the select-statement in the view definition must satisfy the preceding restrictions.

DATA INITIALLY DEFERRED

Specifies that the data is not inserted into the materialized query table when it is created. Use the REFRESH TABLE statement to populate the materialized query table, or use the INSERT statement to insert data into a materialized query table.

DATA INITIALLY IMMEDIATE

Specifies that the data is inserted into the materialized query table when it is created.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated.
MAINTAINED BY USER

Specifies that the materialized query table is maintained by the user. The user can use INSERT, DELETE, UPDATE, or REFRESH TABLE statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for optimization. The default is ENABLE QUERY OPTIMIZATION.

ENABLE QUERY OPTIMIZATION

Specifies that the materialized query table can be used for query optimization. If the select-statement specified does not satisfy the restrictions for query optimization, an error is returned.

DISABLE QUERY OPTIMIZATION

Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

If row level or column level access control is activated for any table that is directly or indirectly referenced in the select-statement, row access control is implicitly activated for the table being created. This restricts direct access to the contents of the materialized query table. A query that explicitly references the table will return a warning that there is no data in the table. To provide access to the materialized query table, an appropriate row permission can be created or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL on the materialized query table can be issued to remove the row level protection if that is appropriate.

Notes

Table attributes: Tables are created as physical files. When a table is created, the file wait time and record wait time attributes are set to the default that is specified on the WAITFILE and WAITRCD keywords of the Create Physical File (CRTPF) command.

SQL tables are created so that space used by deleted rows will be reclaimed by future insert requests. This attribute can be changed via the command CHGPF and specifying the REUSEDLT(No) parameter. For more information about the CHGPF command, see [CL Reference](#).

A distributed table is created on all of the servers across which the table is distributed. For more information about distributed tables, see [Db2 Multisystem](#).

Table journaling: When a table is created, journaling may be automatically started.

- If a data area called QDFJTJRN exists in the same schema that the table is created into and the user is authorized to the data area, journaling will be started to the journal named in the data area if all the following are true:
  - The identified schema for the table must not be QSYS, QSYS2, QRECOVERY, QSPL, QRCL, QRPLOBJ, QGPL, QTEMP, SYSIBM, or any of the iASP equivalents to these libraries.
  - The journal specified in the data area must exist and the user must be authorized to start journaling to the journal.
  - The first 10 bytes of the data area must contain the name of the schema in which to find the journal.
  - The second 10 bytes must contain the name of the journal.
The remaining bytes contain the object types being implicitly journaled and the options that affect when implicit journaling is performed. The object type must include the value *FILE or *ALL. The value *NONE can be used to prevent journaling from being started.

For more information, see [Journal Management](#).

- If the table is created into a schema that has specified (using the STRJRNLIB command) that journaling should implicitly be started.
- If a data area called QDFTJRN does not exist in the same schema that the table is created into or the user is not authorized to the data area and the schema has not specified that journaling should be started, journaling will be started to a journal called QSQJRN if it exists in the same schema that the table is created into.

**Table ownership:** If SQL names were specified:

- If a user profile with the same name as the schema into which the table is created exists, the owner of the table is that user profile.
- Otherwise, the owner of the table is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the table is the user profile or group user profile of the thread executing the statement.

**Table authority:** If SQL names are used, tables are created with the system authority of *EXCLUDE to *PUBLIC. If system names are used, tables are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the table is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the table.

**REPLACE rules:** When a table is recreated by REPLACE using PRESERVE ROWS, the new definition of the table is compared to the old definition and logically, for each difference between the two, a corresponding ALTER operation is performed. When the DELETE ROWS option is used, the table is logically dropped and recreated; as long as objects dependent on the table remain valid, any modification is allowed. For more information see [Table 77 on page 938](#) in ALTER TABLE. For columns, constraints, and partitions, the comparisons are performed based on their names and attributes.

Column names and system column names can be changed by modifying either the column name or the system column name, leaving the other name unchanged. If neither name matches an existing column, a new column is created. The existence of another object dependent on a column name may prevent the name change.

| memory-preference exists only in existing table definition | KEEP IN MEMORY NO |

Any attributes that cannot be specified in the CREATE TABLE statement are preserved:

- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved. However, unlike other objects, REPLACE of a table will generate a ZC (change object) journal audit entry.
- Current data journaling is preserved.
- Comments and labels are preserved.
- Triggers are preserved, if possible. If it is not possible to preserve a trigger, an error is returned.
- Masks and permissions are preserved, if possible. If it is not possible to preserve a mask or permission, an error is returned.
- Temporal table VERSIONING and the history table are preserved.
- Any views, materialized query tables, and indexes dependent on the table will be preserved or recreated, if possible. If it is not possible to preserve a dependent view, materialized query table, or index, an error is returned.

**Using an identity column:** When a table has an identity column, the database manager can automatically generate sequential numeric values for the column as rows are inserted into the table. Thus, identity columns are ideal for primary keys.

Identity columns and ROWID columns are similar in that both types of columns contain values that the database manager generates. ROWID columns can be useful in direct-row access. ROWID columns contain values of the ROWID data type, which returns a 40-byte VARCHAR value that is not regularly ascending or descending. ROWID data values are therefore not well suited to many application uses, such as generating employee numbers or product numbers. For data that does not require direct-row access, identity columns are usually a better approach, because identity columns contain existing numeric data types and can be used in a wide variety of uses for which ROWID values would not be suitable.

When a table is recovered to a point-in-time (using RMVJRNCHG), it is possible that a large gap in the sequence of generated values for the identity column might result. For example, assume a table has an identity column that has an incremental value of 1 and that the last generated value at time T1 was 100 and the database manager subsequently generates values up to 1000. Now, assume that the table is
recovered back to time T1. The generated value of the identity column for the next row that is inserted after the recovery completes will be 1001, leaving a gap from 100 to 1001 in the values of the identity column.

When CYCLE is specified duplicate values for a column may be generated even when the column is GENERATED ALWAYS, unless a unique constraint or unique index is defined on the column.

**Creating materialized query tables:** To ensure that the materialized query table has data before being used by a query:

- DATA INITIALLY IMMEDIATE should be used to create materialized query tables, or
- the materialized query table should be created with query optimization disabled and then enable the table for query optimization after it is refreshed.

The isolation level at the time when the CREATE TABLE statement is executed is the isolation level for the materialized query table. The isolation-clause can be used to explicitly specify the isolation level.

**Considerations for implicitly hidden columns:** A column that is defined as implicitly hidden is not part of the result table of a query that specifies * in a SELECT list. However, an implicitly hidden column can be explicitly referenced in a query. For example, an implicitly hidden column can be referenced in the SELECT list or in a predicate in a query. Additionally, an implicitly hidden column can be explicitly referenced in a COMMENT statement, CREATE INDEX statement, ALTER TABLE statement, INSERT statement, MERGE statement, or UPDATE statement. An implicitly hidden column can be referenced in a referential constraint. A REFERENCES clause that does not contain a column list refers implicitly to the primary key of the parent table. It is possible that the primary key of the parent table includes a column defined as implicitly hidden. Such a referential constraint is allowed.

If the SELECT list of the fullselect of a materialized query definition explicitly refers to an implicitly hidden column, that column will be part of the materialized query table.

If the SELECT list of the fullselect of a view definition (CREATE VIEW statement) explicitly refers to an implicitly hidden column, that column will be part of the view, however the view column is not considered ‘hidden’.

**Considerations for transaction-start-ID columns:** A transaction-start-ID column contains a null value if the column allows null values and there is a row-begin column and the value of the row-begin column is unique from values for row-begin columns generated for other transactions. Given that the column may contain null values, it is recommended that one of the following methods be used when retrieving a value from the column:

```
COALESCE(transaction_start_id_col, row_begin_col)
```

```
CASE WHEN transaction_start_id_col IS NOT NULL THEN transaction_start_id_col ELSE row_begin_col END
```

**Defining a system-period temporal table:** A system-period temporal table definition includes the following:
CREATE TABLE

- A system period named SYSTEM_TIME, which is defined using a row-begin column and a row-end column. See the descriptions of AS ROW BEGIN, AS ROW END, and period-definition.
- A transaction-start-ID column. See the description of AS TRANSACTION START ID.
- A system-period data versioning definition specified on a subsequent ALTER TABLE statement that specifies the ADD VERSIONING clause, which includes the name of the associated history table. See “ADD VERSIONING USE HISTORY TABLE history-table-name” on page 926.

Partitioned table performance: The larger the number of partitions in a partitioned table, the greater the overhead in SQL data change and SQL data statements. You should create a partitioned table with the minimum number of partitions that are required to minimize this overhead. It is also highly recommended that a parallelism degree greater than one be considered when accessing a partitioned table.

Creating a table using a remote select-statement: The select-statement for an as-result-table can refer to tables on a different server than where the table is being created. This can be done by using a three-part object name or an alias that is defined to reference a three-part name of a table or view. The select-statement cannot be for a materialized query table and the result cannot contain a column that has a field procedure defined. If the remote server is Db2 for LUW or Db2 for z/OS, copy-options are not allowed. If the remote server is Db2 for LUW, a column list should be explicitly specified before the AS keyword.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- INLINE LENGTH is a synonym for ALLOCATE.
- constraint-name (without the CONSTRAINT keyword) may be specified following the FOREIGN KEY keywords in a referential-constraint
- DEFINITION ONLY is a synonym for WITH NO DATA
- PARTITIONING KEY is a synonym for DISTRIBUTUE BY HASH.
- PART is a synonym for PARTITION.
- PARTITION partition-number may be specified instead of PARTITION partition-name. A partition-number must not identify a partition that was previously specified in the CREATE TABLE statement.
  If a partition-number is not specified, a unique partition number is generated by the database manager.
- VALUES is a synonym for ENDING AT.
- SUMMARY between CREATE and TABLE when creating a materialized query table.

Maximum row sizes

There are two maximum row size restrictions referred to in the description of column-definition.
- The maximum row buffer size is 32766 or, if a VARCHAR, VARGRAPHIC, VARBINARY, LOB, or XML column is specified, 32740.
- The maximum row data size is 3 758 096 383 if a LOB or XML column is specified; this size is determined when a row is inserted or updated. If a LOB or
XML column is not specified, then the maximum row data size is 32766 or, if a VARCHAR, VARGRAPHIC, or VARBINARY column is specified, 32740.

To determine the length of a row buffer and row data or both, add the corresponding length of each column of that row based on the byte counts of the data type.

The following table gives the byte counts of columns by data type for columns that do not allow null values. If any column allows null values, one byte is required for every eight columns. A column that has a field procedure could have a different count based on the result of the field procedure.

<table>
<thead>

</tr>
</tbody>
</table>

Notes:

\(pad\) is a value from 1 to 15 necessary for boundary alignment.
Precision as described to the database:

- Floating-point fields are defined in the Db2 for i database with a decimal precision, not a bit precision. The algorithm used to convert the number of bits to decimal is \( \text{decimal precision} = \text{CEILING}(n/3.31) \), where \( n \) is the number of bits to convert. The decimal precision is used to determine how many digits to display using interactive SQL.
- SMALLINT fields are stored with a decimal precision of 4.0.
- INTEGER fields are stored with a decimal precision of 9.0.
- BIGINT fields are stored with a decimal precision of 19.0.

**LONG VARCHAR, LONG VARGRAPHIC, and LONG VARBINARY**

The non-standard syntax of LONG VARCHAR, LONG VARGRAPHIC, and LONG VARBINARY is supported, but deprecated. The alternative standard syntax of VARCHAR(integer), VARGRAPHIC(integer), and VARBINARY(integer) is preferred. VARCHAR(integer), VARGRAPHIC(integer), and VARBINARY(integer) are recommended. After the CREATE TABLE statement is processed, the database manager considers a LONG VARCHAR column to be VARCHAR, a LONG VARGRAPHIC column to be VARGRAPHIC, and a LONG VARBINARY column to be VARBINARY. The maximum length is calculated in a product-specific fashion that is not portable.

**LONG VARCHAR**

For a varying length character string whose maximum length is determined by the amount of space available in the row.

**LONG VARGRAPHIC**

For a varying length graphic string whose maximum length is determined by the amount of space available in the row.

**LONG VARBINARY**

For a varying length binary string whose maximum length is determined by the amount of space available in the row.

The maximum length of a LONG column is determined as follows. Let:

- \( i \) be the sum of the row buffer byte counts of all columns in the table that are not LONG VARCHAR, LONG VARGRAPHIC, or LONG VARBINARY
- \( j \) be the number of LONG VARCHAR, LONG VARGRAPHIC, and LONG VARBINARY columns in the table
- \( k \) be the number of columns in the row that allow nulls.

The length of each LONG VARCHAR and LONG VARBINARY column is

\[ \text{INTEGER}((32716 - i-(k+7)/8))/j \]

The length of each LONG VARGRAPHIC column is determined by taking the length calculated for a LONG VARCHAR column and dividing it by 2. The integer portion of the result is the length.

---

100. This option is provided for compatibility with other products. It is recommended that VARCHAR(integer), VARGRAPHIC(integer), or VARBINARY(integer) be specified instead.
Rules for System Name Generation

There are specific instances when the system generates a system table, view, index, or column name. These instances and the name generation rules are described in the following sections.

Rules for Column Name Generation

A system-column-name is generated if the system-column-name is not specified when a table or view is created and the column-name is not a valid system-column-name.

If the column-name does not contain special characters and is longer than 10 characters, a 10-character system-column-name will be generated as:
- The first 5 characters of the name
- A 5 digit unique number

For example:
The system-column-name for LONGCOLUMNNAME would be LONGC00001

If the column name is delimited:
- The first 5 characters from within the delimiters will be used as the first 5 characters of the system-column-name. If there are fewer than 5 characters within the delimiters, the name will be padded on the right with underscore (_) characters. Lower case characters are folded to upper case characters. The only valid characters in a system-column-name are: A-Z, 0-9, @, #, $, and _. Any other characters will be changed to the underscore (_) character. If the first character ends up as an underscore, it will be changed to the letter Q.
- A 5 digit unique number is appended to the 5 characters.

For example:
The system-column-name for "abc" would be ABC__00001
The system-column-name for "COL2.NAME" would be COL2_00001
The system-column-name for "C 3" would be C_3__00001
The system-column-name for "??" would be Q__00001
The system-column-name for "+column1" would be QCOLU00001

Rules for Table Name Generation

A system name will be generated if a table, view, alias, or index is created without using the FOR SYSTEM NAME clause and has either:
- A name longer than 10 characters
- A name that contains characters not valid in a system name

The SQL name or its corresponding system name may both be used in SQL statements to access the file once it is created. However, the SQL name is only recognized by Db2 for i and the system name must be used in other environments.

There are two separate methods for generating the system name:
- If a data area with the name QGENOBLINAM exists in the same schema that the table is created into, the user can influence the generated name.

The data area is subject to the following restrictions:
- The user must be authorized to read the data area.
- The data area must have an attribute of CHAR(10).
CREATE TABLE

- The first 5 characters of the data area value must be '?????'.
- The next 5 characters of the data area value must contain 5 numeric digits.

If any of the above conditions are not satisfied or any error occurs while accessing the starting value in the data area, the default name generation rules will be used as if the data area did not exist at all.

If the data area meets all of the restrictions above, the generated name will be the same as if the default name generation rules below except that after the first 5 (or 4) characters of the name, the unique number will initially contain the 5 digits specified in the data area (instead of '00001' or '0001').

For example, if the value of the data area was '?????00999':

- The system name for "??" would be "___00999"
- The system name for "longtablename" would be "lon00999"
- The system name for "LONGTableName" would be LONG00999
- The system name for "A b " would be "A_b00999"

- Otherwise, the default name generation rules are used:

If the name does not contain special characters and is longer than 10 characters, a 10-character system name will be generated as:

- The first 5 characters of the name
- A 5 digit unique number

For example:

- The system name for LONGTABLENAME would be LONGT00001

If the SQL name contains special characters, the system name is generated as:

- The first 4 characters of the name
- A 4 digit unique number

In addition:

- All special characters are replaced by the underscore (_)
- Any trailing blanks are removed from the name
- The name is delimited by double quotes ("") if the delimiters are required for the name to be a valid system name.

For example:

- The system name for "??" would be "__0001"
- The system name for "longtablename" would be "long0001"
- The system name for "LONGTableName" would be LONG0001
- The system name for "A b " would be "A_b0001"

SQL ensures the system name is unique by searching the cross reference file. If the name already exists in the cross reference file, the number is incremented until the name is no longer a duplicate.

If a unique name cannot be determined using the above rules, an additional character is added to the counter in the name, and the number is incremented until a unique name can be found or the range is exhausted. For example, if creating "longtablename" and names "long0001" through "long9999" already exist, the name would become "lon00001".

Examples

Example 1: Given database administrator authority, create a table named 'ROSSITER.INVENTORY' with the following columns:

- Part number
  - Small integer, must not be null

- Description
  - Character of length 0 to 24, allows nulls
Quantity on hand,
   Integer allows nulls

CREATE TABLE ROSSITER.INVENTORY
   (PARTNO SMALLINT NOT NULL,
    DESCR VARCHAR(24),
    QONHAND INT)

Example 2: Create a table named DEPARTMENT with the following columns:

Department number
   Character of length 3, must not be null

Department name
   Character of length 0 through 36, must not be null

Manager number
   Character of length 6

Administrative dept.
   Character of length 3, must not be null

Location name
   Character of length 16, allows nulls

The primary key is column DEPTNO.

CREATE TABLE DEPARTMENT
   (DEPTNO CHAR(3) NOT NULL,
    DEPTNAME VARCHAR(36) NOT NULL,
    MGRNO CHAR(6),
    ADMRDEPT CHAR(3) NOT NULL,
    LOCATION CHAR(16),
    PRIMARY KEY(DEPTNO))

Example 3: Create a table named REORG_PROJECTS which has the same column definitions as the columns in the view PRJ_LEADER.

CREATE TABLE REORG_PROJECTS
   LIKE PRJ_LEADER

Example 4: Create an EMPLOYEE2 table with an identity column named EMP_NO. Define the identity column so that Db2 for i will always generate the values for the column. Use the default value, which is 1, for the first value that should be assigned and for the incremental difference between the subsequently generated consecutive numbers.

CREATE TABLE EMPLOYEE2
   (EMPNO INTEGER GENERATED ALWAYS AS IDENTITY,
    ID SMALLINT,
    NAME CHAR(30),
    SALARY DECIMAL(5,2),
    DEPTNO SMALLINT)

Example 5: Assume a very large transaction table named TRANS contains one row for each transaction processed by a company. The table is defined with many columns. Create a materialized query table for the TRANS table that contains daily summary data for the date and amount of a transaction.

CREATE TABLE STRANS
   AS (SELECT YEAR AS SYEAR, MONTH AS SMONTH, DAY AS SDAY, SUM(AMOUNT) AS SSUM
      FROM TRANS
      GROUP BY YEAR, MONTH, DAY )

DATA INITIALLY DEFERRED
REFRESH DEFERRED
MAINTAINED BY USER
Example 6: Create a table, policy_info, that uses a SYSTEM_TIME period and create a history table, hist_policy_info. Then issue an ALTER TABLE statement to associate the policy_info table with the hist_policy_info table.

```sql
CREATE TABLE policy_info
(policy_id CHAR(10) NOT NULL,
 coverage INT NOT NULL,
 sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,
 sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,
 create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,
 PERIOD SYSTEM_TIME(sys_start,sys_end));

CREATE TABLE hist_policy_info
(policy_id CHAR(10) NOT NULL,
 coverage INT NOT NULL,
 sys_start TIMESTAMP(12) NOT NULL,
 sys_end TIMESTAMP(12) NOT NULL,
 create_id TIMESTAMP(12));

ALTER TABLE policy_info
ADD VERSIONING USE HISTORY TABLE hist_policy_info;
```

The history table can also be created in the following way since the generated attributes are not copied for LIKE:

```sql
CREATE TABLE hist_policy_info
LIKE policy_info;
```
CREATE TRIGGER

The CREATE TRIGGER statement defines a trigger at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see Privileges necessary to create in a schema.
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- Each of the following:
  - The ALTER privilege on the table or view on which the trigger is defined,
  - The SELECT privilege on the table or view on which the trigger is defined,
  - The SELECT privilege on any table or view referenced in the search-condition in the trigger-action,
  - The UPDATE privilege on the table on which the trigger is defined, if the BEFORE UPDATE trigger contains a SET statement that modifies the NEW correlation variable,
  - The privileges required to execute each triggered-SQL-statement, and
  - The system authority *EXECUTE on the library containing the table or view on which the trigger is defined.
- Database administrator authority

If an INSTEAD OF trigger is added to a view that is not inherently updatable, the *OBJMGT system authority is also required on the view.

In addition, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - *USE on the Add Physical File Trigger (ADDPFTRG) command,
  - *USE on the Create Program (CRTPGM) command
- Database administrator authority

If the SECURED attribute is specified, or the trigger is secured and OR REPLACE is specified:

- The authorization ID of the statement must have security administrator authority. See Administrative authority on page 18.

If SQL names are specified, and a user profile exists that has the same name as the library into which the trigger is created, and the name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- *ALLOBJ and *SECDADM special authority
CREATE TRIGGER

- Database administrator authority

To replace an existing trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the trigger program object
  - All authorities needed to DROP the trigger
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.

Syntax

```sql
CREATE TRIGGER trigger-name
OR REPLACE
trigger-definition
WRAPPED obfuscated-statement-text
```

**trigger-definition:**

- NO CASCADE
- BEFORE
- AFTER
- INSTead OF
- trigger-event
- ON table-name
- view-name
- REFERENCING OLD ROW AS correlation-name
- NEW ROW AS correlation-name
- OLD TABLE AS table-identifier
- NEW TABLE AS table-identifier
- FOR EACH STATEMENT
- triggered-action
- MODE DB2SQL
- MODE DB2ROW

**Notes:**

1. The same clause must not be specified more than once.

**trigger-event:**
CREATE TRIGGER

**Notes:**
1. Each *trigger-event* option can be specified only one time.

**triggered-action:**

```
triged-action:

option-list: SET OPTION-statement WHEN (search-condition)
```

**option-list:**

```
option-list: CONCURRENT ACCESS RESOLUTION USE CURRENTLY COMMITTED WAIT FOR OUTCOME NOT SECURED SECURED ENABLE DISABLE PROGRAM NAME external-program-name
```

**Notes:**
1. The options can be specified in any order. The same clause must not be specified more than once.

**SQL-trigger-body:**

**Description**

**OR REPLACE**

Specifies to replace the definition for the trigger if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the trigger are not affected. This option is ignored if a definition for the trigger does not exist at the current server.

**trigger-name**

Names the trigger. The name, including the implicit or explicit qualifier, must not be the same as a trigger that already exists at the current server. QTEMP cannot be used as the *trigger-name* schema qualifier.

If SQL names were specified, the trigger will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the trigger will be created in the schema that is specified by the qualifier. If not qualified, the trigger will be created in the same schema as the subject table.

If the trigger name is not a valid system name, or if a program with the same name already exists, the database manager will generate a system name. For information about the rules for generating a name, see [“Rules for Table Name Generation” on page 1213](#).

**NO CASCADE**

NO CASCADE is allowed for compatibility with other products and is ignored by Db2 for i.

**BEFORE**

Specifies that the trigger is a *before* trigger. The database manager executes the triggered-action before it applies any changes caused by an insert, delete, or update operation on the subject table. It also specifies that the triggered-action does not activate other triggers because the triggered-action of a before trigger cannot contain any updates.

BEFORE must not be specified when a *view-name* is specified. FOR EACH STATEMENT must not be specified for a BEFORE trigger.

**AFTER**

Specifies that the trigger is an *after* trigger. The database manager executes the triggered-action after it applies any changes caused by an insert, delete, or update operation on the subject table. AFTER must not be specified when *view-name* is also specified.

**INSTEAD OF**

Specifies that the trigger is an instead of trigger. The associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each kind of operation on a given subject view. The database manager executes the triggered-action instead of the insert, delete, or update operation on the subject view.

INSTEAD OF must not be specified when *table-name* is specified. The WHEN clause must not be specified for an INSTEAD OF trigger. FOR EACH STATEMENT must not be specified for an INSTEAD OF trigger.

**trigger-event**

Specifies that the triggered action associated with the trigger is to be executed
CREATE TRIGGER

whenever one of the events is applied to the subject table or view. Any combination of the events can be specified, but each event (INSERT, DELETE, UPDATE) can only be specified once.

**INSERT**
- Specifies that the triggered-action associated with the trigger is to be executed whenever there is an insert operation on the subject table.
  - A BEFORE INSERT trigger cannot be added to a history table.

**DELETE**
- Specifies that the triggered-action associated with the trigger is to be executed whenever there is a delete operation on the subject table.
  - A DELETE trigger cannot be added to a table with a referential constraint of ON DELETE CASCADE.

**UPDATE**
- Specifies that the triggered-action associated with the trigger is to be executed whenever there is an update operation on the subject table.
  - An UPDATE trigger event cannot be added to a table with a referential constraint of ON DELETE SET NULL or ON DELETE SET DEFAULT.
  - A BEFORE UPDATE trigger cannot be added to a history table.

If an explicit column-name list is not specified, an update operation on any column of the subject table, including columns that are subsequently added with the ALTER TABLE statement, activates the triggered-action.

**OF column-name, ...**
- Each column-name specified must be a column of the subject table, and must appear in the list only once. An update operation on any of the listed columns activates the triggered-action. This clause cannot be specified for an INSTEAD OF trigger.

**ON table-name**
- Identifies the subject table of a BEFORE or AFTER trigger definition. The name must identify a base table that exists at the current server, but must not identify a catalog table, a table in QTEMP, or a declared temporary table.

**ON view-name**
- Identifies the subject view of an INSTEAD OF trigger definition. The name must identify a view that exists at the current server, but must not identify a catalog view, or a view in QTEMP. The name must not specify a view that is defined using WITH CHECK OPTION, or a view on which a WITH CHECK OPTION view has been defined, directly or indirectly.

**REFERENCING**
- Specifies the correlation names for the transition tables and the table names for the transition tables. Correlation-names identify a specific row in the set of rows affected by the triggering SQL operation. Table-identifiers identify the complete set of affected rows.

Each row affected by the triggering SQL operation is available to the triggered-action by qualifying columns with correlation-names specified as follows:

**OLD ROW AS correlation-name**
- Specifies a correlation name that identifies the values in the row prior to the triggering SQL operation. If the trigger event is insert, the value for every column in OLD ROW is the NULL value.
NEW ROW AS correlation-name

Specifies a correlation name which identifies the values in the row as modified by the triggering SQL operation and any SET statement in a before trigger that has already executed. If the trigger event is delete, the value for every column in NEW ROW is the NULL value.

The complete set of rows affected by the triggering SQL operation is available to the triggered-action by using a temporary table name specified as follows:

OLD TABLE AS table-identifier

Specifies the name of a temporary table that identifies the values in the complete set of affected rows prior to the triggering SQL operation. The OLD TABLE includes the rows that were affected by the trigger if the current activation of the trigger was caused by statements in the SQL-trigger-body of a trigger. If the trigger event is insert, the temporary table is empty.

NEW TABLE AS table-identifier

Specifies the name of a temporary table that identifies the state of the complete set of affected rows as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed. If the trigger event is delete, the temporary table is empty.

Only one OLD and one NEW correlation-name may be specified for a trigger. Only one OLD_TABLE and one NEW_TABLE table-identifier may be specified for a trigger. All of the correlation-names and table-identifiers must be unique from one another.

The OLD correlation-name and the OLD_TABLE table-identifier are populated only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD correlation-name captures the values of the columns in the deleted row, and the OLD_TABLE table-identifier captures the values in the set of deleted rows. For an update operation, OLD correlation-name captures the values of the columns of a row before the update operation, and the OLD_TABLE table-identifier captures the values in the set of updated rows.

The NEW ROW correlation-name and the NEW TABLE table-identifier are populated only if the triggering event is either an INSERT operation or an UPDATE operation. For both operations, the NEW ROW correlation-name captures the values of the columns in the inserted or updated row, and the NEW TABLE table-identifier captures the values in the set of inserted or updated rows. For before triggers, the values of the updated rows include the changes from any SET statements in the triggered-action of before triggers.

The OLD ROW and NEW ROW correlation-name variables cannot be modified in an AFTER trigger or INSTEAD OF trigger.

The tables below summarizes the allowable combinations of correlation variables and transition tables.

Granularity: FOR EACH ROW
**CREATE TRIGGER**

<table>
<thead>
<tr>
<th>MODE</th>
<th>Activation Time</th>
<th>Triggering Operation</th>
<th>Correlation Variables Allowed</th>
<th>Transition Tables Allowed</th>

</tbody>
</table>

**Granularity:** **FOR EACH STATEMENT**

<table>
<thead>
<tr>
<th>MODE</th>
<th>Activation Time</th>
<th>Triggering Operation</th>
<th>Correlation Variables Allowed</th>
<th>Transition Tables Allowed</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2SQL</td>
<td>AFTER or INSTEAD OF</td>
<td>DELETE</td>
<td>NONE</td>
<td>OLD TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>INSERT</td>
<td>OLD TABLE</td>
<td>NEW TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UPDATE</td>
<td>OLD TABLE, NEW TABLE</td>
<td></td>
</tr>
</tbody>
</table>

A transition variable that has a character data type inherits the CCSID of the column of the subject table. During the execution of the *triggered-action*, the transition variables are treated like variables. Therefore, character conversion might occur.

The temporary transition tables are read-only. They cannot be modified.

The scope of each *correlation-name* and each *table-identifier* is the entire trigger definition.

**FOR EACH ROW**

Specifies that the database manager executes the *triggered-action* for each row of the subject table that the triggering operation modifies. If the triggering operation does not modify any rows, the *triggered-action* is not executed.

**FOR EACH STATEMENT**

Specifies that the database manager executes the *triggered-action* only once for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is still executed once.

FOR EACH STATEMENT cannot be specified for a BEFORE trigger.

FOR EACH STATEMENT cannot be specified for a MODE DB2ROW trigger.

**MODE DB2SQL**

MODE DB2SQL is valid for AFTER triggers. MODE DB2SQL AFTER triggers are activated after all of the row operations have occurred.
MODE DB2SQL is only valid for BEFORE triggers if a REFERENCING clause is not specified and the trigger table is not referenced in the SQL-trigger-body. MODE DB2SQL BEFORE triggers are activated on each row operation.

MODE DB2ROW
MODE DB2ROW triggers are activated on each row operation.
MODE DB2ROW is valid for both the BEFORE and AFTER activation time.

CONCURRENT ACCESS RESOLUTION
Specifies whether the database manager should wait for data that is in the process of being updated. DEFAULT is the default.

DEFAULT
Specifies that the concurrent access resolution is not explicitly set for this trigger. The value that is in effect when the trigger program is invoked will be used.

WAIT FOR OUTCOME
Specifies that the database manager is to wait for the commit or rollback of data in the process of being updated.

USE CURRENTLY COMMITTED
Specifies that the database manager is to use the currently committed version of the data when encountering data that is in the process of being updated.

When the lock contention is between a read transaction and a delete or update transaction, the clause is applicable to scans with isolation level CS (but not for CS KEEP LOCKS).

SECURED or NOT SECURED
Specifies whether the trigger is considered secure for row access control and column access control. NOT SECURED is the default.

SECURED
Specifies that the trigger is considered secure for row access control and column access control.
SECURED must be specified for a trigger whose subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED
Specifies that the trigger is considered not secure for row access control and column access control.
NOT SECURED must not be specified explicitly or implicitly for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

ENABLE or DISABLE
Specifies the state for the trigger. ENABLE is the default.

ENABLE
The trigger will be called during I/O operations.

DISABLE
The trigger will not be called during I/O operations.
CREATE TRIGGER

**WRAPPED** obfuscated-statement-text

Specifies the encoded definition of the trigger. A CREATE TRIGGER statement can be encoded using the WRAP scalar function.

**PROGRAM NAME** external-program-name

Specifies the unqualified name of the program to be created for the trigger. `external-program-name` must be in the form of a program name. It must not be a service program name.

**triggered-action**

Specifies the action to be performed when a trigger is activated. The `triggered-action` is composed of one or more SQL statements and by an optional condition that controls whether the statements are executed.

**SET OPTION**-statement

Specifies the options that will be used to create the trigger. For example, to create a debuggable trigger, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

The default values for the options depend on the options in effect at create time. For more information, see [“SET OPTION” on page 1575](#).

The options CNULIGN, CNULRQD, COMPILEOPT, NAMING, and SQLCA are not allowed in the CREATE TRIGGER statement. The COMMIT option is allowed, but ignored.

The options DATFMT, DATSEP, TIMFMT, and TIMSEP cannot be used if OLD ROW or NEW ROW is specified.

**WHEN** (search-condition)

Specifies a condition that evaluates to true, false, or unknown. The triggered SQL statements are executed only if the `search-condition` evaluates to true. If the WHEN clause is omitted, the associated SQL statements are always executed.

A WHEN clause must not be specified with an INSTEAD OF trigger.

**SQL-trigger-body**

Specifies a single `SQL-procedure-statement`, including a compound statement. See Chapter 8, “SQL control statements,” on page 1645 for more information about defining SQL triggers.

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, SET TRANSACTION, and SET RESULT SETS statement is not allowed in the `triggered-action` of a trigger.

An UNDO handler is not allowed in a trigger.

All tables, views, aliases, distinct types, global variables, sequences, user-defined functions, and procedures referenced in the `triggered-action` must exist at the current server when the trigger is created. The table or view that an alias refers to must also exist when the trigger is created. This includes objects in library QTEMP. While objects in QTEMP can be referenced in the `triggered-action`, dropping those objects in QTEMP will not cause the trigger to be dropped.

All transition variable names are column names of the subject table. System column names of the subject table cannot be used as transition variable names.
The triggered action of a BEFORE trigger on a column of type XML can invoke the XMLVALIDATE function through a SET statement, leave values of type XML unchanged, or assign them to NULL using a SET statement.

A dynamic statement in the triggered-action can use 3-part names to access a remote server. A library with the same name as the trigger program’s library must exist on the remote server. Static statements in the triggered-action cannot use 3-part names.

Static and dynamic statements in the triggered-action can invoke a procedure or a user-defined function that can access a server other than the current server if the procedure or user-defined function runs in a different activation group.

Notes

**Trigger ownership:** If SQL names were specified:
- If a user profile with the same name as the schema into which the trigger is created exists, the *owner* of the trigger is that user profile.
- Otherwise, the *owner* of the trigger is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the trigger is the user profile or group user profile of the thread executing the statement.

**Trigger authority:** The trigger program object authorities are:
- When SQL naming is in effect, the trigger program will be created with the public authority of *EXCLUDE*, and adopt authority from the schema qualifier of the trigger-name if a user profile with that name exists. If a user profile for the schema qualifier does exist, then the owner of the trigger program will be the user profile for the schema qualifier. Note that the special authorities *ALLOBJ* and *SECADM* are required to create the trigger program object in the schema qualifier library if a user profile exists that has the same name as the schema qualifier, and the name is different from the authorization ID of the statement. If a user profile for the schema qualifier does not exist, then the owner of the trigger program will be the user profile or group user profile of the thread executing the SQL CREATE TRIGGER statement. The group user profile will be the owner of the trigger program object, only if OWNER(*GRPPRF) was specified on the user’s profile who is executing the statement. If the owner of the trigger program is a member of a group profile, and if OWNER(*GRPPRF) was specified on the user’s profile, the program will run with the adopted authority of the group profile.
- When System naming is in effect, the trigger program will be created with public authority of *EXCLUDE*, and adopt authority from the user or group user profile of the thread executing the SQL CREATE TRIGGER statement.

**Execution authorization:** The user executing the triggering SQL operation does not need authority to execute a static triggered-SQL-statement. A static triggered-SQL-statement will execute using the authority of the *owner* of the trigger.

**REPLACE rules:** When a trigger is recreated by REPLACE:
- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.
- The firing order of the trigger is not maintained.
Activating a trigger: Only insert, delete, or update operations can activate a trigger. A delete operation that occurs as a result of a referential constraint will not activate a trigger. Hence,

- A trigger with a DELETE trigger event cannot be added to a table with a referential constraint of ON DELETE CASCADE.
- A trigger with an UPDATE trigger event cannot be added to a table with a referential constraint of ON DELETE SET NULL or ON DELETE SET DEFAULT.

The activation of a trigger may cause trigger cascading. This is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The triggered actions may also cause updates as a result of the original modification, which may result in the activation of additional triggers. With trigger cascading, a significant chain of triggers may be activated causing significant change to the database as a result of a single delete, insert or update statement. The number of levels of cascading is limited to 200 or the maximum amount of storage allowed in the job or process, whichever comes first.

Adding triggers to enforce constraints: Adding a trigger to a table that already has rows in it will not cause the triggered actions to be executed. Thus, if the trigger is designed to enforce constraints on the data in the table, the data in the existing rows might not satisfy those constraints.

Considerations for implicitly hidden columns: In the body of a trigger, a trigger transition variable that corresponds to an implicitly hidden column can be referenced. A trigger transition table, that corresponds to a table with an implicitly hidden column, includes that column as part of the transition table.

Likewise, a trigger transition variable will exist for the column that is defined as implicitly hidden. A trigger transition variable that corresponds to an implicitly hidden column can be referenced in the body of a trigger.

Read-only views: The addition of an INSTEAD OF trigger for a view affects the read-only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

Transition variable values and INSTEAD OF triggers: All trigger transition variables in an INSTEAD OF trigger are nullable.

The initial values for new transition variables or new transition table columns visible in an INSTEAD OF INSERT trigger are set as follows:

- If a value is explicitly specified for a column in the INSERT statement, the corresponding new transition variable or new transition table column is that explicitly specified value.
- If a value is not explicitly specified for a column in the INSERT statement or the DEFAULT keyword is specified, the corresponding new transition variable or new transition table column is:
  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger) and not based on a generated column or ROWID,
  - otherwise, the null value.
The initial values for new transition variables or new transition table columns visible in an INSTEAD OF UPDATE trigger are set as follows:

- If a value is explicitly specified for a column in the UPDATE statement, the corresponding new transition variable or new transition table column is that explicitly specified value.
- If the DEFAULT keyword is explicitly specified for a column in the UPDATE statement, the corresponding new transition variable or new transition table column is:
  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger) and not based on a generated column or ROWID,
  - otherwise, the null value.
- Otherwise, the corresponding new transition variable or new transition table column is the existing value of the column in the row.

Obfuscated statements: A CREATE TRIGGER statement can be executed in obfuscated form. In an obfuscated statement, only the trigger name is readable followed by the WRAPPED keyword. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. Obfuscated statements can be produced by invoking the WRAP scalar function. Any debug options that are specified when the trigger is created from an obfuscated statement are ignored.

A trigger that is created from an obfuscated statement cannot be restored to a release where obfuscation is not supported. Consequently, a table with a trigger created from an obfuscated statement cannot be restored to a release where obfuscation is not supported.

Creating a trigger with the SECURED option: The trigger is considered secure after the CREATE TRIGGER statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, Db2 assumes those functions are secure without validation. If those functions can access sensitive data, a user that has security administrator authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for those functions, and that all subsequent ALTER FUNCTION statements are being reviewed through this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control activated.

Creating a trigger with the NOT SECURED option: The CREATE TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if its subject table is a view and one or more of the underlying tables in the view is using row access control or column access control.

Transition variable values and row and column access control: Row and column access control is not enforced for transition variables and transition tables. If row or column access control is enforced for the triggering table, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for transition variables and transition tables that are referenced in the
trigger body or are passed as arguments to user-defined functions invoked within the trigger body. To ensure there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables, the trigger must be created with the SECURED option. If the trigger is not secure, row access control and column access control cannot be enforced for the triggering table and the CREATE TRIGGER statement returns an error.

**Multiple triggers**: Multiple triggers that have the same triggering SQL operation and activation time can be defined on a table. The triggers are activated based on the mode and the order in which they were created:
- MODE DB2ROW triggers (and native triggers created via the ADDPFTRG CL command) are fired first in the order in which they were created
- MODE DB2SQL triggers are fired next in the order in which they were created

For example, a MODE DB2ROW trigger that was created first is executed first, the MODE DB2ROW trigger that was created second is executed second.

A maximum of 300 triggers can be added to any given source table.

When a trigger is recreated using REPLACE, its position in the activation order is not maintained. It behaves as if the trigger were dropped and created again.

**Adding columns to a subject table or a table referenced in the triggered action**: If a column is added to the subject table after triggers have been defined, the following rules apply:
- If the trigger is an UPDATE trigger that was defined without an explicit column list, then an update to the new column will cause the activation of the trigger.
- If the SQL statements in the triggered-action refer to the triggering table, the new column is not accessible to the SQL statements until the trigger is recreated.
- The OLD_TABLE and NEW_TABLE transition tables will contain the new column, but the column cannot be referenced unless the trigger is recreated.

If a column is added to any table referenced by the SQL statements in the triggered-action, the new column is not accessible to the SQL statements until the trigger is recreated.

**Dropping or revoking privileges on a table referenced in the triggered action**: If an object such as a table, view or alias, referenced in the triggered-action is dropped, the access plans of the statements that reference the object will be rebuilt when the trigger is fired. If the object does not exist at that time, the corresponding INSERT, UPDATE or DELETE operation on the subject table will fail.

If a privilege that the creator of the trigger is required to have for the trigger to execute is revoked, the access plans of the statements that reference the object will be rebuilt when the trigger is fired. If the appropriate privilege does not exist at that time, the corresponding INSERT, UPDATE or DELETE operation on the subject table will fail.

**Errors executing triggers**: If a SIGNAL statement is executed in the SQL-trigger-body, an SQLCODE -438 and the SQLSTATE specified in the SIGNAL statement will be returned.

Other errors that occur during the execution of SQL-trigger-body statements are returned using SQLSTATE 09000 and SQLCODE -723.
**Special registers in triggers:** The values of the special registers are saved before a trigger is activated and are restored on return from the trigger. The values of the special registers are inherited from the triggering SQL operation.

**Transaction isolation:** All triggers, when they are activated, perform a SET TRANSACTION statement unless the isolation level of the application program invoking the trigger is the same as the default isolation level of the trigger program. This is necessary so that all of the operations by the trigger are performed with the same isolation level as the application program that caused the trigger to be run. The user may put their own SET TRANSACTION statements in an SQL-control-statement in the SQL-trigger-body of the trigger. If the user places a SET TRANSACTION statement within the SQL-trigger-body of the trigger, then the trigger will run with the isolation level specified in the SET TRANSACTION statement, instead of the isolation level of the application program that caused the trigger to be run.

If the application program that caused a trigger to be activated, is running with an isolation level other than No Commit (COMMIT(*NONE) or COMMIT(*NC)), the operations within the trigger will be run under commitment control and will not be committed or rolled back until the application commits its current unit of work. If ATOMIC is specified in the SQL-trigger-body of the trigger, and the application program that caused the ATOMIC trigger to be activated is running with an isolation level of No Commit (COMMIT(*NONE) or COMMIT(*NC)), the operations within the trigger will not be run under commitment control. If the application that caused the trigger to be activated is running with an isolation level of No Commit (COMMIT(*NONE) or COMMIT(*NC)), then the operations of a trigger are written to the database immediately, and cannot be rolled back.

If both system triggers defined by the Add Physical File Trigger (ADDPFTRG) CL command and SQL triggers defined by the CREATE TRIGGER statement are defined for a table, it is recommended that the system triggers perform a SET TRANSACTION statement so that they are run with the same isolation level as the original application that caused the triggers to be activated. It is also recommended that the system triggers run in the Activation Group of the calling application. If system triggers run in a separate Activation Group (ACTGRP(*NEW)), then those system triggers will not participate in the unit of the work for the calling application, nor in the unit of work for any SQL triggers. System triggers that run in a separate Activation Group are responsible for committing or rolling back any database operations they perform under commitment control. Note that SQL triggers defined by the CREATE TRIGGER statement always run in the caller's Activation Group.

If the triggering application is running with commitment control, the operations of an SQL trigger, and any cascaded SQL triggers, will be captured into a sub-unit of work. If the operations of the trigger and any cascaded triggers are successful, the operations captured in the sub-unit of work will be committed or rolled back when the triggering application commits or rolls back its current unit of work. Any system triggers that run in the same Activation Group as the caller, and perform a SET TRANSACTION to the isolation level of the caller, will also participate in the sub-unit of work. If the triggering application is running without commitment control, then the operations of the SQL triggers will also be run without commitment control.

If an application that causes a trigger to be activated is running with an isolation level of No Commit (COMMIT(*NONE) or COMMIT(*NC)), and it issues an INSERT, UPDATE, or DELETE statement that encounters an error during the
execution of the statement, no other system or SQL triggers will be activated following the error for that operation. However, some number of changes will already have been performed. If the triggering application is running with commitment control, the operations of any triggers that are captured in a sub-unit of work will be rolled back when the first error is encountered, and no additional triggers will be activated for the current INSERT, UPDATE, or DELETE statement.

Performance considerations: Create the trigger under the isolation level that will most often be used by the application programs that cause the trigger to fire. The SET OPTION statement can be used to explicitly choose the isolation level.

ROW triggers (especially MODE DB2ROW triggers) perform much better than TABLE level triggers.

Considerations for implicitly hidden columns: A transition variable will exist for any column defined as implicitly hidden. In the body of a trigger, a transition variable that corresponds to an implicitly hidden column can be referenced.

Triggered actions in the catalog: At the time the trigger is created, the triggered-action is modified as a result of the CREATE TRIGGER statement:
- Naming mode is switched to SQL naming.
- All unqualified object references are explicitly qualified
- All implicit column lists (for example, SELECT *, INSERT with no column list, UPDATE SET ROW) are expanded to be the list of actual column names.

The modified triggered-action is stored in the catalog.

Renaming or moving a table referenced in the triggered action: Any table (including the subject table) referenced in a triggered-action can be moved or renamed. However, the triggered-action will continue to reference the old name or schema. An error will occur if the referenced table is not found when the triggered-action is executed. Hence, you should drop the trigger and then re-create the trigger so that it refers to the renamed or moved table.

Datet ime considerations: If OLD ROW or NEW ROW is specified, the date or time constants and the string representation of dates and times in variables that are used in SQL statements in the triggered-action must have a format of ISO, EUR, JIS, USA, or must match the date and time formats specified when the table was created if it was created using DDS and the CRTPF CL command. If the DDS specifications contain multiple different date or time formats, the trigger cannot be created.

Operations that invalidate triggers: An inoperative trigger is a trigger that is no longer available to be activated. If a trigger becomes invalid, no INSERT, UPDATE, or DELETE operations will be allowed on the subject table or view. A trigger becomes invalid if:
- The SQL statements in the triggered-action reference the subject table or view, the trigger is a self-referencing trigger, and the table or view is duplicated using the system CRTDUPOBJ CL command, or
- The SQL statements in the triggered-action reference tables or views in the from library and the objects are not found in the new library when the table or view is duplicated using the system CRTDUPOBJ CL command, or
The table or view is restored to a new library using the system RSTOBJ or RSTLIB CL commands, and the triggered-action references the subject table or subject view, the trigger is a self-referencing trigger.

An invalid trigger must first be dropped before it can be recreated by issuing a CREATE TRIGGER statement. Note that dropping and recreating a trigger will affect the activation order of a trigger if multiple triggers for the same triggering operation and activation time are defined for the subject table.

**Trigger program object:** When a trigger is created, SQL creates a temporary source file that will contain C source code with embedded SQL statements. A program object is then created using the CRTPGM command. The SQL options used to create the program are the options that are in effect at the time the CREATE TRIGGER statement is executed. The program is created with ACTGRP(*CALLER).

The program is created with STGMDL(*SNGLVL). If the trigger runs on behalf of an application that uses STGMDL(*TERASPACE) and also uses commitment control, the entire application will need to run under a job scoped commitment definition (STRCMTCTL CMTSCOPE(*JOB)).

The trigger will execute with the adopted authority of the owner of the trigger.

**Examples**

**Example 1:** Create two triggers that track the number of employees that a company manages. The triggering table is the EMPLOYEE table, and the triggers increment and decrement a column with the total number of employees in the COMPANY_STATS table. The COMPANY_STATS table has the following properties:

```sql
CREATE TABLE COMPANY_STATS
(NBEMP INTEGER,
 NBPRODUCT INTEGER,
REVENUE DECIMAL(15,0))
```

This example uses row triggers to maintain summary data in another table.

Create the first trigger, NEW_HIRE, so that it increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table, increase the value of column NBEMP in table COMPANY_STATS by 1.

```sql
CREATE TRIGGER NEW_HIRE
AFTER INSERT ON EMPLOYEE
FOR EACH ROW MODE DB2SQL
UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1
```

Create the second trigger, FORM_EMP, so that it decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE, decrease the value of column NBEMP in table COMPANY_STATS by 1.

```sql
CREATE TRIGGER FORM_EMP
AFTER DELETE ON EMPLOYEE
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
  UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
END
```
**CREATE TRIGGER**

*Example 2:* Create a trigger, REORDER, that invokes user-defined function ISSUE_SHIP_REQUEST to issue a shipping request whenever a parts record is updated and the on-hand quantity for the affected part is less than 10% of its maximum stocked quantity. User-defined function ISSUE_SHIP_REQUEST orders a quantity of the part that is equal to the part's maximum stocked quantity minus its on-hand quantity. The function eliminates any duplicate requests to order the same PARTNO and sends the unique order to the appropriate supplier.

This example also shows how to define the trigger as a statement trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```sql
CREATE TRIGGER REORDER
AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
REFERENCING NEW_TABLE AS NTABLE
FOR EACH STATEMENT MODE DB2SQL
BEGIN ATOMIC
  DECLARE REQUEST_VAR INT;
  SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)
  INTO REQUEST_VAR
  FROM NTABLE
  WHERE ON_HAND < 0.10 * MAX_STOCKED;
END
```

*Example 3:* Assume that table EMPLOYEE contains column SALARY. Create a trigger, SAL_ADJ, that prevents an update to an employee’s salary that exceeds 20% and signals such an error. Have the error that is returned with an SQLSTATE of 75001 and a description. This example shows that the SIGNAL SQLSTATE statement is useful for restricting changes that violate business rules.

```sql
CREATE TRIGGER SAL_ADJ
AFTER UPDATE OF SALARY ON EMPLOYEE
REFERENCING OLD AS OLD_EMP
NEW AS NEW_EMP
FOR EACH ROW MODE DB2SQL
WHEN (NEW_EMP.SALARY > (OLD_EMP.SALARY *1.20))
BEGIN ATOMIC
  SIGNAL SQLSTATE '75001'('Invalid Salary Increase - Exceeds 20%');
END
```
CREATE TYPE

The CREATE TYPE statement defines a user-defined data type at the current server.

The following types of user-defined data types can be defined:

- **Array**
  A user-defined data type that is an ordinary array. The elements of an array type are based on one of the built-in data types. See “CREATE TYPE (array)” on page 1236.

- **Distinct**
  A user-defined data type that shares a common representation with one of the built-in data types. Functions that cast between the user-defined distinct type and the source built-in data type are generated when the user-defined distinct type is created. Optionally, support for comparison operations to use with the user-defined distinct type can be generated when the user-defined distinct type is created. See “CREATE TYPE (distinct)” on page 1241.
The CREATE TYPE (array) statement defines an array type at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSTYPES catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the array type is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authority *ADD to the user profile with that name
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

**Syntax**

```sql
CREATE TYPE array-type-name

AS built-in-type ARRAY [integer-constant]
```

**built-in-type:**
CREATE TYPE (array)

ccsid-clause:

ccsid-clause:

ccsid-clause:

ccsid-clause:

ccsid-clause:

ccsid-clause:

ccsid-clause:
CREATE TYPE (array)

**CCSID**—integer

**normalize-clause**:

- NOT NORMALIZED
- NORMALIZED

### Description

**array-type-name**

Names the array. The name, including the implicit or explicit qualifier, must not be the same as a distinct type or array type that already exists at the current server.

If SQL names were specified, the array type will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the array type will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is "LIBL, the array type will be created in the current library (*CURLIB).
- Otherwise, the array type will be created in the current schema.

If the array type name is not a valid system name, Db2 for i will generate a system name. For information about the rules for generating a name, see "Rules for Table Name Generation" on page 1213.

**array-type-name** must not be the name of a built-in data type, or any of the following system-reserved keywords even if you specify them as delimited identifiers.

<table>
<thead>
<tr>
<th>=</th>
<th>&lt;</th>
<th>&gt;</th>
<th>&gt;=</th>
</tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

If a qualified **array-type-name** is specified, the schema name cannot be QSYS, QSYS2, QTEMP, or SYSIBM.
**built-in-type**

Specifies the built-in data type used as the data type for all the elements of the array. See "CREATE TABLE" on page 1159 for a more complete description of each built-in data type.

If a specific value is not specified for the data types that have length, precision, or scale attributes, the default attributes of the data type as shown in the syntax diagram are implied.

If the array type is for a string data type, a CCSID is associated with the array type at the time the array type is created. For more information about data types, see "CREATE TABLE" on page 1159.

**ARRAY [integer-constant]**

Specifies that the array has a maximum cardinality of integer-constant. The value must be a positive number greater than 0. If no value is specified, the maximum integer value of 2147483647 is used. The maximum number of array elements that can be assigned in the array is the number of elements that fit in 4 gigabytes. Each varying length, LOB, and XML array element is allocated as its maximum length.

**Notes**

**Additional generated functions:** Functions are created to convert to and from the array type, but service programs are not created, so you cannot grant or revoke privileges to these functions.

**Names of the generated cast functions:** The unqualified name of one of the cast functions ARRAY. The name of the cast function that converts to the array type is the name of the array type. The input parameter of the cast function has the same data type as the ARRAY.

For example, assume that an array type named T_SHOESIZES is created with the following statement:

```
CREATE TYPE CLAIRE.T_SHOESIZES AS INT ARRAY[]
```

When the statement is executed, the database manager also generates the following cast functions. ARRAY converts from the array type to an array, and T_SHOESIZES converts from an array to the array type.

A generated cast function cannot be explicitly dropped. The cast functions that are generated for an array type are implicitly dropped when the array type is dropped with the DROP statement.

**Array type attributes:** An array type is created as a "SQLUDT object.

**Array type ownership:** If SQL names were specified:

- If a user profile with the same name as the schema into which the array type is created exists, the owner of the array type is that user profile.
- Otherwise, the owner of the array type is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the array type is the user profile or group user profile of the thread executing the statement.
CREATE TYPE (array)

Array type authority: If SQL names are used, array types are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, array types are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the array type is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the array type.

Examples

Example 1: Create an array type named PHONENUMBERS with a maximum of 5 elements that are of the DECIMAL(10,0) data type.

CREATE TYPE PHONENUMBERS AS DECIMAL(10,0) ARRAY[5]

Example 2: Create an array type named NUMBERS in the schema GENERIC for which the maximum number of elements is not known.

CREATE TYPE GENERIC.NUMBERS AS BIGINT ARRAY[]
CREATE TYPE (distinct)

The CREATE TYPE (distinct) statement defines a distinct type at the current server. A distinct type is always sourced on one of the built-in data types.

Successful execution of the statement also generates:
• A function to cast from the distinct type to its source type
• A function to cast from the source type to its distinct type
• As appropriate, support for the use of comparison operators with the distinct type.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:
• The privilege to create in the schema. For more information, see Privileges necessary to create in a schema
• Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:
• For the SYSTYPES catalog table:
  – The INSERT privilege on the table, and
  – The system authority *EXECUTE on library QSYS2
• Database administrator authority

If SQL names are specified and a user profile exists that has the same name as the library into which the distinct type is created, and that name is different from the authorization ID of the statement, then the privileges held by the authorization ID of the statement must include at least one of the following:
• The system authority *ADD to the user profile with that name
• Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.

Syntax

**ccsid-clause:**

- **CCSID**<br>  - integer
- **normalize-clause**
normalize-clause:

- NOT
- NORMALIZED

Description

distinct-type-name

Names the distinct type. The name, including the implicit or explicit qualifier, must not be the same as a distinct type or array type that already exists at the current server.

If SQL names were specified, the distinct type will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the distinct type will be created in the schema that is specified by the qualifier. If not qualified:
- If the value of the CURRENT SCHEMA special register is *LIBL, the distinct type will be created in the current library (*CURLIB).
- Otherwise, the distinct type will be created in the current schema.

If the distinct type name is not a valid system name, Db2 for i will generate a system name. For information about the rules for generating a name, see "Rules for Table Name Generation" on page 1213.

distinct-type-name must not be the name of a built-in data type, or any of the following system-reserved keywords even if you specify them as delimited identifiers.

<table>
<thead>
<tr>
<th>=</th>
<th>&lt;</th>
<th>&gt;</th>

</table>

If a qualified distinct-type-name is specified, the schema name cannot be QSYS, QSYS2, QTEMP, or SYSIBM.

built-in-type

Specifies the built-in data type used as the basis for the internal representation of the distinct type. See "CREATE TABLE" on page 1159 for a more complete description of each built-in data type.
CREATE TYPE (distinct)

For portability of applications across platforms, use the following recommended data type names:
- DOUBLE or REAL instead of FLOAT.
- DECIMAL instead of NUMERIC.

If a specific value is not specified for the data types that have length, precision, or scale attributes, the default attributes of the data type as shown in the syntax diagram are implied.

If the distinct type is sourced on a string data type, a CCSID is associated with the distinct data type at the time the distinct type is created. For more information about data types, see "CREATE TABLE" on page 1159.

Notes

Additional generated functions: Besides the system-generated comparison operators described above, the following functions become available to convert to and from the source type:
- The distinct type to the source type
- The source type to the distinct type
- INTEGER to the distinct type if the source type is SMALLINT
- DOUBLE to the distinct type if the source type is REAL
- VARCHAR to the distinct type if the source type is CHAR
- VARGRAPHIC to the distinct type if the source type is GRAPHIC

These functions are created as if the following statements were executed (except that the service programs are not created, so you cannot grant or revoke privileges to these functions):

```
CREATE FUNCTION source-type-name (distinct-type-name)
    RETURNS source-type-name

CREATE FUNCTION distinct-type-name (source-type-name)
    RETURNS distinct-type-name
```

Names of the generated cast functions: Table 83 on page 1245 contains details about the generated cast functions. The unqualified name of the cast function that converts from the distinct type to the source type is the name of the source data type.

In cases in which a length, precision, or scale is specified for the source data type in the CREATE TYPE statement, the unqualified name of the cast function that converts from the distinct type to the source type is simply the name of the source data type. The data type of the value that the cast function returns includes any length, precision, or scale values that were specified for the source data type on the CREATE TYPE statement.

The name of the cast function that converts from the source type to the distinct type is the name of the distinct type. The input parameter of the cast function has the same data type as the source data type, including the length, precision, and scale.

The cast functions that are generated are created in the same schema as that of the distinct type. A function with the same name and same function signature must not already exist in the current server.
For example, assume that a distinct type named T_SHOESIZE is created with the following statement:

```
CREATE TYPE CLAIRE.T_SHOESIZE AS VARCHAR(2) WITH COMPARISONS
```

When the statement is executed, the database manager also generates the following cast functions. VARCHAR converts from the distinct type to the source type, and T_SHOESIZE converts from the source type to the distinct type.

```
FUNCTION CLAIRE.VARCHAR (CLAIRE.T_SHOESIZE) RETURNS VARCHAR(2)

FUNCTION CLAIRE.T_SHOESIZE (VARCHAR(2) RETURNS CLAIRE.T_SHOESIZE
```

Notice that function VARCHAR returns a value with a data type of VARCHAR(2) and that function T_SHOESIZE has an input parameter with a data type of VARCHAR(2).

A generated cast function cannot be explicitly dropped. The cast functions that are generated for a distinct type are implicitly dropped when the distinct type is dropped with the DROP statement.

For each built-in data type that can be the source data type for a distinct type, the following table gives the names of the generated cast functions, the data types of the input parameters, and the data types of the values that the functions returns.

</tbody>
</table>

NUMERIC and FLOAT are not recommended when creating a distinct type for a portable application. DECIMAL and DOUBLE should be used instead.

**Built-in functions:** The functions described in the above table are the only functions that are generated automatically when distinct types are defined. Consequently, none of the built-in functions (AVG, MAX, LENGTH, and so on) are automatically supported for the distinct type. A built-in function can be used on a distinct type only after a sourced user-defined function, which is based on the built-in function, has been created for the distinct type. See "Extending or overriding a built-in function:" on page 1009.
The schema name of the distinct type must be included in the distinct type for successful use of these operators and cast functions in SQL statements.

**Distinct type attributes:** A distinct type is created as a *SQLUDT object.

**Distinct type ownership:** If SQL names were specified:
- If a user profile with the same name as the schema into which the distinct type is created exists, the owner of the distinct type is that user profile.
- Otherwise, the owner of the distinct type is the user profile or group user profile of the thread executing the statement.

If system names were specified, the owner of the distinct type is the user profile or group user profile of the thread executing the statement.

**Distinct type authority:** If SQL names are used, distinct types are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, distinct types are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the distinct type is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the distinct type.

**Syntax alternatives:** The WITH COMPARISONS clause, which specifies that system-generated comparison operators are to be created for comparing two instances of the distinct type, can be specified as the last clause of the statement. Use WITH COMPARISONS only if it is required for compatibility with other products in the Db2 family.

For compatibility with previous versions of Db2:
- CREATE DISTINCT TYPE can be specified in place of CREATE TYPE.

**Examples**

**Example 1:** Create a distinct type named SHOESIZE that is sourced on the built-in INTEGER data type.

```
CREATE TYPE SHOESIZE AS INTEGER WITH COMPARISONS
```

The successful execution of this statement also generates two cast functions. Function INTEGER(SHOESIZE) returns a value with data type INTEGER, and function SHOESIZE(INTEGER) returns a value with distinct type SHOESIZE.

**Example 2:** Create a distinct type named MILES that is sourced on the built-in DOUBLE data type.

```
CREATE TYPE MILES AS DOUBLE WITH COMPARISONS
```

The successful execution of this statement also generates two cast functions. Function DOUBLE(MILES) returns a value with data type DOUBLE, and function MILES(DOUBLE) returns a value with distinct type MILES.

**Example 3:** Create a distinct type T_DEPARTMENT that is sourced on the built-in CHAR data type.

```
CREATE TYPE CLAIRE.T_DEPARTMENT AS CHAR(3) WITH COMPARISONS
```
CREATE TYPE (distinct)

The successful execution of this statement also generates three cast functions:

- Function CLAIRE.CHAR takes a T_DEPARTMENT as input and returns a value with data type CHAR(3).
- Function CLAIRE.T_DEPARTMENT takes a CHAR(3) as input and returns a value with distinct type T_DEPARTMENT.
- Function CLAIRE.T_DEPARTMENT takes a VARCHAR(3) as input and returns a value with distinct type T_DEPARTMENT.
CREATE VARIABLE

The CREATE VARIABLE statement defines a global variable at the application server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see Privileges necessary to create in a schema.
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYVSERVICES catalog table:
  - The INSERT privilege on the table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

If a distinct type or sequence is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the distinct type or sequence identified in the statement:
  - The USAGE privilege on the distinct type or sequence, and
  - The system authority *EXECUTE on the library containing the distinct type or sequence
- Database administrator authority

If a function is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the function identified in the statement:
  - The EXECUTE privilege on the function, and
  - The system authority *EXECUTE on the library containing the function
- Database administrator authority

If a global variable is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement:
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

If a table or view is referenced directly or indirectly, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each table and view referenced directly or indirectly:
  - The SELECT privilege on the table or view, and
CREATE VARIABLE

- The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

To replace an existing variable, the privileges held by the authorization ID of the statement must include at least one of the following:
- The following system authorities:
  - The system authority of *OBJMGT on the service program for the variable
  - All authorities needed to DROP the variable
  - The system authority *READ to the SYSVARIABLES catalog table
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Sequence and Corresponding System Authorities When Checking Privileges to a Distinct Type.

Syntax

```
CREATE VARIABLE variable-name
OR REPLACE
FOR SYSTEM NAME system-object-identifier
data-type
DEFAULT NULL
DEFAULT constant
special-register
global-variable
(expression)
```

**data-type:**

```
built-in-type
distinct-type-name
```

**built-in-type:**

```
CREATE VARIABLE

ccsid-clause:

- CCSID—integer
CREATE VARIABLE

Description

**OR REPLACE**

Specifies to replace the definition for the variable if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the variable are not affected. This option is ignored if a definition for the variable does not exist at the current server.

**variable-name**

Names the global variable. The name, including the implicit or explicit qualifier, must not identify a global variable that already exists at the current server. If a qualified variable name is specified, the *schema-name* cannot be QSYS2, QSYS, QTEMP, or SYSIBM.

If SQL names were specified, the variable will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the variable will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is *LIBL*, the variable will be created in the current library (*CURLIB).
- Otherwise, the variable will be created in the current schema.

**FOR SYSTEM NAME system-object-identifier**

Identifies the system-object-identifier of the global variable. *system-object-identifier* must not be the same as a global variable that already exists at the current server. The *system-object-identifier* must be an unqualified system identifier.

When *system-object-identifier* is specified, *variable-name* must not be a valid system object name.

**data-type**

Specifies the data type or the global variable.

**built-in-type**

Specifies a built-in data type. See “CREATE TABLE” on page 1159 for a more complete description of each built-in data type.

**distinct-type-name**

Specifies a distinct type. The length, precision, and scale of the global variable are, respectively, and length, precision, and scale of the distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path. The same limitations that apply to built-in types apply to the source type of the distinct type.

**DEFAULT**

Specifies a default value for the global variable. The value can be a constant, a special register, a global variable, an expression, or the keyword NULL. The default value is determined on its first reference if a value is not explicitly specified. If a default value is not specified, the variable is initialized to the null value.

The default expression must not modify SQL data or perform an external action. The expression must be assignment compatible with the data type of the variable.

All tables, views, aliases, distinct types, sequences, global variables, and user-defined functions referenced in the default expression must exist at the current server when the global variable is created. The table or view that an alias refers to must also exist when the variable is created. This includes objects...
in library QTEMP. While objects in QTEMP can be referenced in the default expression, dropping those objects in QTEMP will not cause the global variable to be dropped.

Notes

Session scope: Global variables have a session scope. This means that although they are available to all sessions that are active on the database, their value is private for each session.

Modifications to the value of a global variable: Modifications to the value of a global variable are not under transaction control. The value of the global variable is preserved when a transaction ends with either a COMMIT or a ROLLBACK statement.

Privileges to use a global variable: An attempt to read from or to write to a global variable created by this statement requires that the authorization ID attempting this action hold the appropriate privilege on the global variable. The definer of the variable is implicitly granted all privileges on the variable.

Setting of the default value: A created global variable is instantiated to its default value when it is first referenced within its given scope. Note that if a global variable is referenced in a statement, it is instantiated independently of the control flow for that statement.

Using a newly created session global variable: If a global variable is created within a session, it cannot be used by other sessions until the unit of work has been committed. However, the new global variable can be used within the session that created the variable before the unit of work commits.

Once a global variable is instantiated for a session, changes to the global variable in another session (such as DROP or GRANT) might not affect the variable that has been instantiated.

Creating the global variable: A global variable is created as a *SRVPGM object. If the variable name is a valid system name but a *SRVPGM already exists with that name, an error is issued. If the variable name is not a valid system name, a unique name is generated using the rules for generating system table names. For information about the rules for generating a name, see "Rules for Table Name Generation" on page 1213.

The global variable's definition is saved in the associated service program object. If the *SRVPGM object is saved and then restored to this or another system, the catalogs are automatically updated with the definition.

During restore of the global variable:
• If a *SRVPGM object with the same system name exists, the *SRVPGM will be replaced.

If a global variable and an SQL routine have the same name, naming conflicts can be avoided by creating the global variable first.

Variable ownership: The owner of the variable is the user profile or group user profile of the thread executing the statement.
**CREATE VARIABLE**

**Variable authority:** If SQL names are used, variables are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, variables are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the variable is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the variable.

**Variable instantiation authorization:** When a global variable is instantiated, the DEFAUTH clause is evaluated using the authority of the owner of the global variable.

**REPLACE rules:** When a variable is recreated by REPLACE:
- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved.

**Examples**

*Example 1:* Create a global variable to indicate what printer to use for the session.

```sql
CREATE VARIABLE MYSHEMA.MYJOB_PRINTER VARCHAR(30)
    DEFAULT 'Default printer'
```

*Example 2:* Create a global variable to indicate the department where an employee works.

```sql
CREATE VARIABLE SCHEMA1.GV_DEPTNO INTEGER
    DEFAULT (SELECT DEPTNO FROM HR.EMPLOYEES
                WHERE EMPUSER = SESSION_USER)
```

*Example 3:* Create a global variable to indicate the security level of the current user.

```sql
CREATE VARIABLE SCHEMA2.GV_SECURITY_LEVEL INTEGER
    DEFAULT (GET_SECURITY_LEVEL (SESSION_USER))
```
The CREATE VIEW statement creates a view on one or more tables or views at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see Privileges necessary to create in a schema.
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - *USE to the Create Logical File (CRTL) CL command
  - *CHANGE to the data dictionary if the library into which the view is created is an SQL schema with a data dictionary
- Database administrator authority

The privileges held by the authorization ID of the statement must also include at least one of the following:

- For each table and view referenced directly through the fullselect, or indirectly through views referenced in the fullselect:
  - The SELECT privilege on the table or view
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

To replace an existing view, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJMGT on the view
  - All authorities needed to DROP the view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View and Corresponding System Authorities When Checking Privileges to a Distinct Type.

Syntax

```
CREATE VIEW view-name
  OR REPLACE
  RECURSIVE
  FOR SYSTEM NAME system-object-identifier
```
CREATE VIEW

(column-name)

FOR COLUMN system-column-name

AS

fullselect

WITH common-table-expression

WITH CASCADED CHECK OPTION

LOCAL

Description

OR REPLACE

Specifies to replace the definition for the view if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog with the exception that privileges that were granted on the view are not affected. The existing object cannot be a logical file. This option is ignored if a definition for the view does not exist at the current server.

RECURSIVE

Indicates that the view is potentially recursive.

If a fullselect of the view contains a reference to the view itself in a FROM clause, the view is a recursive view. Views using recursion are useful in supporting applications such as bill of materials (BOM), reservation systems, and network planning.

The restrictions that apply to a recursive view are similar to those for a recursive common table expression:

• A list of column-names must be specified following the view-name unless the result columns of the fullselect are already named.
• The UNION ALL set operator must be specified.
• The first fullselect of the first union (the initialization fullselect) must not include a reference to the view itself in any FROM clause.
• Each fullselect that is part of the recursion cycle must not include any aggregate functions, GROUP BY clauses, or HAVING clauses.
• The FROM clauses of each fullselect can include at most one reference to the view that is part of a recursion cycle.
• The table being defined in the common-table-expression cannot be referenced in a subquery of a fullselect that defines the common-table-expression.
• LEFT OUTER JOIN and FULL OUTER JOIN are not allowed if the common-table-expression is the right operand. RIGHT OUTER JOIN and FULL OUTER JOIN are not allowed if the common-table-expression is the left operand.

If a column name of the view is referred to in the iterative fullselect, the attributes of the result columns are determined using the rules for result columns. For more information see "Rules for result data types" on page 117.

Recursive views are not allowed if the query specifies:

• a distributed table,
• a table with a read trigger,
CREATE VIEW

- a table referenced directly or indirectly in the fullselect must not be a DDS-created logical file, or
- a logical file built over multiple physical file members.

**view-name**
Names the view. The name, including the implicit or explicit qualifier, must not be the same as an alias, file, index, table, or view that already exists at the current server.

If SQL names were specified, the view will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the view will be created in the schema that is specified by the qualifier. If not qualified and there is no default schema, the view name will be created in the same schema as the first table specified on the first FROM clause (including FROM clauses in any common table expressions or nested table expression). If no tables are referenced in the fullselect, the view will be created in the same schema as the first user defined table function. If no table or user defined table function is referenced in the fullselect, the current library (*CURLIB) will be used.

If a view name is not a valid system name and the FOR SYSTEM NAME clause is not used, Db2 for i will generate a system name. For information about the rules for generating the name, see “Rules for Table Name Generation” on page 1213.

**FOR SYSTEM NAME system-object-identifier**
Identifies the system-object-identifier of the view. system-object-identifier must not be the same as a table, view, alias, or index that already exists at the current server. The system-object-identifier must be an unqualified system identifier.

When system-object-identifier is specified, view-name must not be a valid system object name.

**(column-name, ... )**
Names the columns in the view. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each column-name and system-column-name must be unique and unqualified. If a list of column names is not specified, the columns of the view inherit the names of the columns and system names of the columns of the result table of the fullselect.

A list of column names (and system column names) must be specified if the result table of the subselect has duplicate column names, duplicate system column names, or an unnamed column. For more information about unnamed columns, see “Names of result columns” on page 746.

**FOR COLUMN system-column-name**
Provides an IBM i name for the column. Do not use the same name for more than one column of the view or for a column-name of the view.

If the system-column-name is not specified, and the column-name is not a valid system-column-name, a system column name is generated. For more information about how system column names are generated, see “Rules for Column Name Generation” on page 1213.

**AS**
Defines the view.

**WITH common-table-expression**
Defines a common table expression for use with the fullselect that follows. For an explanation of common table expression, see “common-table-expression” on page 801.
CREATE VIEW

**fullselect**
Defines the view. At any time, the view consists of the rows that would result if the fullselect were executed.

*fullselect* must not reference variables, but may reference global variables.

The maximum number of columns allowed in a view is 8000. The column name lengths and the length of the WHERE clause also reduce this number. The maximum number of base tables allowed in the view is 256.

For an explanation of *fullselect*, see “fullselect” on page 794.

*common-table-expression* defines a common table expression for use with the *fullselect* that follows. For more information see “common-table-expression” on page 801.

A declared temporary table must not be referenced in the *fullselect* unless the view is created in schema QTEMP.

The ORDER BY, FETCH, and OFFSET clauses may not be specified in the outer *fullselect* of the view.

**WITH CASCADED CHECK OPTION or WITH LOCAL CHECK OPTION**
Specifies that every row that is inserted or updated through the view must conform to the definition of the view. A row that does not conform to the definition of the view is a row that cannot be retrieved using that view.

CHECK OPTION must not be specified if:
- the view is read-only
- the definition of the view includes a subquery other than a scalar fullselect in the outer select list of the view
- the definition of the view contains a non-deterministic, MODIFIES SQL DATA, or EXTERNAL ACTION function in other than the outer select list of the view
- the definition of the view contains a special register in other than the outer select list of the view
- the view references another view and that view has an INSTEAD OF trigger
- the view is recursive

If CHECK OPTION is specified for an updatable view that does not allow inserts, then the check option applies to updates only.

If CHECK OPTION is omitted, the definition of the view is not used in the checking of any insert or update operations that use the view. Some checking might still occur during insert or update operations if the view is directly or indirectly dependent on another view that includes a CHECK OPTION. Because the definition of the view is not used, rows that do not conform to the definition of the view might be inserted or updated through the view.

The difference between the two forms of the CHECK OPTION clause, CASCADED and LOCAL, is meaningful only when a view is dependent on another view. The default is CASCADED. The view upon which another view is directly or indirectly defined is an underlying view.

**CASCADED**
The WITH CASCADED CHECK OPTION on a view V is inherited by any updatable view that is directly or indirectly dependent on V. Thus, if an updatable view is defined on V, the check option on V also applies to that view, even if WITH CHECK OPTION is not specified on that view. For example, consider the following updatable views:
CREATE VIEW V1 AS SELECT COL1 FROM T1 WHERE COL1 > 10
CREATE VIEW V2 AS SELECT COL1 FROM V1 WITH CHECK OPTION
CREATE VIEW V3 AS SELECT COL1 FROM V2 WHERE COL1 < 100

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>Description of result</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSERT INTO V1 VALUES(5)</td>
<td>Succeeds because V1 does not have a CHECK OPTION clause and it is not dependent on any other view that has a CHECK OPTION clause.</td>
</tr>
<tr>
<td>INSERT INTO V2 VALUES(5)</td>
<td>Results in an error because the inserted row does not conform to the search condition of V1 which is implicitly part of the definition of V2.</td>
</tr>
<tr>
<td>INSERT INTO V3 VALUES(5)</td>
<td>Results in an error because V3 is dependent on V2 which has a CHECK OPTION clause and the inserted row does not conform to the definition of V2.</td>
</tr>
<tr>
<td>INSERT INTO V3 VALUES(200)</td>
<td>Succeeds even though it does not conform to the definition of V3 (V3 does not have the view CHECK OPTION clause specified); it does conform to the definition of V2 (which does have the view CHECK OPTION clause specified).</td>
</tr>
</tbody>
</table>

LOCAL

WITH LOCAL CHECK OPTION is identical to WITH CASCADED CHECK OPTION except that it is still possible to update a row so that it no longer conforms to the definition of the view when the view is defined with the WITH LOCAL CHECK OPTION. This can only happen when the view is directly or indirectly dependent on a view that was defined without either WITH CASCADED CHECK OPTION or WITH LOCAL CHECK OPTION clauses.

WITH LOCAL CHECK OPTION specifies that the search conditions of the following underlying views are checked when a row is inserted or updated:
- views that specify WITH LOCAL CHECK OPTION
- views that specify WITH CASCADED CHECK OPTION
- all underlying views of a view that specifies WITH CASCADED CHECK OPTION

In contrast, WITH CASCADED CHECK OPTION specifies that the search conditions of all underlying views are checked when a row is inserted or updated.

The difference between CASCADED and LOCAL is best shown by example. Consider the following updatable views where x and y represent either LOCAL or CASCADED:

V1 defined on table T0
V2 defined on V1 WITH x CHECK OPTION
V3 defined on V2
V4 defined on V3 WITH y CHECK OPTION
V5 defined on V4

The following table describes which views search conditions are checked during an INSERT or UPDATE operation:
CREATE VIEW

Table 84. Views whose search conditions are checked during INSERT and UPDATE

<table>
<thead>
<tr>
<th>View used in INSERT or UPDATE</th>
<th>x = LOCAL</th>
<th>x = CASCADED</th>
<th>x = LOCAL</th>
<th>x = CASCADED</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>y = LOCAL</td>
<td>y = CASCADED</td>
<td>y = LOCAL</td>
<td>y = LOCAL</td>
</tr>

<td>V4 V3 V2 V1</td>
<td>V4 V3 V2 V1</td>
<td>V4 V2 V1</td>
</tr>
</tbody>
</table>

**RCDMFMT format-name**

An unqualified name that designates the IBM i record format name of the view. A *format-name* is a system identifier.

If a record format name is not specified, the *format-name* is the same as the *system-object-name* of the view.

**Notes**

**View ownership:** If SQL names were specified:

- If a user profile with the same name as the schema into which the view is created exists, the *owner* of the view is that user profile.
- Otherwise, the *owner* of the view is the user profile or group user profile of the thread executing the statement.

If system names were specified, the *owner* of the view is the user profile or group user profile of the thread executing the statement.

**View authority:** If SQL names are used, views are created with the system authority of *EXCLUDE on *PUBLIC. If system names are used, views are created with the authority to *PUBLIC as determined by the create authority (CRTAUT) parameter of the schema.

If the owner of the view is a member of a group profile (GRPPRF keyword) and group authority is specified (GRPAUT keyword), that group profile will also have authority to the view.

The owner always acquires the SELECT privilege WITH GRANT OPTION on the view and the authorization to drop the view.

The owner can also acquire the INSERT, UPDATE, and DELETE privileges on the view. If the view is not read-only, then the same privileges will be acquired on the new view as the owner has on the table or view identified in the first FROM clause of the fullselect. These privileges can be granted only if the privileges from which they are derived can also be granted.

**REPLACE rules:** When a view is recreated by REPLACE:

- Any existing comment or label is discarded.
- Authorized users are maintained. The object owner could change.
- Current journal auditing is preserved. However, unlike other objects, REPLACE of a view will generate a ZC (change object) journal audit entry.
- Any INSTEAD OF triggers defined for the view are dropped (any triggers that reference the view are not dropped).
ANY views and materialized query tables dependent on the view will be recreated, if possible. If it is not possible to recreate a dependent view or materialized query table, an error is returned.

**Deletable views:** A view is deletable if an INSTEAD OF trigger for the delete operation has been defined for the view, or if all of the following are true:

- The outer fullselect identifies only one base table or deletable view that is not a catalog table or view. It cannot be a nested table expression, table function, or a table with a FOR SYSTEM_TIME clause.
- The outer fullselect does not include a VALUES clause.
- The outer fullselect does not include a GROUP BY clause or HAVING clause.
- The outer fullselect does not include aggregate functions in the select list.
- The outer fullselect does not include a UNION, UNION ALL, EXCEPT, or INTERSECT operator.
- The outer fullselect does not include the DISTINCT clause.

**Updatable views:** A view is updatable if an INSTEAD OF trigger for the update operation has been defined for the view, or if all of the following are true:

- Independent of an INSTEAD OF trigger for delete, the view is deletable
- At least one column of the view is updatable

A column of a view is updatable if an INSTEAD OF trigger for the update operation has been defined for the view, or if the corresponding result column of the subselect is derived solely from a column of a table or an updatable column of another view (that is, it is not derived from an expression that contains an operator, scalar function, constant, or a column that itself is derived from such expressions).

**Insertable views:** A view is insertable if an INSTEAD OF trigger has been defined for the view, or if at least one column of the view is updatable.

**Read-only views:** A view is read-only if it is not deletable.

A read-only view cannot be the object of an INSERT, UPDATE, or DELETE statement.

**Special registers for temporal support:** The value of the CURRENT TEMPORAL SYSTEM_TIME special register has no impact on the query expression that defines a view while it is being defined. When a view is used in an SQL statement, the value of the CURRENT TEMPORAL SYSTEM_TIME special register for the session processing the SQL statement is applied to the view if the value of the SYSTIME option is YES.

**Unqualified table names:** If the CREATE VIEW statement refers to an unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression table-identifiers that are specified in the fullselect, the name identifies the common table expression that is in the innermost scope.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

**Considerations for implicitly hidden columns:** It is possible that the result table of the fullselect will include a column of the base table that is defined as implicitly
CREATE VIEW

hidden. This can occur when the implicitly hidden column is explicitly referenced in the fullselect of the view definition. However, the corresponding column of the view does not inherit the implicitly hidden attribute. Columns of a view cannot be defined as hidden.

Collating sequence: The view is created with the collating sequence in effect at the time the CREATE VIEW statement is executed. The collating sequence of the view applies to all comparisons involving SBCS data and mixed data in the view fullselect. When the view is included in a query, an intermediate result table is generated from the view fullselect. The collating sequence in effect when the query is executed applies to any selection specified in the query.

View attributes: Views are created as nonkeyed logical files. When a view is created, the file wait time and record wait time attributes are set to the default that is specified on the WAITFILE and WAITRCD keywords of the Create Logical File (CRTL) command.

The date and time format used for date and time result columns is ISO.

A view created over a distributed table is created on all of the systems across which the table is distributed. If a view is created over more than one distributed table, and those tables are not distributed using the same nodegroup, then the view is created only on the system that performs the CREATE VIEW statement. For more information about distributed tables, see the [DB2 Multisystem] topic collection.

Identity and row change timestamp columns: A column of a view is considered an identity or row change timestamp column if the element of the corresponding column in the fullselect of the view definition is the name of an identity or row change timestamp column of a table, or the name of a column of a view which directly or indirectly maps to the name of an identity or row change timestamp column of a base table. In all other cases, the columns of a view will not get the identity or row change timestamp property. For example:

- the select-list of the view definition includes multiple instances of the name of an identity column (that is, selecting the same column more than once)
- the view definition involves a join
- a column in the view definition includes an expression that refers to an identity column
- the view definition includes a UNION or INTERSECT

Examples

Example 1: Create a view named MA_PROJ over the PROJECT table that contains only those rows with a project number (PROJNO) starting with the letters 'MA'.

CREATE VIEW MA_PROJ
AS SELECT * FROM PROJECT
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'

Example 2: Create a view as in example 1, but select only the columns for project number (PROJNO), project name (PROJNAME) and employee in charge of the project (RESPEMP).

CREATE VIEW MA_PROJ
AS SELECT PROJNO, PROJNAME, RESPEMP FROM PROJECT
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
**Example 3:** Create a view as in example 2, but, in the view, call the column for the employee in charge of the project `IN_CHARGE`.

CREATE VIEW MA_PROJ (PROJNO, PROJNAME, IN_CHARGE)
AS SELECT PROJNO, PROJNAME, IN_CHARGE
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'

*Note:* Even though you are changing only one of the column names, the names of all three columns in the view must be listed in the parentheses that follow `MA_PROJ`.

**Example 4:** Create a view named `PRJ_LEADER` that contains the first four columns (PROJNO, PROJNAME, DEPTNO, RESPEMP) from the `PROJECT` table together with the last name (LASTNAME) of the person who is responsible for the project (RESPEMP). Obtain the name from the `EMPLOYEE` table by matching EMPNO in `EMPLOYEE` to RESEMP in `PROJECT`.

CREATE VIEW PRJ_LEADER
AS SELECT PROJNO, PROJNAME, DEPTNO, RESPEMP, LASTNAME
FROM PROJECT, EMPLOYEE
WHERE RESPEMP = EMPNO

**Example 5:** Create a view as in example 4, but in addition to the columns PROJNO, PROJNAME, DEPTNO, RESEMP and LASTNAME, show the total pay (SALARY + BONUS + COMM) of the employee who is responsible. Also select only those projects with mean staffing (PRSTAFF) greater than one.

CREATE VIEW PRJ_LEADER (PROJNO, PROJNAME, DEPTNO, RESEMP, LASTNAME, TOTAL_PAY)
AS SELECT PROJNO, PROJNAME, DEPTNO, RESEMP, LASTNAME, SALARY+BONUS+COMM
FROM PROJECT, EMPLOYEE
WHERE RESPEMP = EMPNO AND PRSTAFF > 1

**Example 6:** Create a recursive view that returns a similar result as a common table expression, see “Example 1: Single level explosion” on page 805.

CREATE RECURSIVE VIEW RPL (PART, SUBPART, QUANTITY)
AS SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY
FROM PARTLIST ROOT
WHERE ROOT.PART = '01'
UNION ALL
SELECT CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY
FROM RPL PARENT, PARTLIST CHILD
WHERE PARENT.SUBPART = CHILD.PART

SELECT DISTINCT *
FROM RPL
ORDER BY PART, SUBPART, QUANTITY
DEALLOCATE DESCRIPTOR

DEALLOCATE DESCRIPTOR

The DEALLOCATE DESCRIPTOR statement deallocates an SQL descriptor.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

None required.

Syntax

```
SQL LOCAL DEALLOCATE DESCRIPTOR SQL-descriptor-name
GLOBAL
```

Description

**LOCAL**

Specifies the scope of the name of the descriptor to be local to program invocation. The descriptor known in this local scope is deallocated.

**GLOBAL**

Specifies the scope of the name of the descriptor to be global to the SQL session. The descriptor known to any program that executes using the same database connection is deallocated.

**SQL-descriptor-name**

Names the descriptor to deallocate. The name must identify a descriptor that already exists with the specified scope.

Notes

**Descriptor persistence**: Local and global descriptors are also implicitly deallocated. For more information, see [Descriptor persistence](#).

Examples

Deallocate a descriptor called 'NEWDA'.

```
EXEC SQL DEALLOCATE DESCRIPTOR 'NEWDA'
```
DECLARE CURSOR

The DECLARE CURSOR statement defines a cursor.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java.

Authorization

No authorization is required to use this statement. However, to use OPEN or FETCH for the cursor, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each table or view identified in the SELECT statement of the cursor:
  - The SELECT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

The SELECT statement of the cursor is one of the following:

- The prepared select-statement identified by the statement-name.
- The specified select-statement.

If statement-name is specified:

- The authorization ID of the statement is the run-time authorization ID unless USRPRF(*OWNER) and DYNUSRPRF(*OWNER) were specified on the CRTSQLxxx command when the program was created. For more information, see “Authorization IDs and authorization names” on page 69.
- The authorization check is performed when the select-statement is prepared unless DLYPRP(*YES) is specified on the CRTSQLxxx command.
- The authorization check is performed when the cursor is opened for programs compiled with the DLYPRP(*YES) parameter.

If the select-statement is specified:

- If USRPRF(*OWNER) or USRPRF(*NAMING) with SQL naming was specified on the CRTSQLxxx command, the authorization ID of the statement is the owner of the SQL program or package.
- If USRPRF(*USER) or USRPRF(*NAMING) with system naming was specified on the CRTSQLxxx command, the authorization ID of the statement is the run-time authorization ID.
- In REXX, the authorization ID of the statement is the run-time authorization ID.
- The authorization check is performed when the cursor is opened.

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View

Syntax

```
DECLARE cursor-name
```

- ASENSITIVE
- INSENSITIVE
- SENSITIVE
- DYNAMIC
- NO SCROLL
- SCROLL
- CURSOR
DECLARE CURSOR

**Notes:**
1. The HOLD, RETURN, and EXTENDED INDICATORS clauses can be specified in any order.

**Description**

`cursor-name`

Names a cursor. The name must not be the same as the name of another cursor declared in your source program.

**ASENSITIVE, SENSITIVE, or INSENSITIVE**

Specifies whether the cursor is asensitive, sensitive, or insensitive to changes. If `statement-name` is specified, the default is the corresponding prepare attribute of the statement. Otherwise, ASENSITIVE is the default.

**ASENSITIVE**

Specifies that the cursor may behave as SENSITIVE or INSENSITIVE depending on how the `select-statement` is optimized.

**SENSITIVE**

Specifies that changes made to the database after the cursor is opened are visible in the result table. The cursor has some level of sensitivity to any updates or deletes made to the rows underlying its result table after the cursor is opened. The cursor is always sensitive to positioned updates or deletes using the same cursor. Additionally, the cursor can have sensitivity to changes made outside this cursor. If the database manager cannot make changes visible to the cursor, then an error is returned. The database manager cannot make changes visible to the cursor when the cursor implicitly becomes read-only. (See [Result table of a cursor](#)). If SENSITIVE is specified, the SELECT statement cannot contain a `data-change-table-reference`.

**INSENSITIVE**

Specifies that once the cursor is opened, it does not have sensitivity to inserts, updates, or deletes performed by this or any other activation group. If INSENSITIVE is specified, the cursor is read-only and a temporary result is created when the cursor is opened. In addition, the SELECT statement cannot contain an UPDATE clause and the application must allow a copy of the data (ALWCPYDTA(*OPTIMIZE) or ALWCPYDTA(*YES)).

**NO SCROLL or SCROLL**

Specifies whether the cursor is scrollable or not scrollable. If `statement-name` is specified, the default is the corresponding prepare attribute of the statement. Otherwise, NO SCROLL is the default.

**NO SCROLL**

Specifies that the cursor is not scrollable.
**SCROLL**
Specifies that the cursor is scrollable. The cursor may or may not have immediate sensitivity to inserts, updates, and deletes done by other activation groups.

**WITHOUT HOLD or WITH HOLD**
Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation. If `statement-name` is specified, the default is the corresponding prepare attribute of the statement. Otherwise, WITHOUT HOLD is the default.

**WITHOUT HOLD**
Does not prevent the cursor from being closed as a consequence of a commit operation.

**WITH HOLD**
Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared using the WITH HOLD clause is implicitly closed at commit time only if the connection associated with the cursor is ended during the commit operation.

When WITH HOLD is specified, a commit operation commits all the changes in the current unit of work, and releases all locks except those that are required to maintain the cursor position. Afterward, a FETCH statement is required before a Positioned UPDATE or DELETE statement can be executed.

All cursors are implicitly closed by a CONNECT (Type 1) or rollback operation. All cursors associated with a connection are implicitly closed by a disconnect of the connection. A cursor is also implicitly closed by a commit operation if WITH HOLD is not specified, or if the connection associated with the cursor is in the release-pending state.

If a cursor is closed before the commit operation, the effect is the same as if the cursor was declared without the WITH HOLD option.

**WITHOUT RETURN or WITH RETURN**
Specifies that the result table of the cursor is intended to be used as a procedure result set. If `statement-name` is specified, the default is the corresponding prepare attribute of the statement. Otherwise, WITHOUT RETURN is the default.

**WITHOUT RETURN**
Specifies that the result table of the cursor is not intended to be used as a procedure result set.

**WITH RETURN**
Specifies that the result table of the cursor is intended to be used as a procedure result set. If the DECLARE CURSOR statement is not contained within the source code for a procedure, the clause is ignored.

For SQL procedures, result sets are only returned if a DYNAMIC RESULT SETS clause with a nonzero maximum number of result sets is specified on the procedure definition.

- Cursors defined by using the WITH RETURN clause that are still open when the procedure ends define the result sets for the procedure. All other open cursors are closed when the procedure ends, provided the procedure was not created with CLOSQLCR(*ENDACTGRP).
• If no cursors in the stored procedure are defined by using the WITH RETURN or WITHOUT RETURN clause, then any cursor that is open when the stored procedure ends potentially becomes a result set cursor.

• See the DYNAMIC RESULT SETS clause in "CREATE PROCEDURE (SQL)" on page 1130 for further considerations that determine a procedure's result sets.

For external procedures:

• Any cursors that are defined by using the WITH RETURN clause (or identified as a result set cursor in a SET RESULT SETS statement) and that are still open when the procedure ends define the potential result sets for the procedure, provided the procedure was not created with CLOSQLCSR(*ENDACTGRP). All other open cursors remain open.

• If no cursors in the stored procedure are defined by using the WITH RETURN or WITHOUT RETURN clause, and no cursors are identified as a result set cursor in a SET RESULT SETS statement, then any cursor that is open when the stored procedure ends potentially becomes a result set cursor.

• See the DYNAMIC RESULT SETS clause in "CREATE PROCEDURE (external)" on page 1113 for further considerations that determine a procedure's result sets.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

**TO CALLER**

Specifies that the cursor can return a result set to the caller of the procedure. For example, if the caller is a client application, the result set is returned to the client application.

**TO CLIENT**

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger called the procedure either directly or indirectly, result sets cannot be returned to the client and the cursor will be closed after the procedure finishes.

TO CLIENT may be necessary if the result set is returned from an ILE program with multiple modules.

**WITHOUT EXTENDED INDICATORS or WITH EXTENDED INDICATORS**

Specifies whether extended indicators are enabled. If statement-name is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is the attribute specified on the containing program or service program.

**WITHOUT EXTENDED INDICATORS**

Specifies that extended indicator variables are not enabled, and only updatable columns are allowed in the implicit or explicit UPDATE clause or the select-statement.

**WITH EXTENDED INDICATORS**

Specifies that extended indicator variables are enabled, and non-updatable columns are allowed in the implicit or explicit UPDATE clause of the select-statement.
**DECLARE CURSOR**

*select-statement*

Specifies the SELECT statement of the cursor. See “select-statement” on page 800 for more information.

The select-statement must not include parameter markers (except for REXX), but can include references to variables. In host languages, other than REXX, the declarations of the host variables must precede the DECLARE CURSOR statement in the source program. In REXX, parameter markers must be used in place of variables and the statement must be prepared.

*statement-name*

The SELECT statement of the cursor is the prepared select-statement identified by the statement-name when the cursor is opened. The statement-name must not be identical to a statement-name specified in another DECLARE CURSOR statement of the source program. See “PREPARE” on page 1494 for an explanation of prepared statements.

**Notes**

**Placement of DECLARE CURSOR:** The DECLARE CURSOR statement must precede all statements that explicitly reference the cursor by name, except in C and PL/I.

**Result table of a cursor:** A cursor in the open state designates a result table and a position relative to the rows of that table. The table is the result table specified by the SELECT statement of the cursor.

A cursor is deletable if all of the following are true:
- The outer fullselect identifies only one base table or deletable view that is not a catalog table or view and is not in a nested table expression.
- The outer fullselect does not include a VALUES clause.
- The outer fullselect does not include a GROUP BY clause or HAVING clause.
- The outer fullselect does not include aggregate functions in the select list.
- The outer fullselect does not include a UNION, UNION ALL, EXCEPT, or INTERSECT operator.
- The select-clause of the outer fullselect does not include the DISTINCT clause.
- The outer fullselect does not contain a FOR SYSTEM_TIME period specification.
- The outer fullselect does not include a data-change-table-reference in the FROM clause.
- The select-statement does not contain an ORDER BY clause and does not contain the UPDATE clause and SENSITIVE is not specified in the DECLARE CURSOR statement.
- The select-statement does not include a FOR READ ONLY clause.
- The result of the outer fullselect does not make use of a temporary table.
- The select-statement does not include the SCROLL keyword, or the SENSITIVE keyword or UPDATE clause is also specified.
- The select list does not include a DATALINK column unless a UPDATE clause is specified.

A result column in the select list of the outer fullselect associated with a cursor is updatable if all of the following are true:
- The cursor is deletable.
• The result column is derived solely from a column of a table or an updatable column of a view. That is, at least one result column must not be derived from an expression that contains an operator, scalar function, constant, or a column that itself is derived from such expressions.

A cursor is read-only if it is not deletable.

If the UPDATE clause is omitted, only the columns in the SELECT clause of the subselect that can be updated can be changed.

If UPDATE is specified without a list of column names, then the list of columns that can appear as targets in the assignment clause of subsequent positioned UPDATE statements identifying this cursor is determined as follows:

• If WITH EXTENDED INDICATORS is specified, all the columns of the table or view identified in the first FROM clause of the fullselect.
• Otherwise, only the updatable columns of the table or view identified in the first FROM clause of the fullselect.

If UPDATE is specified with a list of column names, only the columns specified in the list of column names can appear as targets in the assignment clause in subsequent positioned UPDATE statements identifying this cursor.

Scope of a cursor: The scope of cursor-name is the source program in which it is defined; that is, the program submitted to the precompiler. Thus, a cursor can only be referenced by statements that are precompiled with the cursor declaration. For example, a program called from another separately compiled program cannot use a cursor that was opened by the calling program.

The scope of cursor-name is also limited to the thread in which the program that contains the cursor is running. For example, if the same program is running in two separate threads in the same job, the second thread cannot use a cursor that was opened by the first thread.

A cursor can only be referred to in the same instance of the program in the program stack unless CLOSQLCSR(*ENDJOB), CLOSQLCSR(*ENDSQL), or CLOSQLCSR(*ENDACTGRP) is specified on the CRTSQLxxx commands.

• If CLOSQLCSR(*ENDJOB) is specified, the cursor can be referred to by any instance of the program on the program stack.
• If CLOSQLCSR(*ENDSQL) is specified, the cursor can be referred to by any instance of the program on the program stack until the last SQL program on the program stack ends.
• If CLOSQLCSR(*ENDACTGRP) is specified, the cursor can be referred to by all instances of the module in the activation group until the activation group ends.

Although the scope of a cursor is the program in which it is declared, each package created from the program includes a separate instance of the cursor and more than one cursor can exist at run time. For example, assume a program using CONNECT (Type 2) statements connects to location X and location Y in the following sequence:

EXEC SQL DECLARE C CURSOR FOR...
EXEC SQL CONNECT TO X;
EXEC SQL OPEN C;
EXEC SQL FETCH C INTO...
EXEC SQL CONNECT TO Y;
EXEC SQL OPEN C;
EXEC SQL FETCH C INTO...
The second OPEN C statement does not cause an error because it refers to a different instance of cursor C.

A SELECT statement is evaluated at the time the cursor is opened. If the same cursor is opened, closed, and then opened again, the results may be different. If the SELECT statement of a cursor contains CURRENT DATE, CURRENT TIME, or CURRENT_TIMESTAMP, all references to these special registers will yield the same respective datetime value on each FETCH. The value is determined when the cursor is opened. Multiple cursors using the same SELECT statement can be opened concurrently. They are each considered independent activities.

**Using sequence expressions:** For information regarding using NEXT VALUE and PREVIOUS VALUE expressions with a cursor, see Using sequence expressions with a cursor.

**Blocking of data:** For more efficient processing of data, the database manager can block data for read-only cursors. If a cursor is not going to be used in a Positioned UPDATE or DELETE statement, it should be declared as FOR READ ONLY.

**Usage in REXX:** If variables are used on the DECLARE CURSOR statement within a REXX procedure, then the DECLARE CURSOR must be the object of a PREPARE and EXECUTE.

**Temporary results:** Certain select-statements may be implemented as temporary result tables.

- A temporary result table is created when:
  - INSENSITIVE is specified
  - The ORDER BY and GROUP BY clauses specify different columns or columns in a different order.
  - The ORDER BY and GROUP BY clauses include a user-defined function or one of the following scalar functions: DLVALUE, DLURLPATH, DLURLPATHONLY, DLURLSERVER, DLURLSCHEME, or DLURLCOMPLETE for DataLinks with an attribute of FILE LINK CONTROL and READ PERMISSION DB.
  - The UNION, EXCEPT, INTERSECT, or DISTINCT clauses are specified.
  - The ORDER BY or GROUP BY clauses specify columns which are not all from the same table.
  - A logical file defined by the JOINDFI data definition specifications (DDS) keyword is joined to another file.
  - A logical file that is based on multiple database file members is specified.
  - The CURRENT or RELATIVE scroll options are specified on the FETCH statement when the select statement of the DECLARE CURSOR contains a GROUP BY clause.
  - The FETCH FIRST n ROWS ONLY clause is specified.
- Queries that include a subquery where:
  - The outermost query does not provide correlated values to any inner subselects.
  - No IN, = ANY, = SOME, or <> ALL subqueries are referenced by the outermost query.
**DECLARE CURSOR**

**Cursor sensitivity:** The ALWCPYDTA precompile option is ignored for DYNAMIC SCROLL cursors. If sensitivity to inserts, updates, and deletes must be maintained, a temporary copy of the data is never made unless a temporary result is required to implement the query.

Scrollable, sensitive cursors with an OFFSET and/or FETCH FIRST clause may return rows either before the specified offset or after the specified number of rows if:

- update, delete, or insert operations occur against the underlying tables of the cursor while fetching data through the cursor, and
- the fetch operations against the cursor attempt to return the same rows that were previously fetched by the cursor.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- DYNAMIC SCROLL is a synonym for SENSITIVE DYNAMIC SCROLL

**Examples**

**Example 1:** Declare C1 as the cursor of a query to retrieve data from the table DEPARTMENT. The query itself appears in the DECLARE CURSOR statement.

```sql
EXEC SQL DECLARE C1 CURSOR FOR
SELECT DEPTNO, DEPTNAME, MGRNO
FROM DEPARTMENT
WHERE ADMRDEPT = 'A00';
```

**Example 2:** Declare C1 as the cursor of a query to retrieve data from the table DEPARTMENT. Assume that the data will be updated later with a searched update and should be locked when the query executes. The query itself appears in the DECLARE CURSOR statement.

```sql
EXEC SQL DECLARE C1 CURSOR FOR
SELECT DEPTNO, DEPTNAME, MGRNO
FROM DEPARTMENT
WHERE ADMRDEPT = 'A00'
FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS;
```

**Example 3:** Declare C2 as the cursor for a statement named STMT2.

```sql
EXEC SQL DECLARE C2 CURSOR FOR STMT2;
```

**Example 4:** Declare C3 as the cursor for a query to be used in positioned updates of the table EMPLOYEE. Allow the completed updates to be committed from time to time without closing the cursor.

```sql
EXEC SQL DECLARE C3 CURSOR WITH HOLD FOR
SELECT *
FROM EMPLOYEE
FOR UPDATE OF WORKDEPT, PHONENO, JOB, EDLEVEL, SALARY;
```

Instead of explicitly specifying the columns to be updated, an UPDATE clause could have been used without naming the columns. This would allow all the updatable columns of the table to be updated. Since this cursor is updatable, it can also be used to delete rows from the table.

**Example 5:** In a C program, use the cursor C1 to fetch the values for a given project (PROJNO) from the first four columns of the EMPPROJECT table a row at a time and put them into the following host variables: EMP(CHAR(6)), PRJ(CHAR(6)),...
ACT(SMALLINT) and TIM(DECIMAL(5,2)). Obtain the value of the project to search for from the host variable SEARCH_PRJ (CHAR(6)). Dynamically prepare the select-statement to allow the project to search by to be specified when the program is executed.

```c
void main ()
{
  EXEC SQL
  BEGIN DECLARE SECTION;
  char EMP[7];
  char PRJ[7];
  char SEARCH_PRJ[7];
  short ACT;
  double TIM;
  char SELECT_STMT[201];
  EXEC SQL END DECLARE SECTION;
  EXEC SQL INCLUDE SQLCA;

  strcpy(SELECT_STMT, "SELECT EMPNO, PROJNO, ACTNO, EMPTIME \\
          FROM EMPPROJECT \\
          WHERE PROJNO = ?");
  
  EXEC SQL PREPARE SELECT_PRJ FROM :SELECT_STMT;
  EXEC SQL DECLARE C1 CURSOR FOR SELECT_PRJ;

  /* Obtain the value for SEARCH_PRJ from the user. */

  EXEC SQL OPEN C1 USING :SEARCH_PRJ;
  EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM;

  if (strcmp(SQLSTATE, "02000", 5) )
  {
    data_not_found();
  }
  else
  {
    while (strcmp(SQLSTATE, "00", 2) || strcmp(SQLSTATE, "01", 2) )
    {
      EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM;
    }
  }

  EXEC SQL CLOSE C1;

  /*
  */
}
```

**Example 6:** The DECLARE CURSOR statement associates the cursor name C1 with the results of the SELECT. C1 is an updatable, scrollable cursor.

```sql
EXEC SQL DECLARE C1 SENSITIVE SCROLL CURSOR FOR
        SELECT DEPTNO, DEPTNAME, MGRNO
        FROM TDEPT
        WHERE ADMRDEPT = 'A00';
```

**Example 7:** Declare a cursor in order to fetch values from four columns and assign the values to variables using the Serializable (RR) isolation level:
DECLARE CURSOR

DECLARE CURSOR1 CURSOR FOR
SELECT COL1, COL2, COL3, COL4
FROM TBLNAME WHERE COL1 = :varname
WITH RR

Example 8: Assume that the EMPLOYEE table has been altered to add a generated column, WEEKLYPAY, that calculates the weekly pay based on the yearly salary. Declare a cursor to retrieve the system generated column value from a row to be inserted.

DECLARE C2 CURSOR FOR
SELECT E.WEEKLYPAY
FROM FINAL TABLE
(INSERT INTO EMPLOYEE
(EMPNO, FIRSTNAME, MIDINIT, LASTNAME, EDLEVEL, SALARY)
VALUES('000420', 'Peter', 'U', 'Bender', 16, 31842)) AS E;
The DECLARE GLOBAL TEMPORARY TABLE statement defines a declared temporary table for the current application process. The declared temporary table description does not appear in the system catalog. It is not persistent and cannot be shared with other application processes. Each application process that defines a declared temporary table of the same name has its own unique description of the temporary table. When the application process ends, the temporary table is dropped.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

If the LIKE or AS select-statement clause is specified, the privileges held by the authorization ID of the statement must include at least one of the following on any table or view specified in the LIKE clause or as-result-table clause:

- The SELECT privilege for the table or view
- Ownership of the table or view
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
  - The USAGE privilege on the distinct type, and
  - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View and Corresponding System Authorities When Checking Privileges to a Distinct Type.

**Syntax**

```sql
DECLARE GLOBAL TEMPORARY TABLE table-name
FOR SYSTEM NAME system-object-identifier

( column-definition,
  period-definition,
  LIKE table-name,
  LIKE view-name,
  copy-options,
  LIKE table-name,
  LIKE view-name,
  copy-options,
  as-result-table )
```
DECLARE GLOBAL TEMPORARY TABLE

WITH REPLACE:
- ON COMMIT DELETE ROWS
- ON COMMIT PRESERVE ROWS
- NOT LOGGED
- ON ROLLBACK DELETE ROWS
- ON ROLLBACK PRESERVE ROWS

RCDFMT: format-name

media-preference:
- UNIT ANY
- UNIT SSD

memory-preference:
- KEEP IN MEMORY
- NO
- YES

column-definition:
- column-name
  - FOR
  - COLUMN
  - system-column-name

(1)

default-clause:
- generated-clause
- FIELDPROC: external-program-name
- NOT NULL
- NOT HIDDEN
- IMPLICITLY HIDDEN

constant

not-null-clause:

(2)

datalink-options

data-type:
- built-in-type
- distinct-type-name

(3)

(4)
Notes:
1. The same clause must not be specified more than once.
2. The optional clauses can be specified in any order.
3. data-type is optional for row change timestamp columns, row-begin and row-end columns, and transaction-start-ID columns.
4. The datalink-options can only be specified for DATALINKs and distinct-types sourced on DATALINKs.

built-in-type:
 DECLARE GLOBAL TEMPORARY TABLE

ccsid-clause:

| CCSID — integer | normalize-clause |
normalize-clause:

allocate-clause:

default-clause:

generated-clause:

Notes:

1  GENERATED can be specified only if the column has a ROWID data type (or a distinct type that is based on a ROWID data type), or the column is an identity column, or the column is a row change timestamp.

identity-options:
DECLARE GLOBAL TEMPORARY TABLE

```
<table>
<thead>
<tr>
<th>AS IDENTITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>(START WITH</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
```

Notes:
1. The same clause must not be specified more than once.

**as-row-change-timestamp-clause:**
```
FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP
```

**as-row-transaction-timestamp-clause:**
```
AS TRANSACTION START ID
```

**as-generated-expression-clause:**
```
AS (non-deterministic-expression)
```

**non-deterministic-expression:**
```
DATA CHANGE OPERATION
   special-register
   built-in-global-variable
```

**special-register:**
DECLARE GLOBAL TEMPORARY TABLE

<table>
<thead>
<tr>
<th>built-in-global-variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>QSYS2.JOB_NAME</td>
</tr>
<tr>
<td>QSYS2.SERVER_MODE_JOB_NAME</td>

| INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES |
DECLARE GLOBAL TEMPORARY TABLE

as-result-table:

\[
\text{column-name} \quad \text{FOR} \quad \text{system-column-name} \\
\quad \text{AS}\quad \left(\text{select-statement}\right) \\
\quad \text{WITH NO DATA} \quad \text{WITH DATA} \quad \text{copy-options}
\]

Notes:
1. The clauses can be specified in any order.

Description

\text{table-name}

Names the temporary table. The qualifier, if specified explicitly, must be SESSION, otherwise an error is returned. If the qualifier is not specified, it is implicitly defined to be SESSION. If a declared temporary table, or an index or view that is dependent on a declared temporary table already exists with the same name, an error is returned.

If a persistent table, view, index, or alias already exists with the same name and the schema name SESSION:

- The declared temporary table is still defined with \text{SESSION.table-name}. An error is not issued because the resolution of a declared temporary table name does not include a permanent library.
- Any references to \text{SESSION.table-name} will resolve to the declared temporary table rather than to a permanent table, view, index, or alias with a name of \text{SESSION.table-name}.

The table will be created in library QTEMP.

\text{FOR SYSTEM NAME system-object-identifier}

Identifies the \text{system-object-identifier} of the table. \text{system-object-identifier} must not be the same as a table, view, alias, or index that already exists at the current server. The \text{system-object-identifier} must be an unqualified system identifier.

When \text{system-object-identifier} is specified, \text{table-name} must not be a valid system object name.

column-definition

Defines the attributes of a column. There must be at least one column definition and no more than 8000 column definitions.

The sum of the row buffer byte counts of the columns must not be greater than 32766 or, if a VARCHAR, VARGRAPHIC, or VARBINARY column is specified, 32740. Additionally, if a LOB or XML column is specified, the sum of the row data byte counts of the columns must not be greater than 3.5 gigabytes. For information about the byte counts of columns according to data type, see “Maximum row sizes” on page 1210.
column-name
Names a column of the table. Do not qualify column-name and do not use the same name for more than one column of the table or for a system-column-name of the table.

FOR COLUMN system-column-name
Provides an IBM i name for the column. Do not use the same name for more than one column of the table or for a column-name of the table.

If the system-column-name is not specified, and the column-name is not a valid system-column-name, a system column name is generated. For more information about how system column names are generated, see “Rules for Column Name Generation” on page 1213.

data-type
Specifies the data type of the column.

built-in-type
Specifies a built-in data type. See “CREATE TABLE” on page 1159 for a description of built-in-type.

A ROWID column or a DATALINK column with FILE LINK CONTROL cannot be specified for a declared temporary table.

distinct-type-name
Specifies that the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

DEFAULT
Specifies a default value for the column. This clause cannot be specified more than once in a column-definition. DEFAULT cannot be specified for the following types of columns because Db2 generates default values:

• an identity column (a column that is defined AS IDENTITY)
• a row change timestamp column
• a row-begin column
• a row-end column
• a transaction-start-ID column
• a generated expression column

For an XML column, the default is NULL unless NOT NULL is specified; in that case there is no default.

If a value is not specified following the DEFAULT keyword, then:
• if the column is nullable, the default value is the null value.
• if the column is not nullable, the default depends on the data type of the column:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character or graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string length of 0</td>
</tr>
<tr>
<td>Date</td>
<td>The current date at the time of INSERT</td>
</tr>
</tbody>
</table>
DECLARE GLOBAL TEMPORARY TABLE

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>The current time at the time of INSERT</td>
</tr>
<tr>
<td>Timestamp</td>
<td>The current timestamp at the time of INSERT</td>
</tr>
<tr>
<td>Datalink</td>
<td>A value corresponding to DLVALUE('','URL','')</td>
</tr>
<tr>
<td>distinct-type</td>
<td>The default value of the corresponding source type of the distinct type.</td>
</tr>
</tbody>
</table>

Omission of NOT NULL and DEFAULT from a *column-definition* is an implicit specification of DEFAULT NULL.

*constant*

Specifies the constant as the default for the column. The specified constant must represent a value that could be assigned to the column in accordance with the rules of assignment as described in “Assignments and comparisons” on page 99. A floating-point constant or decimal floating-point constant must not be used for a SMALLINT, INTEGER, DECIMAL, or NUMERIC column. A decimal constant must not contain more digits to the right of the decimal point than the specified scale of the column.

*USER*

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value of the column. The data type of the column must be CHAR or VARCHAR with a length attribute greater than or equal to the length attribute of the USER special register.

*NULL*

Specifies null as the default for the column. If NOT NULL is specified, DEFAULT NULL must not be specified within the same *column-definition*.

*CURRENT_DATE*

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the column must be DATE or a distinct type based on a DATE.

*CURRENT_TIME*

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the column must be TIME or a distinct type based on a TIME.

*CURRENT_TIMESTAMP* or *CURRENT_TIMESTAMP(integer)*

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the column must be TIMESTAMP or a distinct type based on a TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

*cast-function-name*

This form of a default value can only be used with columns defined as a distinct type, BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME or TIMESTAMP data types. The following table describes the allowed uses of these *cast-functions*.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Cast Function Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distinct type N based on a BINARY, VARBINARY, BLOB, CLOB, or DBCLOB</td>
<td>BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *</td>
</tr>
</tbody>
</table>
**Data Type** | **Cast Function Name**
---|---
Distinct type N based on a DATE, TIME, or TIMESTAMP | N (the user-defined cast function that was generated when N was created) ** or DATE, TIME, or TIMESTAMP *
Distinct type N based on other data types | N (the user-defined cast function that was generated when N was created) **
BINAR Y, VARBINARY, BLOB, CLOB, or DBCLOB | BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *
DATE, TIME, or TIMESTAMP | DATE, TIME, or TIMESTAMP *

**Notes:**

* The name of the function must match the name of the data type (or the source type of the distinct type) with an implicit or explicit schema name of QSYS2.

** The name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type.

---

**constant**

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. For BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME, and TIMESTAMP functions, the constant must be a string constant.

**USER**

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value for the column. The data type of the source type of the distinct type of the column must be CHAR or VARCHAR with a length attribute greater than or equal to the length attribute of the USER special register.

**CURRENT_DATE**

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the source type of the distinct type of the column must be DATE.

**CURRENT_TIME**

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the source type of the distinct type of the column must be TIME.

**CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(integer)**

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the source type of the distinct type of the column must be TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

If the value specified is not valid, an error is returned.
GENERATED
Specifies that the database manager generates values for the column.
GENERATED may be specified if the column is to be considered one of the
following types of columns:
• an identity column
• a row change timestamp column

GENERATED must be specified if the column is to be considered one of the
following types of columns:
• a row-begin column
• a row-end column
• a transaction-start-ID column
• a generated expression column

It may also be specified if the data type of the column is a ROWID (or a
distinct type that is based on a ROWID). Otherwise, it must not be specified.
GENERATED must not be specified with default-clause in a column definition.

ALWAYS
Specifies that the database manager will always generate a value for the column when a row is inserted or updated and a default value must be
generated. ALWAYS is the recommended value.

BY DEFAULT
Specifies that the database manager will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For an identity column or row change timestamp column, the database manager inserts or updates a specified value but does not verify that it is a unique value for the column unless the identity column or row change timestamp column has a unique constraint or a unique index that solely specifies the identity column or row change timestamp column.

AS IDENTITY
Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL or NUMERIC with a scale of zero, or a distinct type based on one of these data types). If a DECIMAL or NUMERIC data type is specified, the precision must not be greater than 31.

An identity column is implicitly NOT NULL. An identity column cannot have a DEFAULT clause. See the AS IDENTITY clause in "CREATE TABLE" on page [1159] for the descriptions of the identity attributes.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP
Specifies that the column is a timestamp and the values will be generated by the database manager. The database manager generates a value for the column for each row as a row is inserted, and for every row in which any column is updated. The value generated for a row change timestamp column is a timestamp corresponding to the time of the insert or update of the row. If multiple rows are inserted with a single SQL statement, the value for the row change timestamp column may be different for each row to reflect when each row was inserted. The generated value is not guaranteed to be unique.

A table can have only one row change timestamp column. If data-type is specified, it must be a TIMESTAMP with a precision of 6 or a distinct type.
based on a TIMESTAMP with a precision of 6. A row change timestamp column cannot have a DEFAULT clause and must be NOT NULL.

**AS ROW BEGIN**

Specifies that the column contains timestamp data and that the values are generated by the database manager. The database manager generates a value for the column for each row as the row is inserted, and for every row in which any column is updated. The generated value is a timestamp that corresponds to the start time that is associated with the most recent transaction. If multiple rows are inserted with a single SQL statement, the values for the transaction start timestamp column are the same for each row.

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value. This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. If multiple rows are inserted or updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction. A row-begin column is required as the begin column of a SYSTEM_TIME period.

A table can have only one row-begin column. If *data-type* is not specified, the column is defined as a TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-begin column is not updatable.

**AS ROW END**

Specifies that a value for the data type of the column is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The assigned value is TIMESTAMP '9999-12-30-00.00.00.000000000000'.

A row-end column is required as the second column of a SYSTEM_TIME period

A table can have only one row-end column. If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-end column is not updatable.

**AS TRANSACTION START ID**

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The database manager assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable and if there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in the table, or a row in a system-period temporal table is deleted. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

A transaction-start-ID column is required for a system-period temporal table.
A table can have only one transaction-start-ID column. If \textit{data-type} is not specified, the column is defined as \texttt{TIMESTAMP(12)}. If \textit{data-type} is specified it must be \texttt{TIMESTAMP(12)}. A transaction-start-ID column cannot have a \texttt{DEFAULT} clause. A transaction-start-ID column is not updatable.

**DATA CHANGE OPERATION**

Specifies that the database manager generates a value for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The column will contain one of the following values:

- \texttt{I} insert operation
- \texttt{U} update operation
- \texttt{D} delete operation

If \textit{data-type} is not specified, the column is defined as \texttt{CHAR(1)}. If \textit{data-type} is specified it must be \texttt{CHAR(1)}. The column cannot have a \texttt{DEFAULT} clause or a field procedure.

**special-register**

Specifies that the value of a special register is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the special register at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

\textit{data-type} must be defined according to the following table:

<table>
<thead>
<tr>
<th>Special register</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT CLIENT_ACCTNG</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_APPLNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_PROGRAMID</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_USERID</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_WRKSTNNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT SERVER</td>
<td>VARCHAR(18)</td>
</tr>
<tr>
<td>SESSION_USER</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>USER</td>
<td>VARCHAR(18)</td>
</tr>
</tbody>
</table>

The column cannot have a \texttt{DEFAULT} clause or a field procedure.

**built-in-global-variable**

Specifies that the value of a built-in global variable is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the built-in global variable at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

\textit{data-type} must be defined according to the following table:

<table>
<thead>
<tr>
<th>Built-in global variable</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>QSYS2.JOB_NAME</td>
<td>VARCHAR(28)</td>
</tr>
</tbody>
</table>
### Built-in global variable

<table>
<thead>
<tr>
<th>Built-in global variable</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>QSYS2.SERVER_MODE_JOB_NAME</td>
<td>VARCHAR(28)</td>
</tr>
<tr>
<td>SYSiBM.CLIENT_HOST</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>SYSiBM.CLIENT_IPADDR</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSiBM.CLIENT_PORT</td>
<td>INTEGER</td>
</tr>
<tr>
<td>SYSiBM.PACKAGE_NAME</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSiBM.PACKAGE_SCHEMA</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSiBM.PACKAGE_VERSION</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SYSiBM.ROUTINE_SCHEMA</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSiBM.ROUTINE_SPECIFIC_NAME</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSiBM.ROUTINE_TYPE</td>
<td>CHAR(1)</td>
</tr>
</tbody>
</table>

The column cannot have a DEFAULT clause or a field procedure.

**FIELDPROC**

Designates an `external-program-name` as the field procedure exit routine for the column. It must be an ILE program that does not contain SQL. It cannot be a service program.

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used, it is passed to the field procedure for decoding.

The field procedure is also invoked during the processing of the CREATE TABLE statement. When so invoked, the procedure provides Db2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information supplied for the column in the CREATE TABLE statement defines the data characteristics of the decoded values.

**constant**

Specifies a parameter that is passed to the field procedure when it is invoked. A parameter list is optional.

A field procedure cannot be defined for a column that is a ROWID or DATALINK or a distinct type based on a ROWID or DATALINK. The column must not be an identity column, a row change timestamp column, a row-begin column, a row-end column, a transaction-start-ID column, or a generated expression column. The column must not have a default value of CURRENT DATE, CURRENT TIME, CURRENT TIMESTAMP, or USER. The column cannot be referenced in a check condition. If it is part of a foreign key, the corresponding parent key column must use the same field procedure. See Embedded SQL programming topic collection for an example of a field procedure.

**NOT NULL**

Prevents the column from containing null values. Omission of NOT NULL implies that the column can be null. NOT NULL is required for a row change timestamp column, a row-begin column, and a row-end column.

**NOT HIDDEN**

Indicates the column is included in implicit references to the table in SQL statements. This is the default.

**IMPLICITLY HIDDEN**

Indicates the column is not visible in SQL statements unless it is referred to
DECLARE GLOBAL TEMPORARY TABLE

explicitly by name. For example, SELECT * does not include any hidden
columns in the result. A table must contain at least one column that is not
IMPICITLY HIDDEN.

datalink-options
Specifies the options associated with a DATALINK data type.

LINKTYPE URL
Defines the type of link as a Uniform Resource Locator (URL).

NO LINK CONTROL
Specifies that there will not be any check made to determine that the
linked files exist. Only the syntax of the URL will be checked. There is no
database manager control over the linked files.

period-definition

PERIOD FOR
Defines a period for the table.

SYSTEM_TIME (begin-column-name, end-column-name)
Defines a system period with the name SYSTEM_TIME. There must not be
a column in the table with the name SYSTEM_TIME. A table can have only
one SYSTEM_TIME period.

begin-column-name
Identifies the column that records the beginning of the period of time in
which a row is valid. The name must identify a column that exists in the
table. begin-column-name must not be the same as end-column-name.
begin-column-name must be defined as AS ROW BEGIN.

end-column-name
Identifies the column that records the end of the period of time in which a
row is valid. In the history table that is associated with a system-period
temporal table, the history table column that corresponds to
end-column-name in the system-period temporal table is set to reflect the
deletion of the row. The name must identify a column that exists in the
table. end-column-name must be defined as AS ROW END.

LIKE

table-name or view-name
Specifies that the columns defined in the specified table or view are included
in this table. The table-name or view-name specified in a LIKE clause must
identify the table or view that already exists at the application server.

The use of LIKE is an implicit definition of n columns, where n is the number
of columns in the identified table or view. The implicit definition includes the
following attributes of the n columns (if applicable to the data type):
• Column name (and system column name)
• Data type, length, precision, and scale
• CCSID

If the LIKE clause is specified immediately following the table-name and not
enclosed in parenthesis, the following column attributes are also included,
otherwise they are not included (the default value, identity, row change
timestamp, and hidden attributes can also be controlled by using the
copy-options):
• Default value, if a table-name is specified (view-name is not specified)
• Identity attributes
• Nullability
• Hidden attributes
• Row change timestamp attribute
• Column heading and text (see "LABEL" on page 1463)

If table-name contains a row change timestamp column, row-begin column,
row-end column, transaction-start-ID column, or generated expression column,
the corresponding column of the new table inherits only the data type of the
source column. The new column is not considered a generated column.

If the specified table or view is a non-SQL created physical file or logical file,
any non-SQL attributes are removed. For example, the date and time format
will be changed to ISO.

The implicit definition does not include any other optional attributes of the
identified table or view. For example, the new table does not automatically
include a primary key or foreign key from a table. The new table has these and
other optional attributes only if the optional clauses are explicitly specified.

**as-result-table**

column-name

Names a column of the table. Do not qualify column-name and do not use the
same name for more than one column of the table or for a
system-column-name of the table.

FOR COLUMN system-column-name

Provides an IBM i name for the column. Do not use the same name for more
than one column of the table or for a column-name of the table.

If the system-column-name is not specified, and the column-name is not a
valid system-column-name, a system column name is generated. For more
information about how system column names are generated, see "Rules for
Column Name Generation" on page 1213.

**select-statement**

Specifies that the columns of the table are to have the same name and
description as the columns that would appear in the derived result table of the
select-statement if the select-statement were to be executed. The use of AS
select-statement is an implicit definition of n columns for the table, where n is
the number of columns that would result from the select-statement. The implicit
definition includes the following attributes of the n columns (if applicable to
the data type):
• Column name (and system column name)
• Data type, length, precision, and scale
• CCSID
• Nullability
• Column heading and text (see "LABEL" on page 1463)

The following attributes are not included (some attributes can be included by
using the copy-options):
• Default value
• Hidden attribute
• Identity attributes
• Row change timestamp attribute
• Row-begin, row-end, and transaction-start-ID attribute
• Generated expression attribute

The implicit definition does not include any other optional attributes of the tables or views referenced in the select-statement.

The implicitly defined columns of the table inherit the names of the columns from the result table of the select-statement. Therefore, a column name must be specified in the select-statement or in the column name list for all result columns. For result columns that are derived from expressions, constants, and functions, the select-statement must include the AS column-name clause immediately after the result column or a name must be specified in the column list preceding the select-statement.

The select-statement must not refer to variables or include parameter markers (question marks). The select-statement must not contain a PREVIOUS VALUE or a NEXT VALUE expression. The UPDATE, SKIP LOCKED DATA, and USE AND KEEP EXCLUSIVE LOCKS clauses may not be specified.

If the select-statement contains an isolation-clause the isolation level specified in the isolation-clause applies to the entire SQL statement.

**WITH DATA**

Specifies that the select-statement is executed. After the table is created, the result table rows of the select-statement are automatically inserted into the table.

**WITH NO DATA**

Specifies that the select-statement is not executed. Therefore, there is no result table with a set of rows with which to automatically populate the table.

**copy-options**

**INCLUDING IDENTITY COLUMN ATTRIBUTES or EXCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies whether identity column attributes are inherited.

**INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that the table inherits the identity attribute, if any, of the columns resulting from select-statement, table-name, or view-name. In general, the identity attribute is copied if the element of the corresponding column in the table, view, or select-statement is the name of a table column or the name of a view column that directly or indirectly maps to the name of a base table column with the identity attribute. If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS select-statement clause, the columns of the new table do not inherit the identity attribute in the following cases:

• The select list of the select-statement includes multiple instances of an identity column name (that is, selecting the same column more than once).

• The select list of the select-statement includes multiple identity columns (that is, a join returned more than one identity column).

• The identity column is included in an expression in the select list.

• The select-statement includes a set operation (UNION or INTERSECT).

If INCLUDING IDENTITY is not specified, the table will not have an identity column.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that the table does not inherit the identity attribute, if any, of the columns resulting from the fullselect, table-name, or view-name.
EXCLUDING COLUMN DEFAULTS or INCLUDING COLUMN DEFAULTS or USING TYPE DEFAULTS

Specifies whether column defaults are inherited.

EXCLUDING COLUMN DEFAULTS

Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on INSERT for the new table.

INCLUDING COLUMN DEFAULTS

Specifies that the table inherits the default values of the columns resulting from the select-statement, table-name, or view-name. A default value is the value assigned to a column when a value is not specified on an INSERT.

Do not specify INCLUDING COLUMN DEFAULTS, if you specify USING TYPE DEFAULTS.

If INCLUDING COLUMN DEFAULTS is not specified, the default values are not inherited.

USING TYPE DEFAULTS

Specifies that the default values for the table depend on the data type of the columns that result from the select-statement, table-name, or view-name. If the column is nullable, then the default value is the null value. Otherwise, the default value is as follows:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character or graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string length of 0</td>
</tr>
<tr>
<td>Date</td>
<td>The current date at the time of INSERT</td>
</tr>
<tr>
<td>Time</td>
<td>The current time at the time of INSERT</td>
</tr>
<tr>
<td>Timestamp</td>
<td>The current timestamp at the time of INSERT</td>
</tr>
<tr>
<td>Datalink</td>
<td>A value corresponding to DLVALUE(,’URL’,”)</td>
</tr>
<tr>
<td>distinct-type</td>
<td>The default value of the corresponding source type of the distinct type.</td>
</tr>
</tbody>
</table>

Do not specify USING TYPE DEFAULTS if INCLUDING COLUMN DEFAULTS is specified.

INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES or EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies whether implicitly hidden columns are inherited.

INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES

Specifies that the table inherits implicitly hidden columns from select-statement, table-name, or view-name and those columns will be defined with the implicitly hidden attribute in the new table.

If INCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES is not specified, the table will not have any implicitly hidden columns.
EXCLUDING IMPLICITLY HIDDEN COLUMN ATTRIBUTES
Specifies that the table does not inherit implicitly hidden columns from the
fullselect, table-name, or view-name.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or EXCLUDING ROW CHANGE
TIMESTAMP COLUMN ATTRIBUTES
Specifies whether the row change timestamp attribute is inherited.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES
Specifies that the table inherits the row change timestamp attribute, if any,
of the columns resulting from select-statement, table-name, or view-name. In
general, the row change timestamp attribute is copied if the element of the
corresponding column in the table, view, or select-statement is the name of a
table column or the name of a view column that directly or indirectly maps
to the name of a base table column with the row change timestamp
attribute. If the INCLUDING ROW CHANGE TIMESTAMP COLUMN
ATTRIBUTES clause is specified with the AS select-statement clause, the
columns of the new table do not inherit the row change timestamp in the
following cases:

- The select list of the select-statement includes multiple instances of a row
  change timestamp column name (that is, selecting the same column
  more than once).
- The select list of the select-statement includes multiple row change
  timestamp columns (that is, a join returned more than one row change
  timestamp column).
- The row change timestamp column is included in an expression in the
  select list.
- The select-statement includes a set operation (UNION or INTERSECT).

If INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES is
not specified, the table will not have a row change timestamp column.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES
Specifies that the table does not inherit the row change timestamp
attribute, if any, of the columns resulting from the fullselect, table-name, or
view-name.

WITH REPLACE
Specifies that, in the case that a declared temporary table already exists with
the specified name, the existing table is replaced with the temporary table
defined by this statement (and all rows of the existing table are deleted).

When WITH REPLACE is not specified, then the name specified must not
identify a declared temporary table that already exists in the current session.

ON COMMIT
Specifies the action taken on the declared temporary table when a COMMIT
operation is performed. The default is DELETE ROWS.

The ON COMMIT clause does not apply if the declared temporary table is
opened under isolation level No Commit (NC) or if a COMMIT HOLD
operation is performed.

DELETE ROWS
All rows of the table will be deleted if no WITH HOLD cursor is open on
the table.

PRESERVE ROWS
Rows of the table will be preserved.
DECLARE GLOBAL TEMPORARY TABLE

NOT LOGGED
Changes to the table are not logged, including creation of the table. When a ROLLBACK (or ROLLBACK TO SAVEPOINT) operation is performed and the table was changed in the unit of work (or savepoint), the changes are not rolled back. If the table was created in the unit of work (or savepoint), then that table will be dropped. If the table was dropped in the unit of work (or savepoint) then the table will be restored, but with no rows.

ON ROLLBACK
Specifies the action taken on the declared temporary table when a ROLLBACK operation is performed.

The ON ROLLBACK clause does not apply if the declared temporary table was opened under isolation level No Commit (NC) or if a ROLLBACK HOLD operation is performed.

DELETE ROWS
All rows of the table will be deleted. This is the default.

PRESERVE ROWS
Rows of the table will be preserved.

RCDFMT format-name
An unqualified name that designates the IBM i record format name of the table. A format-name is a system identifier.

If a record format name is not specified, the format-name is the same as the system-object-name of the table.

media-preference
Specifies the preferred storage media for the table.

UNIT ANY
No storage media is preferred. Storage for the table will be allocated from any available storage media.

UNIT SSD
Solid state disk storage media is preferred. Storage for the table may be allocated from solid state disk storage media, if available.

KEEP IN MEMORY
Specifies whether the data for the table should be brought into a main storage pool when the data is used in a query.

NO The data will not be brought into a main storage pool.

YES
The data will be brought into a main storage pool.

Notes

Instantiation, scope, and termination: Let P denote an application process and let T be a declared temporary table in an application program in P:

• When a program in P issues a DECLARE GLOBAL TEMPORARY TABLE statement, an empty instance of T is created.

• Any program in P can reference T, and any of those references is a reference to that same instance of T. (If a DECLARE GLOBAL TEMPORARY statement is specified within a compound statement of an SQL function, SQL procedure, or trigger; the scope of the declared temporary table is the application process and not the compound statement.)
If T was declared at a remote server, the reference to T must use the same
connection that was used to declare T and that connection must not have been
terminated after T was declared. When the connection to the database server at
which T was declared terminates, T is dropped.

- If T is defined with the ON COMMIT DELETE ROWS clause, when a commit
operation terminates a unit of work in P and no program in P has a WITH
HOLD cursor open that is dependent on T, all rows are deleted.
- If T is defined with the ON ROLLBACK DELETE ROWS clause, when a rollback
operation terminates a unit of work in P, all rows are deleted.
- When the application process that declared T terminates, T is dropped.

Temporary table ownership: The owner of the table is the user profile of the thread
executing the statement.

Temporary table authority: When a declared temporary table is defined, PUBLIC
implicitly is granted all table privileges on the table and authority to drop the
table.

Referring to a declared temporary table in other SQL statements: Many SQL
statements support declared temporary tables. To refer to a declared temporary
table in an SQL statement other than DECLARE GLOBAL TEMPORARY TABLE,
the table must be implicitly or explicitly qualified with SESSION.

If you use SESSION as the qualifier for a table name but the application process
does not include a DECLARE GLOBAL TEMPORARY TABLE statement for the
table name, the database manager assumes that you are not referring to a declared
temporary table. The database manager resolves such table references to a
permanent table.

Restrictions on the use of declared temporary tables:
- Declared temporary tables cannot be specified in an ALTER TABLE, COMMENT,
CREATE ALIAS, GRANT, LABEL, LOCK, RENAME, or REVOKE statement.
- Declared temporary tables cannot be specified as the parent table in referential
constraints
- If a declared temporary table is referenced in a CREATE INDEX or CREATE
VIEW statement, the index or view must be created in SESSION (or library
QTEMP).

Creating a table using a remote select-statement: The select-statement for an
as-result-table can refer to tables on a different server than where the table is being
created. This can be done by using a three-part object name or an alias that is
defined to reference a three-part name of a table or view. The result of the
select-statement cannot contain a column that has a field procedure defined. If the
remote server is Db2 for LUW or Db2 for z/OS, copy-options are not allowed. If the
remote server is Db2 for LUW, a column list should be explicitly specified before
the AS keyword.

Syntax alternatives: The following keywords are synonyms supported for
compatibility to prior releases. These keywords are non-standard and should not
be used:

- INLINE LENGTH is a synonym for ALLOCATE.
- DEFINITION ONLY is a synonym for WITH NO DATA
Examples

Example 1: Define a declared temporary table with column definitions for an employee number, salary, commission, and bonus.

```sql
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
(EMPNO CHAR(6) NOT NULL,
SALARY DECIMAL(9, 2),
BONUS DECIMAL(9, 2),
COMM DECIMAL(9, 2))
ON COMMIT PRESERVE ROWS
```

Example 2: Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

```sql
DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
LIKE USER1.EMPTAB
INCLUDING IDENTITY
ON COMMIT PRESERVE ROWS
```

In the above example, the database manager uses SESSION as the implicit qualifier for TEMPTAB1.
The DECLARE PROCEDURE statement defines an external procedure.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in REXX.

Authorization

None.

Syntax

```

Description

procedure-name

Names the procedure. The name must not be the same as the name of another procedure declared in your source program.

(parameter-declaration,...)

Specifies the number of parameters of the procedure and the data type of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. Although not required, you can give each parameter a name.

The maximum number of parameters allowed in CREATE PROCEDURE depends on the type of language and the parameter style:

- For JAVA and ILE programs and service programs, the maximum is 2000.
- For OPM programs and REXX,
  - If PARAMETER STYLE GENERAL is specified the maximum is 255.
  - If PARAMETER STYLE GENERAL WITH NULLS is specified the maximum is 254.
  - If PARAMETER STYLE SQL is specified the maximum is 254.

The maximum number of parameters can be further limited by the maximum number of parameters allowed by the language.

IN

Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned. 101

OUT

Identifies the parameter as an output parameter that is returned by the procedure.

A DataLink or a distinct type based on a DataLink may not be specified as an output parameter.

INOUT

Identifies the parameter as both an input and output parameter for the procedure.

A DataLink or a distinct type based on a DataLink may not be specified as an input and output parameter.

parameter-name

Names the parameter. The name cannot be the same as any other parameter-name for the procedure.

data-type

Specifies the data type of the parameter.

The data type must be valid for the language specified in the language clause. All data types are valid for SQL procedures. DataLinks are not

---

101. When the language type is REXX, all parameters must be input parameters.
valid for external procedures. For more information about data types, see "CREATE TABLE" on page 1159, and the SQL Programming topic collection.

If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the procedure. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the procedure is called.

Any parameter that has an XML type must specify the XML-cast-type clause.

**AS LOCATOR**
Specifies that the parameter is a locator to the value rather than the actual value. You can specify AS LOCATOR only if the parameter has a LOB or XML data type or a distinct type based on a LOB or XML data type. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

**AS XML-cast-type**
Specifies the data type passed to the procedure for a parameter that is XML type or a distinct type based on XML type. If LOCATOR is specified, the parameter is a locator to the value rather than the actual value.

If a CCSID value is specified, only Unicode CCSID values can be specified for graphic data types. If a CCSID value is not specified, the CCSID is established at the time the containing program, module, or service program is created according to the SQL_XML_DATA_CCSID_QAQINI option setting. The default CCSID is 1208. See “XML Values” on page 89 for a description of this option.

**DYNAMIC RESULT SETS** integer
Specifies the maximum number of result sets that can be returned from the procedure. integer must be greater than or equal to zero and less than 32768. If zero is specified, no result sets are returned. If the SET RESULT SETS statement is issued, the number of results returned is the minimum of the number of result sets specified on this keyword and the SET RESULT SETS statement.

For more information about result sets, see “SET RESULT SETS” on page 1598.

**LANGUAGE**
Specifies the language that the external program is written in. The language clause is required if the external program is a REXX procedure.

If LANGUAGE is not specified, the LANGUAGE is determined from the program attribute information associated with the external program. If the program attribute information associated with the program does not identify a recognizable language, then the language is assumed to be C.

**C**
The external program is written in C.

**C++**
The external program is written in C++.

**CL**
The external program is written in CL.

**COBOL**
The external program is written in COBOL.
The external program is written in ILE COBOL.

JAVA
The external program is written in JAVA.

PLI
The external program is written in PL/I.

REXX
The external program is a REXX procedure.

RPG
The external program is written in RPG.

RPGLE
The external program is written in ILE RPG.

PARAMETER STYLE
Specifies the conventions used for passing parameters to and returning the values from procedures:

SQL
Specifies that in addition to the parameters on the CALL statement, several additional parameters are passed to the procedure. The parameters are defined to be in the following order:

- The first N parameters are the parameters that are specified on the DECLARE PROCEDURE statement.
- N parameters for indicator variables for the parameters.
- A CHAR(5) output parameter for SQLSTATE. The SQLSTATE returned indicates the success or failure of the procedure. The SQLSTATE returned is assigned by the external program. The user may set the SQLSTATE to any valid value in the external program to return an error or warning from the function.
- A VARCHAR(517) input parameter for the fully qualified procedure name.
- A VARCHAR(128) input parameter for the specific name.
- A VARCHAR(1000) output parameter for the message text.

The following additional parameter may be passed as the last parameter:

- A parameter for the dbinfo structure, if DBINFO was specified on the CREATE PROCEDURE statement.

These parameters are passed according to the specified LANGUAGE. For example, if the language is C or C++, the VARCHAR parameters are passed as NUL-terminated strings. For more information about the parameters passed, see the include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

PARAMETER STYLE SQL cannot be used with LANGUAGE JAVA.

DB2GENERAL
Specifies that the procedure will use a parameter passing convention that is defined for use with Java methods.

PARAMETER STYLE DB2GENERAL can only be specified with LANGUAGE JAVA. For details on passing parameters in JAVA, see the IBM Developer Kit for Java topic collection.
DECLARE PROCEDURE

GENERAL
Specifies that the procedure will use a parameter passing mechanism where the procedure receives the parameters specified on the CALL. Additional arguments are not passed for indicator variables.

PARAMETER STYLE GENERAL cannot be used with LANGUAGE JAVA.

GENERAL WITH NULLS
 Specifies that in addition to the parameters on the CALL statement as specified in GENERAL, another argument is passed to the procedure. This additional argument contains an indicator array with an element for each of the parameters of the CALL statement. In C, this would be an array of short INTs. For more information about how the indicators are handled, see the SQL Programming topic collection.

PARAMETER STYLE GENERAL WITH NULLS cannot be used with LANGUAGE JAVA.

JAVA
Specifies that the procedure will use a parameter passing convention that conforms to the Java language and SQLJ Routines specification. INOUT and OUT parameters will be passed as single entry arrays to facilitate returning values. For increased portability, you should write Java procedures that use the PARAMETER STYLE JAVA conventions.

PARAMETER STYLE JAVA can only be specified with LANGUAGE JAVA. For details on passing parameters in JAVA, see the IBM Developer Kit for Java topic collection.

Note that the language of the external function determines how the parameters are passed. For example, in C, any VARCHAR or CHAR parameters are passed as NULL-terminated strings. For more information, see SQL Programming. For Java routines, see IBM Developer Kit for Java.

SPECIFIC specific-name
Specifies a qualified or unqualified name that uniquely identifies the procedure. The specific-name, including the implicit or explicit qualifier, must be the same as the procedure-name.

If no qualifier is specified, the implicit or explicit qualifier of the procedure-name is used. If a qualifier is specified, the qualifier must be the same as the explicit or implicit qualifier of the procedure-name.

If specific-name is not specified, it is the same as the procedure name.

DETERMINISTIC or NOT DETERMINISTIC
Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

NOT DETERMINISTIC
The procedure may not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

DETERMINISTIC
The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, provided the referenced data in the database has not changed.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL
Specifies which SQL statements, if any, may be executed in the procedure or any routine called from this procedure. The default is MODIFIES SQL DATA.
See Appendix B, “Characteristics of SQL statements,” on page 1725 for a detailed list of the SQL statements that can be executed under each data access indication.

MODIFIES SQL DATA
Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA
Specifies that SQL statements that do not modify SQL data can be included in the procedure.

CONTAINS SQL
Specifies that SQL statements that neither read nor modify SQL data can be executed by the procedure.

NO SQL
Specifies that the procedure cannot execute any SQL statements.

CALLED ON NULL INPUT
Specifies that the function is to be invoked, if any, or all, argument values are null, making the function responsible for testing for null argument values. The function can return a null or nonnull value.

FENCED or NOT FENCED
This parameter is allowed for compatibility with other products and is not used by Db2 for i.

PROGRAM TYPE MAIN or PROGRAM TYPE SUB
This parameter is allowed for compatibility with other products. It indicates whether the routine’s external program is a program (*PGM) or a procedure in a service program (*SRVPGM).

PROGRAM TYPE MAIN
Specifies that the routine executes as the main entry point in a program. The external program must be a *PGM object.

PROGRAM TYPE SUB
Specifies that the procedure executes as a procedure in a service program. The external program must be a *SRVPGM object.

DBINFO
Specifies that the database manager should pass a structure containing status information to the procedure. Table 85 contains a description of the DBINFO structure. Detailed information about the DBINFO structure can be found in include sqludf in the appropriate source file in library QSYSINC. For example, for C, sqludf can be found in QSYSINC/H.

DBINFO is only allowed with PARAMETER STYLE DB2SQL.

Table 85. DBINFO fields

</tr>
</tbody>
</table>

**EXTERNAL NAME external-program-name**

Specifies the program that will be executed when the procedure is called by the CALL statement. The program name must identify a program that exists at the application server. The program cannot be an ILE service program.

The validity of the name is checked at the application server. If the format of the name is not correct, an error is returned.

If external-program-name is not specified, the external program name is assumed to be the same as the procedure name.

**Notes**

**DECLARE PROCEDURE scope:** The scope of the procedure-name is the source program in which it is defined; that is, the program submitted to the precompiler. Thus, a program called from another separately compiled program or module will not use the attributes from a DECLARE PROCEDURE statement in the calling program.

**DECLARE PROCEDURE rules:** The DECLARE PROCEDURE statement should precede all CALL statements that reference that procedure.
The DECLARE PROCEDURE statement only applies to static CALL statements. It does not apply to any dynamically prepared CALL statements or a CALL statement where the procedure name is identified by a variable.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL can be used as synonyms for CALLED ON NULL INPUT.
- The keywords SIMPLE CALL can be used as a synonym for GENERAL.
- The value DB2GENRL may be used as a synonym for DB2GENERAL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords PARAMETER STYLE DB2SQL can be used as a synonym for PARAMETER STYLE SQL.

**Example**

Declare an external procedure PROC1 in a C program. When the procedure is called using the CALL statement, a COBOL program named PGM1 in library LIB1 will be called.

```
EXEC SQL
  DECLARE PROC1 PROCEDURE
  (CHAR(10), CHAR(10))
  EXTERNAL NAME LIB1.PGM1
  LANGUAGE COBOL GENERAL;

EXEC SQL
  CALL PROC1 ('FIRSTNAME ','LASTNAME ');
```
DECLARE STATEMENT

The DECLARE STATEMENT statement is used for program documentation. It declares names that are used to identify prepared SQL statements.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. This statement is not allowed in Java or REXX.

Authorization

None required.

Syntax

```
DECLARE statement-name STATEMENT
```

Description

`statement-name`

Lists one or more names that are used in your program to identify prepared SQL statements.

Example

This example shows the use of the DECLARE STATEMENT statement in a C program.

```c
EXEC SQL INCLUDE SQLDA;
void main ()
{
  EXEC SQL BEGIN DECLARE SECTION ;
  char src_stmt[32000];
  char sqlda[32000]
  EXEC SQL END DECLARE SECTION ;
  EXEC SQL INCLUDE SQLCA ;

  strcpy(src_stmt,"SELECT DEPTNO, DEPTNAME, MGRNO \ 
    FROM DEPARTMENT \ 
    WHERE ADMRDEPT = 'A00' ");

  EXEC SQL DECLARE OBJ_STMT STATEMENT;

  (Allocate storage from SQLDA)
  EXEC SQL DECLARE C1 CURSOR FOR OBJ_STMT;

  EXEC SQL PREPARE OBJ_STMT FROM :src_stmt;
  EXEC SQL DESCRIBE OBJ_STMT INTO :sqlda;

  (Examine SQLDA) (Set SQLDATA pointer addresses)

  EXEC SQL OPEN C1;

  while (strncmp(SQLSTATE, "00000", 5) )
  {
    EXEC SQL FETCH C1 USING DESCRIPTOR :sqlda;
```
DECLARE STATEMENT

(Print results)

}

EXEC SQL CLOSE C1;
return;
}

DECLARE VARIABLE

The DECLARE VARIABLE statement is used to assign a subtype or CCSID other than the default to a host variable.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

```
DECLARE variable FOR SBCS DATA
FOR MIXED DATA
CCSID integer
FOR BIT DATA
DATE
TIME
TIMESTAMP
```

Description

`host-variable`

Names a character, graphic, or XML string host variable defined in the program. An indicator variable cannot be specified for the host-variable. The host-variable definition may either precede or follow a DECLARE VARIABLE statement that refers to that variable.

FOR BIT DATA

Specifies that the values of the host-variable are not associated with a coded character set and, therefore, are never converted. The CCSID of a FOR BIT DATA host variable is 65535. FOR BIT DATA cannot be specified for graphic or XML host-variables.

FOR SBCS DATA

Specifies that the values of the host variable contain SBCS (single-byte character set) data. FOR SBCS DATA is the default if the CCSID attribute of the job at the application requester is not DBCS-capable or if the length of the host variable is less than 4. The CCSID of FOR SBCS DATA is determined by the CCSID attribute of the job at the application requester. FOR SBCS DATA cannot be specified for graphic or XML host-variables.

FOR MIXED DATA

Specifies that the values of the host variable contain both SBCS data and DBCS data. FOR MIXED DATA is the default if the CCSID attribute of the job at the application requester is DBCS-capable and the length of the host variable is greater than 3. The CCSID of FOR DBCS DATA is determined by the CCSID attribute of the job at the application requester. FOR MIXED DATA cannot be specified for graphic or XML host-variables.
CCSID  integer
Specifies that the values of the host variable contain data of CCSID integer. If
the integer is an SBCS CCSID, the host variable is SBCS data. If the integer is a
mixed data CCSID, the host variable is mixed data. For character host
variables, the CCSID specified must be an SBCS or mixed CCSID.

If the variable has a graphic string data type, the CCSID specified must be a
DBCS, UTF-16, or UCS-2 CCSID. For a list of valid CCSIDs, see Appendix E,
“CCSID values,” on page 1765. Consider specifying CCSID 1200 or 13488 to
indicate UTF-16 or UCS-2 data. If a CCSID is not specified, the CCSID of the
graphic string variable will be the associated DBCS CCSID for the job.

If the variable has an XML data type, the CCSID specified must be an SBCS,
mixed, or Unicode CCSID. The CCSID must be compatible with the XML AS
datatype. If a CCSID is not specified, the CCSID value as specified by the
SQL_XML_DATA_CCSID_QAAQIN setting is used. See “XML Values” on
page 89 for more information.

For file reference variables, the CCSID specifies the CCSID of the path and file
name, not the data within the file.

DATE
Specifies that the values of the host variable contain data that is a date.

TIME
Specifies that the values of the host variable contain data that is a time.

TIMESTAMP
Specifies that the values of the host variable contain data that is a timestamp.

Notes

Placement restrictions: The DECLARE VARIABLE statement can be specified
anywhere in an application program that SQL statements are valid with the
following exceptions:

- If the host language is COBOL or RPG, the DECLARE VARIABLE statement
  must occur before an SQL statement that refers to a host variable specified in the
  DECLARE VARIABLE statement.
- If DATE, TIME, or TIMESTAMP is specified for a NUL-terminated character
  string in C, the length of the C declaration will be reduced by one.

Precompiler rules: The following situations result in an error message during
precompile:

- A reference is made to a variable that does not exist.
- A reference is made to a numeric variable.
- A reference is made to a variable that has been referred to already.
- A reference is made to a variable that is not unique.
- A reference is made to an ILE RPG variable that is defined as UCS-2.
- A reference is made to an ILE COBOL variable that is defined as NATIONAL.
- The DECLARE VARIABLE statement occurs after an SQL statement where the
  SQL statement and the DECLARE VARIABLE statement refer to the same
  variable.
- The FOR BIT DATA, FOR SBCS DATA, or FOR MIXED DATA clause is specified
  for a graphic or XML host variable.
- A SBCS or mixed CCSID is specified for a graphic host variable.
- A DBCS, UTF-16, or UCS-2 CCSID is specified for a character host variable.
• A DBCS CCSID is specified for an XML host variable.
• DATE, TIME, or TIMESTAMP is specified for a host variable that is not character.
• The length of a host variable used for DATE, TIME, or TIMESTAMP is not long enough for the minimum date, time, or timestamp value.

**Example**

In this example, declare C program variables *fred* and *pete* as mixed data, and *jean* and *dave* as SBCS data with CCSID 37.

```c
void main ()
{
    EXEC SQL BEGIN DECLARE SECTION;
    char fred[10];
    EXEC SQL DECLARE :fred VARIABLE FOR MIXED DATA;

decimal(6,0) mary;
    char pete[4];
    EXEC SQL DECLARE :pete VARIABLE FOR MIXED DATA;

    char jean[30];
    char dave[9];
    EXEC SQL DECLARE :jean, :dave VARIABLE CCSID 37;
    EXEC SQL END DECLARE SECTION;
    EXEC SQL INCLUDE SQLCA;

    ...
}
```
DELETE

The DELETE statement deletes rows from a table or view. Deleting a row from a view deletes the row from the table on which the view is based if no INSTEAD OF DELETE trigger is defined for this view. If such a trigger is defined, the trigger will be activated instead.

There are two forms of this statement:
- The Searched DELETE form is used to delete one or more rows (optionally determined by a search condition).
- The Positioned DELETE form is used to delete exactly one row (as determined by the current position of a cursor).

Invocation

A Searched DELETE statement can be embedded in an application program or issued interactively. A Positioned DELETE must be embedded in an application program. Both forms are executable statements that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:
- For the table or view identified in the statement:
  - The DELETE privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

If the search-condition in a Searched DELETE contains a reference to a column of the table or view, then the privileges held by the authorization ID of the statement must also include one of the following:
- The SELECT privilege on the table or view
- Database administrator authority

If search-condition includes a subquery, the privileges held by the authorization ID of the statement must also include at least one of the following:
- For each table or view identified in the subquery:
  - The SELECT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.

Syntax

Searched DELETE:

```sql
DELETE FROM table-name [view-name] correlation-clause
```
DELETE

WHERE—search-condition

order-by-clause [offset-clause] [fetch-clause]

(1)

-isolation-clause—concurrent-access-resolution-clause

Notes:
1. The same clause must not be specified more than once.

Positioned DELETE:

DELETE FROM table-name
 view-name [correlation-clause]

WHERE CURRENT OF cursor-name

order-by-clause:

ORDER BY sort-key-expression ASC DESC

isolation-clause:

WITH NC UR CS RS RR

Description

FROM table-name or view-name

Identifies the table or view from which rows are to be deleted. The name must identify a table or view that exists at the current server, but it must not identify a catalog table, a view of a catalog table, or a view that is not deletable. For an explanation of deletable views, see “CREATE VIEW” on page 1255.

correlation-clause

Specifies an alternate name that can be used within the search-condition to designate the table or view. For an explanation of correlation-clause, see Chapter 6, “Queries,” on page 741. For an explanation of correlation-name, see “Correlation names” on page 143.
WHERE
Specifies the rows to be deleted. The clause can be omitted, or a search-condition or cursor-name can be specified. If the clause is omitted, all rows of the table or view are deleted.

search-condition
Is any search condition as described in "Search conditions" on page 249. Each column-name in the search-condition, other than in a subquery, must identify a column of the table or view.

The search-condition is applied to each row of the table or view and the deleted rows are those for which the result of the search-condition is true.

If the search-condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references may be executed only once, whereas a subquery with a correlated reference may have to be executed once for each row.

If a subquery refers to the object table of the DELETE statement or a dependent table with a delete rule of CASCADE, SET NULL, or SET DEFAULT, the subquery is completely evaluated before any rows are deleted.

CURRENT OF cursor-name
Identifies the cursor to be used in the delete operation. The cursor-name must identify a declared cursor as explained in the Notes for the DECLARE CURSOR statement.

The table or view identified must also be specified in the FROM clause of the select-statement of the cursor and the cursor must be deletable. For an explanation of deletable cursors, see "DECLARE CURSOR" on page 1265.

The DECLARE CURSOR statement must not have a period-specification for the table or view used by the delete statement.

When the DELETE statement is executed, the cursor must be positioned on a row; that row is the one deleted. After the deletion, the cursor is positioned before the next row of its result table. If there is no next row, the cursor is positioned after the last row.

order-by-clause
Specifies the order of the rows for application of the offset-clause and fetch-clause. An order-by-clause should be specified to ensure a predictable order for determining the set of rows to be deleted based on the offset-clause and fetch-clause.

current-key-expression
An expression that specifies the value that is to be used to order the rows that qualify for the delete operation. If a single sort-key-expression is identified, the rows are ordered by the values of that sort-key-expression. If more than one sort-key-expression is identified, the rows are ordered by the values of the first sort-key-expression, then by the values of the second sort-key-expression, and so on.

The result of the sort-key-expression must not be DATALINK or XML.

ASC
Uses the values of the sort-key-expression in ascending order. This is the default.
**DELETE**

**DESC**

Uses the values of the *sort-key-expression* in descending order.

Ordering is performed in accordance with the comparison rules described in Chapter 2, “Language elements,” on page 49. The null value is higher than all other values. If your ordering specification does not determine a complete ordering, rows with duplicate values of the last identified *sort-key-expression* have an arbitrary order. If you do not specify ORDER BY, the rows to be deleted have an arbitrary order.

**offset-clause**

Limits the effect of the delete by skipping a subset of the qualifying rows. For more information on the *offset-clause*, see “offset-clause” on page 789.

**fetch-clause**

Limits the effect of the delete to a subset of the qualifying rows. For more information on the *fetch-clause*, see “fetch-clause” on page 790.

**isolation-clause**

Specifies the isolation level to be used for this statement.

**WITH**

Introduces the isolation level, which may be one of:

- RR Repeatable read
- RS Read stability
- CS Cursor stability
- UR Uncommitted read
- NC No commit

If *isolation-clause* is not specified the default isolation is used. For more information on the default isolation, see “isolation-clause” on page 811.

**concurrent-access-resolution-clause**

Specifies the concurrent access resolution to use for the select statement. For more information, see “concurrent-access-resolution-clause” on page 813.

**DELETE Rules**

**Triggers:** If the identified table or the base table of the identified view has a delete trigger, the trigger is activated. A trigger might cause other statements to be executed or return error conditions based on the deleted values.

**Referential Integrity:** If the identified table or the base table of the identified table is a parent table, the rows selected must not have any dependents in a relationship with a delete rule of RESTRICT or NO ACTION, and the DELETE must not cascade to descendent rows that have dependents in a relationship with a delete rule of RESTRICT or NO ACTION.

If the delete operation is not prevented by a RESTRICT or NO ACTION delete rule, the selected rows are deleted. Any rows that are dependents of the selected rows are also affected:

- The nullable columns of the foreign keys of any rows that are their dependents in a relationship with a delete rule of SET NULL are set to the null value.
- Any rows that are their dependents in a relationship with a delete rule of CASCADE are also deleted, and the above rules apply, in turn to those rows.
• The columns of the foreign keys of any rows that are their dependents in a relationship with a delete rule of SET DEFAULT are set to the corresponding default value.

The referential constraints (other than a referential constraint with a RESTRICT delete rule), are effectively checked at the end of the statement. In the case of a multiple-row delete, this would occur after all rows were deleted and any associated triggers were activated.

Check Constraints: A check constraint can prevent the deletion of a row in a parent table when there are dependents in a relationship with a delete rule of SET NULL or SET DEFAULT. If deleting a row in the parent table would cause a column in a dependent table to be set to null or a default value and the null or default value would cause a search condition of a check constraint to evaluate to false, the row is not deleted.

Notes

Delete operation errors: If an error occurs while executing any delete operation, changes from this statement, referential constraints, and any triggered SQL statements are rolled back (unless the isolation level is NC for this statement or any other triggered SQL statements).

Locking: Unless appropriate locks already exist, one or more exclusive locks are acquired during the execution of a successful DELETE statement. Until the locks are released by a commit or rollback operation, the effect of the DELETE operation can only be perceived by:
• The application process that performed the deletion
• Another application process using isolation level UR or NC

The locks can prevent other application processes from performing operations on the table. For further information about locking, see the description of the COMMIT, ROLLBACK, and LOCK TABLE statements, and “Isolation level” on page 27.

If an application process deletes a row on which any of its non-updatable cursors are positioned, those cursors are positioned before the next row of their result table. Let C be a cursor that is positioned before the next row R (as the result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a Searched DELETE). In the presence of INSERT, UPDATE, and DELETE operations that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R’ where R’ is a new row that is now the next row of the result table.

A maximum of 4000000 rows can be deleted or changed in any single DELETE statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) was specified. The number of rows changed includes any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger, a CASCADE, SET NULL, or SET DEFAULT referential integrity delete rule.

Position of cursor: If an application process deletes a row on which any of its cursors are positioned, those cursors are positioned before the next row of their result table. Let C be a cursor that is positioned before row R (as a result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a Searched
DELETE

DELETE). In the presence of INSERT, UPDATE, and DELETE operations that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R’, where R’ is a new row that is now the next row of the result table.

**Number of rows deleted:** When a DELETE statement is completed, the number of rows deleted is returned in the ROW_COUNT condition area item in the SQL Diagnostics Area (or SQLERRD(3) in the SQLCA). The value in the ROW_COUNT item does not include the number of rows that were deleted as a result of a CASCADE delete rule or a trigger.

For a description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),” on page 1737.

**DELETE Performance:** An SQL DELETE statement that does not contain a WHERE clause, offset-clause, or fetch-clause will delete all rows of a table. In this case, the rows may be deleted using either a clear operation (if not running under commitment control) or a change file operation (if running under commitment control). If running under commitment control, the deletes can still be committed or rolled back. This implementation will be much faster than individually deleting each row, but individual journal entries for each row will not be recorded in the journal. This technique will only be used if all the following are true:

- The target table is not a view.
- The target table is not a system-period temporal table.
- A significant number of rows are being deleted.
- The job issuing the DELETE statement does not have an open cursor on the file (not including pseudo-closed SQL cursors).
- No other job has a lock on the table.
- The table does not have an active delete trigger.
- The table is not the parent in a referential constraint with a CASCADE, SET NULL, or SET DEFAULT delete rule.
- The user issuing the DELETE statement has *OBJMGT or *OBJALTER system authority on the table in addition to the DELETE privilege.
- The SQL_FAST_DELETE_ROW_COUNT QAQQINI option allows fast delete.

If this technique is successful, the number of increments (see the SIZE keyword on the CHGPF CL command) is set to zero.

The TRUNCATE statement can be used to delete all rows from a table.

**Referential integrity considerations:** The DB2_ROW_COUNT_SECONDARY condition information item in the SQL Diagnostics Area (or SQLERRD(5) in the SQLCA) shows the number of rows affected by referential constraints. It includes rows that were deleted as the result of a CASCADE delete rule and rows in which foreign keys were set to NULL or the default value as the result of a SET NULL or SET DEFAULT delete rule.

For a description of DB2_ROW_COUNT_SECONDARY, see “GET DIAGNOSTICS” on page 1388. For a description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),” on page 1737.

**Deleting rows in a table for which row access control is enforced:** When a DELETE statement is issued for a table for which row access control is enforced, the rules specified in the enabled row permissions determine whether the row can
be deleted. Typically those rules are based on the authorization ID of the statement. The following describes how enabled row permissions and column masks are used during DELETE:

- Row permissions are used to identify the set of rows to be deleted.
  When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID of the DELETE statement. If the WHERE clause is specified in the DELETE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be deleted. If there is no WHERE clause, all the accessible rows are the rows to be deleted.

**Considerations for a system-period temporal table:** If the DELETE statement has a search condition that contains a correlated subquery that references the history table (explicitly referencing the name of the history table or implicitly referenced through the use of a period specification in the FROM clause), the deleted rows that are stored as historical rows are potentially visible for delete operations for the rows that are subsequently processed for the statement.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the underlying target of the DELETE statement must not be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

**Considerations for a history table:** When a row of a system-period temporal table is deleted, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. The database manager assigns the value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for an end column in a history table across transactions. The timestamp value might be adjusted to ensure that rows inserted into the history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. Otherwise an error is returned.

For a delete operation, the adjustment only affects the value for the end column in the history table that corresponds to the row-end column in the associated system-period temporal table. Take these adjustments into consideration on subsequent references to the table when there is a search for the transaction start time in the row-begin column and row-end column for the SYSTEM_TIME period of the associated system-period temporal table.

When the history table is defined with ON DELETE ADD EXTRA ROW, the version of the row prior to the delete is added to the history table. Values for the row begin, row end, and any generated expression columns are generated when this row is added. This information represents when the row was deleted.
DELETE

REXX: Variables cannot be used in the DELETE statement within a REXX procedure. Instead, the DELETE must be the object of a PREPARE and EXECUTE using parameter markers.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:
- The keyword NONE can be used as a synonym for NC.
- The keyword CHG can be used as a synonym for UR.
- The keyword ALL can be used as a synonym for RS.
- The FROM keyword is optional.

Examples

Example 1: Delete department (DEPTNO) ‘D1’ from the DEPARTMENT table.

```sql
DELETE FROM DEPARTMENT
WHERE DEPTNO = 'D1'
```

Example 2: Delete all the departments from the DEPARTMENT table (that is, empty the table).

```sql
DELETE FROM DEPARTMENT
```

Example 3: Use a Java program statement to delete all the subprojects (MAJPROJ is NULL) from the PROJECT table on the connection context ‘ctx’, for a department (DEPTNO) equal to that in the host variable HOSTDEPT (java.lang.String).

```sql
#sql [ctx] {
  DELETE FROM PROJECT
  WHERE DEPTNO = :HOSTDEPT
  AND MAJPROJ IS NULL
};
```

Example 4: Code a portion of a Java program that will be used to display retired employees (JOB) and then, if requested to do so, remove certain employees from the EMPLOYEE table on the connection context ‘ctx’.

```sql
#sql iterator empIterator implements sqlj.runtime.ForUpdate (...);
empIterator C1;

#sql [ctx] C1 = { SELECT * FROM EMPLOYEE
  WHERE JOB = 'RETIRED' };

#sql { FETCH C1 INTO ... }
while (!C1.endFetch()) {
  System.out.println( ... );
  if ( condition for deleting row ) {
    #sql [ctx] { DELETE FROM EMPLOYEE
      WHERE CURRENT OF C1 };
  }
  #sql { FETCH C1 INTO ... }
}
C1.close();
```
The DESCRIBE statement obtains information about a prepared statement.

For an explanation of prepared statements, see “PREPARE” on page 1494.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

None required. See “PREPARE” on page 1494 for the authorization required to create a prepared statement.

Syntax

```
DESCRIBE OUTPUT statement-name

USING SQL DESCRIPTOR LOCAL SQL-descriptor-name

INTO descriptor-name

USING NAMES SYSTEM NAMES LABELS ANY BOTH ALL
```

Description

- **statement-name**
  - Identifies the prepared statement. When the DESCRIBE statement is executed, the name must identify a prepared statement at the application server.
  - If the prepared statement is a fullselect or VALUES INTO statement, the information returned describes the columns in its result table. If the prepared statement is a CALL statement, the information returned describes the OUT and INOUT parameters of the procedure.

- **USING**
  - Identifies an SQL descriptor.

- **LOCAL**
  - Specifies the scope of the name of the descriptor to be local to program invocation.

- **GLOBAL**
  - Specifies the scope of the name of the descriptor to be global to the SQL session.

- **SQL-descriptor-name**
  - Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.
See "GET DESCRIPTOR" on page 1376 for an explanation of the information that is placed in the SQL descriptor.

**INTO descriptor-name**

Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, "SQLDA (SQL descriptor area),” on page 1747. Before the DESCRIBE statement is executed, the following variable in the SQLDA must be set.

- **SQLN** Indicates the number of SQLVAR entries provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE statement is executed. For information about techniques to determine the number of occurrences requires, see “Determining how many SQLVAR occurrences are needed” on page 1750.

The rules for REXX are different. For more information, see the Embedded SQL Programming topic collection.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

- **SQLDAID**
  The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character).
  
  The seventh byte is set based on the result columns described:
  - If the SQLDA contains two, three, or four SQLVAR entries for every select list item (or, column of the result table), the seventh byte is set to '2', '3', or '4'. This technique is used in order to accommodate LOB or distinct type result columns, labels, and system names.
  - Otherwise, the seventh byte is set to the space character.

  The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all result columns.

  The eighth byte is set to the space character.

- **SQLDABC**
  Length of the SQLDA in bytes.

- **SQLD** If the prepared statement is a SELECT, SQLD is set to the number of columns in its result table plus the number of extended SQLVAR entries. For information about extended SQLVAR entries see, “Field descriptions in an occurrence of SQLVAR” on page 1752. If the prepared statement is a CALL statement, SQLD is set to the number of OUT and INOUT parameters of the procedure. If the prepared statement is a VALUES INTO, SQLD is set to the number of expressions in the VALUES clause plus the number of extended SQLVAR entries. Otherwise, SQLD is set to 0.

- **SQLVAR**
  If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

  If the value of SQLD is n, where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column of the result table (or parameter or expression in the VALUES clause), the second occurrence of SQLVAR contains a description of the second column of the result table (or parameter or expression in the
VALUES clause), and so on. For information about the values assigned to SQLVAR occurrences, see “Field descriptions in an occurrence of SQLVAR” on page 1752.

**USING**

Specifies what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist or if the length of a name is greater than 30, SQLNAME is set to a length of 0.

**NAMES**

Assigns the name of the column (or parameter). This is the default. For the DESCRIBE of a prepared statement where the name is explicitly listed in the select-list, the name specified is returned. The column name returned is case sensitive and without delimiters.

**SYSTEM NAMES**

Assigns the system column name of the column.

**LABELS**

Assigns the label of the column. (Column labels are defined by the LABEL statement.) Only the first 20 bytes of the label are returned.

**ANY**

Assigns the column label. If the column has no label, the column name is used instead.

**BOTH**

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2*n or 3*n (where n is the number of columns in the table or view). The first n occurrences of SQLVAR contain the column names. Either the second or third n occurrences contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

**ALL**

Assigns the label, column name, and system column name. In this case three or four occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 3*n or 4*n (where n is the number of columns in the result table). The first n occurrences of SQLVAR contain the system column names. The second or third n occurrences contain the column labels. The third or fourth n occurrences contain the column names if they are different from the system column name. Otherwise the SQLNAME field is set to a length of zero. If there are no distinct types, the labels are returned in the second set of SQLVAR entries and the column names are returned in the third set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries and the column names are returned in the fourth set of SQLVAR entries.

**Notes**

**PREPARE INTO:** Information about a prepared statement can also be obtained by using the INTO clause of the PREPARE statement.
Allocating the SQL descriptor: Before the DESCRIBE statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of result columns, a warning (SQLSTATE 01005) is returned.

Allocating the SQLDA: In C, COBOL, PL/I, and RPG, before the DESCRIBE or PREPARE INTO statement is executed, enough storage must be allocated for some number of SQLVAR occurrences. SQLN must then be set to the number of SQLVAR occurrences that were allocated. To obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR entries must not be less than the number of columns. Furthermore, if the columns include LOBs or distinct types, the number of occurrences of SQLVAR entries should be two times the number of columns. See “Determining how many SQLVAR occurrences are needed” on page 1750 for more information. Among the possible ways to allocate the SQLDA are the three described below:

First technique

Allocate an SQLDA with enough occurrences of SQLVAR entries to accommodate any select list that the application will have to process. At the extreme, the number of SQLVARs could equal two times the maximum number of columns allowed in a result table. Having done the allocation, the application can use this SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

Second technique

Repeat the following three steps for every processed select list:

1. Execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR entries; that is, an SQLDA for which SQLN is zero. The value returned for SQLD is either the required number of occurrences of SQLVAR entries or the number of result columns. Because there were no SQLVAR entries, a warning will be issued.102

2. If the seventh byte of SQLDAID field is not a blank, then allocate an SQLDA with (the value in the seventh byte of SQLDAID) * SQLD occurrences and set SQLN in the new SQLDA to (the value in the seventh byte of SQLDAID) * SQLD. Otherwise, allocate an SQLDA with SQLD occurrences and set SQLN in the new SQLDA to the value of SQLD.

3. Execute the DESCRIBE statement again, using this new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE statements.

Third technique

Allocate an SQLDA that is large enough to handle most, and perhaps all, select lists but is also reasonably small. If an execution of DESCRIBE fails because the SQLDA is too small, allocate a larger SQLDA and execute DESCRIBE again. For the new SQLDA, use the value of SQLD (or double the value of SQLD) returned from the first execution of DESCRIBE for the number of occurrences of SQLVAR entries.

This technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

---

102. If LOBs or UDTs are not in the result set, the warning is only returned if the standards option is specified. For information about the standards option, see “Standards compliance” on page xi.
Considerations for implicitly hidden columns: A DESCRIBE OUTPUT statement only returns information about implicitly hidden columns if the column (of a base table that is defined as implicitly hidden) is explicitly specified as part of the SELECT list of the final result table of the query described. If implicitly hidden columns are not part of the result table of a query, a DESCRIBE OUTPUT statement that returns information about that query will not contain information about any implicitly hidden columns.

Example

In a C program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR entries. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR entries and then execute a DESCRIBE statement using that SQLDA.

```c
EXEC SQL BEGIN DECLARE SECTION;
    char stmt1_str [200];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
struct sqlda initialsqlda;
struct sqlda *sqldaPtr;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

... /* code to prompt user for a query, then to generate */
/* a select-statement in the stmt1_str */
EXEC SQL PREPARE STMT1_NAME FROM :stmt1_str;

... /* code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL DESCRIBE STMT1_NAME INTO :initialsqlda;

if (initialsqlda.sqld == 0); /* statement is a select-statement */
{
    ... /* Code to allocate correct size SQLDA (sets sqldaPtr) */
    if (strcmp(SQLSTATE,"01005") == 0)
    {
        sqldaPtr->sqln = 2*initialsqlda.sqld;
        SETSQLDOUBLED(sqldaPtr, SQLDOUBLED);
    } else
    {
        sqldaPtr->sqln = initialsqlda.sqld;
        SETSQLDOUBLED(sqldaPtr, SQLSINGLED);
    }
EXEC SQL DESCRIBE STMT1_NAME INTO :sqldaPtr;

    ... /* code to prepare for the use of the SQLDA */
EXEC SQL OPEN DYN_CURSOR;

    ... /* loop to fetch rows from result table */
EXEC SQL FETCH DYN_CURSOR USING DESCRIPTOR :sqldaPtr;

    ... }
...
DESCRIBE CURSOR

The DESCRIBE CURSOR statement gets information about a cursor. The information, such as column information, is put into a descriptor.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

```
DESCRIBE CURSOR cursor-name
    variable
USING SQL DESCRIPTOR LOCAL SQL-descriptor-name
    GLOBAL INTO descriptor-name
```

Description

cursor-name or variable

Identifies a cursor that has already been open or allocated in the source program.

If a variable is specified:
- It must be a character-string variable or Unicode graphic-string. It cannot be a global variable.
- It must not be followed by an indicator variable.
- The cursor name that is contained within the variable must be left-justified and must be padded on the right with blanks if its length is less than that of the variable.
- The name of the cursor must be in uppercase unless the cursor name is a delimited name.

USING

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.
The information returned in the descriptor area describes the columns in the result set associated with the named cursor. After the DESCRIBE CURSOR is executed, the contents of the descriptor area are the same as after a DESCRIBE of a SELECT with the following addition.

- DB2_CURSOR_HOLD can be returned from the GET DESCRIPTOR statement to indicate whether the cursor was declared WITH HOLD in the procedure.

See “GET DESCRIPTOR” on page 1376 for an explanation of the information that is placed in the SQL descriptor.

```
INTO descriptor-name
```

Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, “SQLDA (SQL descriptor area),” on page 1747. Before the DESCRIBE CURSOR statement is executed, the following variable in the SQLDA must be set.

**SQLN** Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE CURSOR statement is executed. For information about techniques to determine the number of occurrences required, see “Determining how many SQLVAR occurrences are needed” on page 1750.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

**SQLDAID**

The first 5 bytes are set to ‘SQLRS’. Bytes 6 to 8 are reserved. If the cursor is declared WITH HOLD in the procedure, the high-order bit of the 8th byte is set to 1.

**SQLDABC**

Length of the SQLDA in bytes.

**SQLD**

The number of columns in the result table plus the number of extended SQLVAR entries. For information about extended SQLVAR entries see, Field descriptions in an occurrence of SQLVAR” on page 1752.

**SQLVAR**

If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is \( n \), where \( n \) is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first \( n \) occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column of the result table, the second occurrence of SQLVAR contains a description of the second column of the result table, and so on. For information about the values assigned to SQLVAR occurrences, see “Field descriptions in an occurrence of SQLVAR” on page 1752.

**Notes**

**Allocating the SQL descriptor:** Before the DESCRIBE CURSOR statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of columns in the cursor result set, a warning (SQLSTATE 01005) is returned.
**Allocating the SQLDA:** Before the DESCRIBE CURSOR statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA and enough storage must be allocated to contain SQLN occurrences. To obtain the description of the columns of the cursor result set, the number of occurrences of SQLVAR must not be less than the number of columns.

For a description of techniques that can be used to allocate the SQLDA, see Appendix D, “SQLDA (SQL descriptor area),” on page 1747.

**Example**

Place information about the result set associated with cursor C1 into an SQL descriptor.

```
EXEC SQL ALLOCATE DESCRIPTOR 'DESCR1';
EXEC SQL DESCRIBE CURSOR C1 USING SQL DESCRIPTOR 'DESCR1';
```
DESCRIBE INPUT

The DESCRIBE INPUT statement obtains information about the IN and INOUT parameter markers of a prepared statement.

For an explanation of prepared statements, see "PREPARE" on page 1494.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

Authorization

None required. See "PREPARE" on page 1494 for the authorization required to create a prepared statement.

Syntax

```
DESCRIBE INPUT statement-name
  USING SQL_DESCRIPTOR LOCAL SQL-descriptor-name INTO descriptor-name
```

Description

**statement-name**

Identifies the prepared statement. When the DESCRIBE INPUT statement is executed, the name must identify a prepared statement at the current server.

**USING**

Identifies an SQL descriptor.

**LOCAL**

Specifies the scope of the name of the descriptor to be local to program invocation.

**GLOBAL**

Specifies the scope of the name of the descriptor to be global to the SQL session.

**SQL-descriptor-name**

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See "GET DESCRIPTOR" on page 1376 for an explanation of the information that is placed in the SQL descriptor.

**INTO descriptor-name**

Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, "SQLDA (SQL descriptor area),” on page 1747. Before the DESCRIBE INPUT statement is executed, the following variable in the SQLDA must be set.

**SQLN**

Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the
DESCRIBE INPUT

DESCRIBE INPUT statement is executed. For information about techniques to determine the number of occurrences requires, see
"Determining how many SQLVAR occurrences are needed” on page 1750.

When the DESCRIBE INPUT statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

**SQLDAID**
The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character). The seventh byte is set based on the parameter markers described:
- If the SQLDA contains two SQLVAR entries for every input parameter marker, the seventh byte is set to '2'. This technique is used in order to accommodate LOB input parameters.
- Otherwise, the seventh byte is set to the space character.

The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all input parameter markers.

The eighth byte is set to the space character.

**SQLDABC**
Length of the SQLDA in bytes.

**SQLD**
The number of input parameter markers in the prepared statement.

**SQLVAR**
If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is n, where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first input parameter marker, the second occurrence of SQLVAR contains a description of the second input parameter marker, and so on. For information about the values assigned to SQLVAR occurrences, see “Field descriptions in an occurrence of SQLVAR” on page 1752.

Notes

**Allocating the SQL descriptor:** Before the DESCRIBE INPUT statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. The number of descriptor items allocated must not be less than the number of input parameter markers or an error is returned.

**Allocating the SQLDA:** Before the DESCRIBE INPUT statement is executed, enough storage must be allocated for some number of SQLVAR occurrences. SQLN must then be set to the number of SQLVAR occurrences that were allocated. To obtain the description of the input parameter markers in the prepared statement, the number of occurrences of SQLVAR must not be less than the number of input parameter markers. Furthermore, if the input parameter markers include LOBs or distinct types, the number of occurrences of SQLVAR should be two times the number of input parameter markers. See “Determining how many SQLVAR occurrences are needed” on page 1750 for more information.
If not enough occurrences are provided to return all sets of occurrences, SQLN is set to the total number of occurrences necessary to return all information. Otherwise, SQLN is set to the number of input parameter markers.

Among the possible ways to allocate the SQLDA are the three described below:

**First technique**

Allocate an SQLDA with enough occurrences of SQLVAR entries to accommodate any number of input parameter markers that the application will have to process. At the extreme, the number of SQLVARs could equal two times the maximum number of parameter markers allowed in a prepared statement. Having done the allocation, the application can use this SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular prepared statement.

**Second technique**

Repeat the following three steps for every processed prepared statement:

1. Execute a DESCRIBE INPUT statement with an SQLDA that has no occurrences of SQLVAR entries, that is, an SQLDA for which SQLN is zero. The value returned for SQLD is the number of input parameter markers in the prepared statement. This value is either the required number of occurrences of SQLVAR entries or half the required number. Because there were no SQLVAR entries, a warning will be issued.  
2. If the SQLSTATE accompanying that warning is equal to 01005, allocate an SQLDA with 2 * SQLD occurrences and set SQLN in the new SQLDA to 2 * SQLD. Otherwise, allocate an SQLDA with SQLD occurrences and set SQLN in the new SQLDA to the value of SQLD.
3. Execute the DESCRIBE INPUT statement again, using this new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE INPUT statements.

**Third technique**

Allocate an SQLDA that is large enough to handle most, and perhaps all, parameter markers in prepared statements but is also reasonably small. If an execution of DESCRIBE INPUT fails because the SQLDA is too small, allocate a larger SQLDA and execute DESCRIBE INPUT again. For the new SQLDA, use the value of SQLD (or double the value of SQLD) returned from the first execution of DESCRIBE INPUT for the number of occurrences of SQLVAR entries.

This technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

**Examples**

*Example 1:* In a C program, execute a DESCRIBE INPUT statement with an SQLDA that has enough to describe any number of input parameter markers a prepared statement might have. Assume that five parameter markers at most will need to be described and that the input data does not contain LOBs.

---

103 If LOBs or UDTs are not in the result set, the warning is only returned if the standards option is specified. For information about the standards option, see "Standards compliance" on page xi.
EXEC SQL BEGIN DECLARE SECTION;
    char stmt1_str [200];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
struct sqlda initialsqlda;
struct sqlda *sqldaPtr;

... /* stmt1_str contains INSERT statement with VALUES clause */
EXEC SQL PREPARE STMT1_NAME FROM :stmt1_str;

... /* code to set SQLN to five and to allocate the SQLDA */
EXEC SQL DESCRIBE INPUT STMT1_NAME INTO :SQLDA;

... 

Example 2: Allocate a descriptor called 'NEWDA' large enough to hold 20 item descriptor areas and use it on DESCRIBE INPUT.

EXEC SQL ALLOCATE DESCRIPTOR 'NEWDA'
    WITH MAX 20;

EXEC SQL DESCRIBE INPUT STMT1
    USING SQL DESCRIPTOR 'NEWDA';
DESCRIBE PROCEDURE

The DESCRIBE PROCEDURE statement gets information about the result sets returned by a procedure. The information, such as the number of result sets, is put into a descriptor.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

```
DESCRIBE PROCEDURE procedure-name
ROUTINE (parameter-type)
SPECIFIC PROCEDURE specific-name
ROUTINE PROCEDURE variable

USING SQL LOCAL USING DESCRIPTOR LOCAL SQL-descriptor-name
INTO descriptor-name
GLOBAL INTO SQL-descriptor-name

parameter-type:
  data-type AS LOCATOR

data-type:
  built-in-type
distinct-type-name

built-in-type:
```
ccsid-clause:

| CCSID—integer |

**Description**

*procedure-name* or *specific-name* or *variable*

Identifies the procedure that returned one or more result sets. When the DESCRIBE PROCEDURE statement is executed, the procedure name must identify a procedure that the requester has already invoked using the SQL CALL statement.

**PROCEDURE or SPECIFIC PROCEDURE**

Identifies the procedure to be described. The *procedure-name* must identify a procedure that exists at the current server.

**PROCEDURE** *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

**PROCEDURE** *procedure-name* (*parameter-type*, ...)

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name* (*parameter-type*, ...) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be labeled on. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name* () is specified, the procedure identified must have zero parameters.

**procedure-name**

Identifies the name of the procedure.

(*parameter-type*, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have
to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

**AS LOCATOR**
Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

**SPECIFIC PROCEDURE** *specific-name*
Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

**variable**
Specifies a variable that contains a procedure or specific name. If *variable* is specified:
- It must be a character-string variable or Unicode graphic-string variable.
  - It cannot be a global variable.
- It must not be followed by an indicator variable.
- The name that is contained within the variable must be left-justified and must be padded on the right with blanks if its length is less than that of the variable.
- The name must be in uppercase unless it is a delimited name.

If only one procedure with this name has been invoked using the CALL statement, the variable is used as a procedure name. If multiple procedures with this name have been invoked, the variable is used as a specific name.

**USING**
Identifies an SQL descriptor.

**LOCAL**
Specifies the scope of the name of the descriptor to be local to program invocation.

**GLOBAL**
Specifies the scope of the name of the descriptor to be global to the SQL session.

**SQL-descriptor-name**
Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

After the DESCRIBE PROCEDURE is executed, the following values can be retrieved with the GET DESCRIPTOR statement:
• DB2_RESULT_SETS_COUNT contains the total number of result sets. A value of 0 indicates there are no result sets.

There is one descriptor area item for each result set:
• DB2_RESULT_SET_LOCATOR contains the result set locator value associated with the result set.
• DB2_CURSOR_NAME contains the name of the cursor used by the procedure to return the result set.
• DB2_RESULT_SET_ROWS contains the estimated number of rows in the result set. This is set to -1 if the number is unknown.

See "GET DESCRIPTOR" on page 1376 for an explanation of the information that is placed in the SQL descriptor.

**INTO descriptor-name**

Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, "SQLDA (SQL descriptor area)," on page 1747. Before the DESCRIBE PROCEDURE statement is executed, the following variable in the SQLDA must be set.

**SQLN** Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE PROCEDURE statement is executed.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

**SQLDAID**
- The first 5 bytes are set to 'SQLPR'. Bytes 6 to 8 are reserved.

**SQLDABC**
- Length of the SQLDA in bytes.

**SQLD**
- The total number of result sets. A value of 0 indicates there are no result sets.

**SQLVAR**
- If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.
- If the value of SQLD is n, where n is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first result set, the second occurrence of SQLVAR contains a description of the second result set, and so on. For each SQLVAR entry:
  - The SQLDATA field is set to the result set locator value associated with the result set.
  - The SQLIND field is set to the estimated number of rows in the result set. This is set to -1 if the number is unknown.
  - The SQLNAME field is set to the name of the cursor used by the stored procedure to return the result set. The cursor name is truncated to 30 characters if it is longer than 30 characters.

**Notes**

DESCRIBE PROCEDURE does not return information about the parameters expected by the procedure.
The CALL to the procedure must precede the DESCRIBE PROCEDURE statement.

Allocating the SQL descriptor: Before the DESCRIBE PROCEDURE statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of result sets for the procedure, a warning (SQLSTATE 01005) is returned.

Allocating the SQLDA: Before the DESCRIBE PROCEDURE statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA and enough storage must be allocated to contain SQLN occurrences. To obtain the description of the result sets for the procedure, the number of occurrences of SQLVAR must not be less than the number result sets.

If not enough occurrences are provided to return all sets of occurrences, SQLN is set to the total number of occurrences necessary to return all information. Otherwise, SQLN is set to the number of result sets.

Assignment of locator values: If a SET RESULT SETS statement was executed in the procedure, the SET RESULT SETS statement identifies the result sets. The locator values are assigned to the items in the descriptor area or the SQLVAR entries in the SQLDA in the order specified on the SET RESULT SETS statement. If a SET RESULT SETS statement was not executed in the procedure, locator values are assigned to the items in the descriptor area or to the SQLVAR entries in the SQLDA in the order that the associated cursors are opened at run time. Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later re-opened before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, and C, closes cursor B, and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values are assigned in the order A, C, B.

Alternatively, an ASSOCIATE LOCATORS statement can be used to copy the locator values to result set locator variables.

Example

Place information about the result sets returned by procedure P1 into an SQL descriptor:

EXEC SQL CALL P1;
EXEC SQL ALLOCATE DESCRIPTOR 'DESC1';
EXEC SQL DESCRIBE PROCEDURE P1 USING SQL DESCRIPTOR 'DESC1';
DESCRIBE TABLE

The DESCRIBE TABLE statement obtains information about a table or view.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table or view identified in the statement:
  - The system authority of *OBJOPR on the table or view
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

Syntax

```
DESCRIBE TABLE variable
INCLUDING IMPLICITLY HIDDEN COLUMNS
EXCLUDING IMPLICITLY HIDDEN COLUMNS
```

```
USING DESCRIPTOR SQL
LOCAL
GLOBAL
SQL-descriptor-name
USING NAMES
SYSTEM NAMES
LABELS
ANY
BOTH
ALL
 INTO descriptor-name
```

Description

**variable**

Identifies the table or view to describe. When the DESCRIBE TABLE statement is executed:

- The name must identify a table or view that exists at the application server.
- The **variable** must be a character-string or Unicode graphic-string variable and must not include an indicator variable. It cannot be a global variable.
- The table name that is contained within the **variable** must be left-justified and must be padded on the right with blanks if its length is less than that of the **variable**.
- The name of the table must be in uppercase unless it is a delimited name.

**INCLUDING IMPLICITLY HIDDEN COLUMNS** or **EXCLUDING IMPLICITLY HIDDEN COLUMNS**

Specifies whether information should be returned for implicitly hidden column in a table.
DESCRIBE TABLE

INCLUDING IMPLICITLY HIDDEN COLUMNS
  Specifies that information is returned for columns defined as implicitly hidden. This is the default.

EXCLUDING IMPLICITLY HIDDEN COLUMNS
  Specifies that information is not returned for columns defined as implicitly hidden.

When the DESCRIBE TABLE statement is executed, the database manager assigns values to the variables of the SQL descriptor or SQLDA as follows:

USING
  Identifies an SQL descriptor.

LOCAL
  Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL
  Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name
  Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See "GET DESCRIPTOR" on page 1376 for an explanation of the information that is placed in the SQL descriptor.

INTO descriptor-name
  Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, "SQLDA (SQL descriptor area)," on page 1747. Before the DESCRIBE TABLE statement is executed, the following variable in the SQLDA must be set.

SQLN
  Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE TABLE statement is executed. For information about techniques to determine the number of occurrences requires, see "Determining how many SQLVAR occurrences are needed" on page 1750.

The rules for REXX are different. For more information, see the Embedded SQL Programming topic collection.

When the DESCRIBE statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID
  The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character).

  The seventh byte is set based on the column described:
  • If the SQLDA contains two, three, or four SQLVAR entries for every column of the table, the seventh byte is set to '2', '3', or '4'. This technique is used in order to accommodate LOB or distinct type result columns, labels, and system names.
  • Otherwise, the seventh byte is set to the space character.

  The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all columns.
The eighth byte is set to the space character.

SQLDABC  
Length of the SQLDA in bytes.

SQLD  
The number of columns in the table plus the number of extended SQLVAR entries. For information about extended SQLVAR entries see, “Field descriptions in an occurrence of SQLVAR” on page 1752.

SQLVAR  
If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is \( n \), where \( n \) is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first \( n \) occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column of the table, the second occurrence of SQLVAR contains a description of the second column of the table, and so on. For information about the values assigned to SQLVAR occurrences, see “Field descriptions in an occurrence of SQLVAR” on page 1752.

USING  
Specifies what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist or if the length of a name is greater than 30, SQLNAME is set to a length of 0.

NAMES  
Assigns the name of the column. The column name returned is case sensitive and without delimiters. This is the default.

SYSTEM NAMES  
Assigns the system column name of the column.

LABELS  
Assigns the label of the column. (Column labels are defined by the LABEL statement.) Only the first 20 bytes of the label are returned.

ANY  
Assigns the column label. If the column has no label, the column name is used instead.

BOTH  
Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to \( 2n \) or \( 3n \) (where \( n \) is the number of columns in the table or view). The first \( n \) occurrences of SQLVAR contain the column names if they are different from the system column name. Either the second or third \( n \) occurrences contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

ALL  
Assigns the label, column name, and system column name. In this case three or four occurrences of SQLVAR per column, depending on whether the table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to \( 3n \) or \( 4n \) (where \( n \) is the number of columns in the table). The first \( n \) occurrences of SQLVAR contain the system column
names. The second or third \( n \) occurrences contain the column labels. The third or fourth \( n \) occurrences contain the column names. If there are no distinct types, the labels are returned in the second set of SQLVAR entries and the column names are returned in the third set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries and the column names are returned in the fourth set of SQLVAR entries.

**Notes**

**Allocating the SQL descriptor:** Before the DESCRIBE TABLE statement is executed, the SQL descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. If the number of descriptor items allocated is less than the number of columns in the table or view, a warning (SQLSTATE 01005) is returned.

**Allocating the SQLDA:** Before the DESCRIBE TABLE statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA and enough storage must be allocated to contain SQLN occurrences. To obtain the description of the columns of the table or view, the number of occurrences of SQLVAR must not be less than the number of columns. Furthermore, if USING BOTH or USING ALL is specified, or if the columns include LOBs or distinct types, the number of occurrences of SQLVAR should be two, three, or four times the number of columns. See “Determining how many SQLVAR occurrences are needed” on page 1750 for more information.

If not enough occurrences are provided to return all sets of occurrences, SQLN is set to the total number of occurrences necessary to return all information. Otherwise, SQLN is set to the number of columns.

For a description of techniques that can be used to allocate the SQLDA, see Appendix D, “SQLDA (SQL descriptor area),” on page 1747.

**Example**

In a C program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR and then execute a DESCRIBE statement using that SQLDA.

```
EXEC SQL BEGIN DECLARE SECTION;
    char table_name[201];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQGLDA;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

.../*code to prompt user for a table or view */
.../*code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL DESCRIBE TABLE :table_name INTO :sqlda;

... /* code to check that SQLD is greater than zero, to set */
/* SQLN to SQLD, then to re-allocate the SQLDA */
EXEC SQL DESCRIBE TABLE :table_name INTO :sqlda;
... .
... .
```
DISCONNECT

The DISCONNECT statement ends one or more connections for unprotected conversations.

Invocation

This statement can only be embedded in an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

DISCONNECT is not allowed in a trigger or function.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
DISCONNECT server-name | variable
                        CURRENT
                        ALL
                        ALL SQL
```

Description

**server-name or variable**

Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a character-string variable.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

When the DISCONNECT statement is executed, the specified server name or server name contained in the variable must identify an existing dormant or current connection of the activation group. The identified connection cannot use a protected conversation.

**CURRENT**

Identifies the current connection of the activation group. The activation group must be in the connected state. The current connection must not use a protected conversation.

**ALL or ALL SQL**

Identifies all existing connections of the activation group (local as well as
remote connections). An error or warning does not occur if no connections exist when the statement is executed. None of the connections can use protected conversations.

Notes

DISCONNECT and CONNECT (Type 1): Using CONNECT (Type 1) semantics does not prevent using DISCONNECT.

Connection restrictions: An identified connection must not be a connection that was used to execute SQL statements during the current unit of work and must not be a connection for a protected conversation. To end connections on protected conversations, use the RELEASE statement. Local connections are never considered to be protected conversations.

The DISCONNECT statement should be executed immediately after a commit operation. If DISCONNECT is used to end the current connection, the next executed SQL statement must be CONNECT or SET CONNECTION.

ROLLBACK does not reconnect a connection that has been ended by DISCONNECT.

Successful disconnect: If the DISCONNECT statement is successful, each identified connection is ended. If the current connection is destroyed, the activation group is placed in the unconnected state.

DISCONNECT closes cursors, releases resources, and prevents further use of the connection.

DISCONNECT ALL ends the connection to the local application server. A connection is ended even though it has an open cursor defined with the WITH HOLD clause.

Unsuccessful disconnect: If the DISCONNECT statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Resource considerations for remote connections: Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be ended as soon as possible and a remote connection that is going to be reused should not be destroyed.

Examples

Example 1: The connection to TOROLAB1 is no longer needed. The following statement is executed after a commit operation.

   EXEC SQL DISCONNECT TOROLAB1;

Example 2: The current connection is no longer needed. The following statement is executed after a commit operation.

   EXEC SQL DISCONNECT CURRENT;

Example 3: The existing connections are no longer needed. The following statement is executed after a commit operation.

   EXEC SQL DISCONNECT ALL;
The DROP statement drops an object. Objects that are directly or indirectly
dependent on that object may also be dropped.

Invocation

This statement can be embedded in an application program or issued interactively.
It is an executable statement that can be dynamically prepared.

Authorization

To drop a table, view, index, alias, or package, the privileges held by the
authorization ID of the statement must include at least one of the following:

• The following system authorities:
  – The system authorities of *OBJOPR and *OBJEXIST on the object to be
dropped
  – If the object is a table or view, the system authorities of *OBJOPR and
  *OBJEXIST on any views, indexes, and logical files that are dependent on that
table or view
  – If the object is a system-period temporal table, the system authorities of
  *OBJOPR and *OBJEXIST on the associated history table
  – The system authority *EXECUTE on the library that contains the object to be
dropped

• Database administrator authority

To drop a schema, the privileges held by the authorization ID of the statement
must include at least one of the following:

• The following system authorities:
  – The system authorities of *OBJEXIST, *OBJOPR, *EXECUTE, and *READ on
  the library to be dropped.
  – The system authorities of *OBJOPR and *OBJEXIST on all objects in the
  schema and *OBJOPR and *OBJEXIST on any views, indexes and logical files
  that are dependent on tables and views in the schema.
  – Any additional authorities required to delete other object types that exist in
  the schema. For example, *OBJMGT to the data dictionary if the schema
  contains a data dictionary, and some system data authority to the journal
  receiver. For more information, see Security Reference

• Database administrator authority

To drop a user-defined type, the privileges held by the authorization ID of the
statement must include at least one of the following:

• The following system authorities:
  – The system authorities of *OBJOPR and *OBJEXIST on the type to be
dropped
  – The system authority *EXECUTE on the library that contains the type to be
dropped
  – The DELETE privilege on the SYSTYPES, SYSPARMS, and SYSROUTINES
    catalog tables, and
  – The system authority *EXECUTE on library QSYS2

• Database administrator authority
To drop a global variable, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority of *OBJEXIST on the *SRVPGM object for the global variable to be dropped
  - The system authority *EXECUTE on the library that contains the global variable to be dropped
  - The DELETE privilege on the SYSVARIABLES catalog table, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

To drop an XSR object, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authorities of *OBJOPR and *OBJEXIST on the *SQLXSR object for the XSR object to be dropped
  - The system authority *EXECUTE on the library that contains the XSR object to be dropped
  - The DELETE privilege on the XSROBJECTS, XSROBJECTCOMPONENTS, and XSRANNOTATIONINFO catalog tables, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

To drop a function, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - For SQL functions, the system authority *OBJEXIST on the service program object associated with the function, and
  - The DELETE privilege on the SYSFUNCS, SYSPARMS, and SYSROUTINEDEP catalog tables, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

To drop a procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - For SQL procedures, the system authority *OBJEXIST on the program object associated with the procedure, and
  - The DELETE privilege on the SYSPROCS, SYSPARMS, and SYSROUTINEDEP catalog tables, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

To drop a sequence, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - The system authority *OBJEXIST on the data area associated with the sequence, and
  - The system authority *EXECUTE on the library that contains the sequence to be dropped
The DELETE privilege on the SYSSEQOBJECTS catalog table, and
The system authority *EXECUTE on library QSYS2, and
*USE to the Delete Data Area (DLTDTAARA) command

* Database administrator authority

To drop a trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

* The following privileges:
  - The system authority *USE to the Remove Physical File Trigger (RMVPFTRG) command, and
  - For the subject table or view of the trigger:
    - The ALTER privilege to the subject table or view, and
    - The system authority *EXECUTE on the library containing the subject table or view,
  - If the trigger being dropped is an SQL trigger:
    - The system authority *OBJEXIST on the trigger program object, and
    - The system authority *EXECUTE on the library containing the trigger.

* Database administrator authority

To drop a mask or permission:

* The authorization ID of the statement must have security administrator authority. See "Administrative authority" on page 18.

To drop an object used by a mask or permission:

* The authorization ID of the statement must have security administrator authority. See "Administrative authority" on page 18.

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.

**Syntax**
DROP ALIAS alias-name FUNCTION function-name ROUTINE

SPECIFIC FUNCTION specific-name ROUTINE

INDEX index-name MASK mask-name

PACKAGE package-name VERSION version-id

PERMISSION permission-name PROCEDURE procedure-name ROUTINE

SPECIFIC PROCEDURE specific-name ROUTINE

SCHEMA schema-name RESTRICT CASCADE

SEQUENCE sequence-name TABLE table-name RESTRICT CASCADE

TRIGGER trigger-name TYPE distinct-type-name RESTRICT CASCADE

VARIABLE variable-name ARRAY array-type-name RESTRICT CASCADE

VIEW view-name RESTRICT CASCADE

XSROBJECT xsrobject-name

parameter-type:

data-type:

built-in-type:
DROP

ccsid-clause:

---CCSID--integer---

Description

ALIAS alias-name

Identifies the alias that is to be dropped. The alias-name must identify an alias that exists at the current server.

The specified alias is deleted from the schema. Dropping an alias has no effect on any constraint, view, or materialized query that was defined using the alias. An alias can be dropped whether it is referenced in a function, package, procedure, program, trigger, or variable.

FUNCTION or SPECIFIC FUNCTION

Identifies the function that is to be dropped. The function must exist at the current server and it must be a function that was defined with the CREATE FUNCTION statement. The particular function can be identified by its name, function signature, or specific name.

Functions implicitly generated by the CREATE TYPE statement cannot be dropped using the DROP statement. They are implicitly dropped when the distinct type is dropped.

The function cannot be dropped if another function is dependent on it. A function is dependent on another function if it was identified in the SOURCE clause of the CREATE FUNCTION statement. A function can be dropped whether it is referenced in a function, package, procedure, program, trigger, variable, or view unless RESTRICT is specified. A function cannot be dropped if it is referenced in a mask or permission even if RESTRICT is not specified.

The specified function is dropped from the schema. All privileges on the user-defined function are also dropped. If this is an SQL function or sourced function, the service program (*SRVPGM) associated with the function is also dropped. If this is an external function, the information that was saved in the program or service program specified on the CREATE FUNCTION statement is removed from the object.

FUNCTION function-name

Identifies the function by its name. The function-name must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION function-name (parameter-type, ...)

Identifies the function by its function signature, which uniquely identifies the function. The function-name (parameter-type, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is to be dropped. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If function-name () is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.
Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

**SPECIFIC FUNCTION** *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

**RESTRICT**

Specifies that the function cannot be dropped if it is referenced in an SQL function, SQL procedure, table, mask, permission, SQL trigger, variable, or view.

**RESTRICT not specified**

If the function is referenced in a mask or permission, the drop will fail unless the authorization ID of the statement has security administrator authority.

**INDEX** *index-name*

Identifies the index that is to be dropped. The *index-name* must identify an index that exists at the current server.

The specified index is dropped from the schema. An index can be dropped whether it is referenced in a function, package, procedure, program, or trigger.
DROP

MASK mask-name
Identifies the mask that is to be dropped. The mask-name must identify a mask that exists at the current server.

The specified mask is dropped from the schema. A mask can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

PACKAGE package-name
Identifies the package that is to be dropped. The package-name must identify a package that exists at the current server.

The specified package is dropped from the schema. All privileges on the package are also dropped.

A package can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

VERSION version-id
version-id is the version identifier that was assigned to the package when it was created. If version-id is not specified, a null string is used as the version identifier.

PERMISSION permission-name
Identifies the permission that is to be dropped. The permission-name must identify a permission that exists at the current server.

The specified permission is dropped from the schema. A permission can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

PROCEDURE or SPECIFIC PROCEDURE
Identifies the procedure that is to be dropped. The procedure-name must identify a procedure that exists at the current server.

The specified procedure is dropped from the schema. All privileges on the procedure are also dropped. If this is an SQL procedure, the program (*PGM) or service program (*SRVPGM) associated with the procedure is also dropped. If this is an external procedure, the information that was saved in the program specified on the CREATE PROCEDURE statement is removed from the object.

A procedure can be dropped whether it is referenced in a function, package, procedure, program, or trigger.

PROCEDURE procedure-name
Identifies the procedure by its name. The procedure-name must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE procedure-name (parameter-type, ...)
Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The procedure-name (parameter-type, ...) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be dropped. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If procedure-name () is specified, the procedure identified must have zero parameters.
procedure-name
Identifies the name of the procedure.

(parameter-type, ...)
Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, \texttt{DEC()} will be considered a match for a parameter of a procedure defined with a data type of \texttt{DEC(7,2)}. However, \texttt{FLOAT} cannot be specified with empty parenthesis because its parameter value indicates a specific data type (\texttt{REAL} or \texttt{DOUBLE}).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is \texttt{FLOAT}, the precision does not have to exactly match the value that was specified because matching is based on the data type (\texttt{REAL} or \texttt{DOUBLE}).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the \texttt{FOR DATA} clause or \texttt{CCSID} clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

\textbf{AS LOCATOR}
Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

\textbf{SPECIFIC PROCEDURE specific-name}
Identifies the procedure by its specific name. The \texttt{specific-name} must identify a specific procedure that exists at the current server.

\textbf{RESTRICT}
Specifies that the procedure cannot be dropped if it is referenced in an SQL function, SQL procedure, or SQL trigger.

\textbf{SCHEMA schema-name}
Identifies the schema that is to be dropped. The \texttt{schema-name} must identify a schema that exists at the current server.

The specified schema is dropped. Each object in the schema is dropped as if the appropriate DROP statement was executed with the specified drop option (\texttt{CASCADE}, \texttt{RESTRICT}, or neither). See the DROP description of these object types for information about the handling of objects dependent on these objects.

\textbf{DROP SCHEMA} is only valid when the commit level is `*NONE`. 

DROP

Neither CASCADE nor RESTRICT

Specifies that the schema will be dropped even if it is referenced in a function, package, procedure, program, table, mask, permission, trigger, or variable in another schema.

CASCADE

Specifies that any objects in the schema and any triggers that reference the schema will be dropped. Any masks and permissions in a different schema that reference the schema are dropped if the authorization ID of the statement has security administrator authority.

RESTRICT

Specifies that the schema cannot be dropped if it is referenced in an SQL trigger, mask, or permission in another schema or if the schema contains any SQL objects other than catalog views, the journal, and journal receiver.

SEQUENCE sequence-name

Identifies the sequence that is to be dropped. The sequence-name must identify a sequence that exists at the current server.

RESTRICT

Specifies that the sequence cannot be dropped if it is referenced in an SQL trigger, function, procedure, or variable.

TABLE table-name

Identifies the table that is to be dropped. The table-name must identify a base table that exists at the current server, but must not identify a catalog table or a history table for a system-period temporal table.

The specified table is dropped from the schema. All privileges, constraints, indexes, masks, permissions, and triggers on the table are also dropped.

Any aliases that reference the specified table are not dropped.

Neither CASCADE nor RESTRICT

Specifies that the table will be dropped even if it is referenced in a constraint, index, trigger, mask, permission, view, or materialized query table. All indexes, views, and materialized query tables that reference the table are dropped even if the authorization ID of the statement does not explicitly have privileges to those objects. If the table is a system-period temporal table, the history table is also dropped. If the table is referenced in a mask or permission, the drop will fail unless the authorization ID of the statement has security administrator authority.

CASCADE

Specifies that the table will be dropped even if it is referenced in a constraint, index, trigger, variable, mask, permission, view, XSR object, or materialized query table. All constraints, indexes, triggers, variables, views, XSR objects and materialized query tables that reference the table are dropped even if the authorization ID of the statement does not explicitly have privileges to those objects. If the table is a system-period temporal table, the history table is also dropped. All masks and permissions that reference the table are dropped if the authorization ID of the statement has security administrator authority.

RESTRICT

Specifies that the table cannot be dropped if it is referenced in a constraint, index, mask, permission, trigger, variable, view, XSR object, or materialized query table, or if it is a system-period temporal table.
**TRIGGER** `trigger-name`

Identifies the trigger that is to be dropped. The `trigger-name` must identify a trigger that exists at the current server.

The specified trigger is dropped from the schema. If the trigger is an SQL trigger, the program object associated with the trigger is also deleted from the schema.

If `trigger-name` specifies an INSTEAD OF trigger on a view, another trigger may depend on that trigger through an update against the view.

**TYPE** `distinct-type-name` or `array-type-name`

Identifies the type that is to be dropped. The `distinct-type-name` or `array-type-name` must identify a distinct type or array type that exists at the current server. The specified type is deleted from the schema.

Neither CASCADE nor RESTRICT

Specifies that the type cannot be dropped if any constraints, indexes, masks, permissions, sequences, tables, variables, and views reference the type.

For every procedure or function `R` that has parameters or a return value of the type being dropped, the following DROP statement is effectively executed:

```sql
DROP ROUTINE R
```

For every trigger `T` that references the type being dropped, the following DROP statement is effectively executed:

```sql
DROP TRIGGER T
```

It is possible that this statement would cascade to drop dependent functions or procedures. If all of these functions or procedures are in the list to be dropped because of a dependency on the type, the drop of the type will succeed.

**CASCADE**

Specifies that the type will be dropped even if it is referenced in a constraint, function, index, procedure, sequence, table, trigger, variable, or view. All constraints, functions, indexes, procedures, sequences, tables, triggers, variables, and views that reference the type are dropped. The cascade processing is limited to cases where the type is used to define the routine parameter type, sequence type, variable type and column type. All masks and permissions that reference the type are dropped if the authorization ID of the statement has security administrator authority.

**RESTRICT**

Specifies that the type cannot be dropped if it is referenced in a constraint, function (other than a function that was created when the type was created), index, procedure, sequence, table, mask, permission, trigger, variable, or view. The restrict checking is limited to cases where the type is used to define the routine parameter type, sequence type, variable type and column type.

**VARIABLE** `variable-name`

Identifies the variable that is to be dropped. The `variable-name` must identify a variable that exists at the current server. The specified variable is dropped from the schema.

Neither CASCADE nor RESTRICT

Specifies that the variable will be dropped even if it is referenced in a
trigger, procedure, function, mask, permission, view, or another variable. All tables and views that reference the variable are dropped. If the variable is referenced in a mask or permissions, the drop will fail unless the authorization ID of the statement has security administrator authority.

**CASCADE**
Specifies that the variable will be dropped even if it is referenced in a table, trigger, procedure, function, view, or another variable. All tables, triggers, procedures, functions, views, and variables that reference the variable are dropped. All masks and permissions that reference the variable are dropped if the authorization ID of the statement has security administrator authority.

**RESTRICT**
Specifies that the variable cannot be dropped if it is referenced in a table, trigger, procedure, function, mask, permission, view, or another variable.

**VIEW view-name**
Identifies the view that is to be dropped. The view-name must identify a view that exists at the current server, but must not identify a catalog view.

The specified view is dropped from the schema. When a view is dropped, all privileges and triggers on that view are dropped.

Neither CASCADE nor RESTRICT
Specifies that the view will be dropped even if it is referenced in a trigger, materialized query table, mask, permission, or another view. All views and materialized query tables that reference the view are dropped. If the view is referenced in a mask or permissions, the drop will fail unless the authorization ID of the statement has security administrator authority.

**CASCADE**
Specifies that the view will be dropped even if it is referenced in a trigger, variable, materialized query table, or another view. All triggers, variables, materialized query tables, and views that reference the view are dropped. All masks and permissions that reference the view are dropped if the authorization ID of the statement has security administrator authority.

**RESTRICT**
Specifies that the view cannot be dropped if it is referenced in a trigger, variable, mask, permission, materialized query table, or another view.

**XSROBJECT xsobject-name**
Identifies the XSR object that is to be dropped. The xsobject-name must identify an XSR object that exists at the current server. The specified XSR object is dropped.

**Notes**

**Drop effects:** Whenever an object is dropped, its description is dropped from the catalog. If the object is referenced in a function, package, procedure, program, trigger, or variable; any access plans that reference the object are implicitly prepared again when the access plan is next used. If the object does not exist at that time, an error is returned.

**Dependencies:** Whenever an object is directly or indirectly dropped, other objects that depend on the dropped object might also be dropped. The following semantics determine what happens to a dependent object when the object that it depends on (the underlying object) is dropped:
Three different types of dependencies are shown:

- D: Dependent object is dropped.
- A: Automatic revalidation is required. The database manager will attempt to revalidate the object when it is referenced.
- R: DROP statement fails.

</tbody>
</table>

Notes:

1. If other user-defined functions are sourced on the function being dropped, the function cannot be dropped.
2. DROP SCHEMA will drop all objects in the schema. Any objects in other schemas that reference the schema will not be changed and will require automatic revalidation.
3. DROP SCHEMA CASCADE will drop all objects in the schema. Triggers in other schemas that reference the schema will be dropped. Other objects in other schemas that reference the schema will not be changed and will require automatic revalidation.
4. DROP SCHEMA RESTRICT will fail if any object other than SQL catalog views, journals, and journal receivers exist in the schema. Objects other than triggers in other schemas that reference the schema will not be changed and will require automatic revalidation.
5. Any function or procedure that has a parameter or returns value defined as the type will be dropped.
**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword SYNONYM can be used as a synonym for ALIAS.
- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.
- The keyword PROGRAM can be used as a synonym for PACKAGE.
- The keyword COLLECTION can be used as a synonym for SCHEMA.

**Examples**

*Example 1:* Drop your table named MY_IN_TRAY. Do not allow the drop if any views or indexes are created over this table.

```
DROP TABLE MY_IN_TRAY RESTRICT
```

*Example 2:* Drop your view named MA_PROJ.

```
DROP VIEW MA_PROJ
```

*Example 3:* Drop the package named PERS.PACKA.

```
DROP PACKAGE PERS.PACKA
```

*Example 4:* Drop the distinct type DOCUMENT, if it is not currently in use:

```
DROP DISTINCT TYPE DOCUMENT RESTRICT
```

*Example 5:* Assume that you are SMITH and that ATOMIC_WEIGHT is the only function with that name in schema CHEM. Drop ATOMIC_WEIGHT.

```
DROP FUNCTION CHEM.ATOMIC_WEIGHT RESTRICT
```

*Example 6:* Drop the function named CENTER, using the function signature to identify the function instance to be dropped.

```
DROP FUNCTION CENTER (INTEGER, FLOAT) RESTRICT
```

*Example 7:* Drop CENTER, using the specific name to identify the function instance to be dropped.

```
DROP SPECIFIC FUNCTION JOHNSON.FOCUS97
```

*Example 8:* Assume that procedure OSMOSIS is in schema BIOLOGY. Drop OSMOSIS.

```
DROP PROCEDURE BIOLOGY.OSMOSIS
```

*Example 9:* Assume that trigger BONUS exists in the default schema. Drop BONUS.

```
DROP TRIGGER BONUS
```
END DECLARE SECTION

The END DECLARE SECTION statement marks the end of an SQL declare section.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in RPG, Java, or REXX.

Authorization

None required.

Syntax

```
END DECLARE SECTION
```

Description

The END DECLARE SECTION statement can be coded in the application program wherever declarations can appear in accordance with the rules of the host language. It is used to indicate the end of an SQL declare section. An SQL declare section starts with a BEGIN DECLARE SECTION statement. For more information about the BEGIN DECLARE SECTION statement, see “BEGIN DECLARE SECTION” on page 955.

The BEGIN DECLARE SECTION and the END DECLARE SECTION statements must be paired and cannot be nested.

Examples

See “BEGIN DECLARE SECTION” on page 955 for examples using the END DECLARE SECTION statement.
The EXECUTE statement executes a prepared SQL statement.

**Invocation**

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

**Authorization**

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

The authorization rules are those defined for the SQL statement specified by EXECUTE. For example, see the description of INSERT for the authorization rules that apply when an INSERT statement is executed using EXECUTE.

The authorization ID of the statement is the run-time authorization ID unless DYNUSRPRF(*OWNER) was specified on the CRTSQLxxx command when the program was created. For more information, see “Authorization IDs and authorization names” on page 69.

**Syntax**

```
EXECUTE statement-name

USING variable SQL-descriptors

USING DESCRIPTOR descriptor-name

SQL-descriptors:

INTO SQL_DESCRIPTOR LOCAL SQL-descriptor-name

GLOBAL SQL-descriptor-name

(1)

USING SQL_DESCRIPTOR LOCAL SQL-descriptor-name

GLOBAL SQL-descriptor-name

Notes:

1. If an SQL descriptor is specified in the USING clause and the INTO clause is not specified, USING DESCRIPTOR is not allowed and USING SQL DESCRIPTOR must be specified.
```
Description

statement-name
Identifies the prepared statement to be executed. When the EXECUTE statement is executed, the name must identify a prepared statement at the current server. The prepared statement cannot be a SELECT statement.

USING
Introduces a list of variables whose values are substituted for the parameter markers (question marks) in the prepared statement. For an explanation of parameter markers, see “PREPARE” on page 1494. If the prepared statement includes parameter markers, the USING clause must be used. USING is ignored if there are no parameter markers.

variable,...
Identifies one of more host structures or variables that must be declared in the program in accordance with the rules for declaring host structures and variables. A reference to a host structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The nth variable corresponds to the nth parameter marker in the prepared statement.

A global variable may only be used if the current connection is a local connection (not a DRDA connection).

SQL-descriptors

INTO
Identifies an SQL descriptor which contains valid descriptions of the output variables to be used with the EXECUTE statement. This clause is only valid for a CALL or VALUES INTO statement. Before the EXECUTE statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement.

LOCAL
Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL
Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name
Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “GET DESCRIPTOR” on page 1376 for an explanation of the information that is placed in the SQL descriptor.

USING
Identifies an SQL descriptor which contains valid descriptions of the input variables to be used with the EXECUTE statement. Before the EXECUTE statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement.

LOCAL
Specifies the scope of the name of the descriptor to be local to program invocation. The information is returned from the descriptor known in this local scope.

GLOBAL
Specifies the scope of the name of the descriptor to be global to the SQL session.
SQL session. The information is returned from the descriptor known to any program that executes using the same database connection.

**SQL-descriptor-name**
Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See [“SET DESCRIPTOR” on page 1568](#) for an explanation of the information in the SQL descriptor.

**DESCRIPTOR descriptor-name**
Identifies an SQLDA that must contain a valid description of variables.

Before the EXECUTE statement is processed, the user must set the following fields in the SQLDA. (The rules for REXX are different. For more information, see the [Embedded SQL Programming](#) topic collection.)

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement.
- SQLVAR occurrences to indicate the attributes of the variables.

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the results, there must be additional SQLVAR entries for each parameter. For more information about the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see [“Determining how many SQLVAR occurrences are needed” on page 1750](#).

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The nth variable described by the SQLDA corresponds to the nth parameter marker in the prepared statement.

Note that RPG/400 does not provide the function for setting pointers. Because the SQLDA uses pointers to locate the appropriate variables, you have to set these pointers outside your RPG/400 application.

**Notes**

**Parameter marker replacement:** Before the prepared statement is executed, each parameter marker in the statement is effectively replaced by its corresponding variable. The replacement of a parameter marker is an assignment operation in which the source is the value of the variable, and the target is a variable within the database manager. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see [Table 11](#) on page 1501.

Let V denote a variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P using storage assignment rules as described in [“Assignments and comparisons” on page 99](#). Thus:

- V must be compatible with the target.
If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.

If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.

If the target cannot contain nulls, the value of V must not be null.

However, unlike the storage assignment rules:

If V is a string, the value will be truncated (without an error), if its length is greater than the length attribute of the target.

When the prepared statement is executed, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded with two blanks.

Example

This example of portions of a COBOL program shows how an INSERT statement with parameter markers is prepared and executed.

EXEC SQL BEGIN DECLARE SECTION END-EXEC.

77 EMP PIC X(6).
77 PRJ PIC X(6).
77 ACT PIC S9(4) COMP-4.
77 TIM PIC S9(3)V9(2).
01 HOLDER.
   49 HOLDER-LENGTH PIC S9(4) COMP-4.
   49 HOLDER-VALUE PIC X(80).
EXEC SQL END DECLARE SECTION END-EXEC.

MOVE 70 TO HOLDER-LENGTH.
MOVE "INSERT INTO EMPPROJECT (EMPNO, PROJNO, ACTNO, EMPTIME)"
- "VALUES (?, ?, ?, ?)" TO HOLDER-VALUE.
EXEC SQL PREPARE MYINSERT FROM :HOLDER END-EXEC.

IF SQLCODE = 0
   PERFORM DO-INSERT THRU END-DO-INSERT
ELSE
   PERFORM ERROR-CONDITION.

DO-INSERT.
   MOVE "000010" TO EMP.
   MOVE "AD3100" TO PRJ.
   MOVE 160 TO ACT.
   MOVE .50 TO TIM.
EXEC SQL EXECUTE MYINSERT USING :EMP, :PRJ, :ACT, :TIM END-EXEC.
END-DO-INSERT.

.
EXECUTE IMMEDIATE combines the basic functions of the PREPARE and EXECUTE statements. It can be used to prepare and execute SQL statements that contain neither variables nor parameter markers.

The EXECUTE IMMEDIATE statement:
- Prepares an executable form of an SQL statement from a character string form of the statement
- Executes the SQL statement

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:
- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

The authorization rules are those defined for the SQL statement specified by EXECUTE IMMEDIATE. For example, see "INSERT" on page 1450 for the authorization rules that apply when an INSERT statement is executed using EXECUTE IMMEDIATE.

The authorization ID of the statement is the run-time authorization ID unless DYNUSRPRF('OWNER) was specified on the CRTSQLxxx command when the program was created. For more information, see "Authorization IDs and authorization names" on page 69.

Syntax

```
EXECUTE IMMEDIATE variable expression
```

Description

`variable`
Identifies a variable that must be declared in accordance with the rules for declaring character-string or Unicode graphic variables. An indicator variable must not be specified.

`expression`
An expression of the type described in "Expressions" on page 174, that does not include an aggregate function or column name. It must return a value that is a
character string or a Unicode graphic string. If a variable is specified in the
expression it must not have a CCSID of 65535.\textsuperscript{104}

The value of the identified variable or expression is called a statement string.

The statement string must be one of the following SQL statements:\textsuperscript{106}

\begin{center}
\begin{tabular}{lll}
\textbf{ALTER} & \textbf{LOCK TABLE} & \textbf{SET CURRENT IMPLICIT} \\
\textbf{CALL} & \textbf{MERGE} & \textbf{XMLPARSE OPTION} \\
\textbf{COMMENT} & \textbf{REFRESH TABLE} & \textbf{SET CURRENT TEMPORAL} \\
\textbf{COMMIT} & \textbf{RELEASE SAVEPOINT} & \textbf{SYSTEM_TIME} \\
\textbf{Compound (dynamic)} & \textbf{RENAME} & \textbf{SET ENCRYPTION PASSWORD} \\
\textbf{CREATE} & \textbf{REVOKE} & \textbf{SET PATH} \\
\textbf{DECLARE GLOBAL} & \textbf{SET CURRENT DEGREE} & \textbf{SET SESSION AUTHORIZATION} \\
\textbf{TEMPORARY TABLE} & \textbf{ROLLBACK} & \textbf{SET TRANSACTION} \\
\textbf{DELETE} & \textbf{SAVEPOINT} & \textbf{SET variable}\textsuperscript{105} \\
\textbf{DROP} & \textbf{SET CURRENT DEBUG MODE} & \textbf{TRANSFER OWNERSHIP} \\
\textbf{GRANT} & \textbf{SET CURRENT DEC_FLOAT} & \textbf{TRUNCATE} \\
\textbf{INSERT} & \textbf{ROUNDING MODE} & \\
\textbf{LABEL} & \textbf{SET CURRENT DEGREE} & \textbf{UPDATE} \\
\end{tabular}
\end{center}

The statement string must not:
\begin{itemize}
\item Begin with EXEC SQL.
\item End with END-EXEC or a semicolon.
\item Include references to variables. Global variables are allowed.
\item Include parameter markers.
\end{itemize}

When an EXECUTE IMMEDIATE statement is executed, the specified statement string is parsed and checked for errors. If the SQL statement is not valid, it is not executed and the error condition that prevents its execution is reported in the stand-alone SQLSTATE and SQLCODE. If the SQL statement is valid, but an error occurs during its execution, that error condition is reported in the stand-alone SQLSTATE and SQLCODE. Additional information about the error can be retrieved from the SQL Diagnostics Area (or the SQLCA).

\textbf{Note}

\textbf{Performance considerations:} If the same SQL statement is to be executed more than once, it is more efficient to use the PREPARE and EXECUTE statements rather than the EXECUTE IMMEDIATE statement.

\textbf{Example}

Use C to execute the SQL statement in the variable Qstring.

\begin{verbatim}
void main ()
{
    EXEC SQL BEGIN DECLARE SECTION END-EXEC.
}
\end{verbatim}

\textsuperscript{104} In a PL/I program, a PL/I string expression can also be specified.
\textsuperscript{105} The target of the SET variable statement must be a global variable.
\textsuperscript{106} A select-statement is not allowed. To dynamically process a select-statement, use the PREPARE, DECLARE CURSOR, and OPEN statements.
EXECUTE IMMEDIATE

char Qstring[100] = "INSERT INTO WORK_TABLE SELECT * FROM EMPPROJECT
    WHERE ACTNO >= 100";

EXEC SQL END DECLARE SECTION END-EXEC.
EXEC SQL INCLUDE SQLCA;
.
EXEC SQL EXECUTE IMMEDIATE :Qstring;

    return;

}
FETCH

The FETCH statement positions a cursor on a row of the result table. It can return zero, one, or multiple rows, and it assigns the values of the rows returned to variables.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. Multiple row fetch is not allowed in a REXX procedure.

Authorization

See “DECLARE CURSOR” on page 1265 for an explanation of the authorization required to use a cursor.

If a global variable is specified in the INTO variable list, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

Syntax

```
FETCH [NEXT | PRIOR | FIRST | LAST | BEFORE (1) | AFTER (2) | CURRENT | RELATIVE variable integer] FROM cursor-name
```

---

single-fetch:

```
INTO variable
INTO LOCAL SQL-DESCRIPTOR SQL-descriptor-name
INTO GLOBAL DESCRIPTOR descriptor-name
```
multiple-row-fetch:

```sql
FOR variable integer ROWS
INTO host-structure-array
USING SQL-DESCRIPTOR SQL-descriptor-name
INTO row-storage-area
LOCAL USING DESCRIPTOR descriptor-name
GLOBAL USING DESCRIPTOR descriptor-name
```

row-storage-area:

```sql
:host-identifier-1
INDICATOR :host-identifier-2
```

Notes:
1. If BEFORE is specified, a single-fetch or multiple-row-fetch must not be specified.
2. If AFTER is specified, a single-fetch or multiple-row-fetch must not be specified.

Description

The following keywords specify a new position for the cursor: NEXT, PRIOR, FIRST, LAST, BEFORE, AFTER, CURRENT, and RELATIVE. Of those keywords, only NEXT may be used for cursors that have not been declared SCROLL.

**NEXT**

Positions the cursor on the next row of the result table relative to the current cursor position. NEXT is the default if no other cursor orientation is specified.

**PRIOR**

Positions the cursor on the previous row of the result table relative to the current cursor position.

**FIRST**

Positions the cursor on the first row of the result table.

**LAST**

Positions the cursor on the last row of the result table.

**BEFORE**

Positions the cursor before the first row of the result table.

**AFTER**

Positions the cursor after the last row of the result table.

**CURRENT**

Does not reposition the cursor, but maintains the current cursor position. If the cursor has been declared as DYNAMIC SCROLL and the current row has been updated so its place within the sort order of the result table is changed, an error is returned.

**RELATIVE**

Variable or integer is assigned to an integer value k. RELATIVE positions the cursor to the row in the result table that is either k rows after the current row if k>0, or k rows before the current row if k<0. If a variable is specified, it must be a numeric variable with zero scale and it must not include an indicator variable.

<td>RELATIVE 0</td>
<td>CURRENT</td>
</tr>
</tbody>
</table>

**FROM**

This keyword is provided for clarity only. If a scroll position option is specified, then this keyword is required. If no scrolling option is specified, then the FROM keyword is optional.

**cursor-name**

Identifies the cursor to be used in the fetch operation. The *cursor-name* must identify a declared cursor as explained in “Description” on page 1266 for the DECLARE CURSOR statement or when used in Java, an instance of an SQLJ iterator. When the FETCH statement is executed, the cursor must be in the open state.

If a *single-fetch* or *multiple-row-fetch* clause is not specified, no data is returned to the user. However, the cursor is positioned and a row lock may be acquired. For more information about locking, see “Isolation level” on page 27.

**single-fetch**

**INTO variable,...**

Identifies one or more host structures or variables that must be declared in accordance with the rules for declaring host structures and variables. In the operational form of INTO, a host structure is replaced by a reference to each of its variables. The first value in the result row is assigned to the first variable in the list, the second value to the second variable, and so on.

A global variable may only be used if the current connection is a local connection (not a DRDA connection).

**INTO SQL DESCRIPTOR SQL-descriptor-name**

Identifies an SQL descriptor which contains valid descriptions of the output variables to be used with the FETCH statement. Before the FETCH statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement.

**LOCAL**

Specifies the scope of the name of the descriptor to be local to program invocation.

**GLOBAL**

Specifies the scope of the name of the descriptor to be global to the SQL session.

**SQL-descriptor-name**

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See “SET DESCRIPTOR” on page 1568 for an explanation of the information in the SQL descriptor.

**INTO DESCRIPTOR descriptor-name**

Identifies an SQLDA that must contain a valid description of zero or more variables.
Before the FETCH statement is processed, the user must set the following fields in the SQLDA. (The rules for REXX are different. For more information see the Embedded SQL Programming topic collection.)

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQLDABC must be greater than or equal to 16 + SQLN*(80), where 80 is the length of an SQLVAR occurrence. If LOBs are specified, there must be two SQLVAR entries for each parameter marker and SQLN must be set to two times the number of parameter markers.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. For more information, see Appendix D, “SQLDA (SQL descriptor area),” on page 1747.

The USING DESCRIPTOR clause is not supported for a FETCH statement within a Java program.

**multiple-row-fetch**

**FOR variable or integer ROWS**

Evaluates variable or integer to an integral value that represents the number of rows to fetch. If a variable is specified, it must be a numeric variable with zero scale and it must not include an indicator variable. It must not be a global variable. The value must be in the range of 1 to 32767 and the total size of the rows, excluding LOBs, must be less than 16M. The cursor is positioned on the row specified by the orientation keyword (for example, NEXT), and that row is fetched. Then the next rows are fetched (moving forward in the table), until either the specified number of rows have been fetched or the end of the cursor is reached. After the fetch operation, the cursor is positioned on the last row fetched.

For example, FETCH PRIOR FROM C1 FOR 3 ROWS causes the previous row, the current row, and the next row to be returned, in that order. The cursor is positioned on the next row. FETCH RELATIVE -1 FROM C1 FOR 3 ROWS returns the same result. FETCH FIRST FROM C1 FOR :x ROWS returns the first x rows, and leaves the cursor positioned on row number x.

When a multiple-row-fetch is successfully executed, three statement information items are available in the SQL Diagnostics Area (or the SQLCA):

- ROW_COUNT (or SQLERRD(3) of the SQLCA) shows the number of rows retrieved.
- DB2_ROW_LENGTH (or SQLERRD(4) of the SQLCA) contains the length of the row retrieved.
- DB2_LAST_ROW (or SQLERRD(5) of the SQLCA) contains +100 if the last row was fetched. ¹⁰⁷

¹⁰⁷ If the number of rows returned is equal to the number of rows requested, then an end of data warning may not occur and DB2_LAST_ROW (or SQLERRD(5) of the SQLCA) may not contain +100.
INTO host-structure-array

host-structure-array identifies an array of host structures defined in accordance with the rules for declaring host structures.

The first structure in the array corresponds to the first row, the second structure in the array corresponds to the second row, and so on. In addition, the first value in the row corresponds to the first item in the structure, the second value in the row corresponds to the second item in the structure, and so on. The number of rows to be fetched must be less than or equal to the dimension of the host structure array.

USING SQL DESCRIPTOR SQL-descriptor-name

Identifies an SQL descriptor.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

The COUNT field in the descriptor header must be set to reflect the number of columns in the result set. The TYPE and DATETIME_INTERVAL_CODE (if applicable) must be set for each column in the result set.

USING DESCRIPTOR descriptor-name

Identifies an SQLDA that must contain a valid description of zero or more variables that describe the format of a row in the row-storage-area.

Before the FETCH statement is processed, the user must set the following fields in the SQLDA:

• SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
• SQILDABC to indicate the number of bytes of storage allocated for the SQLDA.
• SQILD to indicate the number of variables used in the SQLDA when processing the statement.
• SQLVAR occurrences to indicate the attributes of the variables.

The values of the other fields of the SQLDA (such as SQLNAME) may not be defined after the FETCH statement is executed and should not be used.

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQILDABC must be greater than or equal to 16 + SQLN*(80), where 80 is the length of an SQLVAR occurrence. If LOBs or distinct types are specified, there must be two SQLVAR entries for each parameter marker and SQLN must be set to two times the number of parameter markers.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. For more information, see Appendix D, “SQLDA (SQL descriptor area),” on page 1747.

On completion of the FETCH, the SQLDATA pointer in the first SQLVAR entry addresses the returned value for the first column in the allocated storage in the
first row, the SQLDATA pointer in the second SQLVAR entry addresses the
returned value for the second column in the allocated storage in the first row,
and so on. The SQLIND pointer in the first nullable SQLVAR entry addresses
the first indicator value, the SQLIND pointer in the second nullable SQLVAR
entry addresses the second indicator value, and so on. The SQLDA must be
allocated on a 16-byte boundary.

```
INTO row-storage-area
host-identifier-1 specified with a variable identifies an allocation of storage in
which to return the rows. The rows are returned into the storage area in the
format described by the SQLDA or SQL descriptor. host-identifier-1 must be
large enough to hold all the rows requested.

host-identifier-2 identifies the optional indicator area. It should be specified if
any of the data types returned are nullable. This variable identifies an
allocation of storage in which to return the indicators. The indicators are
returned as small integers. host-identifier-2 must be large enough to contain an
indicator for each nullable value for each row to be returned.

The GET DIAGNOSTICS statement can be used to return the
DB2_ROW_LENGTH which indicates the length of each row returned into the
row-storage-area.
```

The nth variable identified by the INTO clause or described in the SQLDA
corresponds to the nth column of the result table of the cursor. The data type of
each variable must be compatible with its corresponding column.

Each assignment to a variable is made according to the retrieval assignment rules
described in "Retrieval assignment" on page 103. If the number of variables is
less than the number of values in the row, the SQLSTATE is set to '01503' (or the
SQLWARN3 field of the SQLCA is set to 'W'). Note that there is no warning if
there are more variables than the number of result columns. If the value is null, an
indicator variable must be provided. If an assignment error occurs, the value is not
assigned to the variable, and no more values are assigned to variables. Any values
that have already been assigned to variables remain assigned.

If an error occurs as the result of an arithmetic expression in the SELECT list of an
outer SELECT statement (division by zero, overflow, etc.) or a character conversion
error occurs, the result is the null value. As in any other case of a null value, an
indicator variable must be provided. The value of the variable is undefined. In this
case, however, the indicator variable is set to -2. Processing of the statement
continues as if the error had not occurred. (However, a warning is returned.) If you
do not provide an indicator variable, an error is returned. It is possible that some
values have already been assigned to variables and will remain assigned when the
error occurs.

```
multiple-row-fetch is not allowed if any of the result columns are LOBs or if the
current connection is to a remote server.
```

Notes

Cursor position: An open cursor has three possible positions:

- Before a row
- On a row

---

108. If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For
information on the standards option, see "Standards compliance" on page xi.
After the last row

If a cursor is positioned on a row, that row is called the current row of the cursor. A cursor referenced in an UPDATE or DELETE statement must be positioned on a row. A cursor can only be positioned on a row as a result of a FETCH statement.

It is possible for an error to occur that makes the state of the cursor unpredictable.

**Variable assignment:** The nth variable identified by the INTO clause or described in the SQLDA corresponds to the nth column of the result table of the cursor. The data type of each variable must be compatible with its corresponding column.

Each assignment to a variable is made according to the Retrieval Assignment rules described in "Assignments and comparisons" on page 99. If the number of variables is less than the number of values in the row, the SQLWARN3 field of the SQLCA is set to 'W'. Note that there is no warning if there are more variables than the number of result columns. If the value is null, an indicator variable must be provided. If an assignment error occurs, the values in the variables are unpredictable.

If the specified variable is a string and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA). The actual length of the result is returned in the indicator variable associated with the variable, if an indicator variable is provided.

If the specified variable is a C NUL-terminated variable and is not large enough to contain the result and the NUL-terminator:
- If the *CNULRQD option is specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*YES) on the SET OPTION statement), the following occurs:
  - The result is truncated.
  - The last character is the NUL-terminator.
  - A warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA).
- If the *NOCNULRQD option on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement) is specified, the following occurs:
  - The NUL-terminator is not returned.
  - A warning (SQLSTATE 01004) is returned (and 'N' is assigned to SQLWARN1 in the SQLCA).

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:
- USING DESCRIPTOR may be used as a synonym for INTO DESCRIPTOR in the single-fetch-clause.

**Examples**

*Example 1:* In this C example, the FETCH statement fetches the results of the SELECT statement into the program variables dnum, dname, and mnum. When no more rows remain to be fetched, the not found condition is returned.
EXEC SQL DECLARE C1 CURSOR FOR
    SELECT DEPTNO, DEPTNAME, MGRNO FROM TDEPT
    WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
while (SQLCODE==0) {
    EXEC SQL FETCH C1 INTO :dnum, :dname, :mnum;
}
EXEC SQL CLOSE C1;

Example 2: This FETCH statement uses an SQLDA.
FETCH CURS USING DESCRIPTOR :sqlda3

Example 3: This ILE RPG example uses a row storage area to fetch the data.

DCL-S ONE_ROW_PTR POINTER;
DCL-DS ONE_ROW BASED(ONE_ROW_PTR);
    DEPTNO  CHAR(3);
    DEPTNAME VARCHAR(36);
    MGRNO   CHAR(6);
END-DS;
DCL-S ONE_ROW_IND_PTR POINTER;
DCL-DS ONE_ROW_IND BASED(ONE_ROW_IND_PTR);
    DEPTNOIND INT(5);
    DEPTNAMEIND INT(5);
    MGRNOIND  INT(5);
END-DS;
DCL-S ROWAREA CHAR(450); // 10 records * %SIZE(ONE_ROW)
DCL-S INDAREA CHAR(60);  // 10 records * %SIZE(ONE_ROW_IND)
DCL-S ROWS_RETURNED INT(5);
DCL-S I INT(5);
EXEC SQL DECLARE C1 CURSOR FOR
    SELECT DEPTNO, DEPTNAME, MGRNO FROM CORPDATA.DEPARTMENT;

// Set up the descriptor
EXEC SQL ALLOCATE DESCRIPTOR 'FETCH_ROWS' WITH MAX 10;
EXEC SQL SET DESCRIPTOR 'FETCH_ROWS' COUNT = 3;  // Descriptor contains 3 items
EXEC SQL SET DESCRIPTOR 'FETCH_ROWS' VALUE 1 TYPE = 1, LENGTH = 3; // First is CHAR(3)
EXEC SQL SET DESCRIPTOR 'FETCH_ROWS' VALUE 2 TYPE = 12, LENGTH = 36; // Second is VARCHAR(36)
EXEC SQL SET DESCRIPTOR 'FETCH_ROWS' VALUE 3 TYPE = 1, LENGTH = 6; // Third is CHAR(6)

// Fetch the data
EXEC SQL OPEN C1;
EXEC SQL FETCH C1 FOR 10 ROWS
    USING SQL DESCRIPTOR 'FETCH_ROWS'
    INTO :ROWAREA:INDAREA;
EXEC SQL GET DIAGNOSTICS :ROWS_RETURNED = ROW_COUNT;
EXEC SQL CLOSE C1;

ONE_ROW_PTR = %ADDR(ROWAREA); // Get first row
ONE_ROW_IND_PTR = %ADDR(INDAREA); // Indicators for first row
FOR I = 1 TO ROWS_RETURNED;
    IF MGRNOIND >= 0; // Not a null value
        // Do something with MGRNO
    ENDIF;
    // Handle other values for first row
    ONE_ROW_PTR = ONE_ROW_PTR + %SIZE(ONE_ROW);
    ONE_ROW_IND_PTR = ONE_ROW_IND_PTR + %SIZE(ONE_ROW_IND);
ENDFOR;
The FREE LOCATOR statement removes the association between a locator variable and its value.

**Invocation**

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. FREE LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in Java or REXX.

**Authorization**

None required.

**Syntax**

```
FREE LOCATOR variable,...
```

**Description**

`variable,...`

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, a double-byte character large object locator, or an XML locator.

The `variable` must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a CALL, FETCH, SELECT INTO, assignment statement, SET variable, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is returned.

If more than one locator variable is specified and an error occurs on one of the locators, no locators will be freed.

**Example**

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the column values. In a COBOL program, free the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC.

```
EXEC SQL
FREE LOCATOR :LOCRES, :LOCHIST, :LOCPIC
END-EXEC.
```
The GET DESCRIPTOR statement gets information from an SQL descriptor.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

None required.

Syntax

```sql
GET DESCRIPTOR SQL-descriptor-name

get-header-info:
  variable-1 = COUNT
  DB2_CURSOR_HOLDABILITY
  DB2_CURSOR_RETURNABILITY
  DB2_CURSOR_SCROLLABILITY
  DB2_CURSOR_SENSITIVITY
  DB2_CURSOR_UPDATABILITY
  DB2_MAX_ITEMS
  DB2_RESULT_SETS_COUNT
  DYNAMIC_FUNCTION
  DYNAMIC_FUNCTION_CODE
  KEY_TYPE

get-item-info:
```
variable-2 = CARDINALITY

Description

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation. The information is returned from the descriptor known in this local scope.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session. The information is returned from the descriptor known to any program that executes using the same database connection.
**GET DESCRIPTOR**

*SQL-descriptor-name*
Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

*get-header-info*
Returns information about the prepared SQL statement and SQL descriptor.

**VALUE**
Identifies the item number for which the specified information is retrieved. If the value is greater than the value of COUNT (from the header information), then no result is returned. If the item number is greater than the maximum number of items allocated for the descriptor or the item number is less than 1, an error is returned.

*integer*
An integer constant in the range of 1 to the number of items in the SQL descriptor.

*integer-variable*
Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be SMALLINT, INTEGER, BIGINT, or DECIMAL or NUMERIC with a scale of zero. The value of *integer-variable* must be in the range of 1 to the maximum number of items in the SQL descriptor.

*get-item-info*
Returns information about a specific item in the SQL descriptor.

*get-header-info*

*variable-1*
Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the descriptor information item as specified in Table 88 on page 1384. The variable is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see "Assignments and comparisons" on page 99.

**COUNT**
A count of the number of items in the descriptor.

**DB2_CURSOR_HOLDABILITY**
The hold status of the cursor. The possible values are:
0 The descriptor is not describing a cursor or the cursor was not declared WITH HOLD.
1 The cursor was declared WITH HOLD.

**DB2_CURSOR_RETURNABILITY**
The return status of the cursor’s result set. The possible values are:
0 The descriptor is not describing a cursor or the cursor’s result set is not returnable.
1 The cursor’s result set is returnable to the caller of the procedure.
2 The cursor’s result set is returnable to the client.

**DB2_CURSOR_SCROLLABILITY**
The scroll status of the cursor. The possible values are:
0 The descriptor is not describing a cursor or the cursor was not declared with SCROLL.
1 The cursor was declared with SCROLL.
**DB2_CURSOR_SENSITIVITY**

The sensitivity of the cursor. The possible values are:

- 0 The descriptor is not describing a cursor.
- 1 The cursor is SENSITIVE DYNAMIC.
- 3 The cursor is INSENSITIVE.
- 4 The cursor is ASENSITIVE.

**DB2_CURSOR_UPDATABILITY**

Specifies whether the cursor can be used in an UPDATE statement with WHERE CURRENT OF cursor-name. The possible values are:

- 0 The descriptor is not describing a cursor or the cursor cannot be used in an UPDATE statement with WHERE CURRENT OF cursor-name.
- 1 The cursor can be used in an UPDATE statement with WHERE CURRENT OF cursor-name.

**DB2_MAX_ITEMS**

Represents the value specified as the allocated maximum number of item descriptors on the ALLOCATE DESCRIPTOR statement. If the WITH MAX clause was not specified, the value is the default number of maximum items for the ALLOCATE DESCRIPTOR statement.

**DB2_RESULT_SETS_COUNT**

The number of result sets returned by the procedure. The value will be 0 if this descriptor is not describing a procedure.

**DYNAMIC_FUNCTION**

The type of the prepared SQL statement as a character string. For information on statement type, see Table 91 on page 1408.

**DYNAMIC_FUNCTION_CODE**

The statement code representing the type of the prepared SQL statement. For information on statement codes, see Table 91 on page 1408.

**KEY_TYPE**

The type of key included in the select list. The possible values are:

- 0 The descriptor is not describing the columns of a query or there are no key columns referenced in the query, or there is no unique key.
- 1 The select list includes all the columns of the primary key of the base table referenced by the query.
- 2 The table referenced by the query does not have a primary key but the select list includes a set of columns that are defined as the preferred candidate key. If there is more than one such preferred candidate key included in the select list, the left-most preferred candidate key is used.

**get-item-info**

variable–2

Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the descriptor information item as specified in Table 88 on page 1384. The variable is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see “Assignments and comparisons” on page 99.

When getting the DATA item, in general the variable must have the same data type, length, precision, scale, and CCSID as specified in Table 88 on page 1384. For variable-length types, the variable length must not be less than the LENGTH in the descriptor. For C null-terminated types, the variable length must be at least one greater than the LENGTH in the descriptor.
GET DESCRIPTOR

CARDINALITY
The cardinality of the array data type. If this descriptor is the result of a
DESCRIBE, this is the maximum cardinality of the array data type. The
cardinality is 0 for all other data types.

DATA
The value for the data described by the item descriptor. If the value of
INDICATOR is negative, then the value of DATA is undefined and the
INDICATOR get-item-info must also be specified in the same statement.

DATETIME_INTERVAL_CODE
Codes that define the specific datetime data type.
0  Descriptor item does not have TYPE value of 9.
1  DATE
2  TIME
3  TIMESTAMP

DB2_BASE_CATALOG_NAME
The server name of the base table for the column represented by the item
descriptor.

DB2_BASE_COLUMN_NAME
The name of the column as defined in the base table referenced in the
described query, possibly indirectly through a view. If a column name cannot
be defined or is not applicable, this item will contain the empty string. The
name is returned as case sensitive and without delimiters.

DB2_BASE_SCHEMA_NAME
The schema name of the base table for the column represented by the item
descriptor. If a schema name cannot be defined or is not applicable, this item
will contain the empty string. The name is returned as case sensitive and
without delimiters.

DB2_BASE_TABLE_NAME
The table name of the underlying base table for the column represented by the
item descriptor. If a table name cannot be defined or is not applicable, this item
will contain the empty string. The name is returned as case sensitive and
without delimiters.

DB2_CCSID
The CCSID of character, graphic, or XML data. Value is zero for all types that
are not based on character or graphic string or XML types. Value is 65535 for
binary types or character types with the FOR BIT DATA attribute.

DB2_COLUMN_CATALOG_NAME
The server name of the referenced table or view for the column represented by
the item descriptor. If a column catalog name cannot be defined or is not
applicable, this item will contain the empty string.

DB2_COLUMN_GENERATED
Indicates whether a column is generated. Possible values are:
0  Not generated
1  GENERATED ALWAYS
2  GENERATED BY DEFAULT

DB2_COLUMN_GENERATION_TYPE
Indicates how the column is generated. Possible values are:
0  Not generated
1  IDENTITY column
2  ROWID column
4  Row change timestamp column
GET DESCRIPTOR

5 ROW BEGIN column
6 ROW END column
7 TRANSACTION START ID column
8 Generated expression column

DB2_COLUMN_HIDDEN
Indicates whether the column represented by the item descriptor is hidden. Possible values are:
0 Not hidden
1 Implicitly hidden
3 Implicitly hidden for optimistic locking

DB2_COLUMN_NAME
The name of the column as defined in the table or view referenced in the described query. If a column name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_COLUMN_ROW_CHANGE
Indicates whether the column represented by the item descriptor was added as a result of using the WITH ROW CHANGE COLUMNS prepare attribute. Possible values are:
-1 ROW CHANGE TOKEN (distinct)
-2 ROW CHANGE TOKEN (not distinct)
-3 RID (only valid from a remote relational database)
-4 RID_BIT (only valid from a remote relational database)

DB2_COLUMN_SCHEMA_NAME
The schema name of the referenced table or view for the column represented by the item descriptor. If a column schema name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_COLUMN_TABLE_NAME
The table or view name of the referenced table or view for the column represented by the item descriptor. If a column table name cannot be defined or is not applicable, this item will contain the empty string. The name is returned as case sensitive and without delimiters.

DB2_COLUMN_UPDATABILITY
Indicates whether the column represented by the item descriptor is updatable. Possible values are:
0 Not updatable
1 Updatable

DB2_CORRELATION_NAME
The empty string is always returned.

DB2_CURSOR_NAME
The name of the cursor in the procedure for this result set. This is only set when the descriptor is describing a procedure.

DB2_LABEL
The label defined for the column. If there is no label for the column, this item will contain the empty string.

DB2_PARAMETER_NAME
The name of the parameter for the stored procedure. Only returned for a CALL statement. The name is returned as case sensitive and without delimiters.
GET DESCRIPTOR

**DB2_RESULT_SET_LOCATOR**
The result set locator for this result set. This is only set when the descriptor is describing a procedure.

**DB2_RESULT_SET_ROWS**
The estimated number of rows in the result set. It is set to the value -1 if the number is unknown. This is only set when the descriptor is describing a procedure.

**DB2_SYSTEM_COLUMN_NAME**
The system name of the column. If a system name cannot be defined or is not applicable, this item will contain blanks.

**INDICATOR**
The value for the indicator. A non-negative value is used when the value returned in this descriptor item is given in the DATA field. When extended indicator variables are not enabled, a negative value is used when the value returned in this descriptor item is the null value. When extended indicators are enabled:
- -1, -2, -3, -4, or -6 indicates the value returned in this descriptor is the null value.
- -5 indicates the value returned in this descriptor item is DEFAULT.
- -7 indicates the value returned in this descriptor item is UNASSIGNED.

**KEY_MEMBER**
An indication of whether this column is part of a key.
0 This column is not part of a key.
1 This column is part of a unique key.
2 This column by itself is a unique key.

**LENGTH**
Returns the maximum length of the data. If the data type is a character or graphic string, an XML type, or a datetime type, the length represents the number of characters (not bytes). If the data type is a binary string or any other type, the length represents the number of bytes. For a description of data type codes and lengths, see Table 89 on page 1386.

**LEVEL**
The level of the item descriptor. The value is 0.

**NAME**
The name associated with the select list column described by the item descriptor. The name is returned as case sensitive and without delimiters.

**NULLABLE**
Indicates whether the column or parameter marker is nullable.
0 The select list column or parameter marker cannot have a null value.
1 The select list column or parameter marker can have a null value.

**OCTET_LENGTH**
Returns the maximum length of the data in bytes for all types. For a description of data type codes and lengths, see Table 89 on page 1386.

**PARAMETER_MODE**
The mode of the parameter marker in a CALL statement.
0 The descriptor is not associated with a CALL statement.
1 Input only parameter.
2 Input and output parameter.
4 Output only parameter.
PARAMETER_ORDINAL_POSITION
The ordinal position of the parameter marker in a CALL statement. The value is 0 if the descriptor is not associated with a CALL statement.

PARAMETER_SPECIFIC_CATALOG
The server name of the procedure containing the parameter marker.

PARAMETER_SPECIFIC_NAME
The specific name of the procedure containing the parameter marker. The name is returned as case sensitive and without delimiters.

PARAMETER_SPECIFIC_SCHEMA
The schema name of the procedure containing the parameter marker. The name is returned as case sensitive and without delimiters.

PRECISION
Returns the precision for the data:

- SMALLINT
  5
- INTEGER
  10
- BIGINT
  19
- NUMERIC and DECIMAL
  Defined precision
- REAL
  24
- DOUBLE
  53
- DECFLOAT(7)
  7
- DECFLOAT(16)
  16
- DECFLOAT(34)
  34
- TIME
  0
- TIMESTAMP
  Defined precision (0-12)

Other data types
  0

RETURNED_CARDINALITY
The current cardinality for an array data type returned by FETCH or CALL. The value is 0 when the data type of the item is not an array.

RETURNED_LENGTH
The returned length in characters for character string, graphic string, and XML data types. The returned length in bytes for binary string data types.

RETURNED_OCTET_LENGTH
The returned length in bytes for all string data types.

SCALE
Returns the defined scale if the data type is DECIMAL or NUMERIC. The scale is 0 for all other data types.

TYPE
Returns a data type code representing the data type of the item. For a description of the data type codes and lengths, see Table 89 on page 1386.
UNNAMED
A value of 1 indicates that the NAME value is generated by the database manager. Otherwise, the value is zero and NAME is the derived name of the column in the select list.

USER_DEFINED_TYPE_CATALOG
The server name of the user-defined type. If the type is not a user-defined data type, this item contains the empty string.

USER_DEFINED_TYPE_CODE
Indicates whether the type of the descriptor item is a user-defined type.
0 The descriptor item is not a user-defined type.
1 The descriptor item is a user-defined type.

USER_DEFINED_TYPE_NAME
The name of the user-defined data type. If the type is not a user-defined data type, this item contains the empty string. The name is returned as case sensitive and without delimiters.

USER_DEFINED_TYPE_SCHEMA
The schema name of the user-defined data type. If the type is not a user-defined data type, this item contains the empty string. The name is returned as case sensitive and without delimiters.

Notes

Data types for items: The following table shows the SQL data type for each descriptor item. When a descriptor item is assigned to a variable, the variable must be compatible with the data type of the descriptor item.

**SQL data type codes and lengths:** The following table represents the possible values for TYPE, LENGTH, OCTET_LENGTH, and DATETIME_INTERVAL_CODE descriptor items.

The values in the following table are assigned by the ISO and ANSI SQL Standard and may change as the standard evolves. Include sqlscds in the include source files in library QSYSINC should be used when referencing these values.

Table 89. SQL Data Type Codes and Lengths

**Example**

**Example 1:** Retrieve from the descriptor 'NEWDA' the number of descriptor items.

```sql
EXEC SQL GET DESCRIPTOR 'NEWDA'
  :numitems = COUNT;
```

**Example 2:** Retrieve from the first item descriptor of descriptor 'NEWDA' the data type and the octet length.

```sql
GET DESCRIPTOR 'NEWDA'
  VALUE 1 :dtype  = TYPE,
           :olength = OCTET_LENGTH;
```
GET DIAGNOSTICS

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

None required.

Syntax

```
GET [CURRENT | STACKED] DIAGNOSTICS
  [statement-information]
  [condition-information]
  [combined-information]

statement-information:

  [variable-1 = statement-information-item]
  [variable-1 = DB2_GET_DIAGNOSTICS_DIAGNOSTICS]

condition-information:

  CONDITION [variable-2]
  [integer]

combined-information:

  [variable-4 = ALL]
  [variable-5 = integer]
```

(1)
Notes:

1. **STATEMENT** can only be specified once. If **variable-5** or **integer** is not specified, **CONDITION** and **CONNECTION** can only be specified once.

### condition-information-item:
## Description

### CURRENT or STACKED

Specifies which diagnostics area to access.

---

**GET DIAGNOSTICS**

<table>
<thead>
<tr>
<th>Description</th>
<th>CURRENT or STACKED</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies</td>
<td>which diagnostics</td>
</tr>
<tr>
<td>area to</td>
<td>access.</td>
</tr>
</tbody>
</table>
CURRENT
Specifies to access the first diagnostics area. It corresponds to the previous SQL statement that was executed and that was not a GET DIAGNOSTICS statement. This is the default.

STACKED
Specifies to access the second diagnostics area. The second diagnostics area is only available within a handler. It corresponds to the previous SQL statement that was executed before the handler was entered and that was not a GET DIAGNOSTICS statement. If the GET DIAGNOSTICS statement is the first statement within a handler, then the first diagnostics area and the second diagnostics area contain the same diagnostics information.

statement-information
Returns information about the last SQL statement executed.

variable-1
Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be compatible with the data type as specified in Table 90 on page 1405 for the specified condition information item. The variable is assigned the value of the specified statement information item according to the retrieval assignment rules described in “Retrieval assignment” on page 103. If the value is truncated when assigning it to the variable, a warning (SQLSTATE 01004) is returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information, then the variable is set to a default value based on its data type:
- 0 for an exact numeric diagnostic item,
- an empty string for a VARCHAR diagnostic item,
- and blanks for a CHAR diagnostic item.

condition-information
Returns information about the condition or conditions that occurred when the last SQL statement was executed.

CONDITION variable-2 or integer
Identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic and so on. If the value is 1, then the diagnostic information retrieved corresponds to the condition indicated by the SQLSTATE value actually returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). The variable specified must be declared in the program in accordance with the rules for declaring exact numeric variables with zero scale. It must not be a global variable. The value specified must not be less than one or greater than the number of available diagnostics.

variable-3
Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be compatible with the data type as specified in Table 90 on page 1405 for the specified condition information item. The variable is assigned the value of the specified condition information item according to the retrieval assignment rules described in “Retrieval assignment” on page 103. If the value is truncated when assigning it to the variable, an error is
GET DIAGNOSTICS

returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information, then the variable is set to a default value based on its data type:

- 0 for an exact numeric diagnostic item,
- an empty string for a VARCHAR diagnostic item,
- and blanks for a CHAR diagnostic item.

combined-information

Returns multiple information items combined into one string.

variable–4

Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be VARCHAR. The variable is assigned according to the retrieval assignment rules described in "Retrieval assignment" on page 103. If the length of variable–4 is not sufficient to hold the full returned diagnostic string, the string is truncated, an error is returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

ALL

Indicates that all diagnostic items that are set for the last SQL statement executed should be combined into one string. The format of the string is a semicolon separated list of all of the available diagnostic information in the form:

item-name=character-form-of-the-item-value;

The character form of a positive numeric value will not contain a leading plus sign (+) unless the item is DB2_RETURNED_SQLCODE. In this case, a leading plus sign (+) is added. For example:

NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;

Only items that contain diagnostic information are included in the string. There are also no entries in this string for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS and DB2_SQL_NESTING_LEVEL items.

STATEMENT

Indicates that all statement-information-item diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. The format is the same as described above for ALL.

CONDITION

Indicates that condition-information-item diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. If variable–5 or integer is specified, then the format is the same as described above for the ALL option. If variable–5 or integer is not specified, then the format includes a condition number entry at the beginning of the information for that condition in the form:

CONDITION_NUMBER=X;item-name=character-form-of-the-item-value;

where X is the number of the condition. For example:

CONDITION_NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;
CONDITION_NUMBER=2;RETURNED_SQLSTATE=01004;
CONNECTION
Indicates that connection-information-item diagnostic items that contain diagnostic information for the last SQL statement executed should be combined into one string. If variable-5 or integer is specified, then the format is the same as described above for ALL. If variable-5 or integer is not specified, then the format includes a connection number entry at the beginning of the information for that condition in the form:

```
DB2_CONNECTION_NUMBER=X;item-name=character-form-of-the-item-value;
```

where X is the number of the condition. For example:

```
DB2_CONNECTION_NUMBER=1;CONNECTION_NAME=SVL1;DB2_PRODUCT_ID=DSN07010;
```

variable-5 or integer
Identifies the diagnostic for which ALL CONDITION or ALL CONNECTION information is requested. The variable specified must be declared in the program in accordance with the rules for declaring integer variables. It must not be a global variable. The value specified must not be less than one or greater than the number of available diagnostics.

statement-information-item

COMMAND_FUNCTION
Returns the name of the previous SQL statement. For information about the statement string values, see Table 91 on page 1408.

COMMAND_FUNCTION_CODE
Returns an integer that identifies the previous SQL statement. For information about the statement code values, see Table 91 on page 1408.

DB2_DIAGNOSTIC_CONVERSION_ERROR
Returns the value 1 if there was a conversion error when converting a character data value for one of the GET DIAGNOSTICS statement values. Otherwise, the value zero is returned.

DB2_GET_DIAGNOSTICS_DIAGNOSTICS
After a GET DIAGNOSTICS statement, if any errors or warnings occurred during the execution of the GET DIAGNOSTICS statement, DB2_GET_DIAGNOSTICS_DIAGNOSTICS returns textual information about these errors or warnings. The format of the information is similar to what would be returned by a GET DIAGNOSTICS :hv = ALL statement.

If a request was made for an information item that the server does not understand, for example, if the server was at a lower DRDA level than the requesting client, DB2_GET_DIAGNOSTICS_DIAGNOSTICS returns the text 'Item not supported:' followed by a comma separated list of item names that were requested but that the server does not support.

DB2_LAST_ROW
For a multiple-row-fetch statement, a value of +100 might be returned if the set of rows that have been fetched contains the last row currently in the result table for cursors that are fetching forward, or contains the first row currently in the result table, for cursors that are fetching backward. If the number of rows returned is equal to the number of rows requested, then an end of data warning may not occur and DB2_LAST_ROW may not contain +100.

If a value of +100 for DB2_LAST_ROW is returned for a cursor that is not sensitive to updates, a subsequent FETCH would return with the SQLCODE set to +100 and SQLSTATE set to '02000'. For a cursor that is sensitive to
GET DIAGNOSTICS

updates, a subsequent FETCH might return more data if any rows have been inserted before the FETCH was executed.

For statements other than multiple-row-fetch statements, for multiple-row-fetch statements that do not contain the last row currently in the result table, for cursors that are fetching forwards, or that do not contain the first row currently in the result table, for cursors that are fetching backwards, or if the server only returns an SQLCA, the value zero is returned.

**DB2_NUMBER_CONNECTIONS**
Returns the number of connections that were made in order to get to the server that fulfilled the request from the client. Each such connection may generate a connection information item area which would be available for the single condition.

**DB2_NUMBER_PARAMETER_MARKERS**
For a PREPARE statement, returns the number of parameter markers in the prepared statement. Otherwise, the value zero is returned.

**DB2_NUMBER_RESULT_SETS**
For a CALL statement, returns the actual number of result sets returned by the procedure. Otherwise, the value zero is returned.

**DB2_NUMBER_ROWS**
If the previous SQL statement was an OPEN or a FETCH which caused the size of the result table to be known, returns the number of rows in the result table. For SENSITIVE cursors, this value can be thought of as an approximation since rows inserted and deleted will affect the next retrieval of this value. Otherwise, the value zero is returned.

**DB2_NUMBER_SUCCESSFUL_SUBSTMTS**
For embedded compound SQL statements, returns a count of the number of successful sub-statements. Otherwise, the value zero is returned.

**DB2_RELATIVE_COST_ESTIMATE**
For a PREPARE statement, returns a relative cost estimate of the resources required for every execution. It does not reflect an estimate of the time required. When preparing a dynamically defined statement, this value can be used as an indicator of the relative cost of the prepared statement. The value varies depending on changes to statistics and can vary between releases of the product. It is an estimated cost for the access plan chosen by the optimizer. The value zero is returned if the statement is not a PREPARE statement.

**DB2_RETURN_STATUS**
Identifies the status value returned from the previous SQL CALL statement. If the previous statement is not a CALL statement, the value returned has no meaning and is unpredictable. For more information, see "RETURN statement" on page 1706. Otherwise, the value zero is returned.

For external procedures, if the returned SQLCODE < 0, the SQL_ERROR_CODE1 and DB2_RETURN_STATUS will be set to -1, otherwise SQL_ERROR_CODE1 and DB2_RETURN_STATUS are set to 0.

**DB2_ROW_COUNT_SECONDARY**
Identifies the number of rows associated with secondary actions from the previous SQL statement that was executed. If the previous SQL statement is a DELETE or MERGE, the value is the total number of rows affected by referential constraints, including cascaded actions and the processing of triggered SQL statements from activated triggers. If the previous SQL statement is an INSERT or an UPDATE, the value is the total number of rows
affected as the result of the processing of triggered SQL statements from activated triggers. Otherwise, the value zero is returned.

If the SQL statement is run using isolation level No Commit, this value may be zero.

**DB2_ROW_LENGTH**

For FETCH, if the result row does not contain a LOB, returns the length of the row(s) retrieved. For OPEN, if the result row does not contain a LOB, returns the length of a result row. For FETCH and OPEN, if the result does contain a LOB, the length returned is unpredictable. Otherwise, the value zero is returned.

**DB2_SQL_ATTR_CONCURRENCY**

For an OPEN statement, indicates the concurrency control option of read-only, locking, optimistic using timestamps, or optimistic using values.

- R indicates read-only.
- L indicates locking.
- T indicates comparing row versions using timestamps or ROWIDs.
- V indicates comparing values.

Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_CAPABILITY**

For an OPEN statement, indicates the capability of the cursor, whether a cursor is read-only, deletable, or updatable.

- R indicates that this cursor can only be used to read.
- D indicates that this cursor can be used to read as well as delete.
- U indicates that this cursor can be used to read, delete as well as update.

Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_HOLD**

For an OPEN statement, indicates whether a cursor can be held open across multiple units of work or not.

- N indicates that this cursor will not remain open across multiple units of work.
- Y indicates that this cursor will remain open across multiple units of work.

Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_ROWSET**

For an OPEN statement, whether a cursor can be accessed using rowset positioning or not.

- N indicates that this cursor only supports row positioned operations.
- Y indicates that this cursor supports rowset positioned operations.

Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_SCROLLABLE**

For an OPEN statement, indicates whether a cursor can be scrolled forward and backward or not.

- N indicates that this cursor is not scrollable.
- Y indicates that this cursor is scrollable.

Otherwise, a blank is returned.
GET DIAGNOSTICS

**DB2_SQL_ATTR_CURSOR_SENSITIVITY**
For an OPEN statement, indicates whether a cursor does or does not show updates to cursor rows made by other connections.
- I indicates insensitive.
- P indicates partial sensitivity.
- S indicates sensitive.
- U indicates unspecified.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_TYPE**
For an OPEN statement, indicates whether a cursor type is dynamic, forward-only, or static.
- D indicates a dynamic cursor.
- F indicates a forward-only cursor.
- S indicates a static cursor.
Otherwise, a blank is returned.

**DB2_SQL_NESTING_LEVEL**
Identifies the current level of nesting or recursion in effect when the GET DIAGNOSTICS statement was executed. Each level of nesting corresponds to a nested or recursive invocation of a function, procedure, or trigger. If the GET DIAGNOSTICS statement is executed outside of a level of nesting, the value zero is returned.

If GET DIAGNOSTICS is issued in a user-defined function that is running in parallel, the nesting level is not predictable.

**DYNAMIC_FUNCTION**
Returns a character string that identifies the type of the SQL-statement being prepared or executed dynamically. For information about the statement string values, see Table 91 on page 1408.

**DYNAMIC_FUNCTION_CODE**
Returns a number that identifies the type of the SQL-statement being prepared or executed dynamically. For information about the statement code values, see Table 91 on page 1408.

**MORE**
Indicates whether more errors were raised than could be handled.
- N indicates that all the errors and warnings from the previous SQL statement were stored in the diagnostics area.
- Y indicates that more errors and warnings were raised from the previous SQL statement than there are condition areas in the diagnostics area. The maximum size of the diagnostics area is 90K.

**NUMBER**
Returns the number of errors and warnings detected by the execution of the previous SQL statement, other than a GET DIAGNOSTICS statement, that have been stored in the diagnostics area. If the previous SQL statement returned success (SQLSTATE 00000), or no previous SQL statement has been executed, the number returned is one. The GET DIAGNOSTICS statement itself may return information via the SQLSTATE parameter, but does not modify the previous contents of the diagnostics area, except for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS item.

**ROW_COUNT**
Identifies the number of rows associated with the previous SQL statement that
was executed. If the previous SQL statement is a DELETE, INSERT, REFRESH, or UPDATE statement, ROW_COUNT identifies the number of rows deleted, inserted, or updated by that statement, excluding rows affected by either triggers or referential integrity constraints. If the previous SQL statement is a MERGE statement, ROW_COUNT identifies the total number of rows deleted, inserted, and updated by that statement, excluding rows affected by either triggers or referential integrity constraints. If the previous SQL statement is a multiple-row-fetch, ROW_COUNT identifies the number of rows fetched. Otherwise, the value zero is returned.

**TRANSACTION_ACTIVE**
Returns the value 1 if an SQL transaction is currently active, and 0 if an SQL transaction is not currently active.

**TRANSACTIONS_COMMITTED**
If the previous statement was a CALL, returns the number of transactions that were committed during the execution of the SQL or external procedure. Otherwise, the value zero is returned.

**TRANSACTIONS_ROLLED_BACK**
If the previous statement was a CALL, returns the number of transactions that were rolled back during the execution of the SQL or external procedure. Otherwise, the value zero is returned.

**connection-information-item**

**CONNECTION_NAME**
If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION, returns the name of the server specified in the previous statement. Otherwise, the name of the current connection.

**DB2_AUTHENTICATION_TYPE**
Indicates the authentication type, whether server or client.
- C for client authentication.
- E for DCE security services authentication.
- S for server authentication.
Otherwise, a blank is returned.

**DB2_AUTHORIZATION_ID**
Returns the authorization id used by connected server. Because of userid translation and authorization exits, the local userid may not be the authid used by the server.

**DB2_CONNECTION_METHOD**
For a CONNECT or SET CONNECTION statement, returns the connection method.
- D indicates *DUW (Distributed Unit of Work).
- R indicates *RUW (Remote Unit of Work).

**DB2_CONNECTION_NUMBER**
Returns the number of the connections.

**DB2_CONNECTION_STATE**
Indicates the connection state, whether connected or not.
- -1 indicates the connection is unconnected.
- 1 indicates the connection is connected.
Otherwise, the value zero is returned.
**GET DIAGNOSTICS**

**DB2_CONNECTION_STATUS**
Indicates whether committable update can be performed or not.
- 1 indicates committable updates can be performed on the connection for this unit of work.
- 2 indicates no committable updates can be performed on the connection for this unit of work.

Otherwise, the value zero is returned.

**DB2_CONNECTION_TYPE**
Indicates the connection type (either local, remote, or to a driver program) and whether the conversation is protected or not.
- 1 indicates a connection to a local relational database.
- 2 indicates a connection to a remote relational database with the conversation unprotected.
- 3 indicates a connection to a remote relational database with the conversation protected.
- 4 indicates a connection to an application requester driver program.

Otherwise, the value zero is returned.

**DB2_DYN_QUERY_MGMT**
Returns a value of 1 if DYN_QUERY_MGMT database configuration parameter is enabled. Otherwise, the value zero is returned.

**DB2_ENCRYPTION_TYPE**
Returns the level of encryption.
- A indicates only the authentication tokens (authid and password) are encrypted.
- D indicates all data is encrypted for the connection.

Otherwise, a blank is returned.

**DB2_PRODUCT_ID**
Returns a product signature. If the application server is an IBM relational database product, the form is pppvvrrrm, where:
- ppp identifies the product as follows: ARI for Db2 for VM and VSE, DSN for Db2 for z/OS, QSQ for Db2 for i, and SQL for all other Db2 products
- vv is a two-digit version identifier such as '04'
- rr is a two-digit release identifier such as '01'
- m is a one-digit modification level such as '0'

For example, if the application server is Version 7 of Db2 for z/OS, the value would be 'DSN07010'. Otherwise, the empty string is returned.

**DB2_SERVER_CLASS_NAME**
Returns the server class name. For example, Db2 for z/OS, Db2 for AIX, Db2 for Windows, and Db2 for i.

**DB2_SERVER_NAME**
For a CONNECT or SET CONNECTION statement, returns the relational database name. Otherwise, the empty string is returned.

**condition-information-item**

**CATALOG_NAME**
If the returned SQLSTATE is:
- class 09 (Triggered Action Exception), or
GET DIAGNOSTICS

- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

and the constraint that caused the error is a referential, check, or unique constraint, the server name of the table that owns the constraint is returned.

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the server name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the server name of the view that caused the error is returned. Otherwise, the empty string is returned.

CLASS_ORIGIN
Returns 'ISO 9075' for those SQLSTATEs whose class is defined by ISO 9075.
Returns 'ISO/IEC 13249' for those SQLSTATEs whose class is defined by SQL/MM. Returns 'IBM Db2 SQL' for those SQLSTATEs whose class is defined by IBM Db2 SQL. Returns the value set by user written code if available.
Otherwise, the empty string is returned.

COLUMN_NAME
If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation) and the error was caused by an inaccessible column, the name of the column that caused the error is returned. Otherwise, the empty string is returned.

CONDITION_IDENTIFIER
If the value of the RETURNED_SQLSTATE corresponds to an unhandled user-defined exception (SQLSTATE 45000), then the condition name of the user-defined exception is returned.

CONDITION_NUMBER
Returns the number of the conditions.

CONSTRAINT_CATALOG
If the returned SQLSTATE is:
- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

the name of the server that contains the table that contains the constraint that caused the error is returned. Otherwise, the empty string is returned.

CONSTRAINT_NAME
If the returned SQLSTATE is:
- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

the name of the constraint that caused the error is returned. Otherwise, the empty string is returned.

CONSTRAINT_SCHEMA
If the returned SQLSTATE is:
- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

the name of the schema of the constraint that caused the error is returned. Otherwise, the empty string is returned.
**GET DIAGNOSTICS**

**CURSOR_NAME**
If the returned SQLSTATE is class 24 (Invalid Cursor State), the name of the cursor is returned. Otherwise, the empty string is returned.

**DB2_ERROR_CODE1**
Returns an internal error code. Otherwise, the value zero is returned.

**DB2_ERROR_CODE2**
Returns an internal error code. Otherwise, the value zero is returned.

**DB2_ERROR_CODE3**
Returns an internal error code. Otherwise, the value zero is returned.

**DB2_ERROR_CODE4**
Returns an internal error code. Otherwise, the value zero is returned.

**DB2_INTERNAL_ERROR_POINTER**
For some errors, this will be a negative value that is an internal error pointer. Otherwise, the value zero is returned.

**DB2_LINE_NUMBER**
For a CREATE PROCEDURE for an SQL function, SQL procedure, or SQL trigger where an error is encountered parsing the SQL procedure body, returns the line number where the error possibly occurred. Otherwise, the value zero is returned.

**DB2_MESSAGE_ID**
Returns the message ID corresponding to the MESSAGE_TEXT.

**DB2_MESSAGE_ID1**
Returns the underlying IBM i CPF escape message that originally caused this error. Otherwise, the empty string is returned.

**DB2_MESSAGE_ID2**
Returns the underlying IBM i CPD diagnostic message that originally caused this error. Otherwise, the empty string is returned.

**DB2_MESSAGE_KEY**
For a CALL statement, returns the IBM i message key of the error that caused the procedure to fail. For a trigger error in a DELETE, INSERT, or UPDATE statement, returns the message key of the error that was signaled from the trigger program. The IBM i QMHRCVPM API can be used to return the message description and message data for the message key. Otherwise, the value zero is returned.

**DB2_MODULE_DETECTING_ERROR**
Returns an identifier indicating which module detected the error. For a SIGNAL statement issued from a routine, the value 'ROUTINE' is returned. For other SIGNAL statements, the value 'PROGRAM' is returned.

**DB2_NUMBER_FAILING_STATEMENTS**
For a NOT ATOMIC embedded compound SQL statement, returns the number of statements that failed. Otherwise, the value zero is returned.

**DB2_OFFSET**
For a CREATE PROCEDURE for an SQL procedure where an error is encountered parsing the SQL procedure body, returns the offset into the line number where the error possibly occurred, if available. For an EXECUTE IMMEDIATE or a PREPARE statement where an error is encountered parsing the source statement, returns the offset into the source statement where the error possibly occurred. Otherwise, the value zero is returned.
DB2_ORDINAL_TOKEN_n
Returns the nth token. n must be a value from 1 to 100. For example,
DB2_ORDINAL_TOKEN_1 would return the value of the first token,
DB2_ORDINAL_TOKEN_2 the second token. A numeric value for a token is
converted to character before being returned. If there is no value for the token,
the empty string is returned.

DB2_PARTITION_NUMBER
For a partitioned database, returns the partition number of the database
partition that encountered the error or warning. If no errors or warnings were
encountered, returns the partition number of the current node. Otherwise, the
value zero is returned.

DB2_REASON_CODE
Returns the reason code for errors that have a reason code token in the
message text. Otherwise, the value zero is returned.

DB2_RETURNED_SQLCODE
Returns the SQLCODE for the specified diagnostic.

DB2_ROW_NUMBER
If the previous SQL statement is a multiple row insert or a multiple row fetch,
returns the number of the row where the condition was encountered, when
such a value is available and applicable. Otherwise, the value zero is returned.

DB2_SQLERRD_SET
Returns Y to indicate that the DB2_SQLERRD1 through DB2_SQLERRD6 items
may be set. Otherwise, a blank is returned.

DB2_SQLERRD1
Returns the value of SQLERRD(1) from the SQLCA returned by the server.

DB2_SQLERRD2
Returns the value of SQLERRD(2) from the SQLCA returned by the server.

DB2_SQLERRD3
Returns the value of SQLERRD(3) from the SQLCA returned by the server.

DB2_SQLERRD4
Returns the value of SQLERRD(4) from the SQLCA returned by the server.

DB2_SQLERRD5
Returns the value of SQLERRD(5) from the SQLCA returned by the server.

DB2_SQLERRD6
Returns the value of SQLERRD(6) from the SQLCA returned by the server.

DB2_TOKEN_COUNT
Returns the number of tokens available for the specified diagnostic.

DB2_TOKEN_STRING
Returns a X'FF' delimited string of the tokens for the specified diagnostic.

MESSAGE_LENGTH
Identifies the length (in characters) of the message text of the error, warning, or
successful completion returned from the previous SQL statement that was
executed.

MESSAGE_OCTET_LENGTH
Identifies the length (in bytes) of the message text of the error, warning, or
successful completion returned from the previous SQL statement that was
executed.
GET DIAGNOSTICS

MESSAGE_TEXT
Identifies the message text of the error, warning, or successful completion returned from the previous SQL statement that was executed.

When the SQLCODE is 0, the empty string is returned, even if the RETURNED_SQLSTATE value indicates a warning condition.

PARAMETER_MODE
If the returned SQLSTATE is:
• class 39 (External Routine Invocation Exception), or
• class 38 (External Routine Exception), or
• class 2F (SQL Routine Exception), or
• class 22 (Data Exception), or
• class 23 (Integrity Constraint Violation), or
• class 01 (Warning)

and the condition is related to the ith parameter of the routine, the parameter mode of the ith parameter is returned. Otherwise, the empty string is returned.

PARAMETER_NAME
If the returned SQLSTATE is:
• class 39 (External Routine Invocation Exception), or
• class 38 (External Routine Exception), or
• class 2F (SQL Routine Exception), or
• class 22 (Data Exception), or
• class 23 (Integrity Constraint Violation), or
• class 01 (Warning)

the condition is related to the ith parameter of the routine, and a parameter name was specified for the parameter when the routine was created, the parameter name of the ith parameter is returned. Otherwise, the empty string is returned.

PARAMETER_ORDINAL_POSITION
If the returned SQLSTATE is:
• class 39 (External Routine Invocation Exception), or
• class 38 (External Routine Exception), or
• class 2F (SQL Routine Exception), or
• class 22 (Data Exception), or
• class 23 (Integrity Constraint Violation), or
• class 01 (Warning)

and the condition is related to the ith parameter of the routine, the value of i is returned. Otherwise, the empty string is returned.

RETURNED_SQLSTATE
Returns the SQLSTATE for the specified diagnostic.

ROUTINE_CATALOG
If the returned SQLSTATE is:
• class 39 (External Routine Invocation Exception), or
• class 38 (External Routine Exception), or
• class 2F (SQL Routine Exception), or

and the condition is related to the ith parameter of the routine, or if the returned SQLSTATE is:
GET DIAGNOSTICS

- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the server name of the routine is returned. Otherwise, the empty string is returned.

ROUTINE_NAME
If the returned SQLSTATE is:
- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or

and the condition is related to the \( i \)th parameter of the routine, or if the returned SQLSTATE is:
- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the name of the routine is returned. Otherwise, the empty string is returned.

ROUTINE_SCHEMA
If the returned SQLSTATE is:
- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or

and the condition is related to the \( i \)th parameter of the routine, or if the returned SQLSTATE is:
- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)

and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the schema name of the routine is returned. Otherwise, the empty string is returned.

SCHEMA_NAME
If the returned SQLSTATE is:
- class 09 (Triggered Action Exception), or
- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),

and the constraint that caused the error is a referential, check, or unique constraint, the schema name of the table that owns the constraint is returned.

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the schema name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the schema name of the view that caused the error is returned. Otherwise, the empty string is returned.
GET DIAGNOSTICS

SERVER_NAME
If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION, the name of the server specified in the previous statement is returned. Otherwise, the name of the server where the statement executed is returned.

SPECIFIC_NAME
If the returned SQLSTATE is:
- class 39 (External Routine Invocation Exception), or
- class 38 (External Routine Exception), or
- class 2F (SQL Routine Exception), or
and the condition is related to the $ith parameter of the routine, or if the returned SQLSTATE is:
- class 22 (Data Exception), or
- class 23 (Integrity Constraint Violation), or
- class 01 (Warning)
and the condition was raised as the result of an assignment to an SQL parameter during an routine invocation, the specific name of the procedure or function is returned. Otherwise, the empty string is returned.

SUBCLASS_ORIGIN
Returns 'ISO 9075' for those SQLSTATEs whose subclass is defined by ISO 9075. Returns 'ISO/IEC 9579' for those SQLSTATEs whose subclass is defined by RDA. Returns 'ISO/IEC 13249-1', 'ISO/IEC 13249-2', 'ISO/IEC 13249-3', 'ISO/IEC 13249-4', or 'ISO/IEC 13249-5' for those SQLSTATEs whose subclass is defined SQL/MM. Returns 'DB2 SQL' for those SQLSTATEs whose subclass is defined by IBM Db2 SQL. Returns the value set by user written code if available. Otherwise, the empty string is returned.

TABLE_NAME
If the returned SQLSTATE is:
- class 09 (Triggered Action Exception), or
- class 23 (Integrity Constraint Violation), or
- class 27 (Triggered Data Change Violation), or
- 40002 (Transaction Rollback - Integrity Constraint Violation),
and the constraint that caused the error is a referential, check, or unique constraint, the table name that owns the constraint is returned.

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the table name that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the table name that caused the error is returned. Otherwise, the empty string is returned.

TRIGGER_CATALOG
If the returned SQLSTATE is:
- class 09 (Triggered Action Exception), or
- class 27 (Triggered Data Change Violation),
the name of the trigger is returned. Otherwise, the empty string is returned.

TRIGGER_NAME
If the returned SQLSTATE is:
- class 09 (Triggered Action Exception), or
GET DIAGNOSTICS

- class 27 (Triggered Data Change Violation),
  the name of the trigger is returned. Otherwise, the empty string is returned.

**TRIGGER_SCHEMA**
If the returned SQLSTATE is:
- class 09 (Triggered Action Exception), or
- class 27 (Triggered Data Change Violation),
  the schema name of the trigger is returned. Otherwise, the empty string is returned.

**Notes**

**Considerations for the diagnostics area:** The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2_GET_DIAGNOSTICS_DIAGNOSTICS.

If the GET DIAGNOSTICS statement is specified in an SQL function, SQL procedure, or trigger:
- If information is desired about an error, the GET DIAGNOSTICS statement must be the first executable statement specified in the handler that will handle the error.
- If information is wanted about a warning:
  - If a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first statement specified in that handler.
  - If a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

Otherwise, GET DIAGNOSTICS statement returns information about the last executed statement.

**Considerations for the SQLCODE and SQLSTATE SQL variables:** The GET DIAGNOSTICS statement changes the value of the SQLSTATE and SQLCODE SQL variables.

**Case of return values:** Values for identifiers in returned diagnostic items are not delimited and are case sensitive. For example, a table name of "abc" would be returned, simply as abc.

**Variable assignment:** If an assignment error occurs, the values in the variables are unpredictable.

**Data types for items:** The following table shows, the SQL data type for each diagnostic item. When a diagnostic item is assigned to a variable, the variable must be compatible with the data type of the diagnostic item.

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Data Type</th>

### SQL statement codes and strings:

The following table represents the possible values for `COMMAND_FUNCTION`, `COMMAND_FUNCTION_CODE`, `DYNAMIC_FUNCTION`, and `DYNAMIC_FUNCTION_CODE` diagnostic items.

The values in the following table are assigned by the ISO and ANSI SQL Standard and may change as the standard evolves. Include `sqlscds` in the include source files in library QSYSINC should be used when referencing these values.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword `EXCEPTION` can be used as a synonym for `CONDITION`.
- The keyword `RETURN_STATUS` can be used as a synonym for `DB2_RETURN_STATUS`.  

---

**Chapter 7. Statements**
**GET DIAGNOSTICS**

**Example**

In an SQL procedure, execute a GET DIAGNOSTICS statement to determine how many rows were updated.

```sql
CREATE PROCEDURE sqlprocg (IN deptnbr VARCHAR(3))
  LANGUAGE SQL
BEGIN
  DECLARE SQLSTATE CHAR(5);
  DECLARE rcount INTEGER;
  UPDATE CORPDATA.PROJECT
  SET PRSTAFF = PRSTAFF + 1.5
  WHERE DEPTNO = deptnbr;
  GET DIAGNOSTICS rcount = ROW_COUNT;
  /* At this point, rcount contains the number of rows that were updated. */
END
```

Within an SQL procedure, handle the returned status value from the invocation of a stored procedure called TRYIT. TRYIT could use the RETURN statement to explicitly return a status value or a status value could be implicitly returned by the database manager. If the procedure is successful, it returns a value of zero.

```sql
CREATE PROCEDURE TESTIT ()
  LANGUAGE SQL
A1: BEGIN
  DECLARE RETVAL INTEGER DEFAULT 0;
  ...
  CALL TRYIT
  GET DIAGNOSTICS RETVAL = RETURN_STATUS;
  IF RETVAL <> 0 THEN
    ...
    LEAVE A1;
  ELSE
    ...
  END IF;
END A1
```

In an SQL procedure, execute a GET DIAGNOSTICS statement to retrieve the message text for an error.

```sql
CREATE PROCEDURE divide2 ( IN numerator INTEGER,
  IN denominator INTEGER,
  OUT divide_result INTEGER,
  OUT divide_error VARCHAR(70) )
  LANGUAGE SQL
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLERROR
  GET DIAGNOSTICS CONDITION 1
  divide_error = MESSAGE_TEXT;
  SET divide_result = numerator / denominator;
END;
```
GRANT (function or procedure privileges)

This form of the GRANT statement grants privileges on a function or procedure.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each function or procedure identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the function or procedure
  - The system authority *EXECUTE on the library (or directory if this is a Java routine) containing the function or procedure
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the function or procedure
- Database administrator authority
- Security administrator authority

Syntax
GRANT (function or procedure privileges)

parameter-type:

   data-type

   data-type:

      built-in-type

      distinct-type-name

      array-type-name

built-in-type:

IBM i: Db2 for i SQL Reference
GRANT (function or procedure privileges)

ccsid-clause:

| CCSID—integer |

Notes:

1. The value that is specified for precision does not have to match the value that was specified when the function was created because matching is based on data type (REAL or DOUBLE).

Description

ALL or ALL PRIVILEGES

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified functions or procedures. Note that granting ALL PRIVILEGES on a function or procedure is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

ALTER

Grants the privilege to use the ALTER FUNCTION, ALTER PROCEDURE, or COMMENT statement.

EXECUTE

Grants the privilege to execute the function or procedure.

FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the privilege is granted. The function must exist at the current server and it must be a user-defined function, but not a function that was implicitly generated with the creation of a distinct type. The function can be identified by its name, function signature, or specific name.

FUNCTION function-name

Identifies the function by its name. The function-name must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION function-name (parameter-type, ...)

Identifies the function by its function signature, which uniquely identifies the function. The function-name (parameter-type, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If function-name () is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type, ...)

Identifies the parameters of the function.
If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

**AS LOCATOR**
Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

**SPECIFIC FUNCTION specific-name**
Identifies the function by its specific name. The specific-name must identify a specific function that exists at the current server.

**PROCEDURE or SPECIFIC PROCEDURE**
Identifies the procedure on which the privilege is granted. The procedure-name must identify a procedure that exists at the current server.

**PROCEDURE procedure-name**
Identifies the procedure by its name. The procedure-name must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

**PROCEDURE procedure-name (parameter-type, ...)**
Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The procedure-name (parameter-type, ...) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be granted. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.
GRANT (function or procedure privileges)

If procedure-name () is specified, the procedure identified must have zero parameters.

procedure-name
   Identifies the name of the procedure.

(parameter-type, ...)
   Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

 AS LOCATOR
   Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

 SPECIFIC PROCEDURE specific-name
   Identifies the procedure by its specific name. The specific-name must identify a specific procedure that exists at the current server.

 TO Indicates to whom the privileges are granted.

 USER
   Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

 GROUP
   Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

 authorization-name,...
   Lists one or more authorization IDs.
GRANT (function or procedure privileges)

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 18.

WITH GRANT OPTION
Allows the specified authorization-names to grant privileges on the functions or procedures specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified authorization-names cannot grant privileges on the functions or procedures specified in the ON clause to another user unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

**Corresponding System Authorities:** Privileges granted to either an SQL or external function or procedure are granted to its associated program (*PGM) or service program (*SRVPGM) object. Privileges granted to a Java external function or procedure are granted to the associated class file or jar file. If the associated program, service program, class file, or jar file is not found when the grant is executed, an error is returned.

GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

### Table 92. Privileges Granted to or Revoked from Non-Java Functions or Procedures

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Function or Procedure</th>

</thead>
<tbody>
<tr>
<td>ALTER</td>
<td>*R</td>
<td>*OBJALTER</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>*RX</td>
<td>*EXECUTE</td>
</tr>
</tbody>
</table>

Built-in functions: Privileges cannot be granted on built-in functions.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword RUN can be used as a synonym for EXECUTE.

Example

Grant the EXECUTE privilege on procedure PROCA to PUBLIC.

```
GRANT EXECUTE
ON PROCEDURE PROCA
TO PUBLIC
```
GRANT (package privileges)

This form of the GRANT statement grants privileges on a package.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each package identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the package
  - The system authority *EXECUTE on the library containing the package
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the package
- Database administrator authority
- Security administrator authority

Syntax

```
GRANT PRIVILEGES
   ALL, ALTER
   ON PACKAGE package-name
TO authorization-name
   WITH GRANT OPTION
```

Description

**ALL or ALL PRIVILEGES**

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified packages. Note that granting ALL PRIVILEGES on a package is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.
**GRANT (package privileges)**

**ALTER**
Grants the privilege to use the COMMENT and LABEL statements.

**EXECUTE**
Grants the privilege to execute statements in a package.

**ON PACKAGE package-name**
Identifies the packages on which you are granting the privilege. The `package-name` must identify a package that exists at the current server.

**TO** Indicates to whom the privileges are granted.

**USER**
Specifies that the `authorization-name` identifies a user profile. If USER is specified, `authorization-name` must be a user profile.

**GROUP**
Specifies that the `authorization-name` identifies a group profile. If GROUP is specified, `authorization-name` must be a group profile.

**authorization-name,...**
Lists one or more authorization IDs.

**PUBLIC**
Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 18.

**WITH GRANT OPTION**
Allows the specified `authorization-names` to grant privileges on the packages specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified `authorization-names` cannot grant privileges on the packages specified in the ON clause to another user unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT)*.

**Notes**

**Corresponding System Authorities:** GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Package</th>
</tr>
</thead>
</table>
| ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has) | *OBJALTER  
*OBJOPR  
*EXECUTE  
*OBJMGT (Revoke only) |
| ALTER | *OBJALTER  |
| EXECUTE | *EXECUTE  
*OBJOPR  |
| WITH GRANT OPTION | *OBJMGT |

**Corresponding System Authorities When Checking Privileges to a Package:** The following table describes the system authorities that correspond to the SQL
privileges when checking privileges to a package. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 97. Corresponding System Authorities When Checking Privileges to a Package

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities When Checking Privileges to a Package</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER</td>
<td>*OBJALTER</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>*EXECUTE and *OBJOPR</td>
</tr>
</tbody>
</table>

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword RUN can be used as a synonym for EXECUTE.
- The keyword PROGRAM can be used as a synonym for PACKAGE.

**Example**

Grant the EXECUTE privilege on package PKGA to PUBLIC.

```
GRANT EXECUTE
    ON PACKAGE PKGA
    TO PUBLIC
```
GRANT (schema privileges)

This form of the GRANT statement grants privileges on a schema.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each schema identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the schema
- Database administrator authority
- Security administrator authority

Syntax

```
GRANT PRIVILEGES ALL, CREATEIN USAGE ON SCHEMA schema-name
    TO authorization-name
    WITH GRANT OPTION
```

Description

**ALL or ALL PRIVILEGES**

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified schemas. Note that granting ALL PRIVILEGES on a schema is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.

**CREATEIN**

Grants the privilege to create objects in the schema. Other authorities or privileges required to create the object are still required.

**USAGE**

Grants the privilege to use the schema. USAGE privilege is required to reference any objects that exist in the schema.

**ON SCHEMA schema-name**

Identifies the schemas on which the privilege is granted.
TO Indicates to whom the privileges are granted.

USER Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name,... Lists one or more authorization IDs.

PUBLIC Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 18.

WITH GRANT OPTION Allows the specified authorization-names to grant privileges on the schemas specified in the ON clause to other users.

Notes

Corresponding System Authorities: GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges when granting to a schema. The left column lists the SQL privilege. The right column lists the equivalent system authorities that are granted or revoked.

Table 98. Privileges Granted to or Revoked from Schemas

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Schema</th>
</tr>
</thead>
</table>
| ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has) | *OBJMGT
*OBJOPR
*READ
*EXECUTE
*ADD |
| CREATEIN | *OBJOPR
*READ
*EXECUTE
*ADD |
| USAGE | *OBJOPR
*READ
*EXECUTE |
| WITH GRANT OPTION | *OBJMGT |

Corresponding System Authorities When Checking Privileges to a Schema: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a schema. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Notes

109. Only *ADD is revoked when CREATEIN is revoked.
**Table 99. Corresponding System Authorities When Checking Privileges to a Schema**

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATEIN</td>
<td>*OBJOPR, *READ, *EXECUTE, and *ADD(^{10})</td>
</tr>
<tr>
<td>USAGE</td>
<td>*EXECUTE(^{10})</td>
</tr>
</tbody>
</table>

**GRANT rules:** The GRANT statement will grant only those privileges that the authorization ID of the statement is allowed to grant. If no privileges were granted, an error is returned.

**Example**

*Example 1:* Grant the CREATEIN privilege on schema T_SCORES to user JONES.

```
GRANT CREATEIN
    ON SCHEMA T_SCORES
    TO JONES;
```

---

\(^{10}\) *OBJOPR and *READ are only checked for certain statements (for example CREATEs).
GRANT (sequence privileges)

This form of the GRANT statement grants privileges on a sequence.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each sequence identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the sequence
  - The system authority *EXECUTE on the library containing the sequence
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the sequence
- Database administrator authority
- Security administrator authority

Syntax

```
GRANT PRIVILEGES ALL, ALTER USAGE ON SEQUENCE sequence-name TO authorization-name USER WITH GRANT OPTION GROUP PUBLIC
```

Description

**ALL or ALL PRIVILEGES**

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified sequences. Note that granting ALL PRIVILEGES on a sequence is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.
GRANT (sequence privileges)

ALTER
Grants the privilege to use the ALTER SEQUENCE, COMMENT, and LABEL statements on a sequence.

USAGE
Grants the privilege to use the sequence in NEXT VALUE or PREVIOUS VALUE expressions.

ON SEQUENCE sequence-name
Identifies the sequences on which the privilege is granted. The sequence-name must identify a sequence that exists at the current server.

TO Indicates to whom the privileges are granted.

USER
Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP
Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name,...
Lists one or more authorization IDs.

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page [18].

WITH GRANT OPTION
Allows the specified authorization-names to grant privileges on the sequences specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified authorization-names cannot grant the USAGE privilege to others unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

Corresponding System Authorities: GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

Table 100. Privileges Granted to or Revoked from Sequences

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Sequence</th>
</tr>
</thead>
</table>
| ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has) | *OBJALTER  
*OBJOPR  
*EXECUTE  
*READ  
*ADD  
*DLT  
*UPD  
*OBJMGT (Revoke only) |
| ALTER                                                                       | *OBJALTER                                                             |
Table 100. Privileges Granted to or Revoked from Sequences (continued)

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>USAGE</td>
<td>*OBJOPR *EXECUTE *READ *ADD *DLT *UPD</td>
</tr>
<tr>
<td>WITH GRANT OPTION</td>
<td>*OBJMGT</td>
</tr>
</tbody>
</table>

**Corresponding System Authorities When Checking Privileges to a Sequence:**
The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a sequence. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 101. Corresponding System Authorities When Checking Privileges to a Sequence

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER</td>
<td>*OBJALTER</td>
</tr>
<tr>
<td>USAGE</td>
<td>*OBJOPR and *EXECUTE and *READ and *ADD and *DLT and *UPD</td>
</tr>
</tbody>
</table>

**Example**

Grant any user the USAGE privilege on a sequence called ORG_SEQ.

```
GRANT USAGE
ON SEQUENCE ORG_SEQ
TO PUBLIC
```
GRANT (table or view privileges)

This form of the GRANT statement grants privileges on tables or views.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each table or view identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the table or view
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the table
- Database administrator authority
- Security administrator authority

Syntax
GRANT (table or view privileges)

Description

ALL or ALL PRIVILEGES
Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified tables or views.

Note that granting ALL PRIVILEGES on a table or view is not the same as granting the system authority of *ALL.

ALTER
Grants the privilege to alter the specified table or create or drop a trigger on the specified table. Grants the privilege to use the COMMENT and LABEL statements on tables and views.

DELETE
Grants the privilege to delete rows from the specified table or view. If a view is specified, it must be a deletable view.

INDEX
Grants the privilege to create an index on the specified table. This privilege cannot be granted on a view.

INSERT
Grants the privilege to insert rows into the specified table or view. If a view is specified, it must be an insertable view.

REFERENCES
Grants the privilege to add a referential constraint in which each specified table is a parent. If a list of columns is not specified or if REFERENCES is granted to all columns of the table or view via the specification of ALL PRIVILEGES, the grantee(s) can add referential constraints using all columns of each table specified in the ON clause as a parent key, even those added later via the ALTER TABLE statement. This privilege can be granted on a view, but the privilege is not used for a view.

REFERENCES (column-name,...)
Grants the privilege to add a referential constraint in which each specified table is a parent using only those columns specified in the column list as a parent key. Each column-name must be an unqualified name that identifies a column of each table specified in the ON clause. This privilege can be granted on the columns of a view, but the privilege is not used for a view.

SELECT
Grants the privilege to create a view or read data from the specified table or view. For example, the SELECT privilege is required if a table or view is specified in a query.

UPDATE
Grants the privilege to update rows in the specified table or view. If a list of columns is not specified or if UPDATE is granted to all columns of the table or view via the specification of ALL PRIVILEGES, the grantee(s) can update all
GRANT (table or view privileges)

updatable columns on each table specified in the ON clause, even those added later via the ALTER TABLE statement. If a view is specified, it must be an updatable view.

UPDATE (column-name,...)
Grants the privilege to use the UPDATE statement to update only those columns that are identified in the column list. Each column-name must be an unqualified name that identifies a column of each table and view specified in the ON clause. If a view is specified, it must be an updatable view and the specified columns must be updatable columns.

ON table-name or view-name,...
Identifies the tables or views on which the privileges are granted. The table-name or view-name must identify a table or view that exists at the current server, but must not identify a declared temporary table.

TO Indicates to whom the privileges are granted.

USER
Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP
Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name,...
Lists one or more authorization IDs.

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 18.

WITH GRANT OPTION
Allows the specified authorization-names to grant privileges on the tables and views specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified authorization-names cannot grant privileges on the tables and views specified in the ON clause unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

Corresponding system authorities: The GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges when granting to a table. The left column lists the SQL privilege. The right column lists the equivalent system authorities that are granted or revoked.
Table 102. Privileges Granted to or Revoked from Tables

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Table</th>
</tr>
</thead>
</table>
| ALL (GRANT or revoke of ALL only grants or revokes those privileges the authorization ID of the statement has) | *OBJALTER 111
*OBJMGT (Revoke only)
*OBJOPR
*OBJREF
*ADD
*DLT
*READ
*UPD |
| ALTER | *OBJALTER 112 |
| DELETE | *OBJOPR 113
*DLT |
| INDEX | *OBJALTER 112 |
| INSERT | *OBJOPR 113
*ADD |
| REFERENCES | *OBJREF 112 |
| SELECT | *OBJOPR 113
*READ |
| UPDATE | *OBJOPR 113
*UPD |
| WITH GRANT OPTION | *OBJMGT |

The following table describes the system authorities that correspond to the SQL privileges when granting to a view. The left column lists the SQL privilege. The middle column lists the equivalent system authorities that are granted to or revoked from the view itself. The right column lists the system authorities that are granted to all tables and views referenced in the view’s definition, and if a view is referenced, all tables and views referenced in its definition, and so on. 114

If a view references more than one table or view, the *DLT, *ADD, and *UPD system authorities are only granted to the first table or view in the fullselect of the view definition. The *READ system authority is granted to all tables and views referenced in the view definition.

If more than one system authority will be granted with an SQL privilege, and any one of the authorities cannot be granted, then a warning occurs and no authorities will be granted for that privilege. Unlike GRANT, REVOKE only revokes system authorities to the view. No system authorities are revoked from the referenced tables and views.

111. The SQL INDEX and ALTER privilege correspond to the same system authority of *OBJALTER. Granting both INDEX and ALTER will not provide the user with any additional authorities.

112. If the WITH GRANT OPTION is given to a user, the user will also be able to perform the functions given by ALTER and REFERENCES authority.

113. *OBJOPR is only revoked when the last system privilege other than *OBJOPR is also revoked for the specified authorization ID or PUBLIC.

114. The specified rights are only granted to the tables and views referenced in the view definition if the user to whom the rights are being granted doesn't already have the rights from another authority source, for example public authority.
## GRANT (table or view privileges)

### Table 103. Privileges Granted to or Revoked from Views

<table>

<td>None</td>
</tr>
<tr>
<td>SELECT</td>
<td>*OBJOPR and *READ</td>
<td>*READ</td>
</tr>
<tr>
<td>UPDATE&lt;sup&gt;117&lt;/sup&gt;</td>
<td>*OBJOPR and *UPD</td>
<td>*UPD</td>
</tr>
</tbody>
</table>

**GRANT rules:** The GRANT statement will grant only those privileges that the authorization ID of the statement is allowed to grant. If no privileges were granted, an error is returned.

**Examples**

**Example 1:** Grant all privileges on the table WESTERN_CR to PUBLIC.

```
GRANT ALL PRIVILEGES ON WESTERN_CR TO PUBLIC
```

**Example 2:** Grant the appropriate privileges on the CALENDAR table so that PHIL and CLAIRE can read it and insert new entries into it. Do not allow them to change or remove any existing entries.

```
GRANT SELECT, INSERT ON CALENDAR
TO PHIL, CLAIRE
```

**Example 3:** Grant column privileges on TABLE1 and VIEW1 to FRED. Note that both columns specified in this GRANT statement must be found in both TABLE1 and VIEW1.

```
GRANT UPDATE(column_1, column_2)
ON TABLE1, VIEW1
TO FRED WITH GRANT OPTION
```

---

<sup>115</sup> When a view is created, the owner does not necessarily acquire the DELETE privilege on the view. The owner only acquires the DELETE privilege if the view allows deletes and the owner also has the DELETE privilege on the first table referenced in the subselect.

<sup>116</sup> When a view is created, the owner does not necessarily acquire the INSERT privilege on the view. The owner only acquires the INSERT privilege if the view allows inserts and the owner also has the INSERT privilege on the first table referenced in the subselect.

<sup>117</sup> When a view is created, the owner does not necessarily acquire the UPDATE privilege on the view. The owner only acquires the UPDATE privilege if the view allows updates and the owner also has the UPDATE privilege on the first table referenced in the subselect.
GRANT (type privileges)

This form of the GRANT statement grants privileges on a type.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type or array type identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the type
  - The system authority *EXECUTE on the library containing the type
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the type
- Database administrator authority
- Security administrator authority

Syntax

```
GRANT PRIVILEGES
    ALL,
    ALTER USAGE
    ON
    TYPE distinct-type-name array-type-name
    TO authorization-name
    USER
    GROUP
    PUBLIC
    WITH GRANT OPTION
```

Description

**ALL or ALL PRIVILEGES**

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified distinct types or array types. Note that granting ALL PRIVILEGES on a type is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.
**ALTER**
Grants the privilege to use the COMMENT and LABEL statement.

**USAGE**
Grants the privilege to use the type in tables, functions, procedures, or CAST expressions.

**ON TYPE distinct-type-name or array-type-name**
Identifies the distinct types or array types on which the privilege is granted. The distinct-type-name or array-type-name must identify a user-defined type that exists at the current server.

**TO** Indicates to whom the privileges are granted.

**USER**
Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

**GROUP**
Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

**authorization-name,...**
Lists one or more authorization IDs.

**PUBLIC**
Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 18.

**WITH GRANT OPTION**
Allows the specified authorization-names to grant privileges on the types specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified authorization-names cannot grant the USAGE privilege to others unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

**Notes**

**Corresponding System Authorities:** GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

*Table 106. Privileges Granted to or Revoked from User-defined Types*

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a User-defined Type</th>
</tr>
</thead>
</table>
| ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has) | *OBJALTER  
*OBJOPR  
*EXECUTE  
*OBJMGT (Revoke only) |
| ALTER         | *OBJALTER  |
| USAGE         | *EXECUTE  
*OBJOPR |
| WITH GRANT OPTION | *OBJMGT |
GRANT (type privileges)

Corresponding System Authorities When Checking Privileges to a User-defined Type: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a type. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 107. Corresponding System Authorities When Checking Privileges to a User-defined Type

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a User-defined Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER</td>
<td>*OBJALTER</td>
</tr>
<tr>
<td>USAGE</td>
<td>*EXECUTE and *OBJOPR</td>
</tr>
</tbody>
</table>

When USAGE privilege is required: USAGE privilege is required when a type is explicitly referenced in an SQL statement. For example, in a statement that contains a CAST specification or in a CREATE TABLE statement. The USAGE privilege is not required when a type is indirectly referenced. For example, when a view references a column of a table that has a distinct data type.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.

Example

Grant the USAGE privilege on distinct type SHOE_SIZE to user JONES. This GRANT statement does not give JONES the privilege to execute the cast functions that are associated with the distinct type SHOE_SIZE.

GRANT USAGE ON DISTINCT TYPE SHOE_SIZE TO JONES
GRANT (variable privileges)

This form of the GRANT statement grants privileges on a global variable.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each global variable identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the global variable
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the global variable
- Database administrator authority
- Security administrator authority

Syntax

```
GRANT PRIVILEGES ALL, ALTER, READ, WRITE ON VARIABLE variable-name TO authorization-name
```

Description

**ALL or ALL PRIVILEGES**

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified global variables. Note that granting ALL PRIVILEGES on a global variable is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.
**GRANT (variable privileges)**

**ALTER**
Grants the privilege to use the COMMENT and LABEL statements on a global variable.

**READ**
Grants the privilege to read the value of a global variable.

**WRITE**
Grants the privilege to assign a value to a global variable.

**ON VARIABLE variable-name**
Identifies the global variables on which the privilege is granted. The `variable-name` must identify a global variable that exists at the current server.

**TO**
Indicates to whom the privileges are granted.

**USER**
Specifies that the `authorization-name` identifies a user profile. If USER is specified, `authorization-name` must be a user profile.

**GROUP**
Specifies that the `authorization-name` identifies a group profile. If GROUP is specified, `authorization-name` must be a group profile.

`authorization-name,...`
Lists one or more authorization IDs.

**PUBLIC**
Grants the privileges to a set of users (authorization IDs). For more information, see "Authorization, privileges and object ownership" on page [18].

**WITH GRANT OPTION**
Allows the specified `authorization-names` to grant privileges on the global variables specified in the ON clause to other users.

**Notes**

**Corresponding System Authorities:** GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Global Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has)</td>
<td>*OBJALTER *OBJOPR *EXECUTE *UPD *READ *OBJMGT (Revoke only)</td>
</tr>
<tr>
<td>ALTER</td>
<td>*OBJALTER</td>
</tr>
<tr>
<td>READ</td>
<td>*OBJOPR *EXECUTE *READ</td>
</tr>
</tbody>
</table>
Table 108. Privileges Granted to or Revoked from Global Variables (continued)

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from a Global Variable</th>
</tr>
</thead>
</table>
| WRITE                 | *OBJOPR  
|                       | *EXECUTE  
|                       | *UPD  |
| WITH GRANT OPTION     | *OBJMGT  |

Corresponding System Authorities When Checking Privileges to a Global Variable: The following table describes the system authorities that correspond to the SQL privileges when checking privileges to a global variable. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

Table 109. Corresponding System Authorities When Checking Privileges to a Global Variable

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER</td>
<td>*OBJALTER</td>
</tr>
<tr>
<td>READ</td>
<td>*OBJOPR and *EXECUTE and *READ</td>
</tr>
<tr>
<td>WRITE</td>
<td>*OBJOPR and *EXECUTE and *UPD</td>
</tr>
</tbody>
</table>

Example

Grant the READ and WRITE privileges on global variable MYSCHMA.MYJOB_PRINTER to user ZUBIRI.

```
GRANT READ, WRITE
  ON VARIABLE MYSCHMA.MYJOB_PRINTER
  TO ZUBIRI
```
GRANT (XML schema privileges)

This form of the GRANT statement grants privileges on an XSR object.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each XSR object identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the XSR object
  - The system authority *EXECUTE on the library containing the XSR object
- Database administrator authority
- Security administrator authority

If WITH GRANT OPTION is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- Ownership of the XSR object
- Database administrator authority
- Security administrator authority

Syntax

```
GRANT PRIVILEGES
    ALL, ALTER
    ON XSR OBJECT xsrobject-name
    TO authorization-name
    WITH GRANT OPTION
```

Description

**ALL or ALL PRIVILEGES**

Grants one or more privileges. The privileges granted are all those grantable privileges that the authorization ID of the statement has on the specified XSR object. Note that granting ALL PRIVILEGES on an XSR object is not the same as granting the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword grants the privilege described.
ALTER
Grants the privilege to use the COMMENT and LABEL statements.

USAGE
Grants the privilege to use the XSR object for validation or decomposition.

ON XSROBJECT xsrobject-name
Identifies the XSR objects for which the privilege is granted. The xsrobject-name must identify an XSR object that exists at the current server.

TO
Indicates to whom the privileges are granted.

USER
Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP
Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name,...
Lists one or more authorization IDs.

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see “Authorization, privileges and object ownership” on page 18.

WITH GRANT OPTION
Allows the specified authorization-names to grant privileges on the XSR objects specified in the ON clause to other users.

If WITH GRANT OPTION is omitted, the specified authorization-names cannot grant privileges on the XSR objects specified in the ON clause to another user unless they have received that authority from some other source (for example, from a grant of the system authority *OBJMGT).

Notes

GRANT and REVOKE statements assign and remove system authorities for SQL objects. The following table describes the system authorities that correspond to the SQL privileges:

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities when Granting to or Revoking from an XSR object</th>
</tr>
</thead>
</table>
| ALL (Grant or revoke of ALL grants or revokes only those privileges the authorization ID of the statement has) | *OBJALTER  
*OBJOPR  
*READ  
*EXECUTE  
*OBJMGT (Revokes only) |
| ALTER | *OBJALTER |
| USAGE | *OBJOPR  
*EXECUTE  
*READ |
| WITH GRANT OPTION | *OBJMGT |
Corresponding System Authorities When Checking Privileges to an XSR Object:
The following table describes the system authorities that correspond to the SQL privileges when checking privileges to an XSR object. The left column lists the SQL privilege. The right column lists the equivalent system authorities.

<table>
<thead>
<tr>
<th>SQL Privilege</th>
<th>Corresponding System Authorities</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER</td>
<td>*OBJALTER</td>
</tr>
<tr>
<td>USAGE</td>
<td>*OBJOPR and *EXECUTE and *READ</td>
</tr>
</tbody>
</table>

Example

Grant the USAGE privilege on XSR object XMLSCHEMA to PUBLIC.

```
GRANT USAGE
ON XSROBJECT XMLSCHEMA
TO PUBLIC
```
HOLD LOCATOR

The HOLD LOCATOR statement allows a LOB or XML locator variable to retain its association with a value beyond a unit of work.

Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. HOLD LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in REXX.

Authorization

None required.

Syntax

```
  HOLD LOCATOR variable,...
```

Description

```
variable,...
```

Identifies a variable that must be declared in accordance with the rules for declaring variable locator variables. An indicator variable must not be specified. The locator variable type must be a binary large object locator, a character large object locator, a double-byte character large object locator, or an XML locator.

After the HOLD LOCATOR statement is executed, each locator variable in the `variable` list has the hold property.

The variable must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a CALL, FETCH, SELECT INTO, SET variable, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is raised.

If more than one variable is specified in the HOLD LOCATOR statement and an error occurs on one of the locators, no locators will be held.

Note

A LOB or XML locator variable that has the hold property is freed (has its association between it and its value removed) when:

- The SQL FREE LOCATOR statement is executed for the locator variable.
- The SQL ROLLBACK statement without a HOLD option is executed.
- The SQL session is terminated.

Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the...
values represented by the columns. Give the CLOB locator variables LOCRE$ and
LOCHIST, and the BLOB locator variable LOCPIC the hold property.

HOLD LOCATOR :LOCRE$,:LOCHIST,:LOCPIC
The INCLUDE statement inserts application code, including declarations and statements, into a source program.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

The authorization ID of the statement must have the system authorities *OBJOPR and *READ on the file that contains the member.

Syntax

```
INCLUDE SQLCA
SQLDA
name
*LIBL-/file-name(--member-name--)
*CURLIB-/library-name-/string
```

Description

SQLCA

Indicates the description of an SQL communication area (SQLCA) is to be included. INCLUDE SQLCA must not be specified if the program includes a stand-alone SQLCODE or a stand-alone SQLSTATE. An SQLCA can be specified for C, C++, COBOL, and PL/I. If the SQLCA is not specified, the variable SQLCODE or SQLSTATE must appear in the program.

INCLUDE SQLCA must not be specified more than once in the same program. For more information, see “SQL diagnostic information” on page 826.

The SQLCA should not be specified for RPG programs. In an RPG program, the precompiler automatically includes the SQLCA.

For a description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),” on page 1737.

SQLDA

Specifies the description of an SQL descriptor area (SQLDA) is to be included. INCLUDE SQLDA can be specified in C, C++, COBOL, PL/I, and ILE RPG.

For a description of the SQLDA, see Appendix D, “SQLDA (SQL descriptor area),” on page 1747.

name

Identifies a member or source stream file to be included in the source program.

If precompiling using the SRCFILE parameter, it identifies a member to be included from the file specified on the INCFILE parameter of the CRTSQLxxx command.
INCLUDE

If precompiling using the SRCSTMF parameter, it identifies a file to be included using the path from the INCDIR parameter of the CRTSQLxxx command. No suffix will be appended to the name.

The source can contain any host language statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE member-name must not be specified in other than the DATA DIVISION or PROCEDURE DIVISION.

file-name ( member-name )
Identifies a source file and member to be included in the source program. The library containing the source file is specified in one of these ways:

*LIBL
Libraries in the job's library list are searched until the first match is found.
This is the default.

*CURLIB
The current library for the job is searched. If no library is specified as the current library for the job, QGPL is used.

library-name
Identifies the name of the library to search.

The source can contain any host language statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE must not be specified in other than the DATA DIVISION or PROCEDURE DIVISION.

Including a source file and member is only allowed when precompiling using the SRCFILE parameter.

'string'
Identifies a file to be included using the path from the INCDIR parameter of the CRTSQLxxx command. The string will be handled as a normal SQL string literal; the source stream file rules for escaping characters will not be followed. No suffix will be appended to the string.

The source can contain any host language statements and any SQL statements other than an INCLUDE statement.

Including a stream file is only allowed when precompiling using the SRCSTMF parameter.

When your program is precompiled, the INCLUDE statement is replaced by source statements.

The INCLUDE statement must be specified at a point in your program where the resulting source statements are acceptable to the compiler.

Notes

CCSID considerations: If the CCSID of the file specified on the SRCFILE or SRCSTMF parameter is different from the CCSID of the source for the INCLUDE statement, the INCLUDE source is converted to the CCSID of the source file.

Example

Include an SQL descriptor area in a C program.

EXEC SQL INCLUDE SQLDA;
EXEC SQL DECLARE C1 CURSOR FOR
SELECT DEPTNO, DEPTNAME, MGRNO FROM TDEPT
    WHERE ADMRDEPT = 'A00';

EXEC SQL OPEN C1;

while (SQLCODE==0) {
    EXEC SQL FETCH C1 INTO :dnum, :dname, :mnum;

    /* Print results */
}

EXEC SQL CLOSE C1;
The INSERT statement inserts rows into a table or view. Inserting a row into a view also inserts the row into the table on which the view is based if no INSTEAD OF INSERT trigger is defined on this view. If such a trigger is defined, the trigger will be activated instead.

There are four forms of this statement:
- The INSERT using VALUES form is used to insert one or more rows into the table or view using the values provided or referenced.
- The INSERT using fullselect form is used to insert one or more rows into the table or view using values from other tables or views.
- The INSERT using n ROWS form is used to insert multiple rows into the table or view using the values provided in a host-structure-array.
- The INSERT DEFAULT VALUES form is used to insert a single row using default values for every column.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared with the exception of the n ROWS form, which must be a static statement embedded in an application program. The n ROWS form is not allowed in a REXX procedure.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:
- For the table or view identified in the statement:
  - The INSERT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

If a fullselect is specified, the privileges held by the authorization ID of the statement must also include one of the following:
- For each table or view identified in the fullselect:
  - The SELECT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.

Syntax

```
INSERT INTO table-name [view-name] insert-specification DEFAULT VALUES isolation-clause
```

IBM i: Db2 for i SQL Reference
insert-specification:

include-columns:

insert-multiple-rows:

isolation-clause:

lock-clause:

data-type:
allocate-clause:

ALLOCATE(integer)

ccsid-clause:

CCSID(integer) normalize-clause

normalize-clause:

NOT NORMALIZED
NORMALIZED

Description

INTO table-name or view-name
Identifies the object of the insert operation. The name must identify a table or view that exists at the current server, but it must not identify a history table, a catalog table, a view of a catalog table, or a view that is not insertable. For an explanation of insertable views, see "CREATE VIEW" on page 1255.

DEFAULT VALUES
Specifies that a default value will be assigned to every column in the table. This is the same as specifying a list of values for all the columns with each of the values being the keyword DEFAULT. The value that is inserted depends on how the column was defined, as described for the DEFAULT keyword.

(column-name,...)
Specifies the columns for which insert values are provided. Each name must be a name that identifies a column of the table or view. The same column must not be identified more than once. If extended indicator variables are not enabled, a view column that is not updatable must not be identified. If extended indicator variables are not enabled and the object of the insert operation is a view with such columns, a list of column names must be specified and the list must not identify those columns. For an explanation of updatable columns in views, see "CREATE VIEW" on page 1255.

Omission of the column list is an implicit specification of a list in which every column of the table or view is identified in left-to-right order. Any columns defined with the hidden attribute are omitted. This list is established when the statement is prepared and, therefore, does not include columns that were added to a table after the statement was prepared.

If the INSERT statement is embedded in an application and the referenced table or view exists at create program time, the statement is prepared at create program time. Otherwise, the statement is prepared at the first successful execute of the INSERT statement.

include-columns
Specifies a set of columns that are included, along with the columns of table-name or view-name, in the intermediate result table of the INSERT statement when it is nested in the FROM clause of a fullselect. The include-columns are appended to the end of the list of columns specified by table-name or view-name.
INCLUDE
Specifies a list of columns to be included in the intermediate result table of the INSERT statement. This clause can only be specified if the INSERT statement is nested in the FROM clause of a fullselect.

column-name
Specifies a column of the intermediate result table of the INSERT statement. The name cannot be the same as the name of another include column or a column in table-name or view-name.

FOR COLUMN system-column-name
Provides an IBM i name for the column. The name must not be the same as any column-name or system-column-name in the INCLUDE column list or in table-name or view-name.

data-type
Specifies the data type of the include column. For a description of data-type, see "CREATE TABLE" on page 1159. If a DATALINK data-type is used, FILE LINK CONTROL is not allowed.

OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE
Specifies whether system generated values or user-specified values for a ROWID, identity, or row change timestamp column are used. If OVERRIDING SYSTEM VALUE is specified, the implicit or explicit list of columns for the INSERT statement must contain a ROWID, identity, or row change timestamp column defined as GENERATED ALWAYS. If OVERRIDING USER VALUE is specified, the implicit or explicit list of columns for the INSERT statement must contain a column defined as either GENERATED ALWAYS or GENERATED BY DEFAULT.

OVERRIDING SYSTEM VALUE
Specifies that the value specified in the VALUES clause or produced by a fullselect for a ROWID, identity, or row change timestamp column that is defined as GENERATED ALWAYS is used. A system-generated value is not inserted.

If a value for a row-begin, row-end, transaction-start-ID, or generated expression column is provided, it must be DEFAULT.

OVERRIDING USER VALUE
Specifies that the value specified in the VALUES clause or produced by a fullselect for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is inserted, overriding the user-specified value.

If neither OVERRIDING SYSTEM VALUE nor OVERRIDING USER VALUE is specified:

- A value other than DEFAULT cannot be specified for a ROWID, identity, row change timestamp, row-begin, row-end, transaction-start-ID, or generated expression column that is defined as GENERATED ALWAYS.

- A value can be specified for a ROWID, identity, or row change timestamp column that is defined as GENERATED BY DEFAULT. If a value is specified that value is assigned to the column. However, a value can be inserted into a ROWID column defined BY DEFAULT only if the specified value is a valid row ID value that was previously generated by Db2 for z/OS or Db2 for i. When a value is inserted into an identity or row change timestamp column defined BY DEFAULT, the database manager does not verify that the specified value is a unique value for the column unless the identity or row change timestamp column is the sole key in a unique constraint or unique
index. Without a unique constraint or unique index, the database manager can guarantee unique values only among the set of system-generated values as long as NO CYCLE is in effect.

If a value is not specified the database manager generates a new value.

VALUES
Specifies one or more new rows to be inserted.

Each variable in the clause must identify a host structure or variable that is declared in accordance with the rules for declaring host structures and variables. In the operational form of the statement, a reference to a host structure is replaced by a reference to each of its variables. For further information about variables and structures, see “References to host variables” on page 152 and “Host structures” on page 158.

The number of values for each row in the VALUES clause must equal the number of names in the implicit or explicit column list and the columns identified in the INCLUDE clause. The first value is inserted in the first column in the list, the second value in the second column, and so on.

expression
An expression of the type described in “Expressions” on page 174, that does not include an aggregate function or column name. If expression is a variable, the variable can identify a structure. If extended indicator variables are enabled and the expression is not a single variable, the extended indicator variable values of DEFAULT and UNASSIGNED must not be used for that expression.

DEFAULT
Specifies that the default value is assigned to a column. The value that is inserted depends on how the column was defined, as follows:

- If the column is defined as a generated column based on an expression, the column value is generated by the database manager, based on that expression.
- If the column is a ROWID, an identity column, a row change timestamp column, a row-begin column, a row-end column, or a transaction-start-ID column, the database manager will generate a new value.
- If the WITH DEFAULT clause is used, the default inserted is as defined for the column (see default-clause in column-definition in “CREATE TABLE” on page 1159).
- If the WITH DEFAULT clause or the NOT NULL clause is not used, the value inserted is NULL.
- If the NOT NULL clause is used and the WITH DEFAULT clause is not used or DEFAULT NULL is used, the DEFAULT keyword cannot be specified for that column.

DEFAULT must be specified for a ROWID or a generated column that was defined as GENERATED ALWAYS unless OVERRIDING USER VALUE is specified to indicate that any user-specified value will be ignored and a unique system-generated value will be inserted.

NULL
Specifies the value for a column is the null value. NULL should only be specified for nullable columns.
**INSERT**  

**WITH common-table-expression**  
Specifies a common table expression. For an explanation of common table expression, see "common-table-expression" on page 801.

**fullselect**  
Specifies a set of new rows in the form of the result table of a fullselect. If the result table is empty, SQLSTATE is set to '02000'.  
For an explanation of fullselect, see "fullselect" on page 794.  
When the base object of the INSERT and a base object of any subselect in the fullselect are the same table, the select statement is completely evaluated before any rows are inserted.

The number of columns in the result table must equal the number of names implicitly or explicitly specified in the column-name list. The value of the first column of the result is inserted in the first column in the list, the second value in the second column, and so on.

**isolation-clause**  
Specifies the isolation level to be used for this statement.

**WITH**  
Introduces the isolation level, which may be one of:  
• RR Repeatable read  
• RS Read stability  
• CS Cursor stability  
• UIR Uncommitted read  
• NC No commit

If isolation-clause is not specified the default isolation is used. See "isolation-clause" on page 811 for a description of how the default is determined.

**insert-multiple-rows**  
**integer or variable ROWS**  
Specifies the number of rows to be inserted. If a variable is specified, it must be numeric with zero scale and cannot include an indicator variable.

**VALUES (host-structure-array)**  
Specifies a set of new rows in the form of an array of host structures. The host-structure-array must be declared in the program in accordance with the rules for declaring host structure arrays. A parameter marker may not be used in place of the host-structure-array name.

The number of variables in the host structure must equal the number of names in the implicit or explicit column list and the columns identified in the INCLUDE clause. The first host structure in the array corresponds to the first row, the second host structure in the array corresponds to the second row, and so on. In addition, the first variable in the host structure corresponds with the first column of the row, the second variable in the host structure corresponds with the second column of the row, and so on.

For an explanation of arrays of host structures see "Host structure arrays" on page 160.

**insert-multiple-rows** is not allowed if the current connection is to a non-remote server. **insert-multiple-rows** is not allowed in a data change reference in an RPG/400 or PL/I program.
INSERT Rules

Default Values: The value inserted in any column that is not in the column list is the default value of the column. Columns without a default value must be included in the column list. Similarly, if you insert into a view without an INSTEAD OF INSERT trigger, the default value is inserted into any column of the base table that is not included in the view. Hence, all columns of the base table that are not in the view must have a default value.

Assignment: Insert values are assigned to columns in accordance with the storage assignment rules described in Chapter 2, “Language elements,” on page 49.

Validity: Insert operations must obey the following rules. If they do not, or if any other errors occur during the execution of the INSERT statement, no rows are inserted unless COMMIT(*NONE) was specified.

- Unique constraints and unique indexes: If the identified table, or the base table of the identified view, has one or more unique indexes or unique constraints, each row inserted into the table must conform to the limitations imposed by those indexes and constraints (SQLSTATE 23505).
  All uniqueness checks are effectively made at the end of the statement unless COMMIT(*NONE) was specified. In the case of a multiple-row INSERT statement, this would occur after all rows were inserted. If COMMIT(*NONE) is specified, checking is performed as each row is inserted.

- Check constraints: If the identified table, or the base table of the identified view, has one or more check constraints, each check constraint must be true or unknown for each row inserted into the table (SQLSTATE 23513).
  The check constraints are effectively checked at the end of the statement. In the case of a multiple-row INSERT statement, this would occur after all rows were inserted.

- Views and the CHECK OPTION clause: If a view is identified, the inserted rows must conform to any applicable CHECK OPTION clause (SQLSTATE 44000). For more information, see “CREATE VIEW” on page 1255.

Triggers: If the identified table or the base table of the identified view has an insert trigger, the trigger is activated. A trigger might cause other statements to be executed or raise error conditions based on the insert values. If the INSERT statement is used as a data-change-table-reference, an AFTER INSERT trigger that attempts to modify the inserted rows will cause an error.

Referential Integrity: Each nonnull insert value of a foreign key must equal some value of the parent key of the parent table in the relationship.

The referential constraints (other than a referential constraint with a RESTRICT delete rule) are effectively checked at the end of the statement. In the case of a multiple-row INSERT statement, this would occur after all rows were inserted and any associated triggers were activated.

If the INSERT statement is used as a data-change-table-reference, any referential constraint that attempts to modify the inserted rows will cause an error.

XML values: A value that is inserted into an XML column must be a well-formed XML document.

Inserting rows into a table for which row or column access control is enforced: When an INSERT statement is issued for a table for which row or column access
control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be inserted. Typically those rules are based on the authorization ID of the statement. The following rules describe how the enabled row permissions and column masks are used during INSERT:

- When a column is referenced while deriving the values of a new row, if that column has an enabled column mask, the masked value is used to derive the new values. If the object table also has column access control activated, the column mask that is applied to derive the new values must return the column itself, not a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert and an error is returned.

  If the OVERRIDING USER VALUE clause is specified, the corresponding values in the new row are ignored, and the above rule for column masks is not applicable to those values.

- If the row can be inserted, and there is a BEFORE INSERT trigger for the table, the trigger is activated. Within the trigger actions, the new values for insert can be modified in the transition variables. When the values return from the trigger, the final values for the new values are the ones for insert.

- A row to be inserted must conform to the enabled row permissions. When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. A row that conforms to all enabled row permissions is a row that, if the row is inserted, can be retrieved back using the row access control search condition.

- If the rows can be inserted and there is an AFTER INSERT trigger for the table, the trigger is activated.

The preceding rules do not apply to the include-columns. The include-columns will accept whatever values are assigned to them, which could be either masked or unmasked values.

Masked data can be assigned to a variable used as a value for the insert operation. If an insert violation check constraint does not exist for the column, the masked data will be inserted in the column and no error will be issued.

**Extended indicator variable usage:** If enabled, indicator variable values other than positive values and 0 (zero) through -7 must not be set. The DEFAULT and UNASSIGNED extended indicator variable values must not appear in contexts where they are not supported.

**Extended indicator variables:** In an INSERT statement, the extended indicator value of UNASSIGNED has the effect of setting the column to its default value.

If a target column is not updatable, it must be assigned the extended indicator variable value of UNASSIGNED, unless it is a generated column defined as GENERATED ALWAYS. If the target column is a generated column defined as GENERATED ALWAYS, then it must be assigned the extended indicator variable value of DEFAULT or UNASSIGNED.

**Extended indicator variables and insert triggers:** No change in the activation of insert triggers results from the presence of extended indicator variables. If all columns in the implicit or explicit column list have been assigned to an extended
indicator variable-based value of UNASSIGNED or DEFAULT, an insert where all columns have their respective DEFAULT values is attempted, and if successful, the insert trigger is activated.

Extended indicator variables and deferred error checks: When extended indicator variables are enabled, validation that would normally be done during statement preparation to recognize an insert into a non-updatable column is deferred until the statement is executed.

Notes

Insert operation errors: If an insert value violates any constraints, or if any other error occurs during the execution of an INSERT statement and COMMIT(*NONE) was not specified, all changes from this statement and any triggered SQL statements are rolled back. However, other changes in the unit of work made prior to the error are not rolled back. If COMMIT(*NONE) is specified, changes are not rolled back.

Number of rows inserted: After executing an INSERT statement, the ROW_COUNT statement information item in the SQL Diagnostics Area (or SQLERRD(3) of the SQLCA) is the number of rows that the database manager inserted. The ROW_COUNT item does not include the number of rows that were inserted as a result of a trigger.

For a description of ROW_COUNT, see “GET DIAGNOSTICS” on page 1388. For a description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),” on page 1737.

Locking: If COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) is specified, one or more exclusive locks are acquired during the execution of a successful INSERT statement. Until the locks are released by a commit or rollback operation, an inserted row can only be accessed by:

- The application process that performed the insert
- Another application process using COMMIT(*NONE) or COMMIT(*CHG) through a read-only operation

The locks can prevent other application processes from performing operations on the table. For further information about locking, see the description of the “COMMIT” on page 978, “ROLLBACK” on page 1544, and “LOCK TABLE” on page 1473 statements. Also, see “Isolation level” on page 27 and Database Programming.

If the INSERT is used as a data-change-table-reference where FINAL TABLE is specified, locks are placed on inserted rows until the SELECT is complete. These locks may prevent indirect changes to the inserted rows from within the same job, such as an AFTER TRIGGER attempting to change an inserted row. These locks are acquired for all isolation levels, including COMMIT(*NONE).

A maximum of 500 000 000 rows can be inserted or changed in any single INSERT statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) was specified. The number of rows changed includes any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger.
**Generated columns:** A generated column that is defined as GENERATED ALWAYS should not be specified in the column-list unless the corresponding entry in the VALUES list is DEFAULT. The user can specify the OVERRIDING USER VALUE clause to indicate that any user-specified value will be ignored and the system-generated value at the time of the INSERT will be inserted into this column.

**Inserting into tables with row-begin, row-end, or transaction start-ID columns:**
When a row is inserted into a table with these generated columns (for instance, a system-period temporal table), the database manager assigns values to the following columns:

- A row-begin column is assigned a value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row-begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for a row-begin column across transactions. If multiple rows are inserted within a single SQL transaction, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.

- A row-end column is assigned the maximum value for the column (9999-12-30-00.00.00.0000000000000).

- A transaction start-ID column is assigned a unique timestamp value per transaction or the null value. The null value is assigned to the transaction start-ID column if the column is nullable. Otherwise, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row-begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. If multiple rows are inserted within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

**Inserting into a system-period temporal table:** When a row is inserted into a system-period temporal table, the database manager assigns values to columns as indicated for tables with row-begin, row-end, or transaction start-ID columns. Also, when a row is inserted, no rows are added to the history table associated with the system-period temporal table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the underlying target of the INSERT statement cannot be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

**REXX:** Variables cannot be used in the INSERT statement within a REXX procedure. Instead, the INSERT must be the object of a PREPARE and EXECUTE using parameter markers.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword NONE can be used as a synonym for NC.
- The keyword CHG can be used as a synonym for UR.
• The keyword ALL can be used as a synonym for RS.

Examples

Example 1: Insert a new department with the following specifications into the DEPARTMENT table:
• Department number (DEPTNO) is ‘E31’
• Department name (DEPTNAME) is ‘ARCHITECTURE’
• Managed by (MGRNO) a person with number ‘00390’
• Reports to (ADMRDEPT) department ‘E01’.

```sql
INSERT INTO DEPARTMENT
VALUES ('E31', 'ARCHITECTURE', '00390', 'E01')
```

Example 2: Insert a new department into the DEPARTMENT table as in example 1, but do not assign a manager to the new department.

```sql
INSERT INTO DEPARTMENT (DEPTNO, DEPTNAME, ADMRDEPT)
VALUES ('E31', 'ARCHITECTURE', 'E01')
```

Example 3: Create a table MA_EMPPROJACT with the same columns as the EMPPROJACT table. Populate MA_EMPPROJACT with the rows from the EMPPROJACT table with a project number (PROJNO) starting with the letters ‘MA’.

```sql
CREATE TABLE MA_EMPPROJACT LIKE EMPPROJACT
INSERT INTO MA_EMPPROJACT
SELECT * FROM EMPPROJACT
WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

Example 4: Use a Java program statement to add a skeleton project to the PROJECT table on the connection context 'ctx'. Obtain the project number (PROJNO), project name (PROJNAME), department number (DEPTNO), and responsible employee (RESPEMP) from host variables. Use the current date as the project start date (PRSTDATE). Assign a NULL value to the remaining columns in the table.

```sql
#sql [ctx] { INSERT INTO PROJECT (PROJNO, PROJNAME, DEPTNO, RESPEMP, PRSTDATE)
VALUES (:PRJNO, :PRJNM, :DPTNO, :REMP, CURRENT_DATE) };
```

Example 5: Insert two new departments using one statement into the DEPARTMENT table as in example 2, but do not assign a manager to the new departments.

```sql
INSERT INTO DEPARTMENT (DEPTNO, DEPTNAME, ADMRDEPT)
VALUES ('B11', 'PURCHASING', 'B01'),
('E41', 'DATABASE ADMINISTRATION', 'E01')
```

Example 6: In a PL/I program, use a multiple-row INSERT to add 10 rows to table DEPARTMENT. The host structure array DEPT contains the data to be inserted.

```pli
DCL 1 DEPT(10),
3 DEPT CHAR(3),
3 LASTNAME CHAR(29) VARYING,
3 WORKDEPT CHAR(6),
3 JOB CHAR(3);

EXEC SQL INSERT INTO DEPARTMENT 10 ROWS VALUES (:DEPT);
```

Example 7: Insert a new project into the EMPPROJACT table using the Read Uncommitted (UR, CHG) option:
Example 8: Specify an INSERT statement as the data-change-table-reference within a SELECT statement. Define an extra include column whose values are specified in the VALUES clause, which is then used as an ordering column for the inserted rows.

```sql
SELECT inorder, ordernum
FROM FINAL TABLE (INSERT INTO ORDERS (CUSTNO)
  INCLUDE(INSERTNUM INTEGER)
  VALUES (:cnum1, 1),
          (:cnum2, 2)) InsertedOrders
ORDER BY insertnum
```

```sql
INSERT INTO EMPROJACT
VALUES ('000140', 'PL2100', 30)
WITH CHG
```
The LABEL statement adds or replaces labels in the catalog descriptions of various database objects.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

To label a table, view, alias, column, type, package, sequence, view, or XSR object, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the table, view, alias, type, package, sequence, variable, XSR object, function or procedure identified in the statement,
  - The ALTER privilege on the table, view, alias, type, package, sequence, variable, XSR object, function or procedure, and
  - The system authority *EXECUTE on the library containing the table, view, alias, type, package, sequence, variable, XSR object, function or procedure
- Database administrator authority

To label a constraint or trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the subject table of the constraint or trigger in the statement:
  - The ALTER privilege on the subject table, and
  - The system authority *EXECUTE on the library that contains the subject table
- Database administrator authority

To label an index, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the index identified in the statement,
  - The system authority *OBJALTER on the index, and
  - The system authority *EXECUTE on the library containing the index.
- Database administrator authority

To label a function, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSFUNCS and SYSROUTINES catalog view and table:
  - The UPDATE privilege on SYSROUTINES,
  - The system authority *OBJOPR on SYSFUNCS, and
  - The system authority *EXECUTE on library QSYS2
- Database administrator authority

To label a procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS and SYSROUTINES catalog view and table:
  - The UPDATE privilege on SYSROUTINES,
  - The system authority *OBJOPR on SYSPROCS, and
  - The system authority *EXECUTE on library QSYS2
• Database administrator authority

To label a mask or permission:
• The authorization ID of the statement must have security administrator authority. See “Administrative authority” on page 18.

To label a sequence, the privileges held by the authorization ID of the statement must also include at least one of the following:
• *USE authority to the Change Data Area (CHGDTAARA) CL command
• Database administrator authority

The authorization ID of the statement has the ALTER privilege on an alias when:
• It is the owner of the alias, or
• It has been granted the system authorities of either *OBJALTER or *OBJMGT to the alias

To label a variable, the privileges held by the authorization ID of the statement must also include at least one of the following:
• For the SYSVARIABLES catalog table:
  – The UPDATE privilege on SYSVARIABLES,
  – The system authority *EXECUTE on library QSYS2
• Database administrator authority

To label an XSR object, the privileges held by the authorization ID of the statement must also include at least one of the following:
• For the XSROBJECTS catalog table:
  – The UPDATE privilege on XSROBJECTS,
  – The system authority *EXECUTE on library QSYS2
• Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View, Corresponding System Authorities When Checking Privileges to a Sequence, and Corresponding System Authorities When Checking Privileges to a Package.

Syntax

```
LABEL ON
```
parameter-type:

<table>
<thead>
<tr>
<th>data-type</th>
<th>AS LOCATOR</th>
</tr>
</thead>
</table>

data-type:

<table>
<thead>
<tr>
<th>built-in-type</th>
</tr>
</thead>
<tbody>
<tr>
<td>distinct-type-name</td>
</tr>
<tr>
<td>array-type-name</td>
</tr>
</tbody>
</table>

built-in-type:
ccsid-clause:

```
|CCSID—integer|
```

Description

**ALIAS**
Specifies that the label is for an alias. Labels on aliases are implemented as system object text.

```
alias-name
```
Identifies the alias to which the label applies. The name must identify an alias that exists at the current server.

**COLUMN**
Specifies that the label is for a column. Labels on columns are implemented as system column headings or column text. Column headings are used when displaying or printing query results.

```
table-name.column-name or view-name.column-name
```
Identifies the column to which the label applies. The `table-name` or `view-name` must identify a table or view that exists at the current server, but must not identify a declared temporary table. The `column-name` must identify a column of that table or view.

**TEXT**
Specifies that IBM i column text is specified. If TEXT is omitted, a column heading is specified.

**CONSTRAINT**
Specifies that the label is for a constraint.

```
constraint-name
```
Identifies the constraint to which the label applies. The `constraint-name` must identify a constraint that exists at the current server.

**FUNCTION or SPECIFIC FUNCTION**
Identifies the function on which the label applies. The function must exist at the current server and it must be a user-defined function. The function can be identified by its name, function signature, or specific name.

**FUNCTION**

```
function-name
```
Identifies the function by its name. The `function-name` must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

**FUNCTION**

```
function-name (parameter-type, ...)
```
Identifies the function by its function signature, which uniquely identifies the function. The `function-name (parameter-type, ...)` must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which to label. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If `function-name ()` is specified, the function identified must have zero parameters.
function-name
   Identifies the name of the function.

(parameter-type, ...)  
   Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR
   Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC FUNCTION specific-name
   Identifies the function by its specific name. The specific-name must identify a specific function that exists at the current server.

INDEX
   Specifies that the label is for an index. Labels on indexes are implemented as system object text.

   index-name
      Identifies the index to which the label applies. The name must identify an index that exists at the current server.

MASK
   Specifies that the label is for a mask.

   mask-name
      Identifies the mask to which the label applies. The name must identify a mask that exists at the current server.
PACKAGE

Specifies that the label is for a package. Labels on packages are implemented as system object text.

package-name

Identifies the package to which the label applies. The name must identify a package that exists at the current server.

VERSION version-id

version-id is the version identifier that was assigned to the package when it was created. If version-id is not specified, a null string is used as the version identifier.

PERMISSION

Specifies that the label is for a permission.

permission-name

Identifies the permission to which the label applies. The name must identify a permission that exists at the current server.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure to which the label applies. The procedure-name must identify a procedure that exists at the current server.

PROCEDURE procedure-name

Identifies the procedure by its name. The procedure-name must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE procedure-name (parameter-type, ...)

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The procedure-name (parameter-type, ...) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be labeled on. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If procedure-name () is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR
Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC PROCEDURE specific-name
Identifies the procedure by its specific name. The specific-name must identify a specific procedure that exists at the current server.

SEQUENCE
Specifies that the label is for a sequence. Labels on sequences are implemented as system object text.

sequence-name
Identifies the sequence on which you want to add a label. The sequence-name must identify a sequence that exists at the current server.

TABLE
Specifies that the label is for a table or a view. Labels on tables or views are implemented as system object text.

table-name or view-name
Identifies the table or view on which you want to add a label. The table-name or view-name must identify a table or view that exists at the current server, but must not identify a declared temporary table.

TRIGGER
Specifies that the label is for a trigger.

trigger-name
Identifies the trigger on which you want to add a label. The trigger-name must identify a trigger that exists at the current server.

TYPE distinct-type-name or array-type-name
Identifies the distinct type or array type to which the label applies. The distinct-type-name or array-type-name must identify a type that exists at the current server.

VARIABLE variable-name
Identifies the variable to which the label applies. The variable-name must identify a variable that exists at the current server.
**XSROBJECT xsrobject-name**
Identifies the XSR object to which the label applies. The *xsrobject-name* must identify an XSR object that exists at the current server.

**IS**
Introduces the label you want to provide.

**string-constant**
Can be any SQL character-string constant of up to either 60 bytes in length for column headings or 50 bytes in length for object text or column text. The constant may contain single-byte and double-byte characters.

The label for a column heading consists of three 20-byte segments. Interactive SQL, the Query for IBM i, IBM DB2 Query Manager and SQL Development Kit for i, and other products can display or print each 20-byte segment on a separate line. If the label for a column contains mixed data, each 20-byte segment must be a valid mixed data character string. The shift characters must be paired within each 20-byte segment.

**Notes**

**Column headings:** Column headings are used when displaying or printing query results. The first column heading is displayed or printed on the first line, the second column heading is displayed or printed on the second line, and the third column heading is displayed or printed on the third line. The column headings can be up to 60 bytes in length, where the first 20 bytes is the first column heading, the second 20 bytes is the second column heading, and the third 20 bytes is the third column heading. Blanks are trimmed from the end of each 20-byte column heading.

All 60 bytes of column heading information are available in the catalog view SYSCOLUMNS; however, only the first column heading is returned in an SQLDA on a DESCRIBE or DESCRIBE TABLE statement.

Column text is not returned on a DESCRIBE or DESCRIBE TABLE statement. When the database manager changes the column heading information in a record format description that is shared, the change is reflected in all files sharing the format description. To find out if a file shares a format with another file, use the RCDFMT parameter on the CL command, Display Database Relations (DSPDBR).

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword PROGRAM can be used as a synonym for PACKAGE.
- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.

**Examples**

*Example 1:* Enter a label on the DEPTNO column of table DEPARTMENT.

```sql
LABEL ON COLUMN DEPARTMENT.DEPTNO
   IS 'DEPARTMENT NUMBER'
```

*Example 2:* Enter a label on the DEPTNO column of table DEPARTMENT where the column heading is shown on two separate lines.

```sql
LABEL ON COLUMN DEPARTMENT.DEPTNO
   IS 'Department Number'
```
Example 3: Enter a label on the PAYROLL package.

```
LABEL ON PACKAGE PAYROLL
   IS 'Payroll Package'
```
LOCK TABLE

The LOCK TABLE statement either prevents concurrent application processes from changing a table or prevents concurrent application processes from using a table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table identified in the statement,
  - The system authority of *OBJOPR on the table, and
  - The system authority *EXECUTE on the library containing the table
- Database administrator authority

Syntax

```
<table>
<thead>
<tr>
<th>LOCK TABLE table-name IN SHARE MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXCLUSIVE MODE ALLOW READ</td>
</tr>
<tr>
<td>EXCLUSIVE MODE</td>
</tr>
</tbody>
</table>
```

Description

`table-name`

Identifies the table to be locked. The `table-name` must identify a base table that exists at the current server, but must not identify a catalog table or a declared temporary table.

IN SHARE MODE

Prevents concurrent application processes from executing any but read-only operations on the table.

A shared lock (*SHRNUP) is acquired for the application process in which the statement is executed. Other application processes may also acquire a shared lock (*SHRNUP) and prevent this application process from executing any but read-only operations.

IN EXCLUSIVE MODE ALLOW READ

Prevents concurrent application processes from executing any but read-only operations on the table.

An exclusive allow read lock (*EXCLRD) is acquired for the application process in which the statement is executed. Other application processes may not acquire a shared lock (*SHRNUP) and cannot prevent this application process from executing updates, deletes, and inserts on the table.

IN EXCLUSIVE MODE

Prevents concurrent application processes from executing any operations at all on the table.

An exclusive lock (*EXCL) is acquired for the application process in which the statement is executed.
Notes

**Locks obtained:** Locking is used to prevent concurrent operations.

The lock is released:

- When the unit of work ends, unless the unit of work is ended by a COMMIT HOLD or ROLLBACK HOLD
- When the first SQL program in the program stack ends, unless CLOSQLCSR(*ENDJOB) or CLOSQLCSR(*ENDDACTGRP) was specified on the CRTSQLxxx command
- When the activation group ends
- When the connection is changed using a CONNECT (Type 1) statement
- When the connection associated with the lock is disconnected using the DISCONNECT statement
- When the connection is in the release-pending state and a successful COMMIT occurs

You may also issue the Deallocate Object (DLCOBJ) command to unlock the table.

**Lock wait time:** Conflicting locks already held by other application processes will cause your application to wait up to the default wait time of the job.

**Example**

Obtain a lock on the DEPARTMENT table.

```
LOCK TABLE DEPARTMENT IN EXCLUSIVE MODE
```
The MERGE statement updates a target (a table or view) using data from a source (result of a table reference). Rows in the target that match the input data may be updated or deleted as specified, and rows that do not exist in the target may be inserted as specified. Updating, deleting, or inserting a row in a view updates, deletes, or inserts the row into the tables on which the view is based if no INSTEAD OF trigger is defined on the view.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It is not allowed in a REXX procedure.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- Database administrator authority
- If an insert operation is specified:
  - The INSERT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- If a delete operation is specified:
  - The DELETE privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- If an update operation is specified:
  - The UPDATE privilege on the table or view or
  - The UPDATE privilege on each column to be updated; and
  - The system authority *EXECUTE on the library containing the table or view

If search-condition, insert-operation, or assignment-clause includes a fullselect, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For each table or view identified in the fullselect:
  - The SELECT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

If table-reference contains any query that references a column of a table or view, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For each table or view identified in the fullselect:
  - The SELECT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.
Syntax

```sql
MERGE INTO table-name [ view-name ] [ correlation-clause ]

USING table-reference [ ON search-condition ]

WHEN matching-condition THEN update-operation
    DELETE operation
    INSERT operation
    SIGNAL statement
 ELSE IGNORE

ATOMIC
 NOT ATOMIC
 STOP ON SQL EXCEPTION
 CONTINUE ON SQL EXCEPTION

-isolation-clause - concurrent-access-resolution-clause
```

correlation-clause:

```sql
AS correlation-name [ column-name ]
```

matching-condition:

```sql
NOT MATCHED [ AND search-condition ]
```

update-operation:

```sql
UPDATE SET assignment-clause
    OVERRIDING SYSTEM VALUE
    OVERRIDING USER VALUE
```

delete-operation:

```sql
DELETE
```
insert-operation:

```
| INSERT | column-name | OVERRIDING SYSTEM VALUE |
|        |            | OVERRIDING USER VALUE   |
|        | expression  | DEFAULT NULL             |
```

VALUES:

```
| expression | DEFAULT NULL |
|            |              |
|            |              |
```

assignment-clause:

```
| column-name | expression | DEFAULT NULL |
|             |           |              |
|             |           |              |
```

ROW:

```
| expression | DEFAULT NULL |
|            |              |
|            |              |
```

isolation-clause:

```
| WITH NC    |
|           |
|          |
|          |
```
used to qualify references to the columns of the table or view. When a
correlation-name is specified, column-names can also be specified to give names
to the columns of the table-name or view-name. If a column list is specified, there
must be a name in the column list for each column in the table or view. For
more information, see “Correlation names” on page 143.

**USING** table-reference

Specifies a set of rows as a result table to be merged into the target. If the
result table is empty, a warning is returned.

**ON** search-condition

Specifies the predicates used to determine whether a row from source-table
matches rows in the target table.

Each column-name in the search-condition, other than in a subquery, must name a
column of the target table or view or the table-reference. When the search
condition includes a subquery in which the same table is the base object of
both the merge and the subquery, the subquery is completely evaluated before
any rows are updated or inserted.

The search-condition is applied to each row of the target table and result table of
the table-reference. For those rows of the result table of the table-reference where
the result of the search-condition is true, the specified update or delete operation
is performed. For those rows of the result table where the result of the
search-condition is not true, the specified insert operation is performed.

The search-condition cannot contain a quantified subquery, IN predicate with a
subselect, or EXISTS subquery. It can contain basic predicate subqueries or
scalar-fullselects. It cannot contain expressions that use aggregate functions or
non-deterministic scalar functions.

**WHEN** matching-condition

Specifies the condition under which the update-operation, delete-operation,
insert-operation, or the signal-statement is executed. Each matching-condition is
evaluated in order of specification. Rows for which the matching-condition
evaluates to true are not considered in subsequent matching conditions.

**MATCHED**

Indicates the operation to be performed on the rows where the ON
search-condition is true. Only UPDATE, DELETE, or signal-statement can be
specified after THEN.

**AND** search-condition

Specifies a further search condition to be applied against the rows that
matched the ON search condition for the operation to be performed
after THEN.

The search-condition must not include a subquery in an EXISTS or IN
predicate.

**NOT MATCHED**

Indicates the operation to be performed on the rows where the ON
search-condition is false or unknown. Only INSERT or signal-statement can be
specified after THEN.

**AND** search-condition

Specifies a further search condition to be applied against the rows that
did not match the ON search condition for the operation to be
performed after THEN.

The search-condition must not include a subquery in an EXISTS or IN
predicate.
THEN

Specifies the operation to execute when the matching-condition evaluates to true.

update-operation

Specifies the update operation to be executed for the rows where the matching-condition evaluates to true.

assignment-clause

Specifies a list of column updates.

column-name

Identifies a column to be updated. The column-name must identify a column of the target table or view. The column-name must not identify a view column derived from a scalar function, constant, or expression. A column name must not be specified more than once.

A view column derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same MERGE statement.

ROW

Identifies all the columns of the target table or view except for columns defined with the hidden attribute. If a view is specified, none of the columns of the view may be derived from a scalar function, constant, or expression.

The number of expressions, NULLs, and DEFAULTs (or the number of result columns from a row-fullselect) must match the number of columns in the row.

ROW may not be specified for a view that contains a view column derived from the same column as another column of the view, because both columns cannot be updated in the same UPDATE.

expression

Indicates the new value of the column. The expression must not include an aggregate function except when it occurs within a scalar fullselect.

The expression can contain references to columns of the target table-name or view-name. For each row that is updated, the value of a target column reference in an expression is the value of the column in the row before the row is updated.

If expression is a reference to a single column of the source table, the source table column value may have been specified with an extended indicator variable value. The effects of such indicator variables apply to the corresponding target columns of the assignment-clause.

When extended indicator variables are enabled, the extended indicator variable values of DEFAULT (-5) or UNASSIGNED (-7) must not be used if expression is more complex than the following references:

- A single column of the source table
- A single host variable

DEFAULT

Specifies that the default value is assigned to the column.

DEFAULT can be specified only for columns that have a default
value. For more information about default values, see the
description of the DEFAULT clause in "CREATE TABLE" on page
1159.

DEFAULT must be specified for a column that was defined as
GENERATED ALWAYS unless OVERRIDING USER VALUE is
specified to indicate that any user-specified value will be ignored
and a unique system-generated value will be used. A valid value
can be specified for a column that was defined as GENERATED BY
DEFAULT.

NULL
Specifies the null value as the new value of the column. Specify
NULL only for nullable columns.

delete-operation
Specifies the delete operation to be executed for the rows where the
matching-condition evaluates to true.

insert-operation
Specifies the insert operation to be executed for the rows where the
matching-condition evaluates to true.

INSERT
Introduces a list of column names and row value expressions to be
used for the insert operation.

The number of values in the row value expression must equal the
number of names in the implicit or explicit insert column list. The first
value is inserted in the first column in the list, the second value in the
second column, and so on.

(column-name,...)
Specifies the columns for which insert values are provided. Each name
must be a name that identifies a column of the table or view. The same
column must not be identified more than once. If extended indicator
variables are not enabled, a view column that is not updatable must
not be identified. If extended indicator variables are not enabled and
the object of the insert operation is a view with such columns, a list of
column names must be specified and the list must not identify those
columns. For an explanation of updatable columns in views, see
"CREATE VIEW" on page 1255.

Omission of the column list is an implicit specification of a list in
which every column of the table or view is identified in left-to-right
order. Any columns defined with the hidden attribute are omitted. This
list is established when the statement is prepared and, therefore, does
not include columns that were added to a table after the statement was
prepared.

VALUES
Specifies a new row to be inserted.

Each variable in the clause must identify a variable that is declared in
accordance with the rules for declaring variables. A host structure
cannot be used. For further information about variables, see
"References to host variables" on page 152.

expression
An expression of the type described in "Expressions" on page 174,
that does not include an aggregate function or column name.
When extended indicator variables are enabled, the extended indicator variable values of DEFAULT (-5) or UNASSIGNED (-7) must not be used if expression is more complex than the following references:

- A single column of the source table
- A single host variable
- A host variable being explicitly cast

**DEFAULT**

Specifies that the default value is assigned to the column. DEFAULT can be specified only for columns that have a default value. For more information about default values, see the description of the DEFAULT clause in “CREATE TABLE” on page 1159.

DEFAULT must be specified for a column that was defined as GENERATED ALWAYS unless OVERRIDING USER VALUE is specified to indicate that any user-specified value will be ignored and a unique system-generated value will be used. A valid value can be specified for a column that was defined as GENERATED BY DEFAULT.

**NULL**

Specifies the value for a column is the null value. NULL should only be specified for nullable columns.

**OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE**

Specifies whether system generated values or user-specified values for a ROWID, identity, or row change timestamp column are used. If OVERRIDING SYSTEM VALUE is specified, the implicit or explicit list of columns for the INSERT or the SET clause of the UPDATE must contain a ROWID, identity, or row change timestamp column defined as GENERATED ALWAYS. If OVERRIDING USER VALUE is specified, the implicit or explicit list of columns for the INSERT or the SET clause of the UPDATE must contain a column defined as either GENERATED ALWAYS or GENERATED BY DEFAULT.

**OVERRIDING SYSTEM VALUE**

Specifies that the value specified in the VALUES or SET clause for a column that is defined as GENERATED ALWAYS is used. A system-generated value is not used.

If a value for a row-begin, row-end, transaction-start-ID, or generated expression column is provided, it must be DEFAULT.

**OVERRIDING USER VALUE**

Specifies that the value specified in the VALUES or SET clause for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is used, overriding the user-specified value.

If neither OVERRIDING SYSTEM VALUE nor OVERRIDING USER VALUE is specified:

- A value cannot be specified for a ROWID, identity, row change timestamp, row-begin, row-end, transaction-start-ID, or generated expression column that is defined as GENERATED ALWAYS.
- A value can be specified for a ROWID, identity, or row change timestamp column that is defined as GENERATED BY DEFAULT. If a
value is specified, that value is assigned to the column. However, a value can be assigned to a ROWID column defined BY DEFAULT only if the specified value is a valid row ID value that was previously generated by Db2 for z/OS or Db2 for i. When a value is inserted or updated for an identity or row change timestamp column defined BY DEFAULT, the database manager does not verify that the specified value is a unique value for the column unless the identity or row change timestamp column is the sole key in a unique constraint or unique index. Without a unique constraint or unique index, the database manager can guarantee unique values only among the set of system-generated values as long as NO CYCLE is in effect.

If a value is not specified the database manager generates a new value.

signal-statement
Specifies the SIGNAL statement that is to be executed to return an error when the matching-condition evaluates to true. See "SIGNAL" on page 1615.

ELSE IGNORE
Specifies that no action is to be taken when the matching-condition for all WHEN clauses is false for a row in the USING table-reference. No action is taken in this case whether or not ELSE IGNORE is specified.

ATOMIC or NOT ATOMIC
Specifies how to handle errors

ATOMIC
Specifies that if an error occurs during a update-operation, delete-operation, or insert-operation, the entire MERGE statement is rolled back.

NOT ATOMIC
Specifies that if an error occurs during a update-operation, delete-operation, or insert-operation, only that update-operation, delete-operation, or insert-operation is rolled back.

STOP ON SQL EXCEPTION
Specifies that if an error occurs during a update-operation, delete-operation, or insert-operation, the processing of the MERGE statement stops.

CONTINUE ON SQL EXCEPTION
Specifies that if an error occurs during a update-operation, delete-operation, or insert-operation, the processing of the MERGE statement continues.

isolation-clause
Specifies the isolation level to be used for this statement.

WITH
Introduces the isolation level, which may be one of:

- RR Repeatable read
- RS Read stability
- CS Cursor stability
- UR Uncommitted read
- NC No commit

If isolation-clause is not specified the default isolation is used. See "isolation-clause" on page 81 for a description of how the default is determined.
**concurrent-access-resolution-clause**

Specifies the concurrent access resolution to use for the select statement. For more information, see “concurrent-access-resolution-clause” on page 813.

**MERGE Rules**

- More than one update-operation, delete-operation, insert-operation, or signal-statement can be specified in a single MERGE statement.
- Each row in the target can only be operated on once. A row in the target can only be identified as MATCHED with one row in the result table of the table-reference. A nested SQL operation (RI or trigger except INSTEAD OF trigger) cannot specify the target table (or a table within the same hierarchy) as a target of an UPDATE, DELETE, INSERT, or MERGE statement.

For other rules that affect the update, insert, or delete portion of the MERGE statement, see the "Rules" section of the corresponding statement description.

**Extended indicator variable usage:** If enabled, indicator variable values other than positive values and 0 (zero) through -7 must not be set. The DEFAULT and UNASSIGNED extended indicator variable values must not appear in contexts where they are not supported.

**Extended indicator variables:** In an insert portion of the MERGE statement, the extended indicator value of UNASSIGNED has the effect of setting the column to its default value.

**MERGE restriction:** If the target table of the MERGE statement has triggers or is the parent in a referential integrity constraint, the update-operation or insert-operation must not contain a global variable, a function, or a subselect.

**Notes**

**Logical order of processing:** For a NOT ATOMIC MERGE statement, each source row is processed independently as if a separate MERGE statement were executed for each source row. For example, a source row that causes an update of a target row, will fire any triggers (including statement level triggers) when the update of the row is performed. Thus, if 5 rows are updated, any update triggers (including statement level update triggers) will be fired 5 times.

For an ATOMIC MERGE statement, the source rows are processed as if a set of rows is processed by each WHEN clause. Thus, if 5 rows are updated, any row level update triggers will be fired 5 times, but \( n \) statement level update triggers will be fired, where \( n \) is the number of WHEN clauses that contain an UPDATE, including any WHEN clauses that contain an UPDATE that did not process any of the source rows. For ATOMIC MERGE, the logical order of processing is:

1. Determine the set of rows to be processed from the source and target. If any of the special registers CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP are used in this statement, only one clock reading is done for the whole statement.
2. Use the ON clause to classify these rows as either MATCHED or NOT MATCHED.
3. Evaluate any matching-condition in the WHEN clauses.
4. Evaluate any expression in any assignment-clause and insert-operation.
5. Execute each signal-statement.
6. Apply each update-operation, delete-operation, or insert-operation to the applicable rows in the order of specification. The triggers activated by each update-operation, delete-operation, or insert-operation are executed. Statement level triggers are activated even if no rows satisfy the update-operation, delete-operation, or insert-operation. Each update-operation, delete-operation, or insert-operation can affect the triggers of each subsequent update-operation, delete-operation, or insert-operation.

**Number of rows updated:** After executing a MERGE statement, the ROW_COUNT statement information item in the SQL Diagnostics Area (or SQLERRD(3) of the SQLCA) is the number of rows operated on by the MERGE statement, excluding rows identified by the ELSE IGNORE clause. The ROW_COUNT item and SQLERRD(3) does not include the number of rows that were operated on as a result of triggers. The value in the DB2_ROW_COUNT_SECONDARY statement information item (or SQLERRD(5) of the SQLCA) includes the number of these rows.

For a description of ROW_COUNT and DB2_ROW_COUNT_SECONDARY, see “GET DIAGNOSTICS” on page 1388. For a description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),” on page 1737.

**GET DIAGNOSTICS considerations:** If a MERGE statement completes with one or more errors, the GET DIAGNOSTICS statement can be used after the MERGE statement to check which input row(s) failed. The GET DIAGNOSTICS statement-information-item, NUMBER, indicates the number of conditions (errors of warnings) detected by execution of the MERGE statement. For each condition, the GET DIAGNOSTICS condition-information-item, DB2_ROW_NUMBER, indicates the input source row that caused an error.

**Inserted row cannot also be updated:** No attempt is made to update a row in the target that did not already exist before the MERGE statement was executed; that is, there are no updates of rows that were inserted by the MERGE statement.

**Concurrent row changes in MERGE target:** MERGE processing determines affected rows in the MERGE target before performing any update-operations, delete-operations, or insert-operations. Unless using a restrictive isolation level such as repeatable read, concurrent processes could insert or modify rows in the MERGE target between the time when the set of affected target rows is determined and when a specific row update-operation, delete-operation, or insert-operation is processed. Such concurrent activity could produce an error. For example, MERGE processing could determine that a source row does not exist in the target where a column value in the target has a unique key constraint. Before the MERGE attempts to insert a new row based on the source data, a concurrent process could insert a row with the same key value. This would cause a duplicate key error when the MERGE processing attempts to insert its row.

**Locking:** If COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) is specified, one or more exclusive locks are acquired during the execution of a successful MERGE statement. Until the locks are released by a commit or rollback operation, an inserted or updated row can only be accessed by:

- The application process that performed the insert or update
- Another application process using COMMIT(*NONE) or COMMIT(*CHG) through a read-only operation
The locks can prevent other application processes from performing operations on the table. For further information about locking, see the description of the "COMMIT" on page 978, "ROLLBACK" on page 1544, and "LOCK TABLE" on page 1473 statements. Also, see "Isolation level" on page 27 and Database Programming.

A maximum of 500 000 000 rows can be acquired in any single MERGE statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or COMMIT(*CHG) was specified. The number of row locks includes any rows inserted, updated, or deleted in the MERGE target and any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger. The number of row locks also includes source rows referenced by the USING table-reference is COMMIT(*ALL) is specified.

Tables with active row and column access controls: For information about how enabled row permissions and column masks affect the update and insert operations in the MERGE statement, see the INSERT and UPDATE statement information.

NOT ATOMIC processing: When NOT ATOMIC is specified, the rows of source data are processed separately. Any reference to special registers (such as CURRENT TIMESTAMP) in the MERGE statement are evaluated as each row or source data is processed. Statement level triggers are activated as each row of source data is processed.

If an error occurs during the operation for a row of source data, the row being processed at the time of the error is not inserted, updated, or deleted. Processing of an individual row is an atomic operation. Any other changes previously made during the processing of the MERGE statement are not rolled back. If CONTINUE ON EXCEPTION is specified, execution continues with the next row to be processed.

System-period temporal tables: When a MERGE statement is processed for a system-period temporal table, the rows are affected in the same way as if the specific data change operation was invoked.

Examples

Example 1: For activities whose description has changed, update the description in the archive table. For new activities, insert into the archive table. The archive and activities tables both have activity as a primary key.

MERGE INTO archive ar
USING (SELECT activity, description FROM activities) ac
ON (ar.activity = ac.activity)
WHEN MATCHED THEN
    UPDATE SET description = ac.description
WHEN NOT MATCHED THEN
    INSERT (activity, description) VALUES(ac.activity, ac.description)

Example 2: Using the shipment table, merge rows into the inventory table, increasing the quantity by part count in the shipment table for rows that match; else insert the new partno into the inventory table.

MERGE INTO inventory AS in
USING (SELECT partno, description, count FROM shipment
WHERE shipment.partno IS NOT NULL) AS sh
ON (in.partno = sh.partno)
WHEN MATCHED THEN
UPDATE SET description = sh.description,
    quantity = in.quantity + sh.count
WHEN NOT MATCHED THEN
    INSERT (partno, description, quantity)
    VALUES (sh.partno, sh.description, sh.count)

Example 3: Using the transaction table, merge rows into the account table, updating
the balance from the set of transactions against an account ID and inserting new
accounts from the consolidated transactions where they do not already exist.

MERGE INTO account AS a
    USING (SELECT id, SUM(amount) sum_amount FROM transaction
        GROUP BY id) AS t
    ON a.id = t.id
WHEN MATCHED THEN
    UPDATE SET balance = a.balance + t.sum_amount
WHEN NOT MATCHED THEN
    INSERT (id, balance) VALUES (t.id, t.sum_amount)

Example 4: Using the transaction_log table, merge rows into the employee_file
table, updating the phone and office columns with the latest transaction_log row
based on the transaction time, and inserting a new employee_file row where the
row does not already exist.

MERGE INTO employee_file AS e
    USING (SELECT empid, phone, office
        FROM (SELECT empid, phone, office,
            ROW_NUMBER() OVER (PARTITION BY empid
                ORDER BY transaction_time DESC) rn
        FROM transaction_log) AS nt
    WHERE rn = 1) AS t
    ON e.empid = t.empid
WHEN MATCHED THEN
    UPDATE SET (phone, office) = (t.phone, t.office)
WHEN NOT MATCHED THEN
    INSERT (empid, phone, office)
    VALUES (t.empid, t.phone, t.office)

Example 5: Using dynamically supplied values for an employee row, update the
master employee table if the data corresponds to an existing employee, or insert
the row if the data is for a new employee. The following example is a fragment of
code from a C program.

```
hv1 = "MERGE INTO employee AS t
    USING (VALUES(CAST(? AS CHAR(6)), CAST(? AS VARCHAR(12)),
        CAST(? AS CHAR(1)), CAST(? AS VARCHAR(15)),
        CAST(? AS SMALLINT), CAST(? AS INTEGER)))
    s (empno, firstname, midinit, lastname, edlevel, salary)
    ON t.empno = s.empno
    WHEN MATCHED THEN
        UPDATE SET salary = s.salary
    WHEN NOT MATCHED THEN
        INSERT (empno, firstname, midinit, lastname, edlevel, salary)
        VALUES (s.empno, s.firstname, s.midinit, s.lastname, s.edlevel,
            s.salary)"
EXEC SQL PREPARE s1 FROM :hv1;
EXEC SQL EXECUTE s1 USING :hv2, :hv3, :hv4, :hv5, :hv6, :hv7;
```

Example 6: Update the list of activities organized by Group A in the archive table.
Delete all outdated activities and update the activities information (description and
date) in the archive table if they have been changed. For new upcoming activities,
insert into the archive. Signal an error if the data of the activity is not known. The
date of the activities in the archive table must be specified. Each group has an
activities table. For example, activities_groupA contains all activities that they
organize, and the archive table contains all upcoming activities organized by different groups in a company. The archive table has (group, activity) as the primary key, and data is not nullable. All activities tables have activity as the primary key. The last_modified column in the archive is defined with CURRENT_TIMESTAMP as the default value.

```
MERGE INTO archive ar
USING (SELECT activity, description, date, last_modified
       FROM activities_groupA) ac
ON (ar.activity = ac.activity) AND ar.group = 'A'
WHEN MATCHED AND ac.date IS NULL THEN
  SIGNAL SQLSTATE '70001'
  SET MESSAGE_TEXT = 'Activity cannot be modified. Reason: date is not known'
WHEN MATCHED and ac.date < CURRENT_DATE THEN
  DELETE
WHEN MATCHED AND as.last_modified < ac.last_modified THEN
  UPDATE SET (description, date, last_modified)
       = (ac.description, ac.date, DEFAULT)
WHEN NOT MATCHED AND ac.date IS NULL THEN
  SIGNAL SQLSTATE '70002'
  SET MESSAGE_TEXT = 'Activity cannot be inserted. Reason: date is not known'
WHEN NOT MATCHED AND ac.date >= CURRENT_DATE THEN
  INSERT (group, activity, description, date)
  VALUES ('A', ac.activity, ac.description, ac.date)
ELSE IGNORE
```
The OPEN statement opens a cursor so that it can be used to fetch rows from its result table.

**Invocation**

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

**Authorization**

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

See "DECLARE CURSOR" on page 1265 for the authorization required to use a cursor.

**Syntax**

```
OPEN cursor-name

USING variable

USING SQL DESCRIPTOR LOCAL SQL-descriptor-name

USING DESCRIPTOR descriptor-name
```

**Description**

`cursor-name`

Identifies the cursor to be opened. The `cursor-name` must identify a declared cursor as explained in the Notes for the DECLARE CURSOR statement. When the OPEN statement is executed, the cursor must be in the closed state.

The SELECT statement associated with the cursor is either:

- The `select-statement` specified in the DECLARE CURSOR statement, or
- The prepared `select-statement` identified by the `statement-name` specified in the DECLARE CURSOR statement. If the statement has not been successfully prepared, or is not a `select-statement`, the cursor cannot be successfully opened.

The result table of the cursor is derived by evaluating the SELECT statement. The evaluation uses the current values of any special registers specified in the SELECT statement and the current values of any variables specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table can be derived during the execution of the OPEN statement and a temporary table can be created to hold them; or they can be derived.
during the execution of subsequent FETCH statements. In either case, the
cursor is placed in the open state and positioned before the first row of its
result table. If the table is empty the position of the cursor is effectively “after
the last row.”

**USING**

Introduces a list of variables whose values are substituted for the parameter
markers (question marks) of a prepared statement. For an explanation of
parameter markers, see “PREPARE” on page 1494.

- If a *statement-name* is specified in the DECLARE CURSOR statement that
  includes parameter markers, USING must be used. If the prepared statement
does not include parameter markers, USING is ignored.
- If a *select-statement* is specified in the DECLARE CURSOR statement, USING
  may be used to override the variable values. For more information, see
  Variable value override.

If the DECLARE CURSOR statement names a prepared statement that includes
parameter markers, you must use USING. If the prepared statement does not
include parameter markers, USING is ignored.

**variable,...**

Identifies host structures or variables that must be declared in the program
in accordance with the rules for declaring host structures and variables. A
reference to a host structure is replaced by a reference to each of its
variables. The resulting number of variables must be the same as the
number of parameter markers in the prepared statement. The *n*th variable
corresponds to the *n*th parameter marker in the prepared statement.

A global variable may only be used if the current connection is a local
connection (not a DRDA connection).

**USING SQL DESCRIPTOR**

*SQL-descriptor-name*

Identifies an SQL descriptor.

**LOCAL**

Specifies the scope of the name of the descriptor to be local to program
invocation.

**GLOBAL**

Specifies the scope of the name of the descriptor to be global to the
SQL session.

*SQL-descriptor-name*

Names the SQL descriptor. The name must identify a descriptor that
already exists with the specified scope.

See “SET DESCRIPTOR” on page 1568 for an explanation of the
information in the SQL descriptor.

**USING DESCRIPTOR**

*descriptor-name*

Identifies an SQLDA that must contain a valid description of input
variables.

Before the OPEN statement is processed, the user must set the following
fields in the SQLDA. (The rules for REXX are different. For more
information see [Embedded SQL Programming](#))

- SQLN to indicate the number of SQLVAR occurrences provided in the
SQLDA
- SQLDABC to indicate the number of bytes of storage allocated for the
SQLDA
• SQLD to indicate the number of variables used in the SQLDA when processing the statement
• SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the results, there must be additional SQLVAR entries for each parameter. For more information about the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see Appendix D, “SQLDA (SQL descriptor area),” on page 1747.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The nth variable described by the SQLDA corresponds to the nth parameter marker in the prepared statement.

Note that because RPG/400 does not provide the facility for setting pointers and the SQLDA uses pointers to locate the appropriate variables, you will have to set these pointers outside your RPG/400 application.

Notes

Closed state of cursors: All cursors in a program are in the closed state when:
• The program is called:
  – If CLOSQLCSR(*ENDPGM) is specified, all cursors are in the closed state each time the program is called.
  – If CLOSQLCSR(*ENDSQL) is specified, all cursors are in the closed state only the first time the program is called as long as one SQL program remains on the call stack.
  – If CLOSQLCSR(*ENDJOB) is specified, all cursors are in the closed state only the first time the program is called as long as the job remains active.
  – If CLOSQLCSR(*ENDMOD) is specified, all cursors are in the closed state each time the module is initiated.
  – If CLOSQLCSR(*ENDACTGRP) is specified, all cursors are in the closed state only the first time the module in the program is initiated in the activation group.
• A program starts a new unit of work by executing a COMMIT statement without a HOLD option. Cursors declared with the HOLD option are not closed by a COMMIT statement without a HOLD option. A COMMIT HOLD statement does not close cursors whether they are declared with a HOLD option or not.
• A program starts a new unit of work by executing a ROLLBACK statement without a HOLD option. A ROLLBACK HOLD statement does not close cursors whether they are declared with a HOLD option or not.
• A CONNECT (Type 1) statement was executed.

A cursor can also be in the closed state because:
• A CLOSE statement was executed.
• A DISCONNECT statement disconnected the connection with which the cursor was associated.
• The connection with which the cursor was associated was in the release-pending state and a successful COMMIT occurred.
• A CONNECT (Type 1) statement was executed.
To retrieve rows from the result table of a cursor, the FETCH statement must be executed when the cursor is open. The only way to change the state of a cursor from closed to open is to execute an OPEN statement.

**Effect of temporary tables:** If the result table of a cursor is not read-only, its rows are derived during the execution of subsequent FETCH statements. The same method may be used for a read-only result table. However, if a result table is read-only, Db2 for i may choose to use the temporary table method instead. With this method the entire result table is inserted into a temporary table during the execution of the OPEN statement. When a temporary table is used, the results of a program can differ in several ways:

- An error can occur during OPEN that would otherwise not occur until some later FETCH statement.
- The INSERT, UPDATE, and DELETE statements that are executed while the cursor is open cannot affect the result table.
- Any NEXT VALUE expressions in the SELECT statement are evaluated for every row of the result table during OPEN. Thus, sequence values are generated, for every row of the result table during OPEN.
- Any functions are evaluated for every row of the result table during OPEN.
  Thus, any external actions and SQL statements that modify SQL data within the functions are performed for every row of the result table during OPEN.

Conversely, if a temporary table is not used, INSERT, UPDATE, and DELETE statements executed while the cursor is open can affect the result table, and any NEXT VALUE expressions and functions in the SELECT statement are evaluated as each row is fetched. The effect of such operations is not always predictable. For example, if cursor CUR is positioned on a row of its result table defined as SELECT * FROM T, and a row is inserted into T, the effect of that insert on the result table is not predictable because its rows are not ordered. A subsequent FETCH CUR might or might not retrieve the new row of T.

**Parameter marker replacement:** When the SELECT statement of the cursor is evaluated, each parameter marker in the statement is effectively replaced by its corresponding variable. The replacement of a parameter marker is an assignment operation in which the source is the value of the variable, and the target is a variable within the database manager. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see [Table 112 on page 1501](#).

Let V denote a variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column. Thus:

- V must be compatible with the target.
- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, the value of V must not be null.

However, unlike the rules for assigning a value to a column:

- If V is a string, the value will be truncated (without an error), if its length is greater than the length attribute of the target.
When the SELECT statement of the cursor is evaluated, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6), and the target is CHAR(8), the value used in place of P is the value of V padded with two blanks.

The USING clause is intended for a prepared SELECT statement that contains parameter markers. However, it can also be used when the SELECT statement of the cursor is part of the DECLARE CURSOR statement. In this case the OPEN statement is executed as if each variable in the SELECT statement were a parameter marker, except that the attributes of the target variables are the same as the attributes of the variables in the SELECT statement. The effect is to override the values of the variables in the SELECT statement of the cursor with the values of the variables specified in the USING clause.

**Variable value override:** The USING clause is intended for a prepared SELECT statement that contains parameter markers. However, it can also be used when the SELECT statement of the cursor is part of the DECLARE CURSOR statement. In this case, the OPEN statement is executed as if each variable in the SELECT statement were a parameter marker, except that the attributes of the target variables are the same as the attributes of the variables in the SELECT statement. The effect is to override the values of the variables in the SELECT statement of the cursor with the values of the variables specified in the USING clause.

### Examples

**Example 1:** Write the embedded statements in a COBOL program that will:

1. Define a cursor C1 that is to be used to retrieve all rows from the DEPARTMENT table for departments that are administered by (ADMRDEPT) department ‘A00’
2. Place the cursor C1 before the first row to be fetched.

```sql
EXEC SQL DECLARE C1 CURSOR FOR
SELECT DEPTNO, DEPTNAME, MGRNO FROM DEPARTMENT
WHERE ADMRDEPT = 'A00' END-EXEC.
EXEC SQL OPEN C1 END-EXEC.
```

**Example 2:** Code an OPEN statement to associate a cursor DYN_CURSOR with a dynamically defined select-statement in a C program. Assume each prepared select-statement always defines two items in its select list with the first item having a data type of integer and the second item having a data type of VARCHAR(64). (The related host variable definitions, PREPARE statement, and DECLARE CURSOR statement are also shown in the example below.)

```sql
EXEC SQL BEGIN DECLARE SECTION;
    static short hv_int;
    char hv_vchar64[64];
    char stmt1_str[200];
EXEC SQL END DECLARE SECTION;
EXEC SQL PREPARE STMT1_NAME FROM :stmt1_str;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;
EXEC SQL OPEN DYN_CURSOR USING :hv_int, :hv_vchar64;
```

**Example 3:** Code an OPEN statement as in example 3, but in this case the number and data types of the items in the select statement are not known.
EXEC SQL BEGIN DECLARE SECTION;
    char stmt1_str[200];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;

EXEC SQL PREPARE STMT1_NAME FROM :stmt1_str;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;
EXEC SQL OPEN DYN_CURSOR USING DESCRIPTOR :sqlda;
The PREPARE statement creates an executable form of an SQL statement from a character-string form of the statement. The character-string form is called a statement string, and the executable form is called a prepared statement.

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The authorization rules are the same as those defined for the SQL statement specified by the PREPARE statement. For example, see “select-statement” on page 800 for the authorization rules that apply when a SELECT statement is prepared.

If DLYPRP(*NO) is specified on the CRTSQLxxx command, the authorization checking is performed when the statement is prepared, except:

• If a DROP SCHEMA statement is prepared, privileges on all objects in the schema are not checked until the statement is executed.
• If a DROP TABLE statement is prepared, privileges on all views, indexes, and logical files that reference the table are not checked until the statement is executed.
• If a DROP VIEW statement is prepared, privileges on all views that reference the view are not checked until the statement is executed.
• If a CREATE TRIGGER statement is prepared, privileges on objects referenced in the triggered-action are not checked until the statement is executed.
• If a DROP, COMMENT, or LABEL of a FUNCTION, PROCEDURE, SEQUENCE, TYPE, TRIGGER, VARIABLE, or XSROBJECT statement is prepared, authorities are not checked until the statement is executed.
• If a GRANT or REVOKE statement is prepared, authorities are not checked until the statement is executed.

If DLYPRP(*YES) is specified on the CRTSQLxxx command, all authorization checking is deferred until the statement is executed or used in an OPEN statement.

The authorization ID of the statement is the run-time authorization ID unless USRPRF(*OWNER) and DYNUSRPRF(*OWNER) were specified on the CRTSQLxxx command when the program was created. For more information, see “Authorization IDs and authorization names” on page 69.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

• For the global variable identified in the statement,
  – The READ privilege on the global variable, and
  – The system authority *EXECUTE on the library containing the global variable
• Database administrator authority

Notes:
1 The same clause must not be specified more than once. If the options are not specified, their defaults are whatever was specified for the corresponding options in an associated DECLARE CURSOR and the prepared SELECT statement.
**Description**

*statement-name*

Names the prepared statement. If the name identifies an existing prepared statement, that prepared statement is destroyed if:

- it was prepared in the same instance of the same program, or
- CLOSQLCSR(*ENDJOB), CLOSQLCSR(*ENDACTGRP), or CLOSQLCSR(*ENDSQL) are specified on the CRTSQLxxx commands associated with both prepared statements.

The name must not identify a prepared statement that is the SELECT statement of an open cursor of this instance of the program.

**USING SQL DESCRIPTOR SQL-descriptor-name**

Identifies an SQL descriptor. If USING is specified, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQL descriptor specified by the *SQL-descriptor-name*. Thus, the PREPARE statement:

```sql
EXEC SQL PREPARE S1 USING SQL DESCRIPTOR :sqldescriptor FROM :V1;
```

is equivalent to:

```sql
EXEC SQL PREPARE S1 FROM :V1;
EXEC SQL DESCRIBE S1 USING SQL DESCRIPTOR :sqldescriptor;
```

**LOCAL**

Specifies the scope of the name of the descriptor to be local to program invocation.

**GLOBAL**

Specifies the scope of the name of the descriptor to be global to the SQL session.

*SQL-descriptor-name*

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See **“GET DESCRIPTOR” on page 1376** for an explanation of the information that is placed in the SQL descriptor.

**INTO**

If INTO is used, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQLDA specified by the *descriptor-name*. Thus, the PREPARE statement:

```sql
EXEC SQL PREPARE S1 INTO :SQLDA FROM :V1;
```

is equivalent to:

```sql
EXEC SQL PREPARE S1 FROM :V1;
EXEC SQL DESCRIBE S1 INTO :SQLDA;
```

*descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in Appendix D, “SQLDA (SQL descriptor area),” on page 1747. Before the PREPARE statement is executed, the following variable in the SQLDA must be set (The rules for REXX are different. For more information, see the Embedded SQL Programming topic collection.):

**SQLN**

Indicates the number of variables represented by SQLVAR. (SQLN provides the dimension of the SQLVAR array.) SQLN must be set to a value greater than or equal to zero before the PREPARE statement is
executed. For information about techniques to determine the number of occurrences required, see “Determining how many SQLVAR occurrences are needed” on page 1750.

See “DESCRIBE” on page 1321 for an explanation of the information that is placed in the SQLDA.

USING
Specifies what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist or a name is longer than 30, SQLNAME is set to length 0.

NAMES
Assigns the name of the column. This is the default. For a prepared statement where the names are explicitly specified in the select-list, the name specified is returned.

SYSTEM NAMES
Assigns the system column name of the column.

LABELS
Assigns the label of the column. (Column labels are defined by the LABEL statement.) Only the first 20 bytes of the label are returned.

ANY
Assigns the column label. If the column has no label, the label is the column name.

BOTH
Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2*n or 3*n (where n is the number of columns in the table or view). The first n occurrences of SQLVAR contain the column names. Either the second or third n occurrences contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

If the same SQLDA is used on a subsequent FETCH statement, set SQLN to n after the PREPARE is complete.

ALL
Assigns the label, column name, and system column name. In this case three or four occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 3*n or 4*n (where n is the number of columns in the result table). The first n occurrences of SQLVAR contain the system column names. The second or third n occurrences contain the column labels. The third or fourth n occurrences contain the column names if they are different from the system column name. If there are no distinct types, the labels are returned in the second set of SQLVAR entries and the column names are returned in the third set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries and the column names are returned in the fourth set of SQLVAR entries.

If the same SQLDA is used on a subsequent FETCH statement, set SQLN to n after the PREPARE is complete.
ATTRIBUTES attr-variable

Specifies the attributes for this cursor that are in effect if a corresponding attribute has not been specified as part of the outermost fullselect of the associated SELECT statement. If attributes are specified for the outermost fullselect, they are used instead of the corresponding attributes specified on the PREPARE statement. In turn, if attributes are specified in the PREPARE statement, they are used instead of the corresponding attributes specified on a DECLARE CURSOR statement.

All attributes other than USE CURRENTLY COMMITTED and WAIT FOR OUTCOME are ignored if the prepared statement is not a select-statement.

attr-variable must identify a character-string or Unicode graphic variable that is declared in the program in accordance with the rules for declaring string variables. attr-variable must be a string variable (either fixed-length or varying-length) that has a length attribute that does not exceed the maximum length of a VARCHAR. Leading and trailing blanks are removed from the value of the variable. The variable must contain a valid attribute-string.

An indicator variable can be used to indicate whether attributes are actually provided on the PREPARE statement. Thus, applications can use the same PREPARE statement regardless of whether attributes need to be specified or not. The options that can be specified as part of the attribute-string are as follows:

ASENSITIVE, SENSITIVE, or INSENSITIVE

Specifies whether the cursor is asensitive, sensitive, or insensitive to changes. For more information, see “DECLARE CURSOR” on page 1265.

If SENSITIVE is specified, then a fetch-clause must not be specified. If INSENSITIVE is specified, then an update-clause must not be specified.

NO SCROLL or SCROLL

Specifies whether the cursor is scrollable or not scrollable. For more information, see “DECLARE CURSOR” on page 1265.

WITHOUT HOLD or WITH HOLD

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation. For more information, see “DECLARE CURSOR” on page 1265.

WITHOUT RETURN or WITH RETURN

Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. For more information, see “DECLARE CURSOR” on page 1265.

offset-clause

Specifies the number of rows to skip before any rows are retrieved. For more information, see “offset-clause” on page 789. The offset-row-count must be a constant.

fetch-clause

Specifies that a maximum number of rows should be retrieved. For more information, see “fetch-clause” on page 790. The fetch-row-count must be a constant. The alternate LIMIT syntax is not supported.

read-only-clause or update-clause

Specifies whether the result table is read-only or updatable. The update-clause clause must be specified without column names (FOR UPDATE). For more information, see “read-only-clause” on page 809 and “update-clause” on page 808.
optimize-clause
Specifies that the database manager should assume that the program does not intend to retrieve more than integer rows from the result table. For more information, see “optimize-clause” on page 810.

isolation-clause
Specifies an isolation level at which the select statement is executed. For more information, see “isolation-clause” on page 811.

concurrent-access-resolution-clause
Specifies the concurrent access resolution to use for the select statement. For more information, see “concurrent-access-resolution-clause” on page 813.

WITHOUT EXTENDED INDICATORS or WITH EXTENDED INDICATORS
Specifies whether the values provided for indicator variables during execution of an INSERT or UPDATE follow standard SQL semantics for indicating NULL values, or may use extended capabilities to indicate the assignment of a DEFAULT or UNASSIGNED value.

WITH EXTENDED INDICATORS must only be specified when the statement is an INSERT using VALUES form of the INSERT statement, an UPDATE statement, or when the statement contains an INSERT using VALUES form of the INSERT statement.

WITHOUT ROW CHANGE COLUMNS or WITH ROW CHANGE COLUMNS POSSIBLY DISTINCT
or WITH ROW CHANGE COLUMNS ALWAYS DISTINCT
Specifies whether additional column(s) should be added to the result set of a prepared select-statement that can be subsequently be used to identify whether a value of a column in the row might have changed. Additional row change columns are only added if a single table (or an updatable view) is referenced in the outermost subselect. The DESCRIBE and GET DESCRIPTOR statements will indicate which rows have been added.

WITHOUT ROW CHANGE COLUMNS
Row change columns are not added to the result set. This is the default.

WITH ROW CHANGE COLUMNS POSSIBLY DISTINCT
Row change columns are added to the result set even if they do not uniquely represent a single row. The columns added can be used to determine whether a value of a column in the row might have changed since it was originally fetched.

- If the row change column values have not changed since they were first fetched, then no columns of the row have been changed since they were first fetched.
- If the row change column values have changed since they were first fetched, then columns of the row may or may not have changed since the row change values are not guaranteed to represent a single row.

WITH ROW CHANGE COLUMNS ALWAYS DISTINCT
Row change columns are added to the result set only if they uniquely represent a single row. Otherwise, no row change columns are added to the result set. The columns added can be used to determine whether a value of a column in the row has changed since it was originally fetched. (Note that a table requires a row change timestamp column to guarantee that the row change columns of a row uniquely identify a single row.)
PREPARE

- If the row change column values have not changed since they were first fetched, then no columns of the row have been changed since they were first fetched.
- If the row change column values have changed since they were first fetched, then columns of the row have changed.

A warning is returned (SQLSTATE 0168T) if WITH ROW CHANGE COLUMNS ALWAYS DISTINCT is specified and the database manager is unable to return distinct row change columns.

FROM

Introduces the statement string. The statement string is the value of the specified expression, string-expression, or the identified variable.

**variable**

Identifies a variable that is declared in the program in accordance with the rules for declaring character-string or Unicode graphic variables. An indicator variable must not be specified.

**expression**

An expression of the type described in "Expressions" on page 174, that does not include an aggregate function or column name. It must return a value that is a character string or a Unicode graphic string. If a variable is specified in the expression it must not have a CCSID of 65535.

The statement string must be one of the following SQL statements:

<table>
<thead>
<tr>
<th>ALLOCATE CURSOR</th>
<th>ALTER</th>
<th>ASSOCIATE LOCATORS</th>
<th>CALL</th>
<th>COMMENT</th>
<th>COMMIT</th>
<th>Compound (dynamic)</th>
<th>CREATE</th>
<th>DECLARE GLOBAL TEMPORARY TABLE</th>
<th>DELETE</th>
<th>DROP</th>
<th>FREE LOCATOR</th>
<th>GRANT</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSERT</td>
<td>LABEL</td>
<td>LOCK TABLE</td>
<td>MERGE</td>
<td>REFRESH TABLE</td>
<td>RELEASE SAVEPOINT</td>
<td>RENAME</td>
<td>REVOKE</td>
<td>ROLLBACK</td>
<td>SAVEPOINT</td>
<td>select-statement</td>
<td>SET CURRENT DEBUG MODE</td>
<td>SET CURRENT DECFLOAT</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The statement string must not:
- Begin with EXEC SQL.
- End with END-EXEC or a semicolon.
- Include references to variables. Global variables are allowed.

**Notes**

- **Parameter markers**: Although a statement string cannot include references to host variables, SQL variables, or SQL parameters, it may include parameter markers or

---

118. In a PL/I program, a PL/I string expression can also be specified.
119. The target of the SET variable statement must be a global variable.
global variables. Parameter markers can be replaced by the values of variables when the prepared statement is executed. A parameter marker is a question mark (?) that is used where a variable could be used if the statement string were a static SQL statement. For an explanation of how parameter markers are replaced by values, see "OPEN" on page 1488 and "EXECUTE" on page 1360.

There are two types of parameter markers:

Typed parameter marker
A parameter marker that is specified along with its target data type. It has the general form:

```
CAST(? AS data-type)
```

This notation is not a function call, but a “promise” that the type of the parameter at run time will be of the data type specified or some data type that can be converted to the specified data type. For example, in:

```
UPDATE EMPLOYEE
SET LASTNAME = TRANSLATE(CAST(? AS VARCHAR(12)))
WHERE EMPNO = ?
```

the value of the argument of the TRANSLATE function will be provided at run time. The data type of that value will either be VARCHAR(12), or some type that can be converted to VARCHAR(12). For more information, refer to "CAST specification" on page 195.

Untyped parameter marker
A parameter marker that is specified without its target data type. It has the form of a single question mark. The data type of an untyped parameter marker is provided by context. For example, the untyped parameter marker in the predicate of the above update statement is the same as the data type of the EMPNO column.

Typed parameter markers can be used in dynamic SQL statements wherever a variable is supported and the data type is based on the promise made in the CAST function.

Untyped parameters markers can be used in dynamic SQL statements in selected locations where variables are supported. These locations and the resulting data type are found in the following tables:

<table>

</tbody>
</table>

Error checking: When a PREPARE statement is executed, the statement string is parsed and checked for errors. If the statement string is not valid, a prepared statement is not created and an error is returned.

In local and remote processing, the DLYPREP(*YES) option can cause some SQL statements to receive "delayed" errors. For example, DESCRIBE, EXECUTE, and OPEN might receive an SQLCODE that normally occurs during PREPARE processing.

Reference and execution rules: Prepared statements can be referred to in the following kinds of statements, with the following restrictions shown:

<table>
<thead>
<tr>
<th>Statement</th>
<th>The prepared statement restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESCRIBE</td>
<td>None</td>
</tr>
<tr>
<td>DECLARE CURSOR</td>
<td>Must be SELECT when the cursor is opened</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Must not be SELECT</td>
</tr>
</tbody>
</table>

A prepared statement can be executed many times. If a prepared statement is not executed more than once and does not contain parameter markers, it is more efficient to use the EXECUTE IMMEDIATE statement rather than the PREPARE and EXECUTE statements.

Extended indicator usage: The EXTENDED INDICATORS clause indicates whether extended indicator variable values are enabled in the SET assignment-clause of an UPDATE statement, the VALUES expression-list of an INSERT statement, or the insert operation or update operation of a MERGE statement.

120. If the data type is DATE, TIME, or TIMESTAMP, then VARCHAR(32740) is used.
121. If the escape expression is MIXED data, the data type is VARCHAR(4).
122. The CCSID for XML is determined as described in "XML Values" on page 89.
123. The CCSID is determined based on the attributes of the data-type specified on the AS clause as described in "CAST specification" on page 195. If the data-type is a binary string or bit data, then the SQL_XML_DATA_CCSID is used for the CCSID attribute.
Extended indicator variables and deferred error checks: When extended indicator variables are enabled, the UNASSIGNED indicator variable value effectively causes its target column to be omitted from the statement. Because of this, validation that is normally done during statement preparation is delayed until statement execution.

Prepared statement persistence: All prepared statements are destroyed when:

- A CONNECT (Type 1) statement is executed.
- A DISCONNECT statement disconnects the connection with which the prepared statement is associated.
- A prepared statement is associated with a release-pending connection and a successful commit occurs.
- The associated scope (job, activation group, or program) of the SQL statement ends.

Scope of a statement: The scope of statement-name is the source program in which it is defined. You can only reference a prepared statement by other SQL statements that are precompiled with the PREPARE statement. For example, a program called from another separately compiled program cannot use a prepared statement that was created by the calling program.

The scope of statement-name is also limited to the thread in which the program that contains the statement is running. For example, if the same program is running in two separate threads in the same job, the second thread cannot use a statement that was prepared by the first thread.

Although the scope of a statement is the program in which it is defined, each package created from the program includes a separate instance of the prepared statement and more than one prepared statement can exist at run time. For example, assume a program using CONNECT (Type 2) statements connects to location X and location Y in the following sequence:

```
EXEC SQL CONNECT TO X;
EXEC SQL PREPARE S FROM :hv1;
EXEC SQL EXECUTE S;
.
.
.
EXEC SQL CONNECT TO Y;
EXEC SQL PREPARE S FROM :hv1;
EXEC SQL EXECUTE S;
```

The second prepare of S prepares another instance of S at Y.

A prepared statement can only be referenced in the same instance of the program in the program stack, unless CLOSQLCSR(*ENDJOB), CLOSQLCSR(*ENDACTGRP), or CLOSQLCSR(*ENDSQL) is specified on the CRTSQLxxx commands.

- If CLOSQLCSR(*ENDJOB) is specified, the prepared statement can be referred to by any instance of the program (that prepared the statement) on the program stack. In this case, the prepared statement is destroyed at the end of the job.
- If CLOSQLCSR(*ENDSQL) is specified, the prepared statement can be referred to by any instance of the program (that prepared the statement) on the program stack.

---

124. Prepared statements may be cached and not actually destroyed. However, a cached statement can only be used if the same statement is prepared again.
stack until the last SQL program on the program stack ends. In this case, the
prepared statement is destroyed when the last SQL program on the program
stack ends.

- If CLOSQLCSR(*ENDACTGRP) is specified, the prepared statement can be
  referred to by all instances of the module in the program that prepared the
  statement until the activation group ends. In this case, the prepared statement is
  destroyed when the activation group ends.

Allocating the SQL descriptor: If a USING clause is specified, before the PREPARE
statement is executed, the SQL descriptor must be allocated using the ALLOCATE
DESCRIPTOR statement. If the number of descriptor items allocated is less than
the number of result columns, a warning (SQLSTATE 01005) is returned.

PREPARE and *LIBL: Normally, any unqualified names of objects are resolved
when a statement is prepared. Hence, any changes to the CURRENT SCHEMA or
CURRENT PATH after the statement has been prepared have no effect on which
objects will be referenced when the statement is executed or opened. However, if
system naming is used and an object name is implicitly qualified with *LIBL, the
object is resolved at execute or open time. Any changes to the library list after the
statement is prepared but before execute or open time will affect which objects will
be referenced when the statement is executed or opened.

Examples

Example 1: Prepare and execute a non-select-statement in a COBOL program.
Assume the statement is contained in a variable HOLDER and that the program
will place a statement string into the variable based on some instructions from the
user. The statement to be prepared does not have any parameter markers.

    EXEC SQL  PREPARE STMT_NAME FROM :HOLDER  END-EXEC.
    EXEC SQL  EXECUTE STMT_NAME  END-EXEC.

Example 2: Prepare and execute a non-select-statement as in example 1, except
assume the statement to be prepared can contain any number of parameter
markers.

    EXEC SQL  PREPARE STMT_NAME FROM :HOLDER  END-EXEC.
    EXEC SQL  EXECUTE STMT_NAME USING DESCRIPTOR :INSERT_DA  END-EXEC.

Assume that the following statement is to be prepared:

    INSERT INTO DEPARTMENT VALUES(? , ?, ?, ?)

To insert department number G01 named COMPLAINTS, which has no manager
and reports to department A00, the structure INSERT_DA should have the
following values before executing the EXECUTE statement.
<table>
<thead>
<tr>
<th>SQLDAID</th>
<th>SQLDABC</th>
<th>SQLN</th>
<th>SQLD</th>
<th>SQLTYPE</th>
<th>SQLLEN</th>
<th>SQLDATA</th>
<th>SQLIND</th>
<th>SQLNAME</th>

RBAL3601-0
REFRESH TABLE

The REFRESH TABLE statement refreshes the data in a materialized query table. The statement deletes all rows in the materialized query table and then inserts the result rows from the select-statement specified in the definition of the materialized query table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table identified in the statement,
  - The system authority *OBJMGT on the table
  - The DELETE privilege on the table
  - The INSERT privilege on the table
  - The system authority *EXECUTE on the library containing the table
- Database administrator authority

For information on the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.

Syntax

```
REFRESH TABLE table-name
```

Description

table-name

Identifies the materialized table to be refreshed. The table-name must identify a materialized query table that exists at the current server. REFRESH TABLE evaluates the select-statement in the definition of the materialized query table to refresh the table.

Notes

Refresh use of materialized query tables: No materialized query tables are used to evaluate the select-statement during the processing of REFRESH TABLE statement.

Refresh isolation level: The isolation level used to evaluate the select-statement is either:

- the isolation level specified on the isolation-level clause of the select-statement, or
- if the isolation-level clause was not specified, the isolation level of the materialized query table recorded when CREATE TABLE or ALTER TABLE was issued.
**REFRESH TABLE**

**Number of rows:** After successful execution of a REFRESH TABLE statement, the ROW_COUNT statement information item in the SQL Diagnostics Area (or SQLERRD(3) in the SQLCA) will contain the number of rows inserted into the materialized query table.

**Example**

Refresh the data in the TRANSCOUNT materialized query table.

```
REFRESH TABLE TRANSCOUNT
```
RELEASE (connection)

The RELEASE statement places one or more connections in the release-pending state.

Invocation

This statement can only be embedded within an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

RELEASE is not allowed in a trigger or function.

Authorization

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
> RELEASE server-name
  variable
  CURRENT SQL

> RELEASE ALL
  ALL SQL
```

Description

**server-name or variable**

Identifies a connection by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a character-string variable.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

When the RELEASE statement is executed, the specified server name or the server name contained in the variable must identify an existing connection of the activation group.

**CURRENT**

Identifies the current connection of the activation group. The activation group must be in the connected state.

**ALL or ALL SQL**

Identifies all existing connections of the activation group (local as well as remote connections).
RELEASE (connection)

An error or warning does not occur if no connections exist when the statement is executed.

An application server named ALL can only be identified by a variable or a delimited identifier.

If the RELEASE statement is successful, each identified connection is placed in the release-pending state and will therefore be ended during the next commit operation. If the RELEASE statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Notes

RELEASE and CONNECT (Type 1): Using CONNECT (Type 1) semantics does not prevent using RELEASE.

Scope of RELEASE: RELEASE does not close cursors, does not release any resources, and does not prevent further use of the connection.

Resource considerations for remote connections: Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be in the release-pending state and one that is going to be reused should not be in the release-pending state.

Connection states: ROLLBACK does not reset the state of a connection from release-pending to held.

If the current connection is in the release-pending state when a commit operation is performed, the connection is ended and the activation group is in the unconnected state. In this case, the next executed SQL statement must be CONNECT or SET CONNECTION.

RELEASE ALL places the connection to the local release-pending in the release-pending state. A connection in the release-pending state is ended during a commit operation even though it has an open cursor defined with the WITH HOLD clause.

Examples

Example 1: The connection to TOROLAB1 is not needed in the next unit of work. The following statement will cause it to be ended during the next commit operation.

```
EXEC SQL RELEASE TOROLAB1;
```

Example 2: The current connection is not needed in the next unit of work. The following statement will cause it to be ended during the next commit operation.

```
EXEC SQL RELEASE CURRENT;
```

Example 3: None of the existing connections are needed in the next unit of work. The following statement will cause it to be ended during the next commit operation.

```
EXEC SQL RELEASE ALL;
```
The RELEASE SAVEPOINT statement releases the identified savepoint and any subsequently established savepoints within a unit of work at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

None required.

**Syntax**

```
RELEASE SAVEPOINT savepoint-name
```

**Description**

*savepoint-name*

Identifies the savepoint to release. The name must identify a savepoint that exists at the current server. The named savepoint and all the savepoints at the current server that were subsequently established in the unit of work are released. After a savepoint is released, it is no longer maintained, and rollback to the savepoint is no longer possible.

**Notes**

**Savepoint Names:** The name of the savepoint that was released can be re-used in another SAVEPOINT statement, regardless of whether the UNIQUE keyword was specified on an earlier SAVEPOINT statement specifying this same savepoint name.

**Isolation Level Restriction:** A RELEASE SAVEPOINT statement is not allowed if commitment control is not active for the activation group. For information about determining which commitment definition is used, see “Notes” on page 978 in COMMIT statement.

**Example**

Assume that a main routine sets savepoint A and then invokes a subroutine that sets savepoints B and C. When control returns to the main routine, release savepoint A and any subsequently set savepoints. Savepoints B and C, which were set by the subroutine, are released in addition to A.

```
RELEASE SAVEPOINT A
```
RENAME

The RENAME statement renames a table, view, or index. The name and/or the system object name of the table, view, or index can be changed.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
  - If the name of the object is changed:
    - The system authority of *OBJMGT on the table, view, or index to be renamed
    - The system authority *EXECUTE on the library containing the table, view, or index to be renamed
  - If the system name of the object is changed:
    - The system authority of *OBJMGT on the table, view, or index to be renamed
    - The system authorities *EXECUTE and *UPD on the library containing the table, view, or index to be renamed
- Database administrator authority

Syntax

```
RENAME
  TABLE table-name
  INDEX view-name
  TO target-identifier
  FOR SYSTEM NAME system-object-identifier
```

Description

**TABLE table-name or view-name**

Identifies the table or view that will be renamed. The `table-name` or `view-name` must identify a table or view that exists at the current server, but must not identify a catalog table or a declared temporary table. The specified name can be an alias name. The specified table or view is renamed to the new name. All privileges, constraints, indexes, triggers, views, and logical files on the table or view are preserved.

Any access plans that reference the table or view are implicitly prepared again when a program that uses the access plan is next run. Since the program refers to a table or view with the original name, if a table or view with the original name does not exist at that time, an error is returned.
INDEX index-name
   Identifies the index that will be renamed. The index-name must identify an
   index that exists at the current server. The specified index is renamed to the
   new name.

   Any access plans that reference the index are not affected by rename.

target-identifier
   Identifies the new table-name, view-name, or index-name of the table, view, or
   index, respectively. target-identifier must not be the same as a table, view, alias,
   or index that already exists at the current server. The target-identifier must be an
   unqualified SQL identifier.

SYSTEM NAME system-object-identifier
   Identifies the new system-object-identifier of the table, view, or index,
   respectively. system-object-identifier must not be the same as a table, view, alias,
   or index that already exists at the current server. The system-object-identifier
   must be an unqualified system identifier.

   If the name of the object and the system name of the object are the same and
   target-identifier is not specified, specifying system-object-identifier will be the new
   name and system object name. Otherwise, specifying system-object-identifier will
   only affect the system name of the object and not affect the name of the object.

   If both target-identifier and system-object-identifier are specified, they cannot both
   be valid system object names.

Notes

Effects of the statement: The specified table, view, or index is renamed to the new
name. For a renamed table, all privileges and indexes on the table are preserved.
For a renamed index, all privileges are preserved.

Invalidation of packages and access plans: Any access plans that refer to that
table are invalidated. For more information see "Packages and access plans" on
page 15.

Considerations for aliases: If an alias name is specified for table-name, the table
must exist at the current server, and the table that is identified by the alias is
renamed. The name of the alias is not changed and continues to refer to the old
table name after the rename.

There is no support for changing the name of an alias with the RENAME
statement. To change the name to which the alias refers, the alias must be dropped
and recreated.

Rename rules: The rename operation performed depends on the new name
specified.
  • If the new name is a valid system identifier,
    – the alternative name (if any) is removed, and
    – the system object name is changed to the new name.
  • If the new name is not a valid system identifier,
    – the alternative name is added or changed to the new name, and
    – a new system object name is generated if the system object name (of the table
      or view) was specified as the table, view, or index to rename. For more
      information about generated table name rules, see "Rules for Table Name
      Generation" on page 1213.
RENAMEN

If an alias name is specified for table-name, the alias must exist at the current server, and the table that is identified by the alias is renamed. The name of the alias is not changed and continues to refer to the old table after the rename. There is no support for changing the name of an alias.

Examples

Example 1: Change the name of the EMPLOYEE table to CURRENT_EMPLOYEES:

```
RENAME TABLE EMPLOYEE TO CURRENT_EMPLOYEES
```

Example 2: Change the name of the unique index using EMPNO, called XEMP1, to UXEMPNO:

```
RENAME INDEX XEMP1 TO UXEMPNO
```

Example 3: Rename a table named MY_IN_TRAY to MY_IN_TRAY_94. The system object name will remain unchanged (MY_IN_TRAY).

```
RENAME TABLE MY_IN_TRAY TO MY_IN_TRAY_94
FOR SYSTEM NAME MY_IN_TRAY
```
REVOKE (function or procedure privileges)

This form of the REVOKE statement removes the privileges on a function or procedure.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each function or procedure identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the function or procedure
  - The system authority *EXECUTE on the library (or directory if this is a Java routine) containing the function or procedure
- Database administrator authority
- Security administrator authority

Syntax
REVOKE (function or procedure privileges)

built-in-type:
REVOKE (function or procedure privileges)

ccsid-clause:

| CCSID—integer |

Description

ALL or ALL PRIVILEGES

Revolves one or more function or procedure privileges from each authorization-name. The privileges revoked are those privileges on the identified functions or procedures that were granted to the authorization-names. Note that revoking ALL PRIVILEGES on a function or procedure is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER

Revolves the privilege to use the ALTER FUNCTION, ALTER PROCEDURE, or COMMENT statement.

EXECUTE

Revolves the privilege to execute a function or procedure.

FUNCTION or SPECIFIC FUNCTION

Identifies the function from which the privilege is revoked. The function must exist at the current server and it must be a user-defined function, but not a function that was implicitly generated with the creation of a distinct type. The function can be identified by its name, function signature, or specific name.

FUNCTION function-name

Identifies the function by its name. The function-name must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION function-name (parameter-type, ...)

Identifies the function by its function signature, which uniquely identifies the function. The function-name (parameter-type, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be revoked. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If function-name () is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type, ...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:
Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, \( \text{DEC()} \) will be considered a match for a parameter of a function defined with a data type of \( \text{DEC}(7,2) \). However, \( \text{FLOAT} \) cannot be specified with empty parenthesis because its parameter value indicates a specific data type (\( \text{REAL} \) or \( \text{DOUBLE} \)).

If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is \( \text{FLOAT} \), the precision does not have to exactly match the value that was specified because matching is based on the data type (\( \text{REAL} \) or \( \text{DOUBLE} \)).

If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the \text{FOR DATA} clause or \text{CCSID} clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If \text{AS LOCATOR} is specified, the data type must be a \text{LOB} or \text{XML} or a distinct type based on a \text{LOB} or \text{XML}.

**SPECIFIC FUNCTION** \( \text{specific-name} \)

Identifies the function by its specific name. The \( \text{specific-name} \) must identify a specific function that exists at the current server.

**PROCEDURE** or **SPECIFIC PROCEDURE**

Identifies the procedure from which the privilege is revoked. The \( \text{procedure-name} \) must identify a procedure that exists at the current server.

**PROCEDURE** \( \text{procedure-name} \)

Identifies the procedure by its name. The \( \text{procedure-name} \) must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

**PROCEDURE** \( \text{procedure-name} (\text{parameter-type}, ...) \)

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The \( \text{procedure-name} (\text{parameter-type}, ...) \) must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be revoked. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If \( \text{procedure-name} () \) is specified, the procedure identified must have zero parameters.

\( \text{procedure-name} \)

Identifies the name of the procedure.
REVOKE (function or procedure privileges)

(parameter-type, ...)
   Identifies the parameters of the procedure.

   If an unqualified distinct type or array type name is specified, the
database manager searches the SQL path to resolve the schema name
for the distinct type or array type.

   For data types that have a length, precision, or scale attribute, use one
of the following:
   • Empty parentheses indicate that the database manager ignores the
     attribute when determining whether the data types match. For
     example, DEC() will be considered a match for a parameter of a
     procedure defined with a data type of DEC(7,2). However, FLOAT
     cannot be specified with empty parenthesis because its parameter
     value indicates a specific data type (REAL or DOUBLE).
   • If a specific value for a length, precision, or scale attribute is
     specified, the value must exactly match the value that was specified
     (implicitly or explicitly) in the CREATE PROCEDURE statement. If
     the data type is FLOAT, the precision does not have to exactly match
     the value that was specified because matching is based on the data
     type (REAL or DOUBLE).
   • If length, precision, or scale is not explicitly specified, and empty
     parentheses are not specified, the default attributes of the data type
     are implied. The implicit length must exactly match the value that
     was specified (implicitly or explicitly) in the CREATE PROCEDURE
     statement.

   Specifying the FOR DATA clause or CCSID clause is optional.
   Omission of either clause indicates that the database manager ignores
   the attribute when determining whether the data types match. If either
   clause is specified, it must match the value that was implicitly or
   explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR
   Specifies that the procedure is defined to receive a locator for this
   parameter. If AS LOCATOR is specified, the data type must be a LOB
   or XML or a distinct type based on a LOB or XML.

SPECIFIC PROCEDURE specific-name
   Identifies the procedure by its specific name. The specific-name must
   identify a specific procedure that exists at the current server.

FROM
   Identifies from whom the privileges are revoked.

USER
   Specifies that the authorization-name identifies a user profile. If USER is
   specified, authorization-name must be a user profile.

GROUP
   Specifies that the authorization-name identifies a group profile. If GROUP is
   specified, authorization-name must be a group profile.

authorization-name,...
   Lists one or more authorization IDs. Do not specify the same
   authorization-name more than once.

PUBLIC
   Revokes a grant of the privilege to PUBLIC. For more information, see
   “Authorization, privileges and object ownership” on page 18.
REVOKE (function or procedure privileges)

Notes

**Multiple grants:** If you revoke a privilege on a function or procedure, it nullifies any grant of the privilege on that function or procedure, regardless of who granted it.

**Revokeing WITH GRANT OPTION:** The only way to revoke the WITH GRANT OPTION is to revoke ALL.

**Privilege warning:** Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

**Corresponding system authorities:** When a function or procedure privilege is revoked, the corresponding system authorities are revoked. For information about the system authorities that correspond to SQL privileges see "GRANT (function or procedure privileges)" on page 1413.

Privileges revoked from either an SQL or external function or procedure are revoked from its associated program (*PGM) or service program (*SRVPGM) object. Privileges revoked from a Java external function or procedure are revoked from the associated class file or jar file. If the associated program, service program, class file, or jar file is not found when the revoke is executed, an error is returned.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword RUN can be used as a synonym for EXECUTE.

**Example**

Revoke the EXECUTE privilege on procedure PROCA from PUBLIC.

```
REVOKE EXECUTE
  ON PROCEDURE PROCA
FROM PUBLIC
```
REVOKE (package privileges)

This form of the REVOKE statement removes the privileges on a package.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each package identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the package
  - The system authority *EXECUTE on the library containing the package
- Database administrator authority
- Security administrator authority

Syntax

```
REVOKE [ALL] PRIVILEGES [ALTER EXECUTE] ON PACKAGE package-name
FROM authorization-name
```

Description

**ALL or ALL PRIVILEGES**

Revokes one or more package privileges from each `authorization-name`. The privileges revoked are those privileges on the identified packages that were granted to the `authorization-names`. Note that revoking `ALL PRIVILEGES` on a package is not the same as revoking the system authority of *ALL.

If you do not use `ALL`, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

**ALTER**

Revokes the privilege to use the COMMENT and LABEL statements.

**EXECUTE**

Revokes the privilege to execute statements in a package.

**ON PACKAGE package-name**

Identifies the package from which the EXECUTE privilege is revoked. The `package-name` must identify a package that exists at the current server.
REVOKE (package privileges)

FROM
Identifies from whom the privileges are revoked.

USER
Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP
Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name,...
Lists one or more authorization IDs. Do not specify the same authorization-name more than once.

PUBLIC
Revolves a grant of the privilege to PUBLIC. For more information, see “Authorization, privileges and object ownership” on page 18.

Notes

Multiple grants: If you revoke a privilege on a package, it nullifies any grant of the privilege on that package, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a package privilege is revoked, the corresponding system authorities are revoked. For information about the system authorities that correspond to SQL privileges see “GRANT (package privileges)” on page 1421.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:
• The keyword RUN can be used as a synonym for EXECUTE.
• The keyword PROGRAM can be used as a synonym for PACKAGE.

Example

Example 1: Revoke the EXECUTE privilege on package PKGA from PUBLIC.

REVOKE EXECUTE
ON PACKAGE PKGA
FROM PUBLIC

Example 2: Revoke the EXECUTE privilege on package RRSP_PKG from user FRANK and PUBLIC.

REVOKE EXECUTE
ON PACKAGE RRSP_PKG
FROM FRANK, PUBLIC
REVOKE (schema privileges)

This form of the REVOKE statement removes the privileges on a schema.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each schema identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the schema
- Database administrator authority
- Security administrator authority

Syntax

```
REVOKE ALL PRIVILEGES
    ON SCHEMA schema-name
    FROM authorization-name
```

Description

**ALL or ALL PRIVILEGES**

Revolves one or more schema privileges from each `authorization-name`. The privileges revoked are those privileges on the identified schemas that were granted to the `authorization-names`. Note that revoking ALL PRIVILEGES on a schema is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

**CREATEIN**

Revolves the privilege to create objects in the schema.

**USAGE**

Revolves the privilege to use the schema. USAGE privilege is required to reference any objects that exist in the schema.

**ON SCHEMA schema-name**

Identifies the schema from which the privilege is revoked.
FROM

Identifies from whom the privileges are revoked.

USER

Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP

Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name,...

Lists one or more authorization IDs. Do not specify the same authorization-name more than once.

PUBLIC

Revokes a grant of the privilege to PUBLIC. For more information, see “Authorization, privileges and object ownership” on page 18.

Notes

Multiple grants: If you revoke a privilege on a schema, it nullifies any grant of the privilege on that schema, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a schema privilege is revoked, the corresponding system authorities are revoked. For information on the system authorities that correspond to SQL privileges see “GRANT (schema privileges)” on page 1424.

Example

Example 1: Revoke the CREATEIN privilege on schema T_SCORES from user JONES.

REVOKE CREATEIN
ON SCHEMA T_SCORES
FROM JONES;
REVOKE (sequence privileges)

This form of the REVOKE statement removes the privileges on a sequence.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each sequence identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the sequence
  - The system authority *EXECUTE on the library containing the sequence
- Database administrator authority
- Security administrator authority

Syntax

```
REVOKE PRIVILEGES ALL, ALTER USAGE ON SEQUENCE sequence-name
FROM authorization-name
```

Description

**ALL or ALL PRIVILEGES**

Revoke one or more sequence privileges from each `authorization-name`. The privileges revoked are those privileges on the identified sequences that were granted to the `authorization-names`. Note that revoking ALL PRIVILEGES on a sequence is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revoes the privilege described.

**ALTER**

Revoke the privilege to use the ALTER SEQUENCE, COMMENT, and LABEL statements on a sequence.

**USAGE**

Revoke the privilege to use the sequence in NEXT VALUE or PREVIOUS VALUE expressions.
ON SEQUENCE sequence-name
   Identifies the sequence from which the privilege is revoked. The sequence-name must identify a sequence that exists at the current server.

FROM
   Identifies from whom the privileges are revoked.

USER
   Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP
   Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name,...
   Lists one or more authorization IDs. Do not specify the same authorization-name more than once.

PUBLIC
   Revokes a grant of the privilege to PUBLIC. For more information, see “Authorization, privileges and object ownership” on page 18.

Notes

Multiple grants: If you revoke a privilege on a sequence, it nullifies any grant of the privilege on that sequence, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When a sequence privilege is revoked, the corresponding system authorities are revoked. For information on the system authorities that correspond to SQL privileges see “GRANT (sequence privileges)” on page 1427.

Example

REVOKE the USAGE privilege from PUBLIC on a sequence called ORG_SEQ.

REVOKE USAGE
   ON SEQUENCE ORG_SEQ
   FROM PUBLIC
REVOKE (table or view privileges)

This form of the REVOKE statement removes privileges on a table or view.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each table or view identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the table or view
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority
- Security administrator authority

Syntax
Description

**ALL or ALL PRIVILEGES**
Revoke one or more privileges from each *authorization-name*. The privileges revoked are those privileges on the identified tables and views that were granted to the *authorization-names*. Note that revoking ALL PRIVILEGES on a table or view is not the same as revoking the system authority of *ALL*.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described, but only as it applies to the tables and views named in the ON clause.

**ALTER**
Revoke the privilege to alter the specified table and the privilege to add a comment, add a label, or create an index on the specified table or view.

**DELETE**
Revoke the privilege to delete rows from the specified table or view.

**INDEX**
Revoke the privilege to create an index on the specified table.

**INSERT**
Revoke the privilege to insert rows in the specified table or view.

**REFERENCES**
Revoke the privilege to add a referential constraint in which the table is a parent.

**REFERENCES (column-name,...)**
Revoke the privilege to add a referential constraint using the specified column(s) in the parent key. Each column name must be an unqualified name that identifies a column in each table identified in the ON clause.

**SELECT**
Revoke the privilege to use the SELECT or CREATE VIEW statement.

**UPDATE**
Revoke the privilege to use the UPDATE statement.

**UPDATE (column-name,...)**
Revoke the privilege to update the specified columns. Each column name must be an unqualified name that identifies a column in each table identified in the ON clause.

**ON table-name or view-name,...**
Identify the table or view from which the privileges are revoked. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table.

**FROM**
Identify from whom the privileges are revoked.

**USER**
Specify that the *authorization-name* identifies a user profile. If USER is specified, *authorization-name* must be a user profile.

**GROUP**
Specify that the *authorization-name* identifies a group profile. If GROUP is specified, *authorization-name* must be a group profile.

*authorization-name,...*
Lists one or more authorization IDs. Do not specify the same *authorization-name* more than once.
REVOKE (table or view privileges)

PUBLIC

Revoke a grant of the privilege to PUBLIC. For more information, see "Authorization, privileges and object ownership" on page 18.

Notes

Multiple grants: If the same privilege is granted to the same user more than once, revoking that privilege from that user nullifies all those grants.

If you revoke a privilege, it nullifies any grant of that privilege, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

If more than one system authority will be revoked with an SQL privilege, and any one of the authorities cannot be revoked, then a warning occurs and no authorities will be revoked for that privilege.

Corresponding system authorities: When a table privilege is revoked, the corresponding system authorities are revoked, except:

• When revoking authorities to a table or view, *OBJOPR is revoked only when *ADD, *DLT, *READ, and *UPD have all been revoked.
• When revoking authorities to a view, authorities will not be revoked from any tables or views referenced in the fullselect of the view definition.

For information about the system authorities that correspond to SQL privileges see "GRANT (table or view privileges)” on page 1430.

Revoking either the INDEX or ALTER privilege, revokes the system authority *OBJALTER.

Examples

Example 1: Revoke SELECT privileges on table EMPLOYEE from user ENGLES.

REVOKE SELECT
ON TABLE EMPLOYEE
FROM ENGLES

Example 2: Revoke update privileges on table EMPLOYEE previously granted to all users. Note that grants to specific users are not affected.

REVOKE UPDATE
ON TABLE EMPLOYEE
FROM PUBLIC

Example 3: Revoke all privileges on table EMPLOYEE from users PELLOW and ANDERSON.

REVOKE ALL
ON TABLE EMPLOYEE
FROM PELLOW, ANDERSON
Example 4: Revoke the privilege to update column_1 in VIEW1 from FRED.

```
REVOKE UPDATE(column_1)
  ON VIEW1
  FROM FRED
```
REVOKE (type privileges)

This form of the REVOKE statement removes the privileges on a type.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type or array type identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the type
  - The system authority *EXECUTE on the library containing the type
- Database administrator authority
- Security administrator authority

Syntax

```
REVOKE PRIVILEGES ALL, ALTER USAGE ON TYPE distinct-type-name array-type-name FROM authorization-name
```

Description

**ALL or ALL PRIVILEGES**

Revokes one or more type privileges from each `authorization-name`. The privileges revoked are those privileges on the identified user-defined types that were granted to the `authorization-names`. Note that revoking ALL PRIVILEGES on a type is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

**ALTER**

Revokes the privilege to use the COMMENT and LABEL statements.

**USAGE**

Revokes the privilege to use user-defined types in tables, functions, procedures, or as the source type in a CREATE TYPE statement.
ON TYPE distinct-type-name or array-type-name
Identifies the distinct type from which the privilege is revoked. The
distinct-type-name or array-type-name must identify a user-defined type that
exists at the current server.

FROM
Identifies from whom the privileges are revoked.

USER
Specifies that the authorization-name identifies a user profile. If USER is
specified, authorization-name must be a user profile.

GROUP
Specifies that the authorization-name identifies a group profile. If GROUP is
specified, authorization-name must be a group profile.

authorization-name,...
Lists one or more authorization IDs. Do not specify the same
authorization-name more than once.

PUBLIC
Revolves a grant of the privilege to PUBLIC. For more information, see
"Authorization, privileges and object ownership" on page 18.

Notes

Multiple grants: If authorization ID A granted the same privilege to authorization
ID B more than once, revoking that privilege from B nullifies all those grants.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT
OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily
prevent that user from performing an action that requires that privilege. For
example, the user may still have the privilege through PUBLIC privileges or
database administrator authority.

Corresponding system authorities: When a type privilege is revoked, the
corresponding system authorities are revoked. For information about the system
authorities that correspond to SQL privileges see "GRANT (type privileges)" on
page 1436.

Syntax alternatives: The following keywords are synonyms supported for
compatibility to prior releases. These keywords are non-standard and should not
be used:
• The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for
  TYPE.

Example

Revoke the USAGE privilege on distinct type SHOESIZE from user JONES.

REVOKE USAGE
  ON DISTINCT TYPE SHOESIZE
  FROM JONES
REVOKE (variable privileges)

This form of the REVOKE statement removes the privileges on a created global variable.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each variable identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the global variable
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority
- Security administrator authority

Syntax

```
REVOKE PRIVILEGES
   ALL
   ALTER
   READ
   WRITE
ON VARIABLE
   variable-name
FROM
   authorization-name
```

Description

**ALL or ALL PRIVILEGES**

Revokes one or more global variable privileges from each `authorization-name`. The privileges revoked are those privileges on the identified global variables that were granted to the `authorization-names`. Note that revoking ALL PRIVILEGES on a global variable is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

**ALTER**

Revokes the privilege to use COMMENT and LABEL statements on the specified global variables.
REVOKE (variable privileges)

**READ**
Revokes the privilege to read the value of the specified global variables.

**WRITE**
Revokes the privilege to assign a value to the specified global variables.

**ON VARIABLE** variable-name
Identifies the global variables from which one or more privileges are to be revoked. Each variable-name must identify a global variable that exists at the current server.

**FROM**
Identifies from whom the privileges are revoked.

**USER**
Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

**GROUP**
Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

**authorization-name,...**
Lists one or more authorization IDs. Do not specify the same authorization-name more than once.

**PUBLIC**
Revokes a grant of the privilege to PUBLIC. For more information, see “Authorization, privileges and object ownership” on page 18.

**Notes**

**Multiple grants:** If you revoke a privilege on a variable, it nullifies any grant of the privilege on that variable, regardless of who granted it.

**Revoking WITH GRANT OPTION:** The only way to revoke the WITH GRANT OPTION is to revoke ALL.

**Privilege warning:** Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

**Corresponding system authorities:** When a global variable privilege is revoked, the corresponding system authorities are revoked. For information on the system authorities that correspond to SQL privileges see “GRANT (variable privileges)” on page 1439.

**Example**

REVOKE the WRITE privilege on a global variable MYSCHEMA.MYJOB_PRINTER from user ZUBIRI.

REVOKE WRITE
    ON VARIABLE MYSCHEMA.MYJOB_PRINTER
    FROM ZUBIRI
REVOKE (XML schema privileges)

This form of the REVOKE statement removes the privileges on an XSR object.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each XSR object identified in the statement:
  - Every privilege specified in the statement
  - The system authority of *OBJMGT on the XSR object
  - The system authority *EXECUTE on the library containing the XSR object
- Database administrator authority
- Security administrator authority

Syntax

```
REVOKE PRIVILEGES ALL, ALTER USAGE
FROM xsrobject-name

Description

ALL or ALL PRIVILEGES
Revoke one or more XSR object privileges from each authorization-name. The privileges revoked are those privileges on the identified XSR objects that were granted to the authorization-names. Note that revoking ALL PRIVILEGES on an XSR object is not the same as revoking the system authority of *ALL.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described.

ALTER
Revoke the privilege to use the COMMENT and LABEL statements.

USAGE
Revoke the privilege to use an XSR object.

ON XSROBJECT xsrobject-name
Identifies the XSR objects for which the privilege is revoked. The xsrobject-name must identify an XSR object that exists at the current server.
FROM
Identifies from whom the privileges are revoked.

USER
Specifies that the authorization-name identifies a user profile. If USER is specified, authorization-name must be a user profile.

GROUP
Specifies that the authorization-name identifies a group profile. If GROUP is specified, authorization-name must be a group profile.

authorization-name, ...
Lists one or more authorization IDs. Do not specify the same authorization-name more than once.

PUBLIC
Revokes a grant of the privilege to PUBLIC. For more information, see “Authorization, privileges and object ownership” on page 18.

Notes

Multiple grants: If you revoke a privilege on an XSR object, it nullifies any grant of the privilege on that XSR object, regardless of who granted it.

Revoking WITH GRANT OPTION: The only way to revoke the WITH GRANT OPTION is to revoke ALL.

Privilege warning: Revoking a specific privilege from a user does not necessarily prevent that user from performing an action that requires that privilege. For example, the user may still have the privilege through PUBLIC privileges or database administrator authority.

Corresponding system authorities: When an XSR object privilege is revoked, the corresponding system authorities are revoked. For information about the system authorities that correspond to SQL privileges see “GRANT (XML schema privileges)” on page 1442.

Example

Revoke the USAGE privilege on XSR object XMLSCHEMA from PUBLIC.

REVOKE USAGE
ON XSROBJECT XMLSCHEMA
FROM PUBLIC
The ROLLBACK statement is used to back out changes.

The ROLLBACK statement can be used to either:

- End a unit of work and back out all the relational database changes that were made by that unit of work. If relational databases are the only recoverable resources used by the application process, ROLLBACK also ends the unit of work.
- Back out only the changes made after a savepoint was set within the unit of work without ending the unit of work. Rolling back to a savepoint enables selected changes to be undone.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

ROLLBACK is not allowed in a trigger if the trigger program and the triggering program run under the same commitment definition. ROLLBACK is not allowed in a procedure if the procedure is called on a Distributed Unit of Work connection to a remote application server or if the procedure is defined as ATOMIC. ROLLBACK is not allowed in a function.

**Authorization**

None required.

**Syntax**

```
ROLLBACK WORK
ROLLBACK HOLD TO SAVEPOINT savepoint-name
```

**Description**

When ROLLBACK is used without the TO SAVEPOINT clause, the unit of work in which it is executed is ended. All changes made by SQL schema statements and SQL data change statements during the unit of work are backed out. For more information see [Chapter 7, “Statements,” on page 817](#).

The generation of identity values is not under transaction control. Values generated and consumed by inserting rows into a table that has an identity column are independent of executing the ROLLBACK statement. Also, executing the ROLLBACK statement does not affect the IDENTITY_VAL_LOCAL function.

Special registers are not under transaction control. Executing a ROLLBACK statement does not affect special registers.

Sequences are not under transaction control. Executing a ROLLBACK statement does not affect the current value generated and consumed by executing a NEXT VALUE expression.
Global variables are not under transaction control. Executing a ROLLBACK statement does not affect the value of any instantiated global variable.

The impact of ROLLBACK or ROLLBACK TO SAVEPOINT on the contents of a declared temporary table is determined by the setting of the ON ROLLBACK clause of the DECLARE GLOBAL TEMPORARY TABLE statement.

**WORK**

ROLLBACK WORK has the same effect as ROLLBACK.

**HOLD**

Specifies a hold on resources. If specified, currently open cursors are not closed cursors whether they are declared with a HOLD option or not. All resources acquired during the unit of work, except locks on the rows of tables, are held. Locks on specific rows implicitly acquired during the unit of work, however, are released.

At the end of a ROLLBACK HOLD, the cursor position is the same as it was at the start of the unit of work, unless

- ALWBLK(*ALLREAD) was specified when the program or routine that contains the cursor was created
- ALWBLK(*READ) and ALWCPYDTA(*OPTIMIZE) were specified when the program or routine that contains the cursor was created

**TO SAVEPOINT**

Specifies that the unit of work is not to be ended and that only a partial rollback (to a savepoint) is to be performed. If a savepoint name is not specified, rollback is to the last active savepoint. For example, if in a unit of work, savepoints A, B, and C are set in that order and then C is released, ROLLBACK TO SAVEPOINT causes a rollback to savepoint B. If no savepoint is active, an error is returned.

**savepoint-name**

Identifies the savepoint to which to roll back. The name must identify a savepoint that exists at the current server.

After a successful ROLLBACK TO SAVEPOINT, the savepoint continues to exist.

All database changes (including changes made to declared temporary tables that were declared with the ON ROLLBACK PRESERVE ROWS clause) that were made after the savepoint was set are backed out. All locks and LOB locators are retained.

The impact on cursors resulting from a ROLLBACK TO SAVEPOINT depends on the statements within the savepoint:

- If the savepoint contains SQL schema statements on which a cursor is dependent, the cursor is closed. Attempts to use such a cursor after a ROLLBACK TO SAVEPOINT results in an error.
- Otherwise, the cursor is not affected by the ROLLBACK TO SAVEPOINT (it remains open and positioned).

Any savepoints at the current server that are set after the one to which rollback is performed are released. The savepoint to which rollback is performed is not released.
Notes

Recommended coding practices: Code an explicit COMMIT or ROLLBACK statement at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

Other effects of rollback: Rollback without the TO SAVEPOINT clause and HOLD clause causes the following to occur:

- All cursors that were opened during the unit of work are closed whether they are declared with a HOLD option or not.
- All LOB locators, including those that are held, are freed.
- All locks acquired under this unit of work’s commitment definition are released.

ROLLBACK has no effect on the state of connections.

Implicit ROLLBACK: The ending of the default activation group causes an implicit rollback. Thus, an explicit COMMIT or ROLLBACK statement should be issued before the end of the default activation group.

A ROLLBACK is automatically performed when:
1. The default activation group ends without a final COMMIT being issued.
2. A failure occurs that prevents the activation group from completing its work (for example, a power failure).
   If the unit of work is in the prepared state because a COMMIT was in progress when the failure occurred, a rollback is not performed. Instead, resynchronization of all the connections involved in the unit of work will occur.
   For more information, see the Commitment control topic collection.
3. A failure occurs that causes a loss of the connection to an application server (for example, a communications line failure).
   If the unit of work is in the prepared state because a COMMIT was in progress when the failure occurred, a rollback is not performed. Instead, resynchronization of all the connections involved in the unit of work will occur.
   For more information, see the Commitment control topic collection.
4. An activation group other than the default activation group ends abnormally.

Row lock limit: A unit of work may include the processing of up to and including 4 million rows, including rows retrieved during a SELECT INTO or FETCH statement, and rows inserted, deleted, or updated as part of INSERT, DELETE, and UPDATE operations.\(^{126}\)

Unaffected statements: The commit and rollback operations do not affect the DROP SCHEMA statement, and this statement is not, therefore, allowed if the current isolation level is anything other than No Commit (NC).

---

125. Unless you specified COMMIT(*CHG) or COMMIT(*CS), in which case these rows are not included in this total.
126. This limit also includes:
   - Any rows accessed or changed through files opened under commitment control through high-level language file processing
   - Any rows deleted, updated, or inserted as a result of a trigger or CASCADE, SET NULL, or SET DEFAULT referential integrity delete rule.
ROLLBACK restrictions: A ROLLBACK statement is not allowed if commitment control is not active for the activation group. For information about determining which commitment definition is used, see the commitment definition discussion in the COMMIT statement.

A commit or rollback in a user-defined function in a secondary thread is not allowed.

ROLLBACK has no effect on the state of connections.

If, within a unit of work, a CLOSE is followed by a ROLLBACK, all changes made within the unit of work are backed out. The CLOSE itself is not backed out and the file is not reopened.

Examples

Example 1: See the “Example” on page 980 under COMMIT for examples using the ROLLBACK statement.

Example 2: After a unit of recovery started, assume that three savepoints A, B, and C were set and that C was released:

```
SAVEPOINT A ON ROLLBACK RETAIN CURSORT;
....
SAVEPOINT B ON ROLLBACK RETAIN CURSORT;
....
SAVEPOINT C ON ROLLBACK RETAIN CURSORT;
....
RELEASE SAVEPOINT C
```

Roll back all database changes only to savepoint A:

```
ROLLBACK WORK TO SAVEPOINT A
```

If a savepoint name was not specified (that is, ROLLBACK WORK TO SAVEPOINT), the rollback would be to the last active savepoint that was set, which is B.
SAVEPOINT

The SAVEPOINT statement sets a savepoint within a unit of work to identify a point in time within the unit of work to which relational database changes can be rolled back.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SAVEPOINT savepoint-name
  [UNIQUE]
  [ON ROLLBACK RETAIN LOCKS]
  [ON ROLLBACK RETAIN CURSORS]
```

Notes:
1. The ROLLBACK options can be specified in any order.

Description

`savepoint-name`

Identifies a new savepoint. The specified `savepoint-name` cannot begin with 'SYS'.

UNIQUE

Specifies that the application program cannot reuse the savepoint name within the unit of work. An error occurs if a savepoint with the same name as `savepoint-name` already exists within the unit of work.

Omitting UNIQUE indicates that the application can reuse the savepoint name within the unit of work. If `savepoint-name` identifies a savepoint that already exists within the unit of work and the savepoint was not created with the UNIQUE option, the existing savepoint is destroyed and a new savepoint is created. Destroying a savepoint to reuse its name for another savepoint is not the same as releasing the savepoint. Reusing a savepoint name destroys only one savepoint. Releasing a savepoint with the RELEASE SAVEPOINT statement releases the savepoint and all savepoints that have been subsequently set.

ON ROLLBACK RETAIN CURSORS

Specifies that cursors that are opened after the savepoint is set are not closed upon rollback to the savepoint.

- If SQL schema statements are executed for a table or view within the scope of the SAVEPOINT statement, any cursor that references that table or view is closed. Attempts to use such a cursor after a ROLLBACK TO SAVEPOINT results in an error.
Otherwise, the cursor is not affected by the ROLLBACK TO SAVEPOINT (it remains open and positioned).

Although these cursors remain open after rollback to the savepoint, they might not be usable. For example, if rolling back to the savepoint causes the insertion of a row on which the cursor is positioned to be rolled back, using the cursor to update or delete the row results in an error.

**ON ROLLBACK RETAIN LOCKS**

Specifies that any locks that are acquired after the savepoint is set are not released on rollback to the savepoint.

**Notes**

**Savepoint persistence:** A savepoint, S, is destroyed when:

- A COMMIT or ROLLBACK (without a TO SAVEPOINT clause) statement is executed.
- A ROLLBACK TO SAVEPOINT statement is executed that specifies savepoint S or a savepoint that was established earlier than S in the unit of work.
- A RELEASE SAVEPOINT statement is executed that specifies savepoint S or a savepoint that was established earlier than S in the unit of work.
- A SAVEPOINT statement specifies the same name as an existing savepoint that was not created with the UNIQUE keyword.

**Effect on INSERT:** In an application, inserts may be buffered. The buffer will be flushed when SAVEPOINT, ROLLBACK, or RELEASE TO SAVEPOINT statements are issued.

**SAVEPOINT restriction:** A SAVEPOINT statement is not allowed if commitment control is not active for the activation group. For information about determining which commitment definition is used, see "Notes" on page 978 in COMMIT statement.

**Example**

Assume that you want to set three savepoints at various points in a unit of work. Name the first savepoint A and allow the savepoint name to be reused. Name the second savepoint B and do not allow the name to be reused. Because you no longer need savepoint A when you are ready to set the third savepoint, reuse A as the name of the savepoint.

```
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
.
.
.
SAVEPOINT B UNIQUE ON ROLLBACK RETAIN CURSORS;
.
.
.
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
```
The SELECT statement is a form of query. It can be embedded in an SQLJ application program or issued interactively.

For detailed information, see “select-clause” on page 743 and Chapter 6, “Queries,” on page 741.
The SELECT INTO statement produces a result table consisting of at most one row, and assigns the values in that row to variables.

**Invocation**

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

**Authorization**

The privileges held by the authorization ID of the statement must include at least one of the following:

- For each table or view identified in the statement,
  - The SELECT privilege on the table or view, and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

If a global variable is specified in the INTO variable list, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

**Syntax**

```
select-clause INTO variable from-clause where-clause
group-by-clause having-clause order-by-clause
offset-clause
fetch-clause isolation-clause concurrent-access-resolution-clause
```

**Notes:**

1. Each clause may be specified only once.
SELECT INTO

Description

The result table is derived by evaluating the isolation-clause, concurrent-access-resolution-clause, from-clause, where-clause, group-by-clause, having-clause, order-by-clause, offset-clause, fetch-clause, and select-clause, in this order.

See Chapter 6, “Queries,” on page 741 for a description of the select-clause, from-clause, where-clause, group-by-clause, having-clause, order-by-clause, offset-clause, fetch-clause, isolation-clause, and concurrent-access-resolution-clause.

INTO variable,...

Identifies one or more host structures or variables that must be declared in the program in accordance with the rules for declaring host structures and variables. In the operational form of the INTO clause, a reference to a host structure is replaced by a reference to each of its variables. The first value in the result row is assigned to the first variable in the list, the second value to the second variable, and so on. The data type of each variable must be compatible with its corresponding column.

Notes

Variable assignment: Each assignment to a variable is performed according to the retrieval assignment rules described in “Assignments and comparisons” on page 99.27 If the number of variables is less than the number of values in the row, an SQL warning (SQLSTATE 01503) is returned (and the SQLWARN3 field of the SQLCA is set to 'W'). Note that there is no warning if there are more variables than the number of result columns. If a value is null, an indicator variable must be provided for that value.

If the specified variable is character and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA). The actual length of the result may be returned in the indicator variable associated with the variable, if an indicator variable is provided. For further information, see “Variables” on page 150.

If an assignment error occurs, the value of that variable and any following variables is unpredictable. Any values that have already been assigned to variables remain assigned.

Multiple assignments: If more than one variable is specified in the INTO clause, the query is completely evaluated before the assignments are performed. Thus, references to a variable in the select list are always the value of the variable prior to any assignment in the SELECT INTO statement.

Empty result table: If the result table is empty, the statement assigns '02000' to the SQLSTATE variable and does not assign values to the variables.

Result tables with more than one row: If more than one row satisfies the search condition, statement processing is terminated and an error is returned (SQLSTATE 21000). If an error occurs because the result table has more than one row, values may or may not be assigned to the variables. If values are assigned to the variables, the row that is the source of the values is undefined and not predictable.

127. If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information about the standards option, see “Standards compliance” on page xi.
**Result column evaluation considerations:** If an error occurs while evaluating a result column in the select list of a SELECT INTO statement, as the result of an arithmetic expression (such as division by zero, or overflow) or a numeric or character conversion error, the result is the null value. As in any other case of a null value, an indicator variable must be provided. The value of the variable is undefined. In this case, however, the indicator variable is set to the value -2. Processing of the statement continues and a warning is returned. If an indicator variable is not provided, an error is returned and no more values are assigned to variables. It is possible that some values have already been assigned to variables and will remain assigned when the error is returned.

When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, depending on how much of the value would have to be truncated, a warning or an error is returned. See "Datetime assignments" on page 106 for details.

**Examples**

*Example 1:* Using a COBOL program statement, put the maximum salary (SALARY) from the EMPLOYEE table into the host variable MAX-SALARY (DECIMAL(9,2)).

```cobol
EXEC SQL
SELECT MAX(SALARY) INTO :MAX-SALARY
FROM EMPLOYEE WITH CS
END-EXEC.
```

*Example 2:* Using a Java program statement, select the row from the EMPLOYEE table on the connection context 'ctx' with a employee number (EMPNO) value the same as that stored in the host variable HOST_EMP (java.lang.String). Then put the last name (LASTNAME) and education level (EDLEVEL) from that row into the host variables HOST_NAME (String) and HOST_EDUCATE (Integer).

```sql
#sql [ctx] { SELECT LASTNAME, EDLEVEL INTO :HOST_NAME, :HOST_EDUCATE
FROM EMPLOYEE
WHERE EMPNO = :HOST_EMP
};
```

*Example 3:* Put the row for employee 528671, from the EMPLOYEE table, into the host structure EMPREC. Assume that the row will be updated later and should be locked when the query executes.

```sql
EXEC SQL SELECT *
INTO :EMPREC
FROM EMPLOYEE
WHERE EMPNO = '528671'
WITH RS USE AND KEEP EXCLUSIVE LOCKS
END-EXEC.
```
The SET CONNECTION statement establishes the current server of the activation group by identifying one of its existing connections.

**Invocation**

This statement can only be embedded within an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

SET CONNECTION is not allowed in a trigger or function.

**Authorization**

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

**Syntax**

```
SET CONNECTION server-name
```

**Description**

*server-name* or *variable*

Identifies the connection by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a character-string variable with a length attribute that is not greater than 18.
- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

Let S denote the specified server name or the server name contained in the variable. S must identify an existing connection of the application process. If S identifies the current connection, the state of S and all other connections of the application process are unchanged, but information about S is placed in the SQLERRP field of the SQLCA. The following rules apply when S identifies a dormant connection.

If the SET CONNECTION statement is successful:

- Connection S is placed in the current state.
- S is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the connection-information-items in the SQL Diagnostics Area.
Information about application server S is also placed in the SQLERRP field of the SQLCA. If the application server is an IBM relational database product, the information has the form \( pppvvvrrm \), where:

- \( ppp \) identifies the product as follows:
  - ARI for Db2 for VSE and VM
  - DSN for Db2 for z/OS
  - QSQ for Db2 for i
  - SQL for all other Db2 products
- \( vv \) is a two-digit version identifier such as '04'
- \( rr \) is a two-digit release identifier such as '01'
- \( m \) is a one-digit modification level such as '0'

For example, if the application server is Version 4 of Db2 for z/OS, the value of SQLERRP is 'DSN04010'.

Additional information about the connection is available from the DB2_CONNECTION_STATUS and DB2_CONNECTION_TYPE connection information items in the SQL Diagnostics Area. The DB2_CONNECTION_STATUS connection information item indicates the status of connection for this unit of work. It will have one of the following values:

- 1 - Committable updates can be performed on the connection for this unit of work.
- 2 - No committable updates can be performed on the connection for this unit of work.

The DB2_CONNECTION_TYPE connection information item indicates the type of connection. It will have one of the following values:

- 1 - Connection is to a local relational database.
- 2 - Connection is to a remote relational database with the conversation unprotected.
- 3 - Connection is to a remote relational database with the conversation protected.
- 4 - Connection is to an application requester driver program.

Additional information about the connection is also placed in the SQLERRD(4) field of the SQLCA. SQLERRD(4) will contain a value indicating whether the application server allows committable updates to be performed. Following is a list of values and their meanings for the SQLERRD(4) field of the SQLCA on the CONNECT:

- 1 - Committable updates can be performed and either the connection uses an unprotected conversation, is a connection established to an application requester driver program using a CONNECT (Type 1) statement, or is a local connection established using a CONNECT (Type 1) statement.
- 2 - No committable updates can be performed; conversation is unprotected.
- 3 - It is unknown if committable updates can be performed; conversation is protected.
- 4 - It is unknown if committable updates can be performed; conversation is unprotected.
- 5 - It is unknown if committable updates can be performed and the connection is either a local connection established using a CONNECT (Type 2) statement or a connection to an application requester driver program established using a CONNECT (Type 2) statement.
SET CONNECTION

- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. Refer to Appendix B, "SQL Communication Area" for a description of the information in the SQLERRMC field.
- Any previously current connection is placed in the dormant state.

If the SET CONNECTION statement is unsuccessful, the connection state of the activation group and the states of its connections are unchanged.

Notes

SET CONNECTION for CONNECT (Type 1): The use of CONNECT (Type 1) statements does not prevent the use of SET CONNECTION, but the statement either fails or does nothing because dormant connections do not exist.

Status after connection is restored: When a connection is used, made dormant, and then restored to the current state in the same unit of work, the status of locks, cursors, and prepared statements for that connection reflects its last use by the activation group.

Local connections: A SET CONNECTION to a local connection will fail if the current independent auxiliary Storage pool (IASP) name space does not match the local connection’s relational database.

Example

Execute SQL statements at TOROLAB1, execute SQL statements at TOROLAB2, and then execute more SQL statements at TOROLAB1.

```
EXEC SQL CONNECT TO TOROLAB1;

(Execute statements referencing objects at TOROLAB1)
EXEC SQL CONNECT TO TOROLAB2;

(Execute statements referencing objects at TOROLAB2)
EXEC SQL SET CONNECTION TOROLAB1;

(Execute statements referencing objects at TOROLAB1)
```

The first CONNECT statement creates the TOROLAB1 connection, the second CONNECT statement places it in the dormant state, and the SET CONNECTION statement returns it to the current state.
SET CURRENT DEBUG MODE

The SET CURRENT DEBUG MODE statement assigns a value to the CURRENT DEBUG MODE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None.

Syntax

```
SET CURRENT DEBUG MODE = DISALLOW
```

Description

The value of CURRENT DEBUG MODE is replaced by the specified keyword:

**DISALLOW**

Procedures will be created so they cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is DISALLOW, the procedure can be subsequently altered to change the DEBUG MODE attribute.

**ALLOW**

Procedures will be created so they can be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is ALLOW, the procedure can be subsequently altered to change the DEBUG MODE attribute.

**DISABLE**

Procedures will be created so they cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is DISABLE, the procedure cannot be subsequently altered to change the DEBUG MODE attribute.

Notes

Transaction considerations: The SET CURRENT DEBUG MODE statement is not a committable operation. ROLLBACK has no effect on the current debug mode.

Initial current debug mode: The initial value of the current debug mode is DISALLOW.

Current debug mode scope: The scope of the current debug mode is the activation group.
SET CURRENT DEBUG MODE

Example

*Example 1:* The following statement sets the CURRENT DEBUG MODE to allow subsequent procedures created by the CREATE PROCEDURE (SQL) statement to be debuggable.

```
SET CURRENT DEBUG MODE = ALLOW
```

*Example 2:* The following statement sets the CURRENT DEBUG MODE to disallow subsequent procedures created by the CREATE PROCEDURE (SQL) statement to be debuggable and to prevent those procedures from being altered to make them debuggable.

```
SET CURRENT DEBUG MODE = DISABLE
```
SET CURRENT DECFLOAT ROUNDDING MODE

The SET CURRENT DECFLOAT ROUNDDING MODE statement changes the value of the CURRENT DECFLOAT ROUNDDING MODE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
SET CURRENT DECFLOAT ROUNDDING MODE =
  ROUND_CEILING
  ROUND_DOWN
  ROUND_FLOOR
  ROUND_HALF_DOWN
  ROUND_HALF_EVEN
  ROUND_HALF_UP
  ROUND_UP
  variable
  string-constant
```

Description

**ROUND_CEILING**

Round toward +\(\infty\). If all of the discarded digits are zero or if the sign is negative, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

**ROUND_DOWN**

Round toward zero (truncation). The discarded digits are ignored.

**ROUND_FLOOR**

Round toward -\(\infty\). If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of the discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by one.

**ROUND_HALF_DOWN**

Round to nearest; if equidistant, round down. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

This rounding mode is not recommended when creating a portable application since it is not supported by the IEEE draft standard for floating-point arithmetic.
SET CURRENT DECFLOAT Rounding Mode

**ROUND_HALF_EVEN**
Round to nearest; if equidistant, round so that the final digit is even. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise (they represent exactly half), the result coefficient is unaltered if its rightmost digit is even or incremented by one (rounded up) if its rightmost digit is odd (to make an even digit).

**ROUND_HALF_UP**
Round to nearest; if equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

**ROUND_UP**
Round away from zero. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

This rounding mode is not recommended when creating a portable application since it is not supported by the IEEE draft standard for floating-point arithmetic.

**string-constant**
A character constant that contains a specification of the rounding mode.

**variable**
Specifies a variable which contains the value for the CURRENT DECFLOAT Rounding Mode. The content is not folded to uppercase.

The variable:
- Must be a character-string or Unicode graphic-string variable.
- Must not be followed by an indicator variable.
- Must contain one of the seven rounding mode keywords.
- Must be padded on the right with blanks if the variable is fixed length.

**Notes**

Transaction considerations: The SET CURRENT DECFLOAT Rounding Mode statement is not a committable operation. ROLLBACK has no effect on the CURRENT DECFLOAT Rounding Mode.

Initial CURRENT DECFLOAT Rounding Mode: The initial value of CURRENT DECFLOAT Rounding Mode in an activation group is established by the first SQL statement that is executed in the activation group.

- If the first SQL statement in an activation group is executed from an SQL program or SQL package, the CURRENT DECFLOAT Rounding Mode special register is set to the value of the DECFLTRND parameter.
- Otherwise, the initial value is ROUND_HALF_EVEN.

CURRENT DECFLOAT Rounding Mode scope is activation group.
Examples

*Example 1:* Set the CURRENT DECFLOAT Rounding MODE special register to ROUND_DOWN using a string constant and using a keyword.

```sql
SET CURRENT DECFLOAT Rounding MODE = 'ROUND_DOWN'
SET CURRENT DECFLOAT Rounding MODE = ROUND_DOWN
```
The SET CURRENT DEGREE statement assigns a value to the CURRENT DEGREE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It must not be specified in REXX.

Authorization

The privileges held by the authorization ID of the statement must include *JOBCTL special authority or be authorized to the SQL Administrator function of IBM i through Application Administration in System i Navigator. The Change Function Usage (CHGFCNUSG) command, with a function ID of QIBM_DB_SQLADM, can also be used to change the list of authorized users.

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

• For the global variable identified in the statement,
  – The READ privilege on the global variable, and
  – The system authority *EXECUTE on the library containing the global variable

• Database administrator authority

Syntax

```
SET CURRENT DEGREE = string-constant
or
SET CURRENT DEGREE = variable
```

Description

The value of CURRENT DEGREE is replaced by the value of the string constant or variable.

**string-constant**

Specifies a character string constant. The content is not folded to uppercase.

The length of the string-constant must not exceed 5 after trimming any leading and trailing blanks.

**variable**

Specifies a variable that contains the value for CURRENT DEGREE.

The variable:

• Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. The actual length of the contents of the variable must not be greater than 5 after trimming any leading and trailing blanks.

• Must not be the null value.

• Must have contents in uppercase characters. All characters are case-sensitive and are not converted to uppercase characters.
If the PARALLEL_DEGREE parameter in a current query options file (QAQQINI) is specified, the CURRENT DEGREE will be reset to the PARALLEL_DEGREE. Otherwise, the CURRENT DEGREE will be reset from the degree specified by the QQRYDEGREE system value.

The value of the string constant or variable must be one of the following:

1  No parallel processing is allowed.

2 through 32767  
   Specifies the degree of parallelism that will be used.

ANY  
   Specifies that the database manager can choose to use any number of tasks for either I/O or SMP parallel processing.

   Use of parallel processing and the number of tasks used is determined based on the number of processors available in the system, this job's share of the amount of active memory available in the pool in which the job is run, and whether the expected elapsed time for the operation is limited by CPU processing or I/O resources. The database manager chooses an implementation that minimizes elapsed time based on the job's share of the memory in the pool.

NONE  
   No parallel processing is allowed.

MAX  
   The database manager can choose to use any number of tasks for either I/O or SMP parallel processing. MAX is similar to ANY except the database manager assumes that all active memory in the pool can be used.

I0  
   Any number of tasks can be used when the database manager chooses to use I/O parallel processing for queries. SMP is not allowed.

Notes

Transaction considerations: The SET CURRENT DEGREE statement is not a committable operation. ROLLBACK has no effect on CURRENT DEGREE.

Initial current degree: The initial value of CURRENT DEGREE is equal to the parallelism degree in effect from the CHGQRYA CL command, PARALLEL_DEGREE parameter in the current query options file (QAQQINI), or the QQRYDEGREE system value.

Parallelism degree precedence: The parallelism degree can be controlled in several ways. The actual parallelism degree used is determined as follows:

- If a SET CURRENT DEGREE statement or a CHGQRYA CL command with a DEGREE keyword has been executed, the parallelism degree specified by the most recent of either is the value of CURRENT DEGREE.
- If neither a SET CURRENT DEGREE statement nor a CHGQRYA CL command with a DEGREE keyword has been executed,
  - If a current query options file (QAQQINI) with a PARALLEL_DEGREE parameter has been specified, the parallelism degree specified by the QAQQINI file is the value of CURRENT DEGREE.
  - Otherwise, the parallelism degree specified by the QQRYDEGREE system value is the value of CURRENT DEGREE.
SET CURRENT DEGREE

For more information, see Database Performance and Query Optimization topic collection.

Current degree scope: The scope of CURRENT DEGREE is the job.

Parallel limitations: If the DB2 Symmetric Multiprocessing feature is not installed, a warning is returned and parallelism is not used.

Some SQL statements cannot use parallelism.

Example

Example 1: The following statement sets the CURRENT DEGREE to inhibit parallelism.

```
SET CURRENT DEGREE = '1'
```

Example 2: The following statement sets the CURRENT DEGREE to allow parallelism.

```
SET CURRENT DEGREE = 'ANY'
```
SET CURRENT IMPLICIT XMLPARSE OPTION

The SET CURRENT IMPLICIT XMLPARSE OPTION statement changes the value of the CURRENT IMPLICIT XMLPARSE OPTION special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
►► SET CURRENT IMPLICIT XMLPARSE OPTION = [ "STRIP WHITESPACE" | "PRESERVE WHITESPACE" ]
variable
string-constant
►◄
```

Description

**STRIP WHITESPACE**
- Whitespace is removed on implicit XMLPARSE.

**PRESERVE WHITESPACE**
- Whitespace is not removed on implicit XMLPARSE.

**variable**
- Specifies a variable which contains the value for the CURRENT IMPLICIT XMLPARSE OPTION. The content is folded to uppercase.
  - The variable:
    - Must be a character-string or Unicode graphic-string variable.
    - Must not be followed by an indicator variable.
    - Must contain one of the two implicit XMLPARSE options.
    - Must be padded on the right with blanks if the variable is fixed length.

**string-constant**
- A character constant that contains a specification of the implicit XMLPARSE option. The value must be a left justified string that is either 'STRIP WHITESPACE' or 'PRESERVE WHITESPACE' with exactly one blank character between the keywords. The content is folded to uppercase.

Notes

**Transaction considerations:** The SET CURRENT IMPLICIT XMLPARSE OPTION statement is not a committable operation. ROLLBACK has no effect on the CURRENT IMPLICIT XMLPARSE OPTION.
SET CURRENT IMPLICIT XMLPARSE OPTION

Initial CURRENT IMPLICIT XMLPARSE OPTION: The initial value of CURRENT IMPLICIT XMLPARSE OPTION is ‘STRIP WHITESPACE’.

Both static and dynamic statements are affected by this special register.

The CURRENT IMPLICIT XMLPARSE OPTION scope is the connection.

Example

Set the value of the CURRENT IMPLICIT XMLPARSE OPTION special register to ‘PRESERVE WHITESPACE’.

   SET CURRENT IMPLICIT XMLPARSE OPTION = PRESERVE WHITESPACE
SET CURRENT TEMPORAL SYSTEM_TIME

The SET CURRENT TEMPORAL SYSTEM_TIME statement changes the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT TEMPORAL SYSTEM_TIME = NULL
```

Description

**NULL**

Specifies the null value.

**expression**

An expression that can be assigned to a TIMESTAMP(12). The expression must not contain a scalar fullselect or a function that is non-deterministic, external action, or modifies SQL data.

Notes

**Transaction considerations:** The SET CURRENT TEMPORAL SYSTEM_TIME statement is not a committable operation. ROLLBACK has no effect on CURRENT TEMPORAL SYSTEM_TIME.

**CURRENT TEMPORAL SYSTEM_TIME scope:** The scope of the CURRENT TEMPORAL SYSTEM_TIME special register is the activation group and connection.

Examples

**Example 1:** Set the CURRENT TEMPORAL SYSTEM_TIME special register to the previous month.

```
SET CURRENT TEMPORAL SYSTEM_TIME = CURRENT_TIMESTAMP - 1 MONTH
```

**Example 2:** Set the CURRENT TEMPORAL SYSTEM_TIME special register to the null value.

```
SET CURRENT TEMPORAL SYSTEM_TIME = NULL
```
The SET DESCRIPTOR statement sets information in an SQL descriptor.

**Invocation**

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

**Authorization**

None required.

**Syntax**

```
SET SQL DESCRIPTOR [LOCAL | GLOBAL] SQL-descriptor-name

set-header-info:
  COUNT = constant-1
  [variable-1]

set-item-info:
  CARDINALITY = constant-2
  [variable-2]
  [DATA]
  [DATETIME_INTERVAL_CODE]
  [DB2_CCSID]
  [INDICATOR]
  [LENGTH]
  [LEVEL]
  [PRECISION]
  [SCALE]
  [TYPE]
  [USER_DEFINED_TYPE_CATALOG]
  [USER_DEFINED_TYPE_NAME]
  [USER_DEFINED_TYPE_SCHEMA]
```

**Description**

**LOCAL**

Specifies the scope of the name of the descriptor to be local to program invocation. The information provided is set into the descriptor known in this local scope.
GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session. The information provided is set into the descriptor known to any program that executes using the same database connection.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

set-header-info

Sets attributes into the SQL descriptor. The same descriptor item must not be specified more than once in a single SET DESCRIPTOR statement.

VALUE

Specifies the item number for which the specified information is set. If the item number is greater than the maximum number of items allocated for the descriptor or the item number is less than 1, an error is returned.

integer

An integer constant in the range of 1 to the number of items allocated in the SQL descriptor.

integer-variable

Identifies a variable declared in the program in accordance with the rules for declaring variables. It must not be a global variable. The data type of the variable must be SMALLINT, INTEGER, BIGINT, or DECIMAL or NUMERIC with a scale of zero. The value of variable must be in the range of 1 to the maximum number of items allocated in the SQL descriptor.

set-item-info

Sets information about a specific item into the SQL descriptor. The same descriptor item must not be specified more than once in a single SET DESCRIPTOR statement. Items that are not applicable to the specified type are ignored.

set-header-info

COUNT

A count of the number of items that will be specified in the descriptor.

data type

Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the COUNT header item as specified in Table 88 on page 1384. The variable is assigned (using storage assignment rules) to the COUNT header item. For details on the assignment rules, see “Assignments and comparisons” on page 99.

constant

Identifies a constant value used to set the COUNT header item. The data type of the constant must be compatible with the COUNT header item as specified in Table 88 on page 1384. The constant is assigned (using storage assignment rules) to the COUNT header item. For details on the assignment rules, see “Assignments and comparisons” on page 99.

set-item-info

CARDINALITY

Specifies the cardinality for the item. This is only allowed when TYPE is an array.
DATA
Specifies the value for the data described by the item descriptor. If the value of INDICATOR is negative, then the value of DATA is undefined. The assigned value cannot be a constant.

DATETIME_INTERVAL_CODE
Specifies the specific datetime data type. DATETIME_INTERVAL_CODE must be specified if TYPE is set to 9.
1 DATE
2 TIME
3 TIMESTAMP

DB2_CCSID
Specifies the CCSID of character, graphic, XML, or datetime data. The value is not applicable for all other data types. If the DB2_CCSID is not specified or 0 is specified:
• For XML data, the SQL_XML_DATA_CCSID QAQQINI option setting will be used.
• Otherwise, the CCSID of the variable will be determined by the CCSID of the job.

INDICATOR
Specifies the value for the indicator. A non-negative indicates a DATA value will be provided for this descriptor item. When extended indicator variables are not enabled, a negative value indicates the value described by this descriptor item is the null value. If not set, the value of INDICATOR is 0. When extended indicator variables are enabled:
• -1, -2, -3, -4, or -6 indicates the value described by this descriptor item is the null value.
• -5 indicates the value described by this descriptor item is the DEFAULT value.
• -7 indicates the value described by this descriptor item is the UNASSIGNED value.
• 0 or a positive value indicates a DATA value will be provided for this descriptor item.

LENGTH
Specifies the maximum length of the data. If the data type is a character or graphic string type, XML type, or a datetime type, the length represents the number of characters (not bytes). If the data type is a binary string or any other type, the length represents the number of bytes. If LENGTH is not specified, a default length will be used. For a description of the defaults, see Table 116 on page 1572.

LEVEL
The level of the item descriptor.
0 Item is a primary descriptor entry.
1 Item is for a secondary descriptor entry. This is for an array entry.

PRECISION
Specifies the precision for descriptor items of data type DECIMAL, NUMERIC, DECFLOAT, DOUBLE, REAL, FLOAT, and TIMESTAMP. If PRECISION is not specified, a default precision will be used. For a description of the defaults, see Table 116 on page 1572.
**SCALE**
Specifies the scale for descriptor items of data type DECIMAL or NUMERIC. If SCALE is not specified, a default scale will be used. For a description of the defaults, see Table 116 on page 1572.

**TYPE**
Specifies a data type code representing the data type of the descriptor item. For a description of the data type codes and lengths, see Table 89 on page 1386. Either TYPE or USER_DEFINED_TYPE_NAME and USER_DEFINED_TYPE_SCHEMA (but not both) must be specified for each descriptor item.

**USER_DEFINED_TYPE_CATALOG**
Specifies the server name of the user-defined type. If USER_DEFINED_TYPE_CATALOG is specified, it must be equal to the current server. Otherwise, the USER_DEFINED_TYPE_CATALOG is the current server.

**USER_DEFINED_TYPE_NAME**
Specifies the name of the user-defined data type. Either TYPE or USER_DEFINED_TYPE_NAME and USER_DEFINED_TYPE_SCHEMA (but not both) must be specified for each descriptor item.

**USER_DEFINED_TYPE_SCHEMA**
Specifies the schema containing the user-defined type. Either TYPE or USER_DEFINED_TYPE_NAME and USER_DEFINED_TYPE_SCHEMA (but not both) must be specified for each descriptor item.

**variable-2**
Identifies a variable declared in the program in accordance with the rules for declaring variables, but must not be a file reference variable or a global variable. The data type of the variable must be compatible with the descriptor information item as specified in Table 88 on page 1384. The variable is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see "Assignments and comparisons" on page 99.

When setting the DATA item, in general the variable must have the same data type, length, precision, scale, and CCSID as specified in Table 88 on page 1384. For variable-length types, the variable length must not be less than the LENGTH in the descriptor. For C null-terminated types, the variable length must be at least one greater than the LENGTH in the descriptor.

**constant-2**
Identifies a constant value used to set the descriptor item. The data type of the constant must have the same data type, length, precision, scale, and CCSID as specified in Table 88 on page 1384. The constant is assigned (using storage assignment rules) to the corresponding descriptor item. For details on the assignment rules, see "Assignments and comparisons" on page 99.

If the descriptor item to be set is DATA, constant-2 cannot be specified.

**Notes**

**Default values for descriptor items**: The following table represents the default values for LENGTH, PRECISION, and SCALE, if they are not specified for a descriptor item.
SET DESCRIPTOR

Table 116. Default LENGTH, PRECISION, and SCALE

<table>

Example

Example 1: Set the number of items in descriptor ‘NEWDA’ to the value in :numitems.

```sql
EXEC SQL SET DESCRIPTOR 'NEWDA'
COUNT = :numitems;
```

Example 2: Set the value of the type and length for the first item descriptor of descriptor ‘NEWDA’

```sql
SET DESCRIPTOR 'NEWDA'
VALUE 1 TYPE = :dtype,
LENGTH = :olength;
```
SET ENCRYPTION PASSWORD

The SET ENCRYPTION PASSWORD statement sets the default password and hint that will be used by the encryption and decryption functions. The password is not associated with authentication and is only used for data encryption and decryption.

For information about using this statement, see “ENCRYPT_AES” on page 419, “ENCRYPT_RC2” on page 422, “ENCRYPT_TDES” on page 425, and “DECRYPT_BIT, DECRYPT_BINARY, DECRYPT_CHAR and DECRYPT_DB” on page 402.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
SET ENCRYPTION PASSWORD = password-variable
WITH HINT = hint-variable
```

Description

password-variable
   Specifies a variable that contains an encryption password.

   The variable:
   - Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. The actual length of the contents of the variable must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value.
   - Must not be the null value.
   - All characters are case-sensitive and are not converted to uppercase characters.

password-string-constant
   A character constant. The length of the constant must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the
default encryption password is set to no value. The literal form of the
password is not allowed in static SQL or REXX.

**WITH HINT**

Indicates that a value is specified that will help data owners remember
passwords (for example, 'Ocean' as a hint to remember 'Pacific'). If a hint value
is specified, the hint is used as the default for encryption functions. The hint
can subsequently be retrieved for an encrypted value using the GETHINT
function. If this clause is not specified and a hint is not explicitly specified on
the encryption function, no hint will be embedded in encrypted data result.

**hint-variable**

Specifies a variable that contains an encryption password hint.

The variable:

- Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode
  VARGRAPHIC variable. The actual length of the contents of the variable
  must not be greater than 32. If an empty string is specified, the default
  encryption password hint is set to no value.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase
  characters.

**hint-string-constant**

A character constant. The length of the constant must not be greater than
32. If an empty string is specified, the default encryption password hint is
set to no value.

**Notes**

**Password protection:** To prevent inadvertent access to the encryption password, do
not specify `password-string-constant` in the source for a program, procedure, or
function. Instead, use a variable.

When connected to a remote relational database, the specified password itself is
sent “in the clear”. That is, the password itself is not encrypted. To protect the
password in these cases, consider using a communications encryption mechanism
such as IPSEC (or SSL if connecting between IBM i products).

**Transaction considerations:** The SET ENCRYPTION PASSWORD statement is not a
committable operation. ROLLBACK has no effect on the default encryption
password or default encryption password hint.

**Initial encryption password value:** The initial value of both the default encryption
password and the default encryption password hint is the empty string ("").

**Encryption password scope:** The scope of the default encryption password and
default encryption password hint is the activation group and connection.

**Example**

Set the ENCRYPTION PASSWORD to the value in :hv1.

```
SET ENCRYPTION PASSWORD :hv1
```
The SET OPTION statement establishes the processing options to be used for SQL statements.

**Invocation**

This statement can be used in a REXX procedure or embedded in an application program. If used in a REXX procedure, it is an executable statement. If embedded in an application program, it is not executable and must precede any other SQL statements. This statement cannot be dynamically prepared.

**Authorization**

None required.

**Syntax**

```

Description

ALWBLK

Specifies whether the database manager can use row blocking and the extent to which blocking can be used for read-only cursors. This option will be ignored in REXX.
**ALLREAD**
Rows are blocked for read-only cursors if COMMIT is *NONE, *CHG, or *CS. All cursors in a program that are not explicitly able to be updated are opened for read-only processing even though EXECUTE or EXECUTE IMMEDIATE statements may be in the program.

Specifying *ALLREAD:
- Allows row blocking under commitment control level *CHG and *CS in addition to the blocking allowed for *READ.
- Can improve the performance of almost all read-only cursors in programs, but limits queries in the following ways:
  - The Rollback (ROLLBACK) command, a ROLLBACK statement in host languages, or the ROLLBACK HOLD SQL statement does not reposition a read-only cursor when:
    - ALWBLK(*ALLREAD) was specified when the program or routine that contains the cursor was created
    - ALWBLK(*READ) and ALWCPYDTA(*OPTIMIZE) were specified when the program or routine that contains the cursor was created
  - Dynamic running of a positioned UPDATE or DELETE statement (for example, using EXECUTE IMMEDIATE), cannot be used to update a row in a cursor unless the DECLARE statement for the cursor includes the FOR UPDATE clause.

**NONE**
Rows are not blocked for retrieval of data for cursors.

Specifying *NONE:
- Guarantees that the data retrieved is current.
- May reduce the amount of time required to retrieve the first row of data for a query.
- Stops the database manager from retrieving a block of data rows that is not used by the program when only the first few rows of a query are retrieved before the query is closed.
- Can degrade the overall performance of a query that retrieves a large number of rows.

**READ**
Rows are blocked for read-only retrieval of data for cursors when:
- *NONE is specified on the COMMIT parameter, which indicates that commitment control is not used.
- The cursor is declared with a FOR READ ONLY clause or there are no dynamic statements that could run a positioned UPDATE or DELETE statement for the cursor.

Specifying *READ can improve the overall performance of queries that meet the above conditions and retrieve a large number of rows.

**ALWCPYDTA**
Specifies whether a copy of the data can be used in a SELECT statement. This option will be ignored in REXX.

**OPTIMIZE**
The system determines whether to use the data retrieved directly from the database or to use a copy of the data. The decision is based on which method provides the best performance. If COMMIT is *CHG or *CS and
ALWBLK in not *ALLREAD, or if COMMIT is *ALL or *RR, then a copy of
the data is used only when it is necessary to run a query.

*YES
A copy of the data is used only when necessary.

*NO
A copy of the data is not allowed. If a temporary copy of the data is
required to perform the query, an error message is returned.

BINDOPT

Specifies additional parameters to be used on the CRTPGM or CRTSRVPGM
CL command that is used when creating an SQL function, SQL procedure, or
SQL trigger. The BINDOPT string is added to the CRTPGM or CRTSRVPGM
CL command generated by the precompiler. The contents of the string are not
validated. The bind command will issue an error if any parameter is incorrect.
The following bind options cannot be specified in this string since they are set
by the precompiler: ACTGRP, ALWRINZ, AUT, ENTMOD, EXPORT,
MODULE, REPLACE, STGMDL, TEXT, TGTRLS, and USRPRF.

This option is only allowed in an SQL function, SQL procedure, or SQL trigger.
This option will be ignored in REXX.

*NONE
No additional parameters will be used on the CRTPGM or CRTSRVPGM
CL command.

bind-string-constant
A character constant of no more than 5000 characters containing the bind
options.

CLOSQLCSR

Specifies when SQL cursors are implicitly closed, SQL prepared statements are
implicitly discarded, and LOCK TABLE locks are released. SQL cursors are
explicitly closed when you issue the CLOSE, COMMIT, or ROLLBACK
(without HOLD) SQL statements. This option will be ignored in REXX.
*ENDACTGRP and *ENDMOD are for use by ILE programs and modules, SQL
functions, SQL procedures, or SQL triggers. *ENDPGM, *ENDSQL, and
*ENDDJOB are for use by non-ILE programs.

SQL scalar functions, SQL procedures, and SQL triggers use *ENDMOD as the
default. SQL table functions are always created using *ENDACTGRP.

*ENDACTGRP
SQL cursors are closed, SQL prepared statements are implicitly discarded,
and LOCK TABLE locks are released when the activation group ends.

*ENDMOD
SQL cursors are closed and SQL prepared statements are implicitly
discarded when the module is exited. LOCK TABLE locks are released
when the first SQL program on the call stack ends. Note that a cursor may
only be logically closed and will only be physically closed when the first
program with SQL leaves the stack and only if that program was not
compiled with *ENDACTGRP.

*ENDPGM
SQL cursors are closed and SQL prepared statements are discarded when
the program ends. LOCK TABLE locks are released when the first SQL
program on the call stack ends.

*ENDSQL
SQL cursors remain open between calls and can be fetched without
running another SQL OPEN. One of the programs higher on the call stack must have run at least one SQL statement. SQL cursors are closed, SQL prepared statements are discarded, and LOCK TABLE locks are released when the first SQL program on the call stack ends. If *ENDSQL is specified for a program that is the first SQL program called (the first SQL program on the call stack), the program is treated as if *ENDPGM was specified.

**ENDJOB**

SQL cursors remain open between calls and can be fetched without running another SQL OPEN. The programs higher on the call stack do not need to have run SQL statements. SQL cursors are left open, SQL prepared statements are preserved, and LOCK TABLE locks are held when the first SQL program on the call stack ends. SQL cursors are closed, SQL prepared statements are discarded, and LOCK TABLE locks are released when the job ends.

**CNULIGN**

Specifies whether a NUL-terminator is ignored for character and graphic host variables. This option will only be used for SQL statements in C and C++ programs.

This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

**YES**

Character and graphic host variables defined as NUL-terminated will be treated as fixed length variables for INSERT and UPDATE statements. NUL-terminators are considered part of the data.

**NO**

NUL-terminated character and graphic host variables use NUL-terminators for INSERT and UPDATE statements.

**CNULRQD**

Specifies whether a NUL-terminator is returned for character and graphic host variables. This option will only be used for SQL statements in C and C++ programs.

This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

**YES**

Output character and graphic host variables always contain the NUL-terminator. If there is not enough space for the NUL-terminator, the data is truncated and the NUL-terminator is added. Input character and graphic host variables require a NUL-terminator.

**NO**

For output character and graphic host variables, the NUL-terminator is not returned when the host variable is exactly the same length as the data. Input character and graphic host variables do not require a NUL-terminator.

**COMMIT**

Specifies the isolation level to be used. In REXX, files that are referred to in the source are not affected by this option. Only tables, views, and packages referred to in SQL statements are affected. For more information about isolation levels, see "Isolation level" on page 27

**CHG**

Specifies the isolation level of Uncommitted Read.
SET OPTION

*NONE
Specifies the isolation level of No Commit. If the DROP SCHEMA statement is included in a REXX procedure, *NONE must be used.

*CS
Specifies the isolation level of Cursor Stability.

*ALL
Specifies the isolation level of Read Stability.

*RR
Specifies the isolation level of Repeatable Read.

COMPILEOPT
Specifies additional parameters to be used on the compiler command. The COMPILEOPT string is added to the compiler command built by the precompiler. If 'INCDIR(' is anywhere in the string, the precompiler will call the compiler using the SRCSTMF parameter. The contents of the string is not validated. The compiler command will issue an error if any parameter is incorrect. Using any of the keywords that the precompiler passes to the compiler will cause the compiler command to fail because of duplicate parameters. Refer to the Embedded SQL Programming topic collection for a list of parameters that the precompiler generates for the compiler command. This option will be ignored in REXX.

This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

*NONE
No additional parameters will be used on the compiler command.

character-string
A character constant of no more than 5000 characters containing the compiler options.

CONACC
Specifies the concurrent access resolution to use for select statements.

*CURCMT
Specifies that the database manager is to use the currently committed version of data when encountering a row that is in the process of being updated or deleted. Rows that are in the process of being inserted are skipped. This value will be honored when possible for isolation level of *CS.

*WAIT
Specifies to wait for a commit or rollback for data that is in the process of being updated or deleted by another transaction. This value will be honored when possible for isolation levels of *CS and *ALL.

*DFT
Specifies that the concurrent access option will not be explicitly set for this program. The value that is in effect when the program is invoked will be used.

DATFMT
Specifies the format used when accessing date result columns. All output date fields are returned in the specified format. For input date strings, the specified value is used to determine whether the date is specified in a valid format.

Note: An input date string that uses the format *USA, *ISO, *EUR, or *JIS is always valid.
**JOB:**
The format specified for the job is used. Use the Display Job (DSPJOB) command to determine the current date format for the job.

**ISO**
The International Organization for Standardization (ISO) date format (yyyy-mm-dd) is used.

**EUR**
The European date format (dd.mm.yyyy) is used.

**USA**
The United States date format (mm/dd/yyyy) is used.

**JIS**
The Japanese Industrial Standard date format (yyyy-mm-dd) is used.

**MDY**
The date format (mm/dd/yy) is used.

**DMY**
The date format (dd/mm/yy) is used.

**YMD**
The date format (yy/mm/dd) is used.

**JUL**
The Julian date format (yy/ddd) is used.

**DATSEP**
Specifies the separator used when accessing date result columns.

**Note:** This parameter applies only when *JOB, *MDY, *DMY, *YMD, or *JUL is specified on the DATFMT parameter.

**JOB**
The date separator specified for the job is used. Use the Display Job (DSPJOB) command to determine the current value for the job.

**SLASH** or `'/'
A slash (/) is used.

**PERIOD** or `'.'
A period (.) is used.

**COMMA** or `,`
A comma (,) is used.

**DASH** or `-'
A dash (-) is used.

**BLANK** or ` '``
A blank ( ) is used.

**DBGVIEW**
Specifies whether the object can be debugged by the system debug facilities and the type of debug information to be provided by the compiler. The DBGVIEW parameter can only be specified in the body of SQL functions, procedures, and triggers.

If DEBUG MODE in a CREATE PROCEDURE or ALTER PROCEDURE statement is specified, a DBGVIEW option in the SET OPTION statement must not be specified.

The possible choices are:
**SET OPTION**

*NONE*
A debug view will not be generated.

*SOURCE*
Allows the compiled module object to be debugged using SQL statement source. If *SOURCE* is specified, the modified source is stored in source file QSQDSRC in the same schema as the created function, procedure, or trigger.

*STMT*
Allows the compiled module object to be debugged using program statement numbers and symbolic identifiers.

*LIST*
Generates the listing view for debugging the compiled module object.

If DEBUG MODE is not specified, but a DBGVIEW option in the SET OPTION statement is specified, the procedure cannot be debugged by the Unified Debugger, but can be debugged by the system debug facilities. If neither DEBUG MODE nor a DBGVIEW option is specified, the debug mode used is from the CURRENT DEBUG MODE special register.

**DECFLTRND**
Specifies the DECFLOAT rounding mode used for static SQL statements. The possible choices are:

*CEILING*
Round toward +Infinity. If all of the discarded digits are zero or if the sign is negative the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

*DOWN*
Round toward zero (truncation). The discarded digits are ignored.

*FLOOR*
Round toward -Infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of the discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by one.

*HALFDOWN*
Round to nearest; if equidistant, round down. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

*HALFEVEN*
Round to nearest; if equidistant, round so that the final digit is even. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise (they represent exactly half), the result coefficient is unaltered if its rightmost digit is even or incremented by one (rounded up) if its rightmost digit is odd (to make an even digit).

*HALFUP*
Round to nearest; if equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a one in the next left
position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

*UP
Round away from zero. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

DECMPT
Specifies the symbol that you want to represent the decimal point. The possible choices are:

*PERIOD
The representation for the decimal point is a period.

*COMMA
The representation for the decimal point is a comma.

*SYSVAL
The representation for the decimal point is the system value (QDECFMT).

*JOB
The representation for the decimal point is the job value (DECFMT).

DECRESULT
Specifies the maximum precision, maximum scale, and minimum divide scale that should be used during decimal operations, such as decimal arithmetic. The specified limits only apply to NUMERIC and DECIMAL data types.

max-precision
An integer constant that is the maximum precision that should be returned from decimal operations. The value can be 31 or 63. The default is 31.

max-scale
An integer constant that is the maximum scale that should be returned from decimal operations. The value can range from 0 to the maximum precision. The default is 31.

min-divide-scale
An integer constant that is the minimum scale that should be returned from division operations. The value can range from 1 to 9 and cannot be greater than max-scale. The default is 0, where 0 indicates that no minimum scale is specified.

DFTRDBCOL
Specifies the schema name used for the unqualified names of tables, views, indexes, and SQL packages. This parameter applies only to static SQL statements. This option will be ignored in REXX.

*NONE
The naming convention specified on the OPTION precompile parameter or by the SET OPTION NAMING option will be used.

schema-name
Specify the name of the schema. This value is used instead of the naming convention specified on the OPTION precompile parameter or by the SET OPTION NAMING option.

DLYPRP
Specifies whether the dynamic statement validation for a PREPARE statement is delayed until an OPEN, EXECUTE, or DESCRIBE statement is run. Delaying validation improves performance by eliminating redundant validation. This option will be ignored in REXX.
SET OPTION

*NO
Dynamic statement validation is not delayed. When the dynamic statement is prepared, the access plan is validated. When the dynamic statement is used in an OPEN or EXECUTE statement, the access plan is revalidated. Because the authority or the existence of objects referred to by the dynamic statement may change, you must still check the SQLCODE or SQLSTATE after issuing the OPEN or EXECUTE statement to ensure that the dynamic statement is still valid.

*YES
Dynamic statement validation is delayed until the dynamic statement is used in an OPEN, EXECUTE, or DESCRIBE SQL statement. When the dynamic statement is used, the validation is completed and an access plan is built. If you specify *YES, you should check the SQLCODE and SQLSTATE after running an OPEN, EXECUTE, or DESCRIBE statement to ensure that the dynamic statement is valid.

Note: If you specify *YES, performance is not improved if the INTO clause is used on the PREPARE statement or if a DESCRIBE statement uses the dynamic statement before an OPEN is issued for the statement.

DYNDFTCOL
Specifies the schema name specified for the DFTRDBCOL parameter is also used for dynamic statements. This option will be ignored in REXX.

*NO
Do not use the value specified for DFTRDBCOL for unqualified names of tables, views, indexes, and SQL packages for dynamic SQL statements. The naming convention specified on the OPTION precompile parameter or by the SET OPTION NAMING option will be used.

*YES
The schema name specified for DFTRDBCOL will be used for the unqualified names of the tables, views, indexes, and SQL packages in dynamic SQL statements.

DYNUSRPRF
Specifies the user profile to be used for dynamic SQL statements. This option will be ignored in REXX.

*USER
Local dynamic SQL statements are run under the user profile of the job. Distributed dynamic SQL statements are run under the user profile of the application server job.

*OWNER
Local dynamic SQL statements are run under the user profile of the program's owner. Distributed dynamic SQL statements are run under the user profile of the SQL package's owner.

EVENTF
Specifies whether an event file will be generated. CoOperative Development Environment/400 (CODE/400) uses the event file to provide error feedback integrated with the CODE/400 editor.

*YES
The compiler produces an event file for use by CoOperative Development Environment/400 (CODE/400).
*NO
The compiler will not produce an event file for use by CoOperative Development Environment/400 (CODE/400).

EXTIND
Specifies how to treat indicator variable values passed for SQL statements.

*NO
Specifies that extended indicator variables are not enabled and non-updatable columns are not allowed in the implicit or explicit UPDATE clause of a select-statement.

*YES
Specifies that extended indicator variables are enabled and non-updatable columns are allowed in the implicit or explicit UPDATE clause of a select-statement.

INCFILE
Specifies the name of the source file to use for INCLUDE SQL statements. It will be used to locate any source member listed in an INCLUDE SQL statement when a source file name is not specified in the INCLUDE SQL statement.

This option is only allowed in an SQL function, SQL procedure, or SQL trigger. This option will be ignored in REXX.

file-name
Specify the name of the source file to be used. The name of the file can be qualified by one of the following library values:

*LIBL
All libraries in the user and system portions of the job's library list are searched until the first match is found.

*CURLIB
The current library for the job is searched. If no library is specified as the current library for the job, the QGPL library is used.

library-name
Specifies the name of the library to be searched.

LANGID
Specifies the language identifier to be used when SRTSEQ(*LANGIDUNQ) or SRTSEQ(*LANGIDSHR) is specified.

*JOB or *JOBRUN
The LANGID value for the job is used.

For distributed applications, LANGID(*JOBRUN) is valid only when SRTSEQ(*JOBRUN) is also specified.

language-id
Specify a language identifier to be used. For information about the values that can be used for the language identifier, see the Language identifier topic in the Globalization topic collection.

MONITOR
Specifies whether the statements should be identified as user or system statements when a database monitor is run.

*USER
The SQL statements are identified as user statements. This is the default.
SET OPTION

*SYSTEM
The SQL statements are identified as system statements.

NAMING
Specifies whether the SQL naming convention or the system naming convention is to be used. This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

The possible choices are:

*SYS
The system naming convention will be used.

*SQL
The SQL naming convention will be used.

OPTLOB
Specifies whether accesses to XML and LOBs can be optimized when accessing through DRDA. The possible choices are:

*YES
LOB and XML accesses should be optimized. The first FETCH for a cursor determines how the cursor will be used for LOBs and XML on all subsequent FETCHes. This option remains in effect until the cursor is closed.

If the first FETCH uses a locator to access a LOB or XML column, no subsequent FETCH for that cursor can fetch that LOB or XML column into a LOB or XML variable.

If the first FETCH places the LOB or XML column into a LOB or XML variable, no subsequent FETCH for that cursor can use a locator for that column.

*NO
LOB accesses should not be optimized. There is no restriction on whether a column is retrieved into a LOB locator or into a LOB variable. This option can cause performance to degrade.

OUTPUT
Specifies whether the precompiler and compiler listings are generated. The OUTPUT parameter can only be specified in the body of SQL functions, procedures, and triggers. The possible choices are:

*NONE
The precompiler and compiler listings are not generated.

*PRINT
The precompiler and compiler listings are generated.

RDBCNNMTH
Specifies the semantics used for CONNECT statements. This option will be ignored in REXX.

*DUW
CONNECT (Type 2) semantics are used to support distributed unit of work. Consecutive CONNECT statements to additional relational databases do not result in disconnection of previous connections.

*RUW
CONNECT (Type 1) semantics are used to support remote unit of work. Consecutive CONNECT statements result in the previous connection being disconnected before a new connection is established.
**SQLCA**

Specifies whether the fields in an SQLCA will be set after each SQL statement. The SQLCA option is only allowed for ILE C, ILE C++, ILE COBOL, and ILE RPG. This option is not allowed in an SQL function, SQL procedure, or SQL trigger.

The possible choices are:

* **YES**
  - The fields in an SQLCA will be set after each SQL statement. The user program can reference all the values in the SQLCA following the execution of an SQL statement.

* **NO**
  - The fields in an SQLCA will not be set after each SQL statement. The user program should use the GET DIAGNOSTICS statement to retrieve information about the execution of the SQL statement.
  
  SQLCA(*NO) will typically perform better than SQLCA(*YES).

In other host languages, an SQLCA is required and fields in the SQLCA will be set after each SQL statement.

**SQLCURRULE**

Specifies the semantics used for SQL statements.

* **DB2**
  - The semantics of all SQL statements will default to the rules established for Db2. The following semantics are controlled by this option:
    - Hexadecimal constants are treated as character data.
    - Unicode graphic-string constants are UCS-2 (CCSID 13488).
    - Assignments to SQL-variables and SQL-parameters within the body of a routine or a trigger will use retrieval assignment rules.
    - When describing a select statement into an SQLDA and SQLN is smaller than the required number of SQLVAR entries, SQLSTATE 01005 is returned only when the result table contains LOBs or UDTs.

* **STD**
  - The semantics of all SQL statements will default to the rules established by the ISO and ANSI SQL standards. The following semantics are controlled by this option:
    - Hexadecimal constants are treated as binary data.
    - Unicode graphic-string constants are UTF-16 (CCSID 1200).
    - Assignments to SQL-variables and SQL-parameters within the body of a routine or a trigger will use storage assignment rules.
    - When describing a select statement into an SQLDA and SQLN is smaller than the required number of SQLVAR entries, SQLSTATE 01005 is always returned.

**SQLPATH**

Specifies the path to be used to find procedures, functions, and user defined types in static SQL statements. This option will be ignored in REXX.

* **LIBL**
  - The path used is the library list at runtime.

  character-string
  
  A character constant with one or more schema names that are separated by commas. Only system schema names can be specified.
SET OPTION

SRTSEQ
Specifies the collating sequence table to be used for string comparisons in SQL statements.

Note: *HEX must be specified if a REXX procedure connects to an application server that is not a Db2 for i or a IBM i product whose release level is prior to V2R3M0.

*JOB or *JOBRUN
The SRTSEQ value for the job is used.

*HEX
A collating sequence table is not used. The hexadecimal values of the characters are used to determine the collating sequence.

*LANGIDUNQ
The collating sequence table must contain a unique weight for each character in the code page.

*LANGIDSHR
The shared-weight sort table for the LANGID specified is used.

srtseq-table-name
Specify the name of the collating sequence table to be used with this program. The name of the collating sequence table can be qualified by one of the following library values:

*LIBL
All libraries in the user and system portions of the job's library list are searched until the first match is found.

*CURLIB
The current library for the job is searched. If no library is specified as the current library for the job, the QGPL library is used.

library-name
Specify the name of the library to be searched.

SYSTIME
Specifies whether the CURRENT TEMPORAL SYSTEM_TIME special register affects static and dynamic SQL statements.

The possible choices are:

*YES
Any references to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

*NO
Any references to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

TGTRLS
Specifies the release of the operating system on which the user intends to use the object being created. The TGTRLS parameter can only be specified in the body of SQL functions, procedures, and triggers, or as part of an external function or procedure create statement. The possible choices are:

VxRxMx
Specify the release in the format VxRxMx, where Vx is the version, Rx is the release, and Mx is the modification level. For example, V7R1M0 is
version 7, release 1, modification level 0. The object can be used on a
system with the specified release or with any subsequent release of the
operating system installed.

Valid values depend on the current version, release, and modification level,
and they change with each new release. If you specify a release-level which
is earlier than the earliest release level supported by the database manager,
an error message is sent indicating the earliest supported release.

**TIMFMT**

Specifies the format used when accessing time result columns. All output time
fields are returned in the specified format. For input time strings, the specified
value is used to determine whether the time is specified in a valid format.

**Note:** An input time string that uses the format *USA, *ISO, *EUR, or *JIS is
always valid.

*HMS

The (hh:mm:ss) format is used.

*ISO

The International Organization for Standardization (ISO) time format
(hh.mm.ss) is used.

*EUR

The European time format (hh.mm.ss) is used.

*USA

The United States time format (hh:mm xx) is used, where xx is AM or PM.

*JIS

The Japanese Industrial Standard time format (hh:mm:ss) is used.

**TIMSEP**

Specifies the separator used when accessing time result columns.

**Note:** This parameter applies only when *HMS is specified on the TIMFMT
parameter.

*JOB

The time separator specified for the job is used. Use the Display Job
(DSPJOB) command to determine the current value for the job.

*COLON or ':'

A colon (:) is used.

*PERIOD or '. '

A period (.) is used.

*COMMA or ','

A comma (,) is used.

*BLANK or '

A blank ( ) is used.

**USRPRF**

Specifies the user profile that is used when the compiled program object is run,
including the authority that the program object has for each object in static
SQL statements. The profile of either the program owner or the program user
is used to control which objects can be used by the program object. This option
will be ignored in REXX.
**SET OPTION**

**NAMING**
The user profile is determined by the naming convention. If the naming convention is *SQL, USRPRF(*OWNER) is used. If the naming convention is *SYS, USRPRF(*USER) is used.

**USER**
The profile of the user running the program object is used.

**OWNER**
The user profiles of both the program owner and the program user are used when the program is run.

**Notes**

**Default values:** The default values for the options depend on the language, object type, and the options in effect at create time:

- When an SQL procedure, SQL function, or SQL trigger is created, the default values for the options are those in effect at the time the object is created. For example, if an SQL procedure is created and the current COMMIT option is *CS, *CS is the default COMMIT option. Each option is then updated as it is encountered within the SET OPTION statement.

- For application programs other than REXX, the default values for the options are specified on the CRTSQLxxx command. Each option is then updated as it is encountered within a SET OPTION statement. All SET OPTION statements must precede any other embedded SQL statements.

- At the start of a REXX procedure the options are set to their default value. The default value for each option is the first value listed in the syntax diagram. When an option is changed by a SET OPTION statement, the new value will stay in effect until the option is changed again or the REXX procedure ends.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- *UR can be used as a synonym for *CHG.
- *NC can be used as a synonym for *NONE.
- *RS can be used as a synonym for *ALL.

**Examples**

*Example 1:* Set the isolation level to *ALL and the naming mode to SQL names.

```
EXEC SQL SET OPTION COMMIT = *ALL, NAMING = *SQL
```  

*Example 2:* Set the date format to European, the isolation level to *CS, and the decimal point to the comma.

```
EXEC SQL SET OPTION DATFMT = *EUR, COMMIT = *CS, DECMPT = *COMMA
```
SET PATH

The SET PATH statement changes the value of the CURRENT PATH special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
SET CURRENT_PATH = (1)
```  

Notes:

1. SYSTEM PATH, SESSION_USER, USER, CURRENT_USER, SYSTEM_USER, and CURRENT PATH may each be specified at most once on the right side of the statement.

Description

**schema-name**

Identifies a schema. If a specified schema name is a system schema name, no validation that the schema exists is made at the time the PATH is set. For example, if a schema-name is misspelled, it could affect the way subsequent SQL operates. If the specified schema name is not a system schema name, the schema must exist at the time the PATH is set.
SET PATH

Although not recommended, PATH can be specified as a schema-name if it is specified as "PATH".

**SYSTEM PATH**
Specifies the schema names for the system path. This value is the same as specifying the schema names "QSYS","QSYS2","SYSPROC","SYSIBMADM".

**SESSION_USER or USER**
Specifies the value of the SESSION_USER special register.

**CURRENT USER**
Specifies the value of the CURRENT USER special register.

**SYSTEM_USER**
Specifies the value of the SYSTEM_USER special register.

**CURRENT PATH**
Specifies the value of the CURRENT PATH special register before the execution of this statement. CURRENT PATH is not allowed if the current path is *LIBL.

**variable**
Specifies a variable that contains one or more schema names that are separated by commas. It can be a global variable if it is qualified with schema name.

The variable:
- Must be a CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable. The actual length of the contents of the variable must not exceed the maximum length of a path.
- Must not be followed by an indicator variable.
- Must not be the null value.
- Each schema name must conform to the rules for forming an ordinary or delimited identifier.
- Each schema name must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.
- Must be padded on the right with blanks if the variable is fixed length character.
- If the SET statement is specified in an SQL routine, SQL trigger, or compound statement, variable cannot be a global variable with an unqualified name.

**string-constant**
A character constant with one or more schema names that are separated by commas.

The string constant:
- Each schema name must conform to the rules for forming an ordinary or delimited identifier.
- Each schema name must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.

***LIBL**
The path is set to the library list of the current thread.

**Notes**

Transaction considerations: The SET PATH statement is not a committable operation. ROLLBACK has no effect on the CURRENT PATH.

Rules for the content of the SQL path:
- A schema name must not appear more than once in the path.
- The number of schemas that can be specified is limited by the total length of the CURRENT PATH special register. The special register string is built by taking each schema name specified and removing trailing blanks, delimiting with double quotes, and separating each schema name by a comma. An error is returned if the length of the resulting string exceeds 3483 bytes. A maximum of 268 schema names can be represented in the path.
- There is a difference between specifying a single keyword (such as USER, or PATH, or CURRENT_PATH) as a single keyword, or as a delimited identifier. To indicate that the current value of a special register specified as a single keyword should be used in the SQL path, specify the name of the special register as a keyword. If the name of the special register is specified as a delimited identifier instead (for example, "USER"), it is interpreted as a schema name of that value ('USER'). For example, assuming that the current value of the USER special register is SMITH, then SET PATH = SYSIBM, USER, "USER" results in a CURRENT PATH value of 'SYSIBM','SMITH','USER'.
- The following rules are used to determine whether a value specified in a SET PATH statement is a variable or a schema-name:
  - If name is the same as a parameter or SQL variable in the SQL procedure, name is interpreted as a parameter or SQL variable, and the value in name is assigned to PATH.
  - If name is not the same as a parameter or SQL variable in the SQL procedure, name is interpreted as schema-name, and the value name is assigned to PATH.

The system path: SYSTEM PATH refers to the system path for a platform. The schemas QSYS, QSYS2, SYSPROC, and SYSIBMADM do not need to be specified. If not included in the path, they are implicitly assumed as the last schemas (in this case, it is not included in the CURRENT PATH special register).

The initial value of the CURRENT PATH special register is *LIBL if system naming was used for the first SQL statement run in the activation group. The initial value is "QSYS","QSYS2","SYSPROC","SYSIBMADM","X" (where X is the value of the USER special register) if SQL naming was used for the first SQL statement.

Using the SQL path: The CURRENT PATH special register is used to resolve user-defined types, functions, and procedures in dynamic SQL statements. For more information see "SQL path" on page 64.

Example

The following statement sets the CURRENT PATH special register.

```
SET PATH = FERMAT, "McDuff", SYSIBM
```

The following statement retrieves the current value of the SQL path special register into the host variable called CURPATH.

```
EXEC SQL VALUES (CURRENT PATH) INTO :CURPATH;
```

The value would be "FERMAT","McDuff","SYSIBM" if set by the previous example.
SET RESULT SETS

The SET RESULT SETS statement specifies the result sets that can be returned from a procedure.

Invocation

This statement can only be embedded in an application program or SQL procedure. It is an executable statement that cannot be dynamically prepared. It is not allowed in a Java or REXX procedure.

Authorization

None required.

Syntax

\[
\text{SET RESULT SETS} \begin{cases} 
\text{WITH RETURN} & \text{TO CALLER} \\
\text{TO CLIENT} & 
\end{cases}
\]

\[
\text{ARRAY} \quad \text{host-structure-array} \quad \text{FOR} \quad \text{variable} \quad \text{ROWS} \\
\text{CURSOR} \quad \text{cursor-name} \\
\text{NONE}
\]

Description

\text{WITH RETURN}

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

\text{TO CALLER}

Specifies that the cursor can return a result set to the caller of the procedure. For example, if the caller is a client application, the result set is returned to the client application.

\text{TO CLIENT}

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger called the procedure either directly or indirectly, result sets cannot be returned to the client and the cursor will be closed after the procedure finishes.

\text{CURSOR} \text{ cursor-name}

Identifies a cursor to be used to define a result set that can be returned from a procedure. The \text{cursor-name} must identify a declared cursor as explained in “Description” on page 1266 for the DECLARE CURSOR statement. When the SET RESULT SETS statement is executed, the cursor must be in the open state. It cannot be an allocated cursor.
ARRAY host-structure-array

host-structure-array identifies an array of host structures defined in accordance with the rules for declaring host structures. The array cannot contain a C NUL-terminated host variable.

The first structure in the array corresponds to the first row of the result set, the second structure in the array corresponds to the second row of the result set, and so on. In addition, the first value in the row corresponds to the first item in the structure, the second value in the row corresponds to the second item in the structure, and so on.

LOBs and XML cannot be returned in an array when using DRDA.

Only one array can be specified in a SET RESULT SETS statement, including any RETURN TO CLIENT array result sets from nested calls to procedures.

FOR variable ROWS

Specifies the number of rows in the result set. The variable must be a numeric variable with zero scale, and it must not include an indicator variable. It must not be a global variable. The number of rows specified must be in the range of 0 to 32767 and must be less than or equal to the dimension of the host structure array.

NONE

Specifies that no result sets will be returned. Cursors left open when the procedure ends will not be returned.

Notes

For more information about result sets, see the Result sets from procedures and WITH RETURN clause.

External procedures: There are three ways to return result sets from an external procedure:

• If a SET RESULT SETS statement is executed in the procedure, the SET RESULT SETS statement identifies the result sets. The result sets are returned in the order specified on the SET RESULT SETS statement.

• If a SET RESULT SETS statement is not executed in the procedure,
  – If no cursors have specified a WITH RETURN clause, each cursor that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.
  – If any cursors have specified a WITH RETURN clause, each cursor that is defined with the WITH RETURN clause that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.

When a result set is returned using an open cursor, the rows are returned starting with the current cursor position.

The RESULT SETS clause should be specified on the ALTER PROCEDURE (external), CREATE PROCEDURE (external) statement, or DECLARE PROCEDURE statement to return result sets from a procedure. The maximum number of result sets returned cannot be larger than the number specified on the ALTER PROCEDURE (external), CREATE PROCEDURE (external) statement, or DECLARE PROCEDURE statement.
**SET RESULT SETS**

**SQL procedures:** In order to return result sets from an SQL procedure, the procedure must be created with the RESULT SETS clause. Each cursor that is defined with the WITH RETURN clause that the procedure opens and leaves open when it returns identifies a result set.

- If a SET RESULT SETS statement is executed in the procedure, the SET RESULT SETS statement identifies which of these result sets to return. The result sets are returned in the order specified on the SET RESULT SETS statement.
- If a SET RESULT SETS statement is not executed in the procedure the result sets are returned in the order in which the cursors are opened.

When a result set is returned using an open cursor, the rows are returned starting with the current cursor position.

The RESULT SETS clause must be specified on the CREATE PROCEDURE (SQL) statement to return any result sets from an SQL procedure. The maximum number of result sets returned cannot be larger than the number specified on the CREATE PROCEDURE statement.

**Example**

The following SET RESULT SETS statement specifies cursor X as the result set that will be returned when the procedure is called. For more information and complete examples showing the use of result sets from ODBC clients, see the **IBM i Access Family** topic collection.

```
EXEC SQL SET RESULT SETS CURSOR X;
```
The SET SCHEMA statement changes the value of the CURRENT SCHEMA special register.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:
- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

**Syntax**

```
SET CURRENT_SCHEMA = schema-name
```

**Description**

`schema-name`
Identifies a schema. If the specified schema name is a system schema name, no validation that the schema exists is made at the time the current schema is set. If the specified schema name is not a system schema name, the schema must exist at the time the current schema is set.

If the value specified does not conform to the rules for a `schema-name`, an error is returned.

`SESSION_USER` or `USER`
This value is the SESSION_USER special register.

`CURRENT_USER`
Specifies the value of the CURRENT USER special register.

`SYSTEM_USER`
This value is the SYSTEM_USER special register.

`variable`
Specifies a variable which contains a schema name. It can be a global variable if it is qualified with schema name. The content is not folded to uppercase.

The variable:
SET SCHEMA

- Must be a character-string or Unicode graphic variable. The actual length of the contents of the variable after trimming any trailing blanks must not exceed the length of a schema name. See Appendix A, “SQL limits,” on page 1715.
- Must not be followed by an indicator variable.
- Must not be the null value.
- Must conform to the rules for forming an ordinary or delimited identifier.
- Must be padded on the right with blanks if the variable is fixed length.
- Must not be the keyword SESSION_USER, CURRENT_USER, SYSTEM_USER, or USER.
- If the SET statement is specified in an SQL routine, SQL trigger, or compound statement, variable cannot be a global variable with an unqualified name.

string-constant
A character constant with a schema name.

The string constant:
- Must have a length after trimming any trailing blanks that does not exceed the maximum length of a schema name
- Must include a schema name that is left justified and conforms to the rules for forming an ordinary or delimited identifier.
- Must not be the keyword SESSION_USER, CURRENT_USER, SYSTEM_USER, or USER.

DEFAULT
The CURRENT SCHEMA is set to its initial value. The initial value for SQL naming is USER. The initial value for system naming is *LIBL.

Notes

Considerations for keywords: There is a difference between specifying a single keyword (such as USER) as a single keyword or as a delimited identifier. To indicate that the current value of the USER special register should be used for setting the current schema, specify USER as a keyword. If USER is specified as a delimited identifier instead (for example, "USER"), it is interpreted as a schema name of that value ("USER").

Transaction considerations: The SET SCHEMA statement is not a committable operation. ROLLBACK has no effect on the CURRENT SCHEMA.

Impact on other special registers: Setting the CURRENT SCHEMA special register does not affect the CURRENT PATH special register. Hence, the CURRENT SCHEMA will not be included in the SQL path and functions, procedures and user-defined type resolution may not find these objects. To include the current schema value in the SQL path, whenever the SET SCHEMA statement is issued, also issue the SET PATH statement including the schema name from the SET SCHEMA statement.

CURRENT SCHEMA: The value of the CURRENT SCHEMA special register is used as the qualifier for some unqualified names in all dynamic SQL statements except in programs where the DYNDFTCOL has been specified. If DYNDFTCOL is specified in a program, its schema name is used instead of the CURRENT SCHEMA schema name. For information about qualification of names, see “Qualification of unqualified object names” on page 64.
For SQL naming, the initial value of the CURRENT SCHEMA special register is equivalent to USER. For system naming, the initial value of the CURRENT SCHEMA special register is '*LIBL'.

**Syntax alternatives:** CURRENT SQLID is accepted as a synonym for CURRENT SCHEMA and the effect of a SET CURRENT SQLID statement will be identical to that of a SET CURRENT SCHEMA statement. No other effects, such as statement authorization changes, will occur.

SET SCHEMA is equivalent to calling the QSQCHGDC API.

**Examples**

*Example 1:* The following statement sets the CURRENT SCHEMA special register.

```
SET SCHEMA = RICK
```

*Example 2:* The following example retrieves the current value of the CURRENT SCHEMA special register into the host variable called CURSCHEMA.

```
EXEC SQL VALUES(CURRENT SCHEMA) INTO :CURSCHEMA
```

The value would be RICK, set by the previous example.
SET SESSION AUTHORIZATION

The SET SESSION AUTHORIZATION statement changes the value of the SESSION_USER and USER special registers. It also changes the name of the user profile associated with the current thread.

Invocation

This statement can be embedded within an application program or issued interactively. It is an executable statement that can be dynamically prepared. It must not be specified in REXX.

SET SESSION AUTHORIZATION is not allowed in an SQL trigger, SQL function, or SQL procedure.

Authorization

If the authorization name specified on the statement is different than the value in the SYSTEM_USER special register, the privileges held by the authorization ID of the statement must include the system authority of *ALLOBJ.

No authorization is required to execute this statement if the authorization name specified on the statement is the same as the SYSTEM_USER special register.

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
►► SET SESSION AUTHORIZATION authorization-name
  SET SESSION_USER user-name
  CURRENT_USER
  CURRENT_USER
  SESSION_USER variable string-constant
  ▼◄
```

Description

authorization-name

Identifies an authorization ID that is to be used as the new value for the SESSION_USER special register and the runtime authorization ID.

The authorization ID must be a valid user profile or group user profile that exists at the current server. Several system user profiles that do not have a user profile handle may not be used. For more information, see the Get Profile Handle API.
CURRENT USER
The SESSION_USER special register and the runtime authorization ID are set to the CURRENT USER special register.

SESSION_USER or USER
The SESSION_USER special register and the runtime authorization ID are set to the USER special register.

SYSTEM_USER
The SESSION_USER special register and the runtime authorization ID are set to the SYSTEM_USER special register.

variable
A variable which contains an authorization ID name. It can be a global variable if it is qualified with schema name.

The variable:
• Must be a character-string variable.
• If variable has an associated indicator variable, the value of that indicator variable must not indicate a null value
• Must include an authorization ID that is left justified and must conform to the rules for forming an ordinary or delimited identifier.
• Must be padded on the right with blanks.
• Must not be the null value.
• Must not be the keyword USER, SESSION_USER, SYSTEM_USER, or CURRENT_USER.

string-constant
A character constant with an authorization ID.

Notes

Other effects of SET SESSION AUTHORIZATION: SET SESSION AUTHORIZATION causes the following to occur:
• All cursors that were opened during the unit of work are closed.
• All LOB locators are freed.
• All locks acquired under this unit of work’s commitment definition are released.
• All prepared statements are destroyed.
• All SQL descriptor areas are deallocated.
• All procedure result sets are cleared.
• The encryption password is reset.
• All open native database files and Integrated File System (IFS) files are closed, including sockets, NTC sessions, and memory maps.

Other resources are preserved when SET SESSION AUTHORIZATION is executed, including global variables and declared temporary tables. It is recommended that all declared temporary tables be dropped or cleared and global variables be cleared before executing the SET SESSION AUTHORIZATION statement.

SET SESSION AUTHORIZATION restrictions: This statement can only be issued as the first statement that results in work that might be backed out during the unit of work. The following executable statements may be issued prior to executing SET SESSION AUTHORIZATION:
• All SQL transaction statements
SET SESSION AUTHORIZATION

- All SQL connection statements
- All SQL session statements
- GET DIAGNOSTICS

SET SESSION AUTHORIZATION is not allowed if any connections other than the connection to the current server exist, including any local connections to a non-default activation group.

SET SESSION AUTHORIZATION is not allowed if any held cursors are open or any held locators exist.

**SET SESSION AUTHORIZATION scope**: The scope of the SET SESSION AUTHORIZATION is the current thread. Other threads in the application process are unaffected.

**Examples**

*Example 1*: The following statement sets the SESSION_USER special register.

```
SET SESSION_USER = RAJIV
```

*Example 2*: Set the session authorization ID (the SESSION_USER special register) to be the value of the system authorization ID, which is the ID that established the connection on which the statement has been issued.

```
SET SESSION AUTHORIZATION SYSTEM_USER
```
SET TRANSACTION

The SET TRANSACTION statement sets the isolation level, read only attribute, or diagnostics area size for the current unit of work.

Invocation

This statement can be embedded within an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If a global variable is referenced in the statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
  - The READ privilege on the global variable, and
  - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

```
SET TRANSACTION 
  ISOLATION LEVEL [SERIALIZABLE | NO COMMIT | READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ]
  READ ONLY | READ WRITE
  DIAGNOSTICS SIZE [integer | variable]
```

Notes:

1 Only one ISOLATION LEVEL clause, one READ WRITE or READ ONLY clause, and one DIAGNOSTICS SIZE clause may be specified.

Description

**ISOLATION LEVEL**

Specifies the isolation level of the transaction. If the ISOLATION LEVEL clause is not specified, ISOLATION LEVEL SERIALIZABLE is implicit

- **NO COMMIT**
  Specifies isolation level NC (COMMIT(*NONE)).

- **READ UNCOMMITTED**
  Specifies isolation level UR (COMMIT(*CHG)).

- **READ COMMITTED**
  Specifies isolation level CS (COMMIT(*CS)).

- **REPEATABLE READ**
  Specifies isolation level RS (COMMIT(*ALL)).

- **SERIALIZABLE**
  Specifies isolation level RR (COMMIT(*RR)).
SET TRANSACTION

READ WRITE or READ ONLY
Specifies whether the transaction allows data change operations.

READ WRITE
Specifies that all SQL operations are allowed. This is the default unless ISOLATION LEVEL READ UNCOMMITTED is specified.

READ ONLY
Specifies that only SQL operations that do not change SQL data are allowed. If ISOLATION LEVEL READ UNCOMMITTED is specified, this is the default.

DIAGNOSTICS SIZE
Specifies the maximum number of GET DIAGNOSTICS condition areas for the current transaction. The GET DIAGNOSTICS statement-information-item MORE will be set to 'Y' for the current statement if the statement exceeds the maximum number of condition areas for the current transaction. The maximum size of the diagnostics area is 90K. The specified maximum number of condition areas must be between 1 and 32767.

integer
An integer constant that specifies the maximum number of condition areas for the current transaction.

variable
Identifies a variable which contains the maximum number of condition areas for the current transaction. The variable must be a numeric variable with a zero scale and must not be followed by an indicator variable.

Notes

Scope of SET TRANSACTION: The SET TRANSACTION statement sets the isolation level for SQL statements for the current activation group of the process. If that activation group has commitment control scoped to the job, then the SET TRANSACTION statement sets the isolation level of all other activation groups with job commit scoping as well.

If an isolation clause is specified in an SQL statement, that isolation level overrides the transaction isolation level and is used for dynamic SQL statements.

The scope of the SET TRANSACTION statement is based on the context in which it is run. If the SET TRANSACTION statement is run in a trigger, the isolation level specified applies to all subsequent SQL statements until another SET TRANSACTION statement occurs or until the trigger completes, whichever happens first. If the SET TRANSACTION statement is run outside a trigger, the isolation level specified applies to all subsequent SQL statements (except those statements within a trigger that are executed after a SET TRANSACTION statement in the trigger) until a COMMIT or ROLLBACK operation occurs.

For more information about isolation levels, see "Isolation level" on page 27.

SET TRANSACTION restrictions: The SET TRANSACTION statement can only be executed when it is the first SQL statement in a unit of work, unless:
- all previous statements executed in the unit of work are SET TRANSACTION statements or statements that are executed under isolation level NC, or
- it is executed in a trigger.
In a trigger, SET TRANSACTION with READ ONLY is allowed only on a COMMIT boundary. The SET TRANSACTION statement can be executed in a trigger at any time, but it is recommended that it be executed as the first statement in the trigger. The SET TRANSACTION statement is useful within triggers to set the isolation level for SQL statements in the trigger to the same level as the application which caused the trigger to be activated.

A SET TRANSACTION statement is not allowed if the current connection is to a remote application server unless it is in a trigger at the current server. Once a SET TRANSACTION statement is executed, CONNECT and SET CONNECTION statements are not allowed until the unit of work is committed or rolled back.

SET TRANSACTION is not allowed as the first statement in a secondary thread.

The SET TRANSACTION statement has no effect on WITH HOLD cursors that are still open when the SET TRANSACTION statement is executed.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords NC or NONE can be used as synonyms for NO COMMIT.
- The keywords UR and CHG can be used as synonyms for READ UNCOMMITTED.
- The keyword CS can be used as a synonym for READ COMMITTED.
- The keywords RS or ALL can be used as synonyms for REPEATABLE READ.
- The keyword RR can be used as a synonym for SERIALIZABLE.

Examples

Example 1: The following SET TRANSACTION statement sets the isolation level to NONE (equivalent to specifying *NONE on the SQL precompiler command).

```sql
EXEC SQL SET TRANSACTION ISOLATION LEVEL NO COMMIT;
```

Example 2: The following SET TRANSACTION statement sets the isolation level to SERIALIZABLE.

```sql
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE
```
SET transition-variable

The SET transition-variable statement assigns values to new transition variables.

Invocation

This statement can only be used as an SQL statement in a BEFORE trigger. It is an executable statement that cannot be dynamically prepared.

Authorization

If a row-fullselect is specified, see “fullselect” on page 794 for an explanation of the authorization required for each subselect.

Syntax

```
SET transition-variable = expression
(NULL | DEFAULT)

(row-fullselect)
```

Notes:

1. The number of expressions, NULLs, and DEFAULTs must match the number of transition-variables.
2. The number of columns in the select list must match the number of transition-variables.

Description

```
transition-variable
```

Identifies the column to be updated in the new row. A transition-variable must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value. An OLD transition-variable must not be identified.

A transition-variable must not be identified more than once in the same SET transition-variable statement.

The data type of each transition-variable must be compatible with its corresponding result column. Values are assigned to transition-variables according to the storage assignment rules. For more information see “Assignments and comparisons” on page 99.

```
expression
```

Specifies the new value of the transition-variable. The expression is any expression of the type described in “Expressions” on page 174. The expression cannot include an aggregate function.

An expression may contain references to OLD and NEW transition-variables. If the CREATE TRIGGER statement contains both OLD and NEW clauses, references to transition-variables must be qualified by the correlation-name.
NULL
Specifies the null value. NULL can only be specified for nullable columns.

DEFAULT
Specifies that the default value of the column associated with the transition-variable will be used. DEFAULT is not allowed if the column is an IDENTITY column, a row change timestamp column, or has a ROWID data type.

row-fullselect
A fullselect that returns a single result row. The result column values are assigned to each corresponding transition-variable. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

Notes

Multiple assignments: If more than one assignment is included in the same SET transition-variable statement, all expressions are evaluated before the assignments are performed. Thus, references to transition-variables in an expression are always the value of the transition-variables prior to any assignment in the SET statement.

Examples

Example 1: Ensure that the salary column is never greater than 50000. If the new value is greater than 50000, set it to 50000.

```
CREATE TRIGGER LIMIT_SALARY
BEFORE INSERT ON EMPLOYEE
REFERENCING NEW AS NEW_VAR
FOR EACH ROW MODE DB2SQL
WHEN (NEW_VAR.SALARY > 50000)
BEGIN ATOMIC
    SET NEW_VAR.SALARY = 50000;
END
```

Example 2: When the job title is updated, increase the salary based on the new job title. Assign the years in the position to 0.

```
CREATE TRIGGER SET_SALARY
BEFORE UPDATE OF JOB ON STAFF
REFERENCING OLD AS OLD_VAR
NEW AS NEW_VAR
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
    SET (NEW_VAR.SALARY, NEW_VAR.YEARS) =
        (OLD_VAR.SALARY * CASE NEW_VAR.JOB
            WHEN 'Sales' THEN 1.1
            WHEN 'Mgr' THEN 1.05
            ELSE 1 END ,0);
END
```
**SET variable**

The SET variable statement produces a result table consisting of at most one row and assigns the values in that row to variables.

**Invocation**

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared if the all variables being set are global variables. It must not be specified in REXX.

**Authorization**

If a row-fullselect is specified, see "fullselect" on page 794 for an explanation of the authorization required for each subselect.

If a global variable is specified on the left hand side of the assignment, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

**Syntax**

```
SET variable = expression
```

```
row-fullselect:
```

```
fullselect
```

```
common-table-expression
```

**Description**

Identifies one or more variables or host structures that must be declared in accordance with the rules for declaring variables (see "References to host variables" on page 152). A host structure is logically replaced by a list of variables that represent each of the elements of the host structure.

The value to be assigned to each variable can be specified immediately following the variable, for example, `variable = expression`, `variable = expression`. Or, sets of parentheses can be used to specify all the variables and then all the values, for example, `(variable, variable) = (expression, expression)`. 
The data type of each variable must be compatible with its corresponding result column. Each assignment is made according to the rules described in "Assignments and comparisons" on page 99. The number of variables specified to the left of the equal operator must equal the number of values in the corresponding result specified to the right of the equal operator. If the value is null, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the variable, and no more values are assigned to variables. Any values that have already been assigned to variables remain assigned.

If an error occurs as the result of an arithmetic expression in the expression or SELECT list of the subselect (division by zero, or overflow) or a character conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided. The value of the variable is undefined. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, a warning is returned.) If you do not provide an indicator variable, an error is returned. It is possible that some values have already been assigned to variables and will remain assigned when the error occurs.

expression

Specifies the new value of the variable. The expression is any expression of the type described in "Expressions" on page 174. It must not include a column name.

NULL

Specifies that the new value for the variable is the null value.

DEFAULT

Specifies that the new value for the variable is its initial default value. DEFAULT can only be assigned to a global variable. Only one variable can be assigned in the SET statement when DEFAULT is used.

row-fullselect

A fullselect that returns a single result row. The result column values are assigned to each corresponding variable. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

WITH common-table-expression

Specifies a common table expression. For an explanation of common table expression, see "common-table-expression" on page 801.

fullselect

A fullselect that returns a single result row. The result column values are assigned to each corresponding variable. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

Notes

Variable assignment: If the specified variable is character and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA). The actual length of the result is returned in the indicator variable associated with the variable, if an indicator variable is provided.

If the specified variable is a C NUL-terminated variable and is not large enough to contain the result and the NUL-terminator:
SET variable

- If the *CNULRQD option is specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*YES) on the SET OPTION statement), the following occurs:
  - The result is truncated.
  - The last character is the NUL-terminator.
  - The value ‘W’ is assigned to SQLWARN1 in the SQLCA.
- If the *NOCNULRQD option on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement) is specified, the following occurs:
  - The NUL-terminator is not returned.
  - The value ‘N’ is assigned to SQLWARN1 in the SQLCA.

**Multiple assignments:** If more than one assignment is included in the same SET statement, all expressions and row-fullselects are completely evaluated before the assignments are performed. Thus, references to a target variable in an expression or row-fullselect are always the value of the target variable prior to any assignment in the SET statement.

**Examples**

**Example 1:** Assign the value of the CURRENT PATH special register to host variable HV1.

```
EXEC SQL SET :HV1 = CURRENT PATH;
```

**Example 2:** Assume that LOB locator LOB1 is associated with a CLOB value. Assign a portion of the CLOB value to host variable DETAILS using the LOB locator.

```
EXEC SQL SET :DETAILS = SUBSTR(:LOB1,1,35);
```
The SIGNAL statement signals an error or warning condition. It causes an error or warning to be returned with the specified SQLSTATE and optional condition-information-items.

**Invocation**

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

**Authorization**

None required.

**Syntax**

```
SIGNAL SQLSTATE [VALUE] sqlstate-string-constant | sqlstate-string-variable
| signal-information
```

**signal-information:**

```
SET MESSAGE_TEXT = variable diagnostic-string-constant
```

**Description**

**SQLSTATE VALUE**

Specifies the SQLSTATE that will be signalled. The specified value must not be null and must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00' since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is returned.
SIGNAL

sqlstate-string-constant

The sqlstate-string-constant must be a character string constant with exactly 5 characters.

sqlstate-string-variable

The sqlstate-string-variable must be a character or Unicode graphic variable. It cannot be a global variable. The actual length of the contents of the variable must be 5.

SET

Introduces the assignment of values to condition-information-items. The condition-information-item values can be accessed using the GET DIAGNOSTICS statement. The only condition-information-item that can be accessed in the SQLCA is MESSAGE_TEXT.

MESSAGE_TEXT

Specifies a string that describes the error or warning.

If an SQLCA is used,

- the string is returned in the SQLERRMC field of the SQLCA
- if the actual length of the string is longer than 1000 bytes, it is truncated without a warning.

CONSTRANIT_CATALOG

Specifies a string that indicates the name of the database that contains a constraint related to the signalled error or warning.

CONSTRANIT_SCHEMA

Specifies a string that indicates the name of the schema that contains a constraint related to the signalled error or warning.

CONSTRANIT_NAME

Specifies a string that indicates the name of a constraint related to the signalled error or warning.

CATALOG_NAME

Specifies a string that indicates the name of the database that contains a table or view related to the signalled error or warning.

SCHEMA_NAME

Specifies a string that indicates the name of the schema that contains a table or view related to the signalled error or warning.

TABLE_NAME

Specifies a string that indicates the name of a table or view related to the signalled error or warning.

COLUMN_NAME

Specifies a string that indicates the name of a column in the table or view related to the signalled error or warning.

CURSOR_NAME

Specifies a string that indicates the name of a cursor related to the signalled error or warning.

CLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE class related to the signalled error or warning.

SUBCLASS_ORIGIN

Specifies a string that indicates the origin of the SQLSTATE subclass related to the signalled error or warning.
variable
Identifies a variable that must be declared in accordance with the rules for
declaring variables (see “References to host variables” on page 152). The
variable contains the value to be assigned to the condition-information-item.
The variable must be defined as CHAR, VARCHAR, Unicode GRAPHIC,
or Unicode VARGRAPHIC variable. It cannot be a global variable.

diagnostic-string-constant
Specifies a character string constant that contains the value to be assigned
to the condition-information-item.

Notes

SQLSTATE values: Any valid SQLSTATE value can be used in the SIGNAL
statement. However, it is recommended that programmers define new SQLSTATEs
based on ranges reserved for applications. This prevents the unintentional use of
an SQLSTATE value that might be defined by the database manager in a future
release.

SQLSTATE values are comprised of a two-character class code value, followed by a
three-character subclass code value. Class code values represent classes of
successful and unsuccessful execution conditions.
  • SQLSTATE classes that begin with the characters ‘7’ through ‘9’ or ‘I’ through ‘Z’
    may be defined. Within these classes, any subclass may be defined.
  • SQLSTATE classes that begin with the characters ‘0’ through ‘6’ or ‘A’ through ‘H’
    are reserved for the database manager. Within these classes, subclasses that
    begin with the characters ‘0’ through ‘H’ are reserved for the database manager.
    Subclasses that begin with the characters ‘I’ through ‘Z’ may be defined.

For more information about SQLSTATEs, see the SQL Messages and Codes

Assignment: When the SIGNAL statement is executed, the value of each of the
specified string-constants and variables is assigned to the corresponding
condition-information-item. However, if the length of a string-constant or variable
is longer than the maximum length of the corresponding condition-information-item, it
is truncated without a warning. For details on the assignment rules, see
“Assignments and comparisons” on page 99. For details on the maximum length of
specific condition-information-items, see “GET DIAGNOSTICS” on page 1388.

Processing a SIGNAL statement: When a SIGNAL statement is issued, the
SQLCODE is based on the SQLSTATE value as follows:
  • If the specified SQLSTATE class is either ‘01’ or ‘02’, a warning or not found is
    signalled and the SQLCODE is set to +438.
  • Otherwise, an exception is signalled and the SQLCODE is set to –438.

Examples

Example 1: Signal SQLSTATE ‘75002’ with a descriptive message text.
EXEC SQL SIGNAL SQLSTATE ‘75002’
  SET MESSAGE_TEXT = 'Customer number is not known';

Example 2: Signal SQLSTATE ‘75002’ with a descriptive message text and associate a
specific table with the error.
EXEC SQL SIGNAL SQLSTATE '75002'
  SET MESSAGE_TEXT = 'Customer number is not known',
  SCHEMA_NAME = 'CORPDATA',
  TABLE_NAME = 'CUSTOMER';
TRANSFER OWNERSHIP

The TRANSFER OWNERSHIP statement transfers ownership of a database object.

Invocation

This statement can be embedded in an application program or issued interactivelly. It is an executable statement that can be dynamically prepared.

Authorization

To transfer ownership for a table, view, or index, the authorization ID of the statement must be the owner of the object and the privileges held must include at least one of the following:

- The following system authorities:
  - The system authorities of *OBJOPR and *OBJEXIST on the object to be transferred
  - The system authority *EXECUTE on the library that contains the object to be transferred
- Database administrator authority
- Security administrator authority

For information about the system authorities corresponding to SQL privileges, see Corresponding System Authorities When Checking Privileges to a Table or View.

Syntax

```
TRANSFER OWNERSHIP OF object TO new-owner

object:

INDEX index-name
TABLE table-name
VIEW view-name

new-owner:

USER authorization-name
CURRENT USER
SESSION_USER
USER
SYSTEM_USER

REVOKE PRIVILEGES
PRESERVE PRIVILEGES
```

Description

**INDEX** *index-name*
Identifies the index that is to have its ownership transferred. The *index-name* must identify an index that exists at the current server.

**TABLE** *table-name*
Identifies the table that is to have its ownership transferred. The *table-name*
must identify a base table that exists at the current server, but must not identify a declared global temporary table or a catalog table.

**VIEW** view-name
Identifies the view that is to have its ownership transferred. The view-name must identify a view that exists at the current server, but must not identify a catalog view.

**USER** authorization-name
Specifies the authorization ID to which ownership of the object is being transferred.

**CURRENT USER or CURRENT_USER**
Specifies that the value of the CURRENT USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

**SESSION_USER or USER**
Specifies that the value of the SESSION_USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

**SYSTEM_USER**
Specifies that the value of the SYSTEM_USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

**REVOKE PRIVILEGES or PRESERVE PRIVILEGES**
Specifies the privileges of the current owner of the object after the ownership is transferred.

**REVOKE PRIVILEGES**
Specifies that the current owner will not have any explicit privileges to the object after the transfer is complete.

**PRESERVE PRIVILEGES**
Specifies that the current owner of an object that is to have its ownership transferred will continue to hold any existing privileges on the object after the transfer. For example, any privileges that were granted to the creator of a view continue to be held by the original owner even after ownership has been transferred to another user.

**Rules**

Ownership of most system-defined objects cannot be transferred.

Ownership of objects in a schema whose name starts with 'SYS' or 'Q' cannot be transferred.

An authorization ID that has security administrator authority cannot transfer ownership of an object to itself, if it is not already the owner of the object.

**Notes**

- All privileges that the current owner has on the object are transferred to the new owner.
- When the ownership of a database object is transferred, the new owner will not necessarily have privileges for the object’s dependencies.
- If an attempt is made to transfer ownership of an object to its owner, a warning is returned.
Examples

*Example 1:* Transfer ownership of table T1 to PAUL.

```
TRANSFER OWNERSHIP OF TABLE WALID.T1
    TO USER PAUL PRESERVE PRIVILEGES
```  

Paul becomes the owner of table WALID.T1 and is granted all the privileges that the previous owner of the table had. The prior owner retains all privileges as well.

*Example 2:* Transfer ownership of view V1 to HENRY and remove privileges from the previous owner

```
TRANSFER OWNERSHIP OF VIEW V1
    TO USER HENRY
```  

Henry becomes the owner of view V1 and is granted all the privileges that the previous owner of the view had. The prior owner no longer has any explicit privileges on the view.
The TRUNCATE statement deletes all of the rows from a table.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table identified in the statement:
  - The DELETE privilege on the table, and
  - The system authority *EXECUTE on the library containing the table.
- Database administrator authority

If the IGNORE DELETE TRIGGERS option is specified, the privileges held by the authorization ID of the statement must include the following:

- The ALTER privilege on the table and the system authority of *OBJOPR on the table.

If row access control or column access control is activated for the table, the privileges held by the authorization ID of the statement must include the following:

- The system authorities of *OBJOPR and *OBJEXIST on the table.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

**Syntax**

```
TRUNCATE [TABLE] table-name [DROP STORAGE | REUSE STORAGE]
```

**Description**

- **table-name**
  Identifies the table from which rows are to be deleted. The name must identify a table that exists at the current server. It must not identify a catalog table, a view, or a system-period temporal table.

- **DROP STORAGE** or **REUSE STORAGE**
  Specifies whether to drop or reuse the existing storage that is allocated for the table.

- **DROP STORAGE**
  All storage allocated for the table is released and made available. This is the default.
REUSE STORAGE
All storage allocated for the table will continue to be allocated for the table, but the storage will be considered empty.

IGNORE DELETE TRIGGERS or RESTRICT WHEN DELETE TRIGGERS
Specifies what to do when delete triggers are defined on the table.

IGNORE DELETE TRIGGERS
Specifies that any delete triggers that are defined for the table are not activated by the truncation operation. This is the default.

RESTRICT WHEN DELETE TRIGGERS
Specifies that an error is returned if delete triggers are defined on the table.

CONTINUE IDENTITY or RESTART IDENTITY
Specifies how to handle generation of identity column values.

CONTINUE IDENTITY
If an identity column exists for the table, the next identity column value generated continues with the next value that would have been generated if the TRUNCATE statement had not been executed. This is the default.

RESTART IDENTITY
If an identity column exists for the table, the next identity column value generated is the initial value that was specified when the identity column was defined.

IMMEDIATE
Specifies that the truncate operation is processed immediately and cannot be undone.

The truncated table is immediately available for use in the same unit of work. Although a ROLLBACK statement is allowed to execute after a TRUNCATE statement, the truncate operation is not undone, and the table remains in a truncated state. For example, if another data change operation is done on the table after the TRUNCATE IMMEDIATE statement and then the ROLLBACK statement is executed, the truncate operation will not be undone, but all other data change operations are undone.

The truncate operation cannot be performed if any session has a cursor open on the table or holds a lock on the table.

If IMMEDIATE is not specified, a ROLLBACK statement can undo the truncate operation.

Notes

Referential Integrity: The identified table cannot be a parent table in a referential constraint.

Number of rows deleted: The ROW_COUNT condition area item in the SQL Diagnostics Area (or SQLERRD(3) in the SQLCA) is set to -1 for the truncate operation. The total number of rows that were deleted from the table is not returned.

If no rows exist in the table, a SQLSTATE value of '02000' is returned.

For a description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),” on page 1737.
Examples

Example 1: Empty an unused inventory table regardless of any existing triggers and return its allocated space.

```sql
TRUNCATE TABLE INVENTORY
   DROP STORAGE
   IGNORE DELETE TRIGGERS;
```

Example 2: Empty an unused inventory table regardless of any existing triggers but preserve its allocated space for later reuse.

```sql
TRUNCATE TABLE INVENTORY
   REUSE STORAGE
   IGNORE DELETE TRIGGERS;
```

Example 3: Empty an unused inventory table permanently (a ROLLBACK statement cannot undo the truncate operation when the IMMEDIATE option is specified) regardless of any existing triggers and preserve its allocated space for reuse.

```sql
TRUNCATE TABLE INVENTORY
   REUSE STORAGE
   IGNORE DELETE TRIGGERS
   IMMEDIATE;
```
The UPDATE statement updates the values of specified columns in rows of a table or view. Updating a row of a view updates a row of its base table, if no INSTEAD OF UPDATE trigger is defined on this view. If such a trigger is defined, the trigger will be activated instead.

There are two forms of this statement:

- The *Searched* UPDATE form is used to update one or more rows (optionally determined by a search condition).
- The *Positioned* UPDATE form is used to update exactly one row (as determined by the current position of a cursor).

**Invocation**

A Searched UPDATE statement can be embedded in an application program or issued interactively. A Positioned UPDATE must be embedded in an application program. Both forms are executable statements that can be dynamically prepared.

**Authorization**

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table or view identified in the statement:
  - The UPDATE privilege on the table or view, or
  - The UPDATE privilege on each column to be updated; and
  - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

If the *expression* in the *assignment-clause* contains a reference to a column of the table or view, or if the *search-condition* in a Searched UPDATE contains a reference to a column of the table or view, then the privileges held by the authorization ID of the statement must also include one of the following:

- The SELECT privilege on the table or view
- security administrator authority

If the *search-condition* includes a subquery or if the *assignment-clause* includes a *scalar-fullselect* or *row-fullselect*, see [Chapter 6, “Queries,” on page 741](#) for an explanation of the authorization required for each subselect.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

**Syntax**

**Searched UPDATE:**

```sql
UPDATE table-name [view-name] [correlation-clause]
```
UPDATE

- OVERRIDING SYSTEM VALUE
- OVERRIDING USER VALUE

WHERE search-condition

| order-by-clause | offset-clause | fetch-clause |

| isolation-clause |
| concurrent-access-resolution-clause |

Positioned UPDATE:

UPDATE table-name | view-name | correlation-clause

- OVERRIDING SYSTEM VALUE
- OVERRIDING USER VALUE

WHERE CURRENT OF cursor-name

assignment-clause:

| column-name | expression |
| NULL | DEFAULT |

| column-name | expression |
| NULL | DEFAULT |

ROW | expression |
| NULL | DEFAULT |

row-fullselect
order-by-clause:

ORDER BY sort-key-expression ASC, DESC

isolation-clause:

WITH NC UR CS RS RR

Description

table-name or view-name

Identifies the table or view to be updated. The name must identify a table or view that exists at the current server, but it must not identify a history table, a catalog table, a view of a catalog table, or a read-only view. For an explanation of read-only views and updatable views, see "CREATE VIEW" on page 1255.

correlation-clause

Can be used within search-condition or assignment-clause to designate the table or view. For an explanation of correlation-clause, see "table-reference" on page 748. For an explanation of correlation-name, see "Correlation names" on page 143.

OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE

Specifies whether system-generated values or user-specified values for a ROWID, identity, or row change timestamp column are used. If OVERRIDING SYSTEM VALUE is specified, the implicit or explicit list of columns in the SET clause must contain a ROWID, identity, or row change timestamp column defined as GENERATED ALWAYS. If OVERRIDING USER VALUE is specified, the implicit or explicit list of columns in the SET clause must contain a column defined as either GENERATED ALWAYS or GENERATED BY DEFAULT.

OVERRIDING SYSTEM VALUE

Specifies that the value specified in the SET clause for a ROWID, identity, or row change timestamp column that is defined as GENERATED ALWAYS is used. A system-generated value is not used.

If a value for a row-begin, row-end, transaction-start-ID, or generated expression column is provided, it must be DEFAULT.

OVERRIDING USER VALUE

Specifies that the value specified in the SET clause for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is used, overriding the user-specified value.

If neither OVERRIDING SYSTEM VALUE or OVERRIDING USER VALUE is specified:

• A value cannot be specified for a ROWID, identity, row change timestamp, row-begin, row-end, transaction-start-ID, or generated expression column that is defined as GENERATED ALWAYS.
UPDATE

- A value can be specified for a ROWID column that is defined as GENERATED BY DEFAULT. If a value is specified, that value is assigned to the column. However, a value in a ROWID column defined BY DEFAULT can be updated only if the specified value is a valid row ID value that was previously generated by Db2 for z/OS or Db2 for i.

- A value can be specified for an identity or row change timestamp column that is defined as GENERATED BY DEFAULT. When a value of an identity column or row change timestamp column defined BY DEFAULT is updated, the database manager does not verify that the specified value is a unique value for the column unless the identity column or row change timestamp column is the sole key in a unique constraint or unique index. Without a unique constraint or unique index, the database manager can guarantee unique values only among the set of system-generated values as long as NO CYCLE is in effect.

If a value is not specified the database manager generates a new value.

SET

Introduces the assignment of values to column names.

assignment-clause

column-name

Identifies a column to be updated. The column-name must identify a column of the specified table or view. If extended indicator variables are not enabled, that column must not identify a view column derived from a scalar function, constant, or expression. A column must not be specified more than once.

For a Positioned UPDATE:

- If the UPDATE clause was specified in the SELECT statement of the cursor, each column name in the SET list must also appear in the UPDATE clause.
- If the UPDATE clause was not specified in the SELECT statement of the cursor, the name of any updatable column may be specified.

For more information, see "update-clause" on page 808.

A view column derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same UPDATE statement.

If a list of column-names is specified, the number of expressions, NULLs, and DEFAULTS must match the number of column-names.

ROW

Identifies all the columns of the specified table or view except for columns defined with the hidden attribute. If a view is specified, none of the columns of the view may be derived from a scalar function, constant, or expression.

The number of expressions, NULLs, and DEFAULTs (or the number of result columns from a row-fullselect) must match the number of columns in the row.

For a Positioned UPDATE, if the UPDATE clause was specified in the SELECT statement of the cursor, each column of the table or view must also appear in the UPDATE clause. For more information, see "update-clause" on page 808.
ROW may not be specified for a view that contains a view column derived from the same column as another column of the view, because both columns cannot be updated in the same UPDATE statement.

**expression**

Specifies the new value of the column. The expression is any expression of the type described in “Expressions” on page 174. It must not include an aggregate function.

A column-name in an expression must name a column of the named table or view. For each row updated, the value of the column in the expression is the value of the column in the row before the row is updated.

Each variable in the clause must identify a host structure or variable that is declared in accordance with the rules for declaring host structures and variables. In the operational form of the statement, a reference to a host structure is replaced by a reference to each of its variables. If expression is a single host variable, the host variable can include an indicator that is enabled for extended indicator variables. If extended indicator variables are enabled and an expression in the assignment clause is not a single host variable, the extended indicator variable values of DEFAULT and UNASSIGNED must not be used. For further information about variables and structures, see “References to host variables” on page 152 and “Host structures” on page 158. If a host structure is specified, the keyword ROW must be specified.

**NULL**

Specifies the new value for a column is the null value. NULL should only be specified for nullable columns.

**DEFAULT**

Specifies that the default value is assigned to a column. The value that is used depends on how the column was defined, as follows:

- If the column is defined as a generated column based on an expression, the column value will be generated by the database manager, based on the expression.
- If the column is a ROWID, identity column, row-begin column, row-end column, or transaction-start-ID column, the database manager will generate a new value.
- If the WITH DEFAULT clause is used, the default used is as defined for the column (see default-clause in column-definition in “CREATE TABLE” on page 1159).
- If the WITH DEFAULT clause or the NOT NULL clause is not used, the value used is NULL.
- If the column is defined as a row change timestamp column, a new row change timestamp value is assigned to the column.

If the NOT NULL clause is used and the WITH DEFAULT clause is not used, or if DEFAULT NULL is used, the DEFAULT keyword cannot be specified for that column.

DEFAULT must be specified for an identity column defined as GENERATED ALWAYS unless OVERRIDING SYSTEM VALUE is used.

The only value that a row-begin, row-end, transaction-start-ID, or generated expression column can be set to is DEFAULT.

**row-fullselect**

A fullselect that returns a single result row. The number of result columns
in the select list must match the number of column-names (or if ROW is specified, the number of columns in the row) specified for assignment. The result column values are assigned to each corresponding column-name. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

The row-fullselect may contain references to columns of the target table of the UPDATE statement. For each row updated, the value of such a column in the expression is the value of the column in the row before the row is updated.

WHERE

Specifies the rows to be updated. The clause can be omitted, or a search-condition or cursor-name can be specified. If the clause is omitted, all rows of the table or view are updated.

search-condition

Is any search described in "Search conditions" on page 249. Each column-name in the search condition, other than in a subquery, must name a column of the table or view. When the search condition includes a subquery in which the same table is the base object of both the UPDATE and the subquery, the subquery is completely evaluated before any rows are updated.

The search-condition is applied to each row of the table or view. The updated rows are those for which the results of the search-condition are true.

If the search-condition contains a subquery, the subquery can be thought of as being executed each time the search-condition is applied to a row, and the results of that subquery used in applying the search-condition. In actuality, a subquery with no correlated references may be executed only once. A subquery with a correlated reference may have to be executed once for each row.

CURRENT OF cursor-name

Identifies the cursor to be used in the update operation. The cursor-name must identify a declared cursor as explained in "DECLARE CURSOR" on page 1265.

The table or view named must also be named in the FROM clause of the SELECT statement of the cursor, and the result table of the cursor must not be read-only. For an explanation of read-only result tables, see "DECLARE CURSOR" on page 1265.

The DECLARE CURSOR statement must not have a period-specification for the table or view used by the update statement.

When the UPDATE statement is executed, the cursor must be positioned on a row; that row is updated.

order-by-clause

Specifies the order of the rows for application of the offset-clause and fetch-clause. An order-by-clause should be specified to ensure a predictable order for determining the set of rows to be updated based on the offset-clause and fetch-clause.

sort-key-expression

An expression that specifies the value that is to be used to order the rows that qualify for the update operation. If a single sort-key-expression is identified, the rows are ordered by the values of that sort-key-expression. If
more than one sort-key-expression is identified, the rows are ordered by the 
values of the first sort-key-expression, then by the values of the second 
sort-key-expression, and so on.

The result of the sort-key-expression must not be DATALINK or XML.

ASC
Uses the values of the sort-key-expression in ascending order. This is the 
default.

DESC
Uses the values of the sort-key-expression in descending order.

Ordering is performed in accordance with the comparison rules described in 
Chapter 2, “Language elements,” on page 49. The null value is higher than all 
other values. If your ordering specification does not determine a complete 
ordering, rows with duplicate values of the last identified sort-key-expression 
have an arbitrary order. If you do not specify ORDER BY, the rows to be 
updated have an arbitrary order.

offset-clause
Limits the effect of the update by skipping a subset of the qualifying rows. For 
more information on the offset-clause, see "offset-clause” on page 789.

fetch-clause
Limits the effect of the update to a subset of the qualifying rows. For more 
information on the fetch-clause, see "fetch-clause” on page 790.

isolation-clause
Specifies the isolation level to be used for this statement.

WITH
Introduces the isolation level, which may be one of:
• RR Repeatable read
• RS Read stability
• CS Cursor stability
• UR Uncommitted read
• NC No commit

If isolation-clause is not specified the default isolation is used. See 
"isolation-clause” on page 811 for a description of how the default is 
determined.

concurrent-access-resolution-clause
Specifies the concurrent access resolution to use for the select statement. For 
more information, see "concurrent-access-resolution-clause” on page 813.

UPDATE Rules

Assignment: Update values are assigned to columns in accordance with the 
storage assignment rules described in "Assignments and comparisons” on page 99.

Validity: Updates must obey the following rules. If they do not, or if any other 
errors occur during the execution of the UPDATE statement, no rows are updated.
• Fullselects: The row-fullselect or scalar-fullselect shall return no more than one row 
(SQLSTATE 21000).
• Unique constraints and unique indexes: If the identified table, or the base table of 
the identified view, has one or more unique indexes or unique constraints, each
row update in the table must conform to the limitations imposed by those indexes and constraints (SQLSTATE 23505).

All uniqueness checks are effectively made at the end of the statement. In the case of a multiple-row UPDATE statement of a column involved in a unique index or unique constraint, this would occur after all rows were updated.

- **Check constraints:** If the identified table, or the base table of the identified view, has one or more check constraints, each check constraint must be true or unknown for each row updated in the table (SQLSTATE 23513).

All check constraints are effectively validated at the end of the statement. In the case of a multiple-row UPDATE statement, this would occur after all rows were updated.

- **Views and the WITH CHECK OPTION:** If a view is identified, the updated rows must conform to any applicable WITH CHECK OPTION (SQLSTATE 44000). For more information, see “[CREATE VIEW” on page 1255].

**Triggers:** If the identified table or the base table of the identified view has an update trigger, the trigger is activated. A trigger might cause other statements to be executed or raise error conditions based on the updated values.

**Referential Integrity:** The value of the parent key in a parent row row must not be changed.

If the update values produce a foreign key that is nonnull, the foreign key must be equal to some value of the parent key of the parent table of the relationship.

The referential constraints (other than a referential constraint with a RESTRICT delete rule) are effectively checked at the end of the statement. In the case of a multiple-row UPDATE statement, this would occur after all rows were updated.

**XML values:** When an XML column is updated, the new value must be a well-formed XML document.

**Updating rows in a table for which row or column access control is enforced:**
When an UPDATE statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be updated. Typically those rules are based on the authorization ID of the statement. The following describes how enabled row permissions and column masks are used during UPDATE:

- **Row permissions are used to identify the set of rows to be updated.**
  When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID of the statement. If the WHERE clause is specified in the UPDATE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be updated. If there is no WHERE clause, all the accessible rows are the rows to be updated.

- **If there are rows to be updated, the following rules determine whether those rows can be updated:**
  - When a column is referenced while deriving the values of a new row, if the column has an enabled column mask, the masked value is used to derive the new values. If the object table also has column access control activated, the column mask that is applied to derive the new values must return the column
itself, not a constant or an expression. If the column mask does not mask the
column to itself, the new value cannot be used for update and an error is
returned.

- If the rows are updatable, and there is a BEFORE UPDATE trigger for the
table, the trigger is activated.
  Within the trigger actions, the new values for update might be modified in
  transition variables. When the final values are returned from the trigger, the
  new values are used for the update.
- The rows that are to be updated must conform to the enabled row
  permissions:
    For each row that is to be updated, the old values are replaced with the new
    values that were specified in the UPDATE statement. A row that conforms to
    the enabled row permissions is a row that, if updated, can be retrieved using
    the derived row access control search condition.
- If the rows are updatable, and there is an AFTER UPDATE trigger for the
  table, the trigger is activated.

Masked data can be assigned to a variable used as a value for the update
operation. If an update violation check constraint does not exist for the column, the
masked data will be updated into the column and no error will be issued.

Updating a partitioning key of a partitioned table: If a partitioning key of a row
of a partitioned table is updated such that the row belongs in a different partition:
- The specified target table must not be an alias that references a single partition
  of the table.
- The specified target table must be journaled.

Extended indicator variable usage: If enabled, indicator variable values other than
positive values and 0 (zero) through -7 must not be used. The DEFAULT and
UNASSIGNED extended indicator variable values must not appear in contexts in
which they are not supported.

Extended indicator variables: In the assignment-clause of an UPDATE statement, an
expression that is a reference to a single host variable can result in assigning an
extended indicator variable value. Assigning an extended indicator variable value
of UNASSIGNED has the same effect as if the column hadn't been specified in the
assignment-clause. Assigning an extended indicator variable value of DEFAULT can
only be used for a column that has a default value or that is defined as
GENERATED ALWAYS and will have a new value generated, such as a row
change timestamp column.

If a target column is not updatable, it must be assigned the extended indicator
variable value of UNASSIGNED, unless it is a generated column defined as
GENERATED ALWAYS. If the target column is a generated column defined as
GENERATED ALWAYS, then it must be assigned the extended indicator variable
value of DEFAULT or UNASSIGNED.

An UPDATE statement must not assign all target columns from an extended
indicator variable value of UNASSIGNED.

Extended indicator variables and update triggers: If a target column has been
assigned an extended indicator variable value of UNASSIGNED, that column is
not considered to have been updated.
Extended indicator variables and deferred error checks: When extended indicator variables are enabled, validation that would otherwise be done during statement preparation to recognize an update of a non-updatable column is deferred until the statement is executed.

Considerations for a system-period temporal table: When a row of a system-period temporal table is updated, the database manager updates the values of the row-begin and transaction-start-ID columns as follows:

- A row-begin column is assigned a value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. If multiple rows are updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.

- A transaction start-ID column is assigned a unique timestamp value per transaction or the null value. The null value is assigned to the transaction start-ID column if the column is nullable and there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. If multiple rows are updated within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

If the UPDATE statement has a search condition containing a correlated subquery that references historical rows (explicitly referencing the name of the history table name or implicitly through the use of a period specification in the FROM clause), the old version of the updated rows that are inserted as historical rows (into the history table if any) are potentially visible to update operations for the rows subsequently processed for the statement.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the underlying target (direct or indirect) of the UPDATE statement cannot be a system-period temporal table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value and the value of the SYSTIME option is YES, the target of an UPDATE statement cannot be a view defined with the WITH CHECK OPTION if the view definition includes a WHERE clause containing an invocation of an external routine with a data access indication other than NO SQL.

Considerations for a history table: When a row of a system-period temporal table is updated, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change.
operation. The database manager assigns the value that is generated using a
reading of the time-of-day clock during execution of the first data change
statement in the transaction that requires a value to be assigned to the row begin
or transaction start-ID column in a table, or a row in a system-period temporal
table is deleted. The database manager ensures uniqueness of the generated values
for an end column in a history table across transactions. The timestamp value
might be adjusted to ensure that rows inserted into the history table have the end
timestamp value greater than the begin timestamp value which can happen when
a conflicting transaction is updating the same row in the system-period temporal
table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for
this adjustment to the timestamp value to occur. Otherwise, an error is returned.

For an update operation, the adjustment only affects the value for the end column
corresponding to the row-end column in the history table associated with the
system-period temporal table. Take these adjustments into consideration on
subsequent references to the table whether there is a search for the transaction start
time in the values for the columns corresponding to the row-begin and row-end
columns of the period in the associated system-period temporal table.

Notes

Update operation errors: If an update value violates any constraints, or if any
other error occurs during the execution of the UPDATE statement and
COMMIT(*NONE) was not specified, all changes made during the execution of the
statement are backed out. However, other changes in the unit of work made prior
to the error are not backed out. If COMMIT(*NONE) is specified, changes are not
backed out.

It is possible for an error to occur that makes the state of the cursor unpredictable.

Number of rows updated: When an UPDATE statement completes execution, the
number of rows updated is returned in the ROW_COUNT statement information
item in the SQL Diagnostics Area (and SQLERRD(3) in the SQLCA). For a
description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),”
on page 1737.

For a description of ROW_COUNT, see “GET DIAGNOSTICS” on page 1388. For a
description of the SQLCA, see Appendix C, “SQLCA (SQL communication area),”
on page 1737.

Locking: Unless appropriate locks already exist, one or more exclusive locks are
acquired by the execution of a successful UPDATE statement. Until these locks are
released by a commit or rollback operation, the updated rows can only be accessed by:

• The application process that performed the update.
• Another application process using COMMIT(*NONE) or COMMIT(*CHG)
  through a read-only operation

The locks can prevent other application processes from performing operations on
the table. For further information about locking, see the description of the
COMMIT, ROLLBACK, and LOCK TABLE statements, and isolation levels in
“Isolation level” on page 27. Also, see the Database Programming topic collection.

A maximum of 500 000 000 rows can be updated or changed in any single
UPDATE statement when COMMIT(*RR), COMMIT(*ALL), COMMIT(*CS), or
COMMIT(*CHG) has been specified. The number of rows changed includes any rows inserted, updated, or deleted under the same commitment definition as a result of a trigger.

**REXX:** Variables cannot be used in the UPDATE statement within a REXX procedure. Instead, the UPDATE must be the object of a PREPARE and EXECUTE using parameter markers.

**Datalinks:** If the URL value of a DATALINK column is updated, this is the same as deleting the old DATALINK value then inserting the new one. First, if the old value was linked to a file, that file is unlinked. Then, unless the linkage attributes of the DATALINK value are empty, the specified file is linked to that column.

The comment value of a DATALINK column can be updated without relinking the file by specifying an empty string as the URL path (for example, as the data-location argument of the DLVALUE scalar function or by specifying the new value to be the same as the old value). If a DATALINK column is updated with a null, it is the same as deleting the existing DATALINK value.

An error may occur when attempting to update a DATALINK value if the file server of either the existing value or the new value is no longer registered with the database server.

**Syntax alternatives:** The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword NONE can be used as a synonym for NC.
- The keyword CHG can be used as a synonym for UR.
- The keyword ALL can be used as a synonym for RS.

**Examples**

**Example 1:** Change the job (JOB) of employee number (EMPNO) ‘000290’ in the EMPLOYEE table to ‘LABORER’.

```
UPDATE EMPLOYEE
SET JOB = 'LABORER'
WHERE EMPNO = '000290'
```

**Example 2:** Increase the project staffing (PRSTAFF) by 1.5 for all projects that department (DEPTNO) ‘D21’ is responsible for in the PROJECT table.

```
UPDATE PROJECT
SET PRSTAFF = PRSTAFF + 1.5
WHERE DEPTNO = 'D21'
```

**Example 3:** All the employees except the manager of department (WORKDEPT) ‘E21’ have been temporarily reassigned. Indicate this by changing their job (JOB) to NULL and their pay (SALARY, BONUS, COMM) values to zero in the EMPLOYEE table.

```
UPDATE EMPLOYEE
SET JOB=NULL, SALARY=0, BONUS=0, COMM=0
WHERE WORKDEPT = 'E21' AND JOB <> 'MANAGER'
```

**Example 4:** In a Java program display the rows from the EMPLOYEE table on the connection context ‘ctx’ and then, if requested to do so, change the job (JOB) of certain employees to the new job keyed in (NEWJOB).
#sql iterator empIterator implements sqlj.runtime.ForUpdate
with(updateColumns='JOB')
(...);
empIterator C1;

#sql [ctx] C1 = { SELECT * FROM EMPLOYEE };

#sql { FETCH :C1 INTO ... };
while (!C1.endFetch()) {
    System.out.println(...);
    ...
    if (condition for updating row) {
        #sql [ctx] { UPDATE EMPLOYEE
            SET JOB = :NEWJOB
            WHERE CURRENT OF :C1 };
    }
    #sql { FETCH :C1 INTO ... };
}
C1.close();
VALUES

The VALUES statement is a form of query. It can be embedded in an SQLJ application program or issued interactively.

For detailed information, see “fullselect” on page 794.
VALUES INTO

The VALUES INTO statement produces a result table consisting of at most one row and assigns the values in that row to variables.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared, but cannot be issued interactively unless all variables being assigned are global variables. It must not be specified in REXX or Java.

Authorization

If a row-fullselect is specified, see Chapter 6, “Queries,” on page 741 for an explanation of the authorization required for each subselect.

If a global variable is specified on the right hand side of the assignment, the privileges held by the authorization ID of the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

Syntax

\[
\text{VALUES} \ (\text{expression} \ (\text{null}) \ (, \text{expression} \ (\text{null}) \text{row-fullselect}) \ \text{INTO} \ \text{variable},...\]

Description

VALUES

Introduces a single row consisting of one or more columns.

expression

Specifies the new value of the variable. The expression is any expression of the type described in “Expressions” on page 174. It must not include a column name. Host structures are not supported.

NULL

Specifies that the new value for the variable is the null value.

row-fullselect

A fullselect that returns a single result row. The result column values are assigned to each corresponding variable. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

INTO variable,...

Identifies one or more host structures or variables that must be declared in the program in accordance with the rules for declaring host structures and
variables. In the operational form of INTO, a reference to a host structure is replaced by a reference to each of its variables. The first value specified is assigned to the first variable, the second value to the second variable, and so on.

Notes

Variable assignment: Each assignment to a variable is performed according to the retrieval assignment rules described in "Assignments and comparisons" on page 99. If the number of variables is less than the number of values in the row, an SQL warning (SQLSTATE 01503) is returned (and the SQLWARN3 field of the SQLCA is set to 'W'). Note that there is no warning if there are more variables than the number of result columns. If a value is null, an indicator variable must be provided for that value.

If the specified variable is character and is not large enough to contain the result, a warning (SQLSTATE 01004) is returned (and 'W' is assigned to SQLWARN1 in the SQLCA). The actual length of the result may be returned in the indicator variable associated with the variable, if an indicator variable is provided. For further information, see "Variables" on page 150.

If an assignment error occurs, the value is not assigned to the variable, and no more values are assigned to variables. Any values that have already been assigned to variables remain assigned.

If the specified variable is a C NUL-terminated host variable and is not large enough to contain the result and the NUL-terminator:

- If the *CNULRQD option is specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*YES) on the SET OPTION statement), the following occurs:
  - The result is truncated.
  - The last character is the NUL-terminator.
  - The value 'W' is assigned to SQLWARN1 in the SQLCA.
- If the *NOCNULRQD option on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement) is specified, the following occurs:
  - The NUL-terminator is not returned.
  - The value 'N' is assigned to SQLWARN1 in the SQLCA.

Result column evaluation considerations: If an error occurs while evaluating a result column in the expression list of a VALUES INTO statement as the result of an arithmetic expression (such as division by zero, or overflow) or a numeric or character conversion error, the result is the null value. As in any other case of a null value, an indicator variable must be provided. The value of the variable is undefined. In this case, however, the indicator variable is set to the value of -2. Processing of the statement continues and a warning is returned. If an indicator variable is not provided, an error is returned and no more values are assigned to variables. It is possible that some values have already been assigned to variables and will remain assigned when the error is returned.

128. If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information about the standards option, see "Standards compliance" on page xi.
When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, depending on how much of the value would have to be truncated, a warning or error is returned. See "Datetime assignments" on page 106 for details.

**Multiple assignments:** If more than one variable is specified in the INTO clause, all expressions are evaluated before the assignments are performed. Thus, references to a variable in an expression are always the value of the variable prior to any assignment in the VALUES INTO statement.

**Examples**

*Example 1:* Assign the value of the CURRENT PATH special register to host variable HV1.

```
EXEC SQL VALUES CURRENT PATH
    INTO :HV1;
```

*Example 2:* Assume that LOB locator LOB1 is associated with a CLOB value. Assign a portion of the CLOB value to host variable DETAILS using the LOB locator, and assign CURRENT TIMESTAMP to the host variable TIMETRACK.

```
EXEC SQL VALUES (SUBSTR(:LOB1,1,35), CURRENT TIMESTAMP)
    INTO :DETAILS, :TIMETRACK;
```
WHenever

WHenever

The WHENEVER statement specifies the action to be taken when a specified exception condition occurs.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX. See the Embedded SQL Programming topic collection for information about handling errors in REXX.

Authorization

None required.

Syntax

```
WHENEVER NOT FOUND SQLERROR SQLWARNING CONTINUE GOTO host-label
```

Description

The NOT FOUND, SQLERROR, or SQLWARNING clause is used to identify the type of exception condition.

**NOT FOUND**

Identifies any condition that results in an SQLSTATE of '02000' or an SQLCODE of +100.

**SQLERROR**

Identifies any condition that results in a negative SQLCODE.

**SQLWARNING**

Identifies any condition that results in an SQLSTATE value where the first two characters are '01' or a warning condition (SQLWARN0 is 'W'), or that results in a positive SQLCODE other than +100.

The CONTINUE or GO TO clause are used to specify the next statement to be executed when the identified type of exception condition exists.

**CONTINUE**

Specifies the next sequential instruction of the source program.

**GOTO or GO TO host-label**

Specifies the statement identified by host-label. For host-label, substitute a single token, optionally preceded by a colon. The form of the token depends on the host language. In a COBOL program, for example, it can be a section-name or an unqualified paragraph-name.

Notes

**WHenever statement scope**: Every executable SQL statement in a program is within the scope of one implicit or explicit WHENEVER statement of each type. The scope of a WHENEVER statement is related to the listing sequence of the statements in the program, not their execution sequence.
An SQL statement is within the scope of the last WHENEVER statement of each type that is specified before that SQL statement in the source program. If a WHENEVER statement of some type is not specified before an SQL statement, that SQL statement is within the scope of an implicit WHENEVER statement of that type in which CONTINUE is specified.

SQL does support nested programs in COBOL, C, and RPG. However, SQL does not honor normal COBOL, C, and RPG scoping rules. That is, the last WHENEVER statement specified in the program source prior to the nested procedure is still in effect for that nested program. The label referenced in the WHENEVER statement must be duplicated within that inner program. Alternatively, the inner program could specify a new WHENEVER statement.

**Example**

The following statements can be embedded in a COBOL program.

*Example 1:* Go to the label HANDLER for any statement that produces an error.

```sql
EXEC SQL WHENEVER SQLERROR GOTO HANDLER END-EXEC.
```

*Example 2:* Continue processing for any statement that produces a warning.

```sql
EXEC SQL WHENEVER SQLWARNING CONTINUE END-EXEC.
```

*Example 3:* Go to the label ENDDATA for any statement that does not return data when expected to do so.

```sql
EXEC SQL WHENEVER NOT FOUND GOTO ENDDATA END-EXEC.
```
WHENEVER
Chapter 8. SQL control statements

Control statements are SQL statements that allow SQL to be used in a manner similar to writing a program in a structured programming language. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

**SQL-control-statement:**

<table>
<thead>
<tr>
<th>assignment-statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL-statement</td>
</tr>
<tr>
<td>CASE-statement</td>
</tr>
<tr>
<td>compound-statement</td>
</tr>
<tr>
<td>FOR-statement</td>
</tr>
<tr>
<td>GET DIAGNOSTICS-statement</td>
</tr>
<tr>
<td>GOTO-statement</td>
</tr>
<tr>
<td>IF-statement</td>
</tr>
<tr>
<td>ITERATE-statement</td>
</tr>
<tr>
<td>LEAVE-statement</td>
</tr>
<tr>
<td>LOOP-statement</td>
</tr>
<tr>
<td>PIPE-statement</td>
</tr>
<tr>
<td>REPEAT-statement</td>
</tr>
<tr>
<td>RESIGNAL-statement</td>
</tr>
<tr>
<td>RETURN-statement</td>
</tr>
<tr>
<td>SIGNAL-statement</td>
</tr>
<tr>
<td>WHILE-statement</td>
</tr>
</tbody>
</table>

Control statements are supported in SQL procedures, SQL functions, SQL triggers, and compound (dynamic) statements.

SQL procedures are created by specifying an SQL routine body on the CREATE PROCEDURE statement. SQL functions are created by specifying an SQL routine body on the CREATE FUNCTION statement. SQL routines are SQL procedures or SQL functions. SQL triggers are created by specifying an SQL routine body on the CREATE TRIGGER statement. A compound (dynamic) statement is defined by specifying an SQL routine body on the compound (dynamic) statement.

An SQL procedure can also be altered. A new SQL routine body can be specified on the ALTER PROCEDURE statement. An SQL function can also be altered. A new SQL routine body can be specified on the ALTER FUNCTION statement.

An SQL routine body must be a single SQL statement which may be an SQL control statement.

The SQL routine body is the executable part of the procedure, function, or trigger that is transformed by the database manager into a program or service program. When an SQL routine, trigger, or global variable is created, SQL creates temporary source files (QTEMP/QSQLSRC and QTEMP/QSQLT0000) that will contain C source code with embedded SQL statements. When SQL creates these temporary source files, a record length of 160 is used and the CCSID value of the source statement is set as the CCSID value for the new file. If either of these source files exist, they will be modified if needed to have the same CCSID as the source. The record length of these source files should be 160 or unexpected results may occur.
The name of the source file member is the same as the system name of the routine, trigger, or global variable. If DBGVIEW(*SOURCE) is specified, SQL creates the root source for the routine or trigger in source file QSQDSRC in the same library as the procedure, function, or trigger.

An SQL procedure or SQL trigger is created as a program (*PGM) object using the CRTPGM command. An SQL function is created as a service program (*SRVPGM) object using the CRTSRVPGM command. The program or service program is created in the library that is the implicit or explicit qualifier of the procedure, function, or trigger name.

When the program or service program is created, the SQL statements other than certain control statements become embedded SQL statements in the program or service program. The CALL, SIGNAL, RESIGNAL, and GET DIAGNOSTIC control statements also become embedded SQL statements in the program or service program.

The specified procedure or function is registered in the SYSROUTINES and SYSPARMS catalog tables, and an internal link is created from SYSROUTINES to the program. When the procedure is called using the SQL CALL statement or when the function is invoked in an SQL statement, the program associated with the routine is called. The specified SQL trigger is registered in the SYSTRIGGER catalog table.
References to SQL parameters and SQL variables

SQL parameters and SQL variables can be referenced anywhere in an SQL procedure statement where an expression or variable can be specified.

Host variables cannot be specified in SQL functions, SQL procedures, SQL triggers, or compound (dynamic) statements. SQL parameters can be referenced anywhere in the routine and can be qualified with the routine name. SQL variables can be referenced anywhere in the compound statement in which they are declared, including any statement that is directly or indirectly nested within that compound statement. If the compound statement where the variable is declared has a label, references to the variable name can be qualified with that label.

All SQL parameters and SQL variables are considered nullable except SQL variables that are explicitly declared as NOT NULL. The name of an SQL parameter or SQL variable in an SQL routine can be the same as the name of a column in a table or view referenced in the routine. The name of an SQL variable can also be the same as the name of another SQL variable declared in the same routine. This can occur when the two SQL variables are declared in different compound-statements. The compound-statement that contains the declaration of an SQL variable determines the scope of that variable. See [“compound-statement” on page 1664] for more information.

Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, global variable, SQL variable, or SQL parameter. If the name is not qualified, or qualified but still ambiguous, the following rules describe how the name is resolved. The name is resolved by checking for a match in the following order:

- If the tables and views specified in an SQL routine body exist at the time the routine is created, the name will first be checked as a column name.
- If not found as a column, it will then be checked as an SQL variable name. The SQL variable can be declared within the compound-statement that contains the reference, or within a compound statement in which that compound statement is nested. If two SQL variables are within the same scope and have the same name, the SQL variable that is declared in the innermost compound statement is used.
- If not found as an SQL variable name, the name will be checked as an SQL parameter name.

If the name is still not resolved as a column, SQL variable, or SQL parameter and the scope of the name included a table or view that does not exist at the current server, it will be assumed to be a column or global variable. If all the tables and views exist at the current server, it will be assumed to be a global variable. If the SQL_GVAR_BUILD_RULE QAQQINI option is *EXIST and the global variable does not exist, an error will be issued.

The name of an SQL variable or SQL parameter in an SQL routine can be the same as the name of an identifier used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to the identifier or to the SQL parameter or SQL variable. Qualified SQL parameters and SQL variables are not supported for these names.

---

129. Which can happen if they are declared in different compound statements.
SQL parameters and SQL variables

- In the SET PATH and SET SCHEMA statements, the name is checked as an SQL parameter name or SQL variable name. If not found as an SQL variable or SQL parameter name, it will then be used as an identifier.
- In the CONNECT, DISCONNECT, RELEASE, and SET CONNECTION statements, the name is used as an identifier.
- In the CALL statement, the name is used as an identifier.
- In the ASSOCIATE LOCATORS and DESCRIBE PROCEDURE statements when used in a CREATE TRIGGER statement, the name is used as an identifier.
References to SQL condition names

The name of an SQL condition can be the same as the name of another SQL condition declared in the same routine. This can occur when the two SQL conditions are declared in different compound-statements.

The compound-statement that contains the declaration of an SQL condition name determines the scope of that condition name. A condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used. See ”compound-statement” on page 1664, for more information.
SQL cursor names

References to SQL cursor names

The name of an SQL cursor can be the same as the name of another SQL cursor declared in the same routine. This can occur when the two SQL cursors are declared in different compound-statements. The cursor name specified in a FOR statement can be the same as the name of another SQL cursor declared in the same compound-statement.

The compound-statement that contains the declaration of an SQL cursor determines the scope of that cursor name. A cursor name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a cursor name, the cursor that is declared in the innermost compound statement is the cursor that is used. See "compound-statement" on page 1664, for more information.
References to SQL labels

Labels can be specified at the beginning of most SQL procedure statements. If a label is specified on an SQL procedure statement, it must be unique from other labels within the same scope. A label must not be the same as any other label within the same compound statement, must not be the same as a label specified on the compound statement itself, and if the compound statement is nested within another compound statement, the label must not be the same as the label specified on any higher level compound statement. The label must not be the same as the name of the SQL function, SQL procedure, or SQL trigger that contains the SQL procedure statement.

Specifying a label for an SQL procedure statement defines that label and determines the scope of that label. A label name can only be referenced within the compound statement in which it is defined, including any statement that is directly or indirectly nested within that compound statement. A label can be specified as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for the statement that references the label as a target.
### Summary of 'name' scoping in nested compound statements

Nested compound statements can be used within an SQL routine to define the scope of SQL variable declarations, cursors, condition names, and condition handlers.

Additionally, labels have a defined scope in the context of nested compound statements. However the rules for name space, and how non-unique names can be referenced, differs depending on the type of name. The following table summarizes these differences.

**Table 117. Summary of 'Name' Scoping in Nested Compound Statements**

<table>
<thead>
<tr>
<th>Type of name</th>
<th>Must be unique within...</th>
<th>Qualification allowed?</th>
<th>Can be referenced within...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL variable</td>
<td>the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement.</td>
<td>Yes, can be qualified with the label of the compound statement in which the variable was declared.</td>
<td>the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When multiple SQL variables are defined with the same name you can use a label to explicitly refer to a specific variable that is not the most local in scope.</td>
</tr>
<tr>
<td>condition</td>
<td>the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement.</td>
<td>No</td>
<td>the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Can be used in the declaration of a condition handler, or in a SIGNAL or RESIGNAL statement. <strong>Note:</strong> When multiple conditions are defined with the same name there is no way to explicitly refer to the condition that is not the most local in scope.</td>
</tr>
<tr>
<td>cursor</td>
<td>the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement.</td>
<td>No</td>
<td>the compound statement in which it is declared, including any compound statements that are nested within that compound statement. <strong>Note:</strong> When multiple cursors are defined with the same name there is no way to explicitly refer to the cursor that is not the most local in scope. However, if the cursor is defined as a result set cursor (for example, the WITH RETURN clause was specified as part of the cursor declaration), the invoking application can access the result set.</td>
</tr>
<tr>
<td>label</td>
<td>the compound statement that declared the variable, including any declarations in compound statements that are nested within that compound statement.</td>
<td>No</td>
<td>the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Use a label to qualify the name of an SQL variable or as the target of a GOTO, LEAVE, or ITERATE statement.</td>
</tr>
</tbody>
</table>
### SQL-procedure-statement

An SQL control statement may allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

#### Syntax:

```
<table>
<thead>
<tr>
<th>SQL-control-statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE CURSOR-statement</td>
</tr>
<tr>
<td>ALLOCATE DESCRIPTOR-statement</td>
</tr>
<tr>
<td>ALTER FUNCTION-statement (2)</td>
</tr>
<tr>
<td>ALTER MASK-statement</td>
</tr>
<tr>
<td>ALTER PERMISSION-statement</td>
</tr>
<tr>
<td>ALTER PROCEDURE-statement (2)</td>
</tr>
<tr>
<td>ALTER SEQUENCE-statement</td>
</tr>
<tr>
<td>ALTER TABLE-statement</td>
</tr>
<tr>
<td>ALTER TRIGGER-statement</td>
</tr>
<tr>
<td>ASSOCIATE LOCATORS-statement</td>
</tr>
<tr>
<td>CLOSE-statement</td>
</tr>
<tr>
<td>COMMENT-statement</td>
</tr>
<tr>
<td>COMMIT-statement (1)</td>
</tr>
<tr>
<td>CONNECT-statement (1)</td>
</tr>
<tr>
<td>CREATE ALIAS-statement</td>
</tr>
<tr>
<td>CREATE FUNCTION (external scalar)-statement</td>
</tr>
<tr>
<td>CREATE FUNCTION (external table)-statement</td>
</tr>
<tr>
<td>CREATE FUNCTION (sourced)-statement</td>
</tr>
<tr>
<td>CREATE INDEX-statement</td>
</tr>
<tr>
<td>CREATE MASK-statement</td>
</tr>
<tr>
<td>CREATE PERMISSION-statement</td>
</tr>
<tr>
<td>CREATE PROCEDURE (external)-statement</td>
</tr>
<tr>
<td>CREATE SCHEMA-statement</td>
</tr>
<tr>
<td>CREATE SEQUENCE-statement</td>
</tr>
<tr>
<td>CREATE TABLE-statement</td>
</tr>
<tr>
<td>CREATE TYPE-statement</td>
</tr>
<tr>
<td>CREATE VIEW-statement</td>
</tr>
<tr>
<td>DEALLOCATE DESCRIPTOR-statement</td>
</tr>
<tr>
<td>DECLARE GLOBAL TEMPORARY TABLE-statement</td>
</tr>
<tr>
<td>DELETE-statement</td>
</tr>
<tr>
<td>DESCRIBE-statement</td>
</tr>
<tr>
<td>DESCRIBE CURSOR-statement</td>
</tr>
<tr>
<td>DESCRIBE INPUT-statement</td>
</tr>
<tr>
<td>DESCRIBE PROCEDURE-statement</td>
</tr>
<tr>
<td>DESCRIBE TABLE-statement</td>
</tr>
<tr>
<td>DISCONNECT-statement (1)</td>
</tr>
<tr>
<td>DROP-statement</td>
</tr>
<tr>
<td>EXECUTE-statement</td>
</tr>
<tr>
<td>EXECUTE IMMEDIATE-statement</td>
</tr>
<tr>
<td>FETCH-statement</td>
</tr>
<tr>
<td>GET DESCRIPTOR-statement</td>
</tr>
<tr>
<td>GRANT-statement</td>
</tr>
<tr>
<td>INCLUDE-statement</td>
</tr>
<tr>
<td>INSERT-statement</td>
</tr>
<tr>
<td>LABEL-statement</td>
</tr>
<tr>
<td>LOCK TABLE-statement</td>
</tr>
<tr>
<td>MERGE-statement</td>
</tr>
</tbody>
</table>
```
SQL-procedure-statement

Syntax (continued):

<table>
<thead>
<tr>
<th>OPEN-statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREPARE-statement</td>
</tr>
<tr>
<td>REFRESH TABLE-statement</td>
</tr>
<tr>
<td>RELEASE-statement</td>
</tr>
<tr>
<td>RELEASE SAVEPOINT-statement</td>
</tr>
<tr>
<td>RENAME-statement</td>
</tr>
<tr>
<td>REVOKE-statement</td>
</tr>
<tr>
<td>ROLLBACK-statement</td>
</tr>
<tr>
<td>SAVEPOINT-statement</td>
</tr>
<tr>
<td>SELECT INTO-statement</td>
</tr>
<tr>
<td>SET CONNECTION-statement</td>
</tr>
<tr>
<td>SET CURRENT DEBUG MODE-statement</td>
</tr>
<tr>
<td>SET CURRENT DECFLAT ROUNding MODE-statement</td>
</tr>
<tr>
<td>SET CURRENT DEGREE-statement</td>
</tr>
<tr>
<td>SET CURRENT IMPLICIT XMLPARSE OPTION-statement</td>
</tr>
<tr>
<td>SET CURRENT TEMPORAL SYSTEM TIME-statement</td>
</tr>
<tr>
<td>SET DESCRIPTOR-statement</td>
</tr>
<tr>
<td>SET ENCRYPTION PASSWORD-statement</td>
</tr>
<tr>
<td>SET PATH-statement</td>
</tr>
<tr>
<td>SET RESULT SETS-statement</td>
</tr>
<tr>
<td>SET SCHEMA-statement</td>
</tr>
<tr>
<td>SET TRANSACTION-statement</td>
</tr>
<tr>
<td>SET transition-variable-statement</td>
</tr>
<tr>
<td>TRANSFER OWNERSHIP-statement</td>
</tr>
<tr>
<td>TRUNCATE-statement</td>
</tr>
<tr>
<td>UPDATE-statement</td>
</tr>
<tr>
<td>VALUES INTO-statement</td>
</tr>
</tbody>
</table>

Notes:

1. A COMMIT, ROLLBACK, CONNECT, DISCONNECT, SET CONNECTION, or SET RESULT SETS statement is only allowed in an SQL procedure.
2. An ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), or ALTER FUNCTION (SQL table) statement with a REPLACE keyword is not allowed in an SQL-routine-body.
3. A SET TRANSACTION statement is only allowed in an SQL function or trigger.
4. A SET transition-variable-statement is only allowed in a trigger. A fullselect and VALUES-statement can also be specified in a trigger.

Notes

Comments: Comments can be included within the body of an SQL procedure. In addition to the double-dash form of comments (--), a comment can begin with /* and end with */. The following rules apply to this form of a comment.

- The beginning characters /* must be adjacent and on the same line.
- The ending characters */ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

Detecting and processing error and warning conditions: As an SQL statement is executed, the database manager stores information about the processing of the statement in a diagnostics area (including the SQLSTATE and SQLCODE), unless otherwise noted in the description of the SQL statement. A completion condition indicates the SQL statement completed successfully, completed with a warning.
condition, or completed with a not found condition. An exception condition indicates that the SQL statement was not successful.

A condition handler can be defined in a compound statement to execute when an exception condition, a warning condition, or a not found condition occurs. The declaration of a condition handler includes the code that is to be executed when the condition handler is activated. When a condition other than a successful completion occurs in the processing of SQL-procedure-statement, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition. See “compound-statement” on page 1664 for information about defining condition handlers. The code in the condition handler can check for a warning condition, not found condition, or exception condition and take the appropriate action. Use one of the following methods at the beginning of the body of a condition handler to check the condition in the diagnostics area that caused the handler to be activated:

- Issue a GET DIAGNOSTICS statement to request the condition information. See “GET DIAGNOSTICS statement” on page 1677.
- Test the SQL variables SQLSTATE and SQLCODE.

If the condition is a warning and there is not a handler for the condition, the above two methods can also be used outside of the body of a condition handler immediately following the statement for which the condition is wanted. If the condition is an error and there is not a handler for the condition, the routine or trigger terminates with the error condition.
The assignment-statement assigns a value to an SQL parameter or SQL variable.

**Syntax**

```
label: SET assignment-clause

assignment-clause:

<table>
<thead>
<tr>
<th>SQL-parameter-name</th>
<th>=</th>
<th>expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL-variable-name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>global-variable</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(row-fullselect):

```

fullselect

WITH

RECURSIVE

common-table-expression

Description

**label**

Specifies the label for the assignment-statement statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

**SQL-parameter-name**

Identifies the SQL parameter that is the assignment target. The SQL parameter must be specified in parameter-declaration in the CREATE PROCEDURE or CREATE FUNCTION statement.

**SQL-variable-name**

Identifies the SQL variable that is the assignment target. SQL variables can only be declared in a compound-statement or be a transition variable.

**global-variable**

Identifies the global variable that is the assignment target.

**expression** or **NULL**

Specifies the expression or value that is the source for the assignment.
DEFAULT
Specifies that the default value for the column associated with the transition variable will be used. This can only be specified for a global variable and in SQL triggers for transition variables. Only one global variable can be assigned in the SET statement when DEFAULT is used.

row-fullselect
A fullselect that returns a single result row. The result column values are assigned to the corresponding SQL variable or parameter. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

WITH common-table-expression
Specifies a common table expression. For an explanation of common table expression, see “common-table-expression” on page 801.

fullselect
A fullselect that returns a single result row. The result column values are assigned to each corresponding variable. If the result of the fullselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result.

array-variable-name
Identifies an SQL variable or parameter. The variable or parameter must be of an array type.

[array-index]
Numeric expression that specifies which element in the array will be the target of the assignment. The array index must be of an exact numeric type with zero scale; it cannot be null. Its value must be between 1 and the maximum cardinality defined for the array.

array-constructor
Specifies the value of an array constructor. See “ARRAY constructor” on page 190.

TRIM_ARRAY function
Specifies the TRIM_ARRAY scalar function. See “TRIM_ARRAY” on page 620.

Notes
Assignment rules: Assignments in the assignment statement must conform to the SQL retrieval assignment rules as described in “Assignments and comparisons” on page 99.

If the assignment is of the form SET A[idx] = rhs, where A is an array variable name, idx is an expression used as the array index, and rhs is an expression of a compatible type as the array element, then:
1. If array A is the null value, set A to the empty array.
2. Let C be the cardinality of array A.
3. If idx is less than or equal to C, the value in the position identified by idx is replaced by the value of rhs.
4. If idx is greater than C, then:
   a. The value in position i, for i greater than C and less that idx, is set to the null value.

130. If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information about the standards option, see “Standards compliance” on page xi.
b. The value in position \( idx \) is set to the value of \( rhs \).
c. The cardinality of \( A \) is set to \( idx \).

Assignments involving SQL parameters: An IN parameter can appear on the left or right side of an assignment-statement. When control returns to the caller, the original value of the IN parameter is retained. An OUT parameter can also appear on the left or right side of an assignment-statement. If used without first being assigned a value, the value is null. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller. For an INOUT parameter, the first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.

Multiple SQL parameter or SQL variable assignments: If more than one SQL parameter or SQL variable is specified as the target of the assignment-statement, the targets of the assignment-statement are completely evaluated before the assignments are performed. Thus, references to an SQL parameter or SQL variable in a target expression is always the value of the SQL parameter or SQL variable prior to any assignment.

Arrays: If an assignment is to an array or array element, only one assignment is allowed in the statement.

Special Registers: If a variable has been declared with an identifier that matches the name of a special register (such as PATH), then the variable must be delimited to distinguish it from assignment to the special register (for example, SET "PATH" = 1; for a variable called PATH declared as an integer).

Considerations for SQLSTATE and SQLCODE variables: Assignment to these variables is not prohibited; however, it is not recommended as assignment does not affect the diagnostics area or result in the activation of condition handlers. The SQLCODE and SQLSTATE will be reset and the diagnostics area or SQLCA initialized for each assignment-statement other than assignment-statements that:
- assign the SQLSTATE or SQLCODE variable to another variable or
- set a constant value into the SQLSTATE or SQLCODE variable.

Example

Example 1: Increase the SQL variable \( p\_salary \) by 10 percent.

\[
\text{SET } p\_salary = p\_salary + (p\_salary \times .10)
\]

Example 2: Set SQL variable \( p\_salary \) to the null value

\[
\text{SET } p\_salary = \text{NULL}
\]

Example 3: Set the SQL array variable \( p\_phonenumbers \) to an array of fixed numbers.

\[
\text{SET } p\_phonenumbers = \text{ARRAY}[9055553907, 4165554213, 4085553678]
\]

Example 4: Set the SQL array variable \( p\_phonenumbers \) to an array of numbers retrieved from the PHONENUMBER table.

\[
\text{SET } p\_phonenumbers = \text{ARRAY}
\[
\begin{align*}
\text{[SELECT NUMBER FROM PHONENUMBERS} \\
\text{\quad WHERE EMPID = 624]}
\end{align*}
\]

Example 5: Assign \( p\_mynumber \) to the first and tenth elements of the SQL array variable \( p\_phonenumbers \). After the first assignment, the cardinality of
p_phonenumbers is 1. After the second assignment, the cardinality is 10, and elements 2 to 9 have been implicitly assigned the null value.

```sql
SET p_phonenumbers[1] = p_mynumber
SET p_phonenumbers[10] = p_mynumber
```
CALL statement

The CALL statement invokes a procedure. The syntax of CALL in an SQL function, SQL procedure, or SQL trigger is a subset of what is supported as a CALL statement in other contexts.

See “CALL” on page 957 for details.

Syntax

```
CALL label: procedure-name argument-list
```

**argument-list:**

```
(expression, parameter-name => DEFAULT NULL)
```

**Description**

**label**

Specifies the label for the CALL statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

**procedure-name**

Identifies the procedure to call. The procedure-name must identify a procedure that exists at the current server.

**argument-list**

Identifies a list of values to be passed as parameters to the procedure. The nth unnamed argument corresponds to the nth parameter in the procedure.

Each parameter defined (using CREATE PROCEDURE) as OUT must be specified as either a SQL-variable-name or a SQL-parameter-name. A default cannot be specified for an OUT parameter. If a default is used for an INOUT parameter, then the default expression is used to initialized the parameter for input to the procedure. No value is returned for this parameter when the procedure exits.

When a procedure is called, arguments must be specified for all parameters that are not defined to have a default value. When an argument is assigned to a parameter using the named syntax, then all the arguments that follow it must also be assigned using the named syntax.

Any references to date, time, or timestamp special register values in the argument list will use one clock reading for any default expressions and a separate clock reading for any references in the explicit arguments.

The number of arguments specified must be the same as the number of parameters of a procedure defined at the current server with the specified procedure-name.
The application requester assumes all parameters that are variables are INOUT parameters. All parameters that are not variables are assumed to be input parameters. The actual attributes of the parameters are determined by the current server.

**parameter-name**
Name of the parameter to which the argument value is assigned. The name must match a parameter name defined for the procedure. Named arguments correspond to the same named parameter regardless of the order in which they are specified in the argument list. When an argument is assigned to a parameter by name, all the arguments that follow it must also be assigned by name.

A named argument must be specified only one time (implicitly or explicitly).

Named arguments are not allowed on a call to a procedure that was not defined using a CREATE PROCEDURE statement.

**expression**
An expression of the type described in [“Expressions” on page 174](#), that does not include an aggregate function or column name.

**DEFAULT**
Specifies the default as defined in the CREATE PROCEDURE statement is used as an argument to the procedure; otherwise the NULL value is used.

**NULL**
Specifies a null value as an argument to the procedure.

**Notes**

**Rules for arguments to OUT and INOUT parameters:** Each OUT or INOUT parameter must be specified as an SQL parameter or SQL variable.

**Special registers:** The initial value of a special register in a procedure is inherited from the caller of the procedure. A value assigned to a special register within the procedure is used for the entire SQL procedure and will be inherited by any procedure subsequently called from that procedure. When a procedure returns to its caller, the special registers are restored to the original values of the caller.

**Related information:** See [“CALL” on page 957](#) for more information.

**Example**

Call procedure `proc1` and pass SQL variables as parameters.

```sql
CALL proc1(v_empno, v_salary)
```
CASE statement

The CASE statement selects an execution path based on multiple conditions.

Syntax

CASE label:
simple-when-clause
searched-when-clause
else-clause
END CASE

simple-when-clause:

expression
WHEN expression
THEN SQL-procedure-statement
;

searched-when-clause:

WHEN search-condition
THEN SQL-procedure-statement
;

else-clause:

ELSE SQL-procedure-statement
;

Description

label
Specifies the label for the CASE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

simple-when-clause
The value of the expression prior to the first WHEN keyword is tested for equality with the value of each expression that follows the WHEN keyword. If the comparison is true, the statements in the associated THEN clause are executed and processing of the CASE statement ends. If the result is unknown or false, processing continues to the next comparison. If the result does not match any of the comparisons, and an ELSE clause is present, the statements in the ELSE clause are executed.

searched-when-clause
The search-condition following the WHEN keyword is evaluated. If it evaluates to true, the statements in the associated THEN clause are executed and processing of the CASE statement ends. If it evaluates to false, or unknown, the next search-condition is evaluated. If no search-condition evaluates to true and an ELSE clause is present, the statements in the ELSE clause are executed.

else-clause
If none of the conditions specified in the simple-when-clause or searched-when-clause are true, then the statements in the else-clause are executed.
If none of the conditions specified in the WHEN are true, and an ELSE clause is not specified, an error is issued at runtime, and the execution of the CASE statement is terminated (SQLSTATE 20000).

**SQL-procedure-statement**
Specifies a statement to execute. See “SQL-procedure-statement” on page 1653.

### Notes

**Nesting of CASE statements:** CASE statements that use a *simple-when-clause* can be nested up to three levels. CASE statements that use a *searched-when-clause* have no limit to the number of nesting levels.

**Considerations for SQLSTATE and SQLCODE variables:** When the first SQL-procedure-statement in the CASE statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the expressions or search-conditions of that CASE statement. If a CASE statement does not include an ELSE clause and none of the search-conditions evaluate to true, then any error returned from the expression is returned.

### Examples

**Example 1:** Depending on the value of SQL variable v_workdept, update column DEPTNAME in table DEPARTMENT with the appropriate name.

The following example shows how to do this using the syntax for a *simple-when-clause*.

```sql
CASE v_workdept
  WHEN 'A00'
    THEN UPDATE department SET deptname = 'DATA ACCESS 1';
  WHEN 'B01'
    THEN UPDATE department SET deptname = 'DATA ACCESS 2';
  ELSE UPDATE department SET deptname = 'DATA ACCESS 3';
END CASE
```

**Example 2:** The following example shows how to do this using the syntax for a *searched-when-clause*:

```sql
CASE
  WHEN v_workdept = 'A00'
    THEN UPDATE department SET deptname = 'DATA ACCESS 1';
  WHEN v_workdept = 'B01'
    THEN UPDATE department SET deptname = 'DATA ACCESS 2';
  ELSE UPDATE department SET deptname = 'DATA ACCESS 3';
END CASE
```
compound-statement

A compound statement groups other statements together in an SQL procedure. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

Syntax

```
label: BEGIN NOT ATOMIC

SQL-variable-declaration ;
SQL-condition-declaration
return-codes-declaration
INCLUDE-statement

DECLARE CURSOR-statement ;
INCLUDE-statement

handler-declaration ;
INCLUDE-statement

SQL-procedure-statement ;

END label
```

**SQL-variable-declaration:**

```
DECLARE SQL-variable-name
```
SQL-condition-declaration:

```sql
DECLARE SQL-condition-name

CONDITION FOR SQLSTATE string-constant
```

return-codes-declaration:

```sql
DECLARE SQLSTATE CHARACTER(5)
    DEFAULT '00000'

SQLCODE INTEGER
    DEFAULT 0
```

default-declaration:

```sql
DECLARE CONTINUE HANDLER FOR specific-condition-value
    EXIT general-condition-value
    UNDO
```

specific-condition-value:

```sql
SQLSTATE STRING
```

Chapter 8. SQL control statements 1665
compound-statement

general-condition-value:

\[
\begin{array}{c}
\text{SQLEXCEPTION} \\
\text{SQLWARNING} \\
\text{NOT FOUND} \\
\end{array}
\]

(3)

data-type:

\[
\begin{array}{c}
\text{built-in-type} \\
\text{distinct-type-name} \\
\end{array}
\]

Notes:

1. The DEFAULT and NOT NULL clauses can be specified in either order.
2. specific-condition-value and general-condition-value cannot be specified in the same handler declaration.
3. The same clause must not be specified more than once.

built-in-type:
compound-statement

ccsid-clause:

| CCSID—integer |

Description

label
Specifies the label for the compound-statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

ATOMIC
ATOMIC indicates that an unhandled exception condition within the compound-statement causes the compound-statement to be rolled back. If ATOMIC is specified, COMMIT or ROLLBACK statements cannot be specified in the compound statement (ROLLBACK TO SAVEPOINT may be specified).

NOT ATOMIC
NOT ATOMIC indicates that an unhandled exception condition within the compound-statement does not cause the compound-statement to be rolled back. If NOT ATOMIC is specified in the outermost compound statement of an SQL trigger, it is treated as ATOMIC.

If ATOMIC is specified in an SQL procedure or function, the routine must have a data classification of MODIFIES SQL DATA.

SQL-variable-declaration
Declares a variable that is local to the compound-statement.

SQL-variable-name
Defines the name of a local SQL variable. The database manager converts all undelimited SQL variable names to uppercase. The name must not be the same as another SQL variable within the same compound-statement, excluding any declarations in compound-statements nested within the compound-statement. Do not name SQL variables the same as column names or parameter names. See "References to SQL parameters and SQL variables" on page 1647 for how SQL variable names are resolved when there are columns with the same name involved in a statement. Variable names should not begin with ‘SQL’.

data-type
Specifies the data type of the variable. See "CREATE TABLE" on page 1159 for a description of data type.

If the data-type is a graphic string data type, consider specifying CCSID 1200 or 13488 to indicate UTF-16 or UCS-2 data. If a CCSID is not specified, the CCSID of the graphic string variable will be the associated DBCS CCSID for the job.

array-type-name
Specifies that the SQL variable is an array as defined with the CREATE TYPE (Array) statement.

DEFAULT constant or NULL
Defines the default for the SQL variable. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in "Assignments and comparisons" on page 99. The variable is initialized when the compound-statement in which it is declared is entered. If a default value is not specified, the SQL variable is
initialized to NULL. SQL variables of type XML cannot have a default
value specified. SQL variables of array-type are always initialized to NULL.

NOT NULL
Prevents the SQL variable from containing the NULL value. Omission of
NOT NULL implies that the variable can be null. SQL variables of type
XML cannot have NOT NULL specified

CONSTANT constant or NULL
Specifies that the SQL variable has a fixed value that cannot be changed.
An SQL variable that is defined using CONSTANT cannot be used as the
target of any assignment operation. The specified constant must represent a
value that could be assigned to the variable in accordance with the rules of
assignment as described in Assignments and comparisons on page 99.

RESULT_SET_LOCATOR VARYING
Specifies the data type for a result set locator variable.

SQL-condition-declaration
Declares a condition name and corresponding SQLSTATE value.

SQL-condition-name
Specifies the name of the condition. The condition name must be unique
within the compound-statement (excluding any declarations in
compound-statements nested within the compound-statement ) in which it is
declared.

FOR SQLSTATE string-constant
Specifies the SQLSTATE associated with this condition. The string constant
must be specified as 5 characters. The SQLSTATE class (the first 2
characters) must not be '00'.

return-codes-declaration
Declares special SQL variables called SQLSTATE and SQLCODE that are set for
the first condition in the diagnostics area after executing an SQL statement
other than GET DIAGNOSTICS or an empty compound-statement. The
SQLSTATE and SQLCODE variables can only be declared in the outermost
compound-statement of an SQL procedure, SQL function, or SQL trigger.

The SQLSTATE and SQLCODE special variables are only intended to be used
as a means of obtaining the SQL return codes that resulted from processing the
previous SQL statement other than GET DIAGNOSTICS. If there is any
intention to use the SQLSTATE and SQLCODE values, save the values
immediately to other SQL variables to avoid having the values replaced by the
SQL return codes returned after executing the next SQL statement. If a handler
is defined that handles an SQLSTATE, you can use an assignment statement to
save that SQLSTATE (or the associated SQLCODE) value in another SQL
variable, if the assignment is the first statement in the handler.

Assignment to these variables is not prohibited; however, it is not
recommended. Assignment to these special variables is ignored by condition
handlers. The SQLSTATE and SQLCODE special variables cannot be set to
NULL.

DECLARE CURSOR-statement
Declares a cursor in the routine body. The cursor name must be unique within
the compound-statement, excluding any declarations in compound-statements
nested within the compound-statement.
**compound-statement**

A cursor-name can only be referenced within the compound-statement in which it is declared, including any compound-statements nested within the compound-statement.

Use an OPEN statement to open the cursor, and a FETCH statement to read rows using the cursor. If the cursor in an SQL procedure and is intended for use as a result set:

- specify WITH RETURN when declaring the cursor
- create the procedure using the DYNAMIC RESULT SETS clause with a non-zero value
- do not specify a CLOSE statement in the compound-statement.

Any open cursor that does not meet these criteria is closed at the end of the compound-statement.

For more information about declaring a cursor, refer to "DECLARE CURSOR" on page 1265.

**handler-declaration**

Specifies a handler, an SQL-procedure-statement to execute when an exception or completion condition occurs in the compound-statement.

A condition handler declaration cannot reference the same condition value or SQLSTATE value more than once, and cannot reference an SQLSTATE value and a condition name that represent the same SQLSTATE value. For a list of SQLSTATE values as well as more information, see the SQL messages and codes topic collection.

Furthermore, when two or more condition handlers are declared in a compound statement, no two condition handler declarations may specify the same:

- general condition category or
- specific condition, either as an SQLSTATE value or as a condition name that represents the same value.

A condition handler is active for the set of SQL-procedure-statements that follow the handler-declarations within the compound-statement in which it is declared, including any nested compound statements.

A handler for a condition may exist at several levels of nested compound statements. For example, assume that compound statement n1 contains another compound statement n2 which contains another compound statement n3. When an exception condition occurs within n3, any active handlers within n3 are first allowed to handle the condition. If no appropriate handler exists in n3, then the condition is ressignalled to n2 and the active handlers within n2 may handle the condition. If no appropriate handler exists in n2, then the condition is ressignalled to n1 and the active handlers within n1 may handle the condition. If no appropriate handler exists in n1, the condition is considered unhandled.

There are three types of condition handlers:

**CONTINUE**

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement following the one that raised the exception. If the error occurs while executing a comparison as in an IF, CASE, FOR, WHILE, or REPEAT, control returns to the statement following the corresponding END IF, END CASE, END FOR, END WHILE, or END REPEAT.
EXIT
Specifies that after the condition handler is activated and completes successfully, control is returned to the end of the compound statement that declared the condition handler.

UNDO
Specifies that when the condition handler is activated changes made by the compound-statement are rolled back. When the handler completes successfully, control is returned to the end of the compound-statement. If UNDO is specified, then ATOMIC must be specified.

UNDO cannot be specified in the outermost compound-statement of an SQL function or SQL trigger.

The conditions under which the handler is activated are:

SQLSTATE string
Specifies that the handler is invoked when the specific SQLSTATE occurs. The SQLSTATE class (the first 2 characters) must not be '00'.

SQL-condition-name
Specifies that the handler is invoked when the specific SQLSTATE associated with the condition name occurs. The SQL-condition-name must be previously defined in a SQL-condition-declaration.

SQLEXCEPTION
Specifies that the handler is invoked when an exception condition occurs. An exception condition is represented by an SQLSTATE value where the first two characters are not '00', '01', or '02'.

SQLWARNING
Specifies that the handler is invoked when a warning condition occurs. A warning condition is represented by an SQLSTATE value where the first two characters are '01'.

NOT FOUND
Specifies that the handler is invoked when a NOT FOUND condition occurs. A NOT FOUND condition is represented by an SQLSTATE value where the first two characters are '02'.

Notes

Nesting compound statements: Compound statements can be nested. Nested compound statements can be used to scope variable definitions, condition names, condition handlers, and cursors to a subset of the statements in the compound-statement. This can simplify the processing done for each SQL procedure statement. Support for nested compound statements enables the use of a compound statement within the declaration of a condition handler.

Condition handlers: Condition handlers in a compound-statement are similar to WHENEVER statements used in external SQL application programs. A condition handler can be defined to automatically get control when an exception, warning, or not found condition occurs. The body of a condition handler contains code that is executed when the condition handler is activated. A condition handler can be activated as a result of an exception, warning, or not found condition that is returned by the database manager for the processing of an SQL statement, or the activating condition can be the result of a SIGNAL or RESIGNAL statement issued within the procedure body.
A condition handler is declared within a compound statement, and it is active for the set of SQL-procedure-statements that follow all of the condition handler declarations within the compound statement in which the condition handler is declared. To be more specific, the scope of a condition handler declaration H is the list of SQL-procedure-statements that follows the condition handler declarations contained within the compound statement in which H appears. This means that the scope of H does not include the statements contained in the body of the condition handler H, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two condition handlers H1 and H2 declared in the same compound statement, H1 will not handle conditions arising in the body of H2, and H2 will not handle conditions arising in the body of H1.

The declaration of a condition handler specifies the condition that activates it, the type of the condition handler (CONTINUE, EXIT, or UNDO), and the handler action. The type of the condition handler determines where control is returned to after successful completion of the handler action.

**Condition handler activation:** When a condition other than successful completion occurs in the processing of an SQL-procedure-statement, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition.

In a routine with nested compound statements, condition handlers that could handle a specific condition may exist at several levels of the nested compound statements. The condition handler that is activated is a condition handler that is declared innermost to the scope in which the condition was encountered. If more than one condition handler at that nesting level could handle the condition, the condition handler that is activated is the most appropriate handler declared in that compound statement.

The most appropriate handler is a handler that is defined in the compound-statement which most closely matches the SQLSTATE of the exception or completion condition.

For example, if the innermost compound statement declares a specific handler for SQLSTATE 22001 as well as a handler for SQLEXCEPTION, the specific handler for SQLSTATE 22001 is the most appropriate handler when an SQLSTATE 22001 is encountered. In this case, the specific handler is activated.

When a condition handler is activated, the condition handler action is executed. If the handler action completes successfully or with an unhandled warning, the diagnostics area is cleared, and the type of the condition handler (CONTINUE, EXIT, or UNDO handler) determines where control is returned. Additionally, the SQLSTATE and SQLCODE SQL variables are cleared when a handler completes successfully or with an unhandled warning.

If the handler action does not complete successfully, and an appropriate handler exists for the condition encountered in the handler action, that condition handler is activated. Otherwise, the condition encountered within the condition handler is unhandled.

**Unhandled conditions:** If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the SQL procedure, SQL function, or SQL trigger containing the failing statement is terminated with an unhandled exception condition.
• If the unhandled condition is a warning or not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

Considerations for using SIGNAL or RESIGNAL statements with nested compound statements: If an SQL-procedure-statement specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound statement terminates with the specified exception. This happens even if this condition handler or another condition handler in the same compound statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If the compound statement is nested in another compound statement, condition handlers in the higher level compound statement may handle the exception because those condition handlers are within the scope of the exception.

Null values in SQL parameters and SQL variables: If the value of an SQL parameter or SQL variable is null and it is used in an SQL statement (such as CONNECT or DESCRIBE) that does not allow an indicator variable, an error is returned.

Effect on open cursors: Upon exit from the compound-statement for any reason, all open cursors that are declared in that compound statement are closed, unless they are declared to return result sets or unless *ENDACTGRP is specified.

Considerations for SQLSTATE and SQLCODE SQL variables: The compound statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within that compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE variables were not changed within the compound statement, they contain the same values as when the compound statement was entered.

Examples

Create a procedure body with a compound statement that performs the following actions.

1. Declares SQL variables.
2. Declares a cursor to return the salary of employees in a department determined by an IN parameter.
3. Declares an EXIT handler for the condition NOT FOUND (end of file) which assigns the value 6666 to the OUT parameter medianSalary.
4. Select the number of employees in the given department into the SQL variable v_numRecords.
5. Fetch rows from the cursor in a WHILE loop until 50% + 1 of the employees have been retrieved.
6. Return the median salary.

```
CREATE PROCEDURE DEPT_MEDIAN
(IN deptNumber SMALLINT,
  OUT medianSalary DOUBLE)
LANGUAGE SQL
BEGIN
```
DECLARE v_numRecords INTEGER DEFAULT 1;
DECLARE v_counter INTEGER DEFAULT 0;
DECLARE c1 CURSOR FOR
    SELECT salary FROM staff
    WHERE DEPT = deptNumber
    ORDER BY salary;
DECLARE EXIT HANDLER FOR NOT FOUND
    SET medianSalary = 6666;
    /* initialize OUT parameter */
    SET medianSalary = 0;
SELECT COUNT(*) INTO v_numRecords FROM staff
    WHERE DEPT = deptNumber;
OPEN c1;
WHILE v_counter < (v_numRecords / 2 + 1) DO
    FETCH c1 INTO medianSalary;
    SET v_counter = v_counter + 1;
END WHILE;
CLOSE c1;
END
FOR statement

The FOR statement executes a statement or group of statements for each row of a table.

Syntax

```
label: FOR for-loop-name AS

cursor-name CURSOR WITHOUT HOLD FOR WITH HOLD select-statement DO

SQL-procedure-statement ; END FOR label
```

Description

**label**

Specifies the label for the FOR statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

**for-loop-name**

Specifies the label for the implicit compound-statement that is generated to implement the FOR statement. It follows the rules for the label of a compound-statement except that it cannot be used with an ITERATE, GOTO, or LEAVE statement within the FOR statement. The for-loop-name is used to qualify the column names returned by the specified select-statement. It must not be the same as any label within the same scope. For more information, see “References to SQL labels” on page 1651.

Either the for-loop-name or label can be used to qualify other SQL variable names in the statement.

If for-loop-name is specified, then it should be used to qualify any other SQL variable names in the statement when debugging the SQL function, SQL procedure, or SQL trigger.

**cursor-name**

Names a cursor.

**WITH HOLD**

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared using the WITH HOLD clause is implicitly closed at commit time only if the connection associated with the cursor is ended during the commit operation. For more information, see “DECLARE CURSOR” on page 1265.

**select-statement**

Specifies the select statement of the cursor.
FOR statement

Each expression in the select list must have a name. If an expression is not a simple column name, the AS clause must be used to name the expression. If the AS clause is specified, that name is used for the variable and must be unique.

SQL-procedure-statement
Specifies the SQL statements to be executed for each row of the result table of the cursor. The SQL statements should not include an OPEN, FETCH, or CLOSE specifying the cursor name of the FOR statement.

Notes

FOR statement rules: The FOR statement executes one or multiple statements for each row in a result table of the cursor. The cursor is defined by specifying a select list that describes the columns and rows selected. The statements within the FOR statement are executed for each row selected.

The select list must consist of unique column names and the objects referenced in the select-statement must exist when the function, procedure, or trigger is created.

The cursor specified in a FOR statement cannot be referenced outside the FOR statement and cannot be specified on an OPEN, FETCH, or CLOSE statement.

Handler warning: Handlers may be used to handle errors that might occur on the open of the cursor or fetch of a row using the cursor in the FOR statement. Handlers defined to handle these open or fetch conditions should not be CONTINUE handlers as they may cause the FOR statement to loop indefinitely.

Example

In this example, the FOR statement is used to specify a cursor that selects 3 columns from the employee table. For every row selected, SQL variable fullname is set to the last name followed by a comma, the first name, a blank, and the middle initial. Each value for fullname is inserted into table TNAMES.

```
BEGIN
  DECLARE fullname CHAR(40);
  FOR vl AS cl CURSOR FOR
  SELECT firstname, midinit, lastname FROM employee
  DO
    SET fullname = lastname || ', ' || firstname || ' ' || midinit;
    INSERT INTO TNAMES VALUES ( fullname );
  END;
END;
```
GET DIAGNOSTICS statement

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed. The syntax of GET DIAGNOSTICS in an SQL function, SQL procedure, or SQL trigger is a subset of what is supported as a GET DIAGNOSTICS statement in other contexts.

See “GET DIAGNOSTICS” on page 1388 for details.

Syntax

statement-information:

```
SQL-variable-name-1 = statement-information-item
```

condition-information:

```
CONDITION SQL-variable-name-2 SQL-parameter-name-2
```

combined-information:

```
SQL-variable-name-4 = SQL-parameter-name-4
```

Notes:

1. STATEMENT can only be specified once. If SQL-variable-name-5,
SQL-parameter-name-5, or integer is not specified, CONDITION and CONNECTION can only be specified once.

### statement-information-item:

- `COMMAND_FUNCTION`
- `COMMAND_FUNCTION_CODE`
- `DB2_DIAGNOSTIC_CONVERSION_ERROR`
- `DB2_LAST_ROW`
- `DB2_NUMBER_CONNECTIONS`
- `DB2_NUMBER_PARAMETER_MARKERS`
- `DB2_NUMBER_RESULT_SETS`
- `DB2_NUMBER_ROWS`
- `DB2_NUMBER_SUCCESSFUL_SUBSTMTS`
- `DB2_RELATIVE_COST_ESTIMATE`
- `DB2_RETURN_STATUS`
- `DB2_ROW_COUNT_SECONDARY`
- `DB2_ROW_LENGTH`
- `DB2_SQL_ATTR_CONCURRENCY`
- `DB2_SQL_ATTR_CURSOR_CAPABILITY`
- `DB2_SQL_ATTR_CURSOR_HOLD`
- `DB2_SQL_ATTR_CURSOR_ROWSET`
- `DB2_SQL_ATTR_CURSOR_SCROLLABLE`
- `DB2_SQL_ATTR_CURSOR_SENSITIVITY`
- `DB2_SQL_ATTR_CURSOR_TYPE`
- `DB2_SQL_NESTING_LEVEL`
- `DYNAMIC_FUNCTION`
- `DYNAMIC_FUNCTION_CODE`
- `MORE`
- `NUMBER`
- `ROW_COUNT`
- `TRANSACTION_ACTIVE`
- `TRANSACTIONS_COMMITTED`
- `TRANSACTIONS_ROLLED_BACK`

### connection-information-item:

- `CONNECTION_NAME`
- `DB2_AUTHENTICATION_TYPE`
- `DB2.Authorization_ID`
- `DB2_CONNECTION_METHOD`
- `DB2_CONNECTION_NUMBER`
- `DB2_CONNECTION_STATE`
- `DB2_CONNECTION_STATUS`
- `DB2_CONNECTION_TYPE`
- `DB2_DYN_QUERY_MGMT`
- `DB2_ENCRYPTION_TYPE`
- `DB2_PRODUCT_ID`
- `DB2_SERVER_CLASS_NAME`
- `DB2_SERVER_NAME`

### condition-information-item:
**Description**

*label*

Specifies the label for the GET DIAGNOSTICS statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be
**GET DIAGNOSTICS statement**

the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

**CURRENT or STACKED**

Specifies which diagnostics area to access.

**CURRENT**

Specifies to access the first diagnostics area. It corresponds to the previous SQL statement that was executed and that was not a GET DIAGNOSTICS statement. This is the default.

**STACKED**

Specifies to access the second diagnostics area. The second diagnostics area is only available within a handler. It corresponds to the previous SQL statement that was executed before the handler was entered and that was not a GET DIAGNOSTICS statement. If the GET DIAGNOSTICS statement is the first statement within a handler, then the first diagnostics area and the second diagnostics area contain the same diagnostics information.

**statement-information**

Returns information about the last SQL statement executed.

**SQL-variable-name-1 or SQL-parameter-name-1**

Identifies a variable described in the program in accordance with the rules for declaring SQL variables and SQL parameters. The data type of the SQL variable or SQL parameter must be compatible with the data type as specified in Table 90 on page 1405 for the specified condition information item. The variable is assigned the value of the specified statement information item according to the retrieval assignment rules described in “Retrieval assignment” on page 103. If the value is truncated when assigning it to the SQL variable or SQL parameter, a warning is returned (SQLSTATE 01004) and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information, then the SQL variable or SQL parameter is set to a default value, based on its data type: 0 for an exact numeric diagnostic item, an empty string for a VARCHAR diagnostic item and blanks for a CHAR diagnostic item.

**condition-information**

Returns information about the condition or conditions that occurred when the last SQL statement was executed.

**CONDITION SQL-variable-name-2 or SQL-parameter-name-2 or integer**

Identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic and so on. If the value is 1, then the diagnostic information retrieved corresponds to the condition indicated by the SQLSTATE value actually returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). The SQL variable or SQL parameter specified must be described in the program in accordance with the rules for declaring exact numeric variables with zero scale. The value specified must not be less than one or greater than the number of available diagnostics.

**SQL-variable-name-3 or SQL-parameter-name-3**

Identifies a variable described in the program in accordance with the rules for declaring SQL variables or SQL parameters. The data type of the SQL variable or SQL parameter must be compatible with the data type as
specified in Table 90 on page 1405 for the specified condition information item. The SQL variable or SQL parameter is assigned the value of the specified condition information item according to the retrieval assignment rules described in “Retrieval assignment” on page 103. If the value is truncated when assigning it to the SQL variable or SQL parameter, a warning is returned (SQLSTATE 01004) and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

If a specified diagnostic item does not contain diagnostic information, then the SQL variable or SQL parameter is set to a default value, based on its data type: 0 for an exact numeric diagnostic item, an empty string for a VARCHAR diagnostic item and blanks for a CHAR diagnostic item.

combined-information

Returns multiple information items combined into one string.

If the GET DIAGNOSTICS statement is specified in an SQL function, SQL procedure, or trigger, the GET DIAGNOSTICS statement must be the first statement specified in the handler that will handle the error.

If information is wanted about a warning,

- If a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first statement specified in that handler.
- If a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

SQL-variable-name-4 or SQL-parameter-name-4

Identifies a variable described in the program in accordance with the rules for declaring SQL variables or SQL parameters. The data type of the SQL variable or SQL parameter must be VARCHAR. The SQL variable or SQL parameter is assigned according to the retrieval assignment rules described in “Retrieval assignment” on page 103. If the length of SQL-variable-name-4 or SQL-parameter-name-4 is not sufficient to hold the full returned diagnostic string, the string is truncated, a warning is returned (SQLSTATE 01004) and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

ALL

Indicates that all diagnostic items that are set for the last SQL statement executed should be combined into one string. The format of the string is a semicolon separated list of all of the available diagnostic information in the form:

item-name=character-form-of-the-item-value;

The character form of a positive numeric value will not contain a leading plus sign (+) unless the item is RETURNED_SQLCODE. In this case, a leading plus sign (+) is added. For example:

NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;

Only items that contain diagnostic information are included in the string. There are also no entries in this string for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS and DB2_SQL_NESTING_LEVEL items.
GET DIAGNOSTICS statement

**STATEMENT**
Indicates that all statement-information-item diagnostic items that contain
diagnostic information for the last SQL statement executed should be
combined into one string. The format is the same as described above
for ALL.

**CONDITION**
Indicates that condition-information-item diagnostic items that contain
diagnostic information for the last SQL statement executed should be
combined into one string. If SQL-variable-name-5 or
SQL-parameter-name-5 or integer is specified, then the format is the same
as described above for the ALL option. If SQL-variable-name-5 or
SQL-parameter-name-5 or integer is not specified, then the format
includes a condition number entry at the beginning of the information
for that condition in the form:

```
CONDITION_NUMBER=X;item-name=character-form-of-the-item-value;
```

where X is the number of the condition. For example:

```
CONDITION_NUMBER=1;RETURNED_SQLSTATE=02000;RETURNED_SQLCODE=-100;
CONDITION_NUMBER=2;RETURNED_SQLSTATE=01004;
```

**CONNECTION**
Indicates that connection-information-item diagnostic items that contain
diagnostic information for the last SQL statement executed should be
combined into one string. If SQL-variable-name-5 or
SQL-parameter-name-5 or integer is specified, then the format is the same
as described above for ALL. If SQL-variable-name-5 or
SQL-parameter-name-5 or integer is not specified, then the format
includes a connection number entry at the beginning of the
information for that condition in the form:

```
CONNECTION_NUMBER=X;item-name=character-form-of-the-item-value;
```

where X is the number of the condition. For example:

```
CONNECTION_NUMBER=1;CONNECTION_NAME=SVL1;DB2_PRODUCT_ID=DSN07010;
```

**SQL-variable-name-5 or SQL-parameter-name-5 or integer**
Identifies the diagnostic for which ALL CONDITION or ALL
CONNECTION information is requested. The SQL variable or SQL
parameter specified must be described in the program in accordance
with the rules for declaring integer SQL variables or SQL parameters.
The value specified must not be less than one or greater than the
number of available diagnostics.

**statement-information-item**
For a description of the statement-information-items, see
“statement-information-item” on page 1393.

**connection-information-item**
For a description of the connection-information-items, see
“connection-information-item” on page 1397.

**condition-information-item**
For a description of the condition-information-items, see
“condition-information-item” on page 1398.
GET DIAGNOSTICS statement

Notes

Effect of statement: The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2_GET_DIAGNOSTICS_DIAGNOSTICS.

Considerations for the SQLCODE and SQLSTATE SQL variables: The GET DIAGNOSTICS statement changes the value of the SQLSTATE and SQLCODE SQL variables.

Case of return values: Values for identifiers in returned diagnostic items are not delimited and are case sensitive. For example, a table name of "abc" would be returned, simply as abc.

Data types for items: When a diagnostic item is assigned to a SQL variable or SQL parameter, the SQL variable or SQL parameter must be compatible with the data type of the diagnostic item. For more information, see Table 90 on page 1405.

Keyword Synonym: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

• The keyword EXCEPTION can be used as a synonym for CONDITION.
• The keyword RETURN_STATUS can be used as a synonym for DB2_RETURN_STATUS.

Example

Example 1: In an SQL procedure, execute a GET DIAGNOSTICS statement to determine how many rows were updated.

```
CREATE PROCEDURE sqlprocg (IN deptnbr VARCHAR(3))
  LANGUAGE SQL
  BEGIN
    DECLARE SQLSTATE CHAR(5);
    DECLARE rcount INTEGER;
    UPDATE CORPDATA.PROJECT
      SET PRSTAFF = PRSTAFF + 1.5
      WHERE DEPTNO = deptnbr;
    GET DIAGNOSTICS rcount = ROW_COUNT;
    /* At this point, rcount contains the number of rows that were updated. */
  END
```

Example 2: Within an SQL procedure, handle the returned status value from the invocation of a stored procedure called TRYIT. TRYIT could use the RETURN statement to explicitly return a status value or a status value could be implicitly returned by the database manager. If the procedure is successful, it returns a value of zero.

```
CREATE PROCEDURE TESTIT ()
  LANGUAGE SQL
A1: BEGIN
  DECLARE RETVAL INTEGER DEFAULT 0;
  ...
  CALL TRYIT
  GET DIAGNOSTICS RETVAL = RETURN_STATUS;
  IF RETVAL <> 0 THEN
    ...
  LEAVE A1;
```
Example 3: In an SQL procedure, execute a GET DIAGNOSTICS statement to retrieve the message text for an error.

```sql
CREATE PROCEDURE divide2 ( IN numerator INTEGER,
                          IN denominator INTEGER,
                          OUT divide_result INTEGER,
                          OUT divide_error VARCHAR(70) )
LANGUAGE SQL
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    GET DIAGNOSTICS EXCEPTION 1
    divide_error = MESSAGE_TEXT;
    SET divide_result = numerator / denominator;
END;
```
GOTO statement

The GOTO statement branches to a user-defined label within an SQL function, SQL procedure, or SQL trigger.

Syntax

```
label1: GOTO label2
```

Description

**label1**

Specifies the label for the GOTO statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

**label2**

Specifies the labelled statement where processing is to continue. The labelled statement and the GOTO statement must both be in the same scope:

- If the GOTO statement is defined in a FOR statement, **label2** must be defined inside the same FOR statement, excluding a nested FOR statement or nested compound statement.
- If the GOTO statement is defined outside a FOR statement, **label2** must not be defined within a FOR statement or nested compound statement.
- If the GOTO statement is defined in a condition handler, **label2** must be defined inside the same handler.
- If the GOTO statement is defined outside a condition handler, **label2** must not be defined within a condition handler.

If **label2** is not defined within a scope that the GOTO statement can reach, an error is returned.

Notes

**Using a GOTO statement**: It is recommended that the GOTO statement be used sparingly. This statement interferes with normal sequence of processing SQL statements, thus making a routine more difficult to read and maintain. Before using a GOTO statement, determine whether another statement, such as IF or LEAVE, can be used in place, to eliminate the need for a GOTO statement.

**Effect on open cursors**: When a GOTO statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contains the GOTO statement are closed, unless they are declared to return result sets or unless *ENDACTGRP is specified.

**Effect on ATOMIC compound statements**: When a GOTO statement transfers control out of an ATOMIC compound statement, the savepoint that was implicitly started when the ATOMIC compound statement was entered is released.

**Considerations for SQLSTATE and SQLCODE variables**: The GOTO statement does not affect the SQLSTATE and SQLCODE SQL variables. At the end of the GOTO statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last statement executed before that GOTO statement.
Example

In the following statement, the parameters `rating` and `v_empno` are passed in to the procedure. The time in service is returned as a date duration in output parameter `return_parm`. If the time in service with the company is less then 6 months, the GOTO statement transfers control to the end of the procedure and `new_salary` is left unchanged.

```
CREATE PROCEDURE adjust_salary
    (IN v_empno CHAR(6),
     IN rating INTEGER,
     OUT return_parm DECIMAL(8,2))
LANGUAGE SQL
MODIFIES SQL DATA
BEGIN
    DECLARE new_salary DECIMAL(9,2);
    DECLARE service DECIMAL(8,2);

    SELECT salary, CURRENT_DATE - hiredate
    INTO new_salary, service
    FROM employee
    WHERE empno = v_empno;

    IF service < 600
    THEN GOTO exit1;
    END IF;

    IF rating = 1
    THEN SET new_salary = new_salary + (new_salary * .10);
    ELSEIF rating = 2
    THEN SET new_salary = new_salary + (new_salary * .05);
    END IF;

    UPDATE employee
    SET salary = new_salary
    WHERE empno = v_empno;

    EXIT1: SET return_parm = service;
END
```
IF statement

The IF statement executes different sets of SQL statements based on the result of search conditions.

Syntax

```
IF search-condition THEN SQL-procedure-statement ;
ELSEIF search-condition THEN SQL-procedure-statement ;
ELSE SQL-procedure-statement ;
END IF
```

Description

- **label**
  Specifies the label for the IF statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

- **search-condition**
  Specifies the search-condition for which an SQL statement should be executed. If the condition is unknown or false, processing continues to the next search condition, until either a condition is true or processing reaches the ELSE clause.

- **SQL-procedure-statement**
  Specifies an SQL statement to execute if the preceding search-condition is true.

Notes

**Considerations for SQLSTATE and SQLCODE SQL variables:** When the first SQL-procedure-statement in the IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search-conditions of that IF statement. If an IF statement does not include an ELSE clause and none of the search-conditions evaluate to true, then when the statement that follows the IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search conditions of that IF statement.

Example

The following SQL procedure accepts two IN parameters: an employee number and an employee rating. Depending on the value of rating, the employee table is updated with new values in the salary and bonus columns.

```
CREATE PROCEDURE UPDATE_SALARY_IF
  (IN employee_number CHAR(6), INOUT rating SMALLINT)
  LANGUAGE SQL
```
MODIFIES SQL DATA
BEGIN
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE EXIT HANDLER FOR not_found
        SET rating = -1;
    IF rating = 1
        THEN UPDATE employee
            SET salary = salary * 1.10, bonus = 1000
            WHERE empno = employee_number;
    ELSEIF rating = 2
        THEN UPDATE employee
            SET salary = salary * 1.05, bonus = 500
            WHERE empno = employee_number;
    ELSE UPDATE employee
        SET salary = salary * 1.03, bonus = 0
        WHERE empno = employee_number;
    END IF;
END
END
The INCLUDE statement inserts application code, including declarations and statements, into an SQL routine body. The included code can either be SQL code that is immediately added to the routine definition or ILE C code to be added during the create of the SQL procedure, SQL function, or SQL trigger.

**Authorization**

The authorization ID of the statement must have the system authorities *OBJOPR and *READ on the file that contains the member.

**Syntax**

```
INCLUDE SQL member-name
   +LIBL file-name (member-name)
   +CURLIB file-name (member-name)
   /library-name (member-name)
   /string
   /library-name /file-name (member-name) /string
```

**Description**

The INCLUDE statement must be specified at a point in the source where the included source statements are syntactically acceptable. Both forms of the INCLUDE statement can be specified as an SQL-procedure-statement within the body of a compound-statement. An INCLUDE SQL statement can also be specified within the declarations and handlers of a compound-statement. There is no limit to the number of includes that can be specified in one statement, but the included source cannot contain an embedded include.

**SQL**

The included source contains only SQL syntax that is allowed in an SQL-routine-body or SQL-trigger-body. These statements will be expanded inline as part of the SQL-routine-body or SQL-trigger-body. They will be processed as if they are directly part of the statement text for the statement. The statement text saved for the SQL procedure, function, or trigger will contain this included source. If the QSYS2.GENERATE_SQL procedure is used, the generated source will show the expanded SQL statements wherever an INCLUDE SQL was used.

`member-name`

Identifies a member to be included within the SQL procedure, SQL function, or SQL trigger. The source file and library will be determined using the INFILE option on the SET OPTION statement. For more information, see “SET OPTION” on page 1575.

`file-name (member-name)`

Identifies a source file and member to be included within the SQL procedure, SQL function, or SQL trigger. The library containing the source file is specified in one of these ways:

`*LIBL`

All libraries in the job’s library list are searched until the first match is found. This is the default.
INCLUDE statement

+CURLIB

The current library for the job is searched. If no library is specified as the current library for the job, QGPL is used.

library-name

Identifies the name of the library.

'string'

Identifies a source stream file to be included. The string will be handled as a normal SQL string literal; the source stream file rules for escaping characters will not be followed. No suffix will be appended to the string.

SQL not specified

The included source contains only ILE C language statements or embedded SQL statements prefixed with EXEC SQL. A corresponding EXEC SQL INCLUDE statement will be generated as part of the program source that is generated for this SQL procedure, SQL function, or SQL trigger.

If the include requires additional service programs to be bound during the creation of the procedure, function, or trigger, you can use the BNDOPT option on the SET OPTION statement to add a BNDSRVPGM parameter to reference exports found in other service programs. For more information, see “SET OPTION” on page 1575.

library-name / file-name ( member-name )

Specifies the fully qualified source file and member containing ILE C language statements to be included during the creation of the SQL procedure, SQL function, or SQL trigger.

'string'

Specifies the complete path for a source stream file containing ILE C language statements to be included during the creation of the SQL procedure, SQL function, or SQL trigger.

Notes

CCSID considerations: If the CCSID of the SQL statement is different from the CCSID of the source for the INCLUDE statement, the INCLUDE source is converted to the CCSID of the SQL statement.

Source considerations: The source of a C include should not exceed 160 source columns. Anything beyond that position will be truncated.

String literals in an SQL include cannot be longer than the width of the embedding source.

The source of an SQL include should contain complete SQL statements. Although not enforced, unpredictable results may occur if this rule is violated.

SQL trigger consideration: When an SQL trigger uses the INCLUDE statement to include ILE C, any operation that requires the trigger program to be rebuilt has a runtime dependency on the include file. If the trigger program is not found, it can be automatically rebuilt by the database when the trigger is fired, when the table is copied, or when the table is restored. If the include file is not available, the trigger will not create and any function requiring the trigger will fail.

Examples

- Use the INCLUDE statement to embed a common condition handler in an SQL function.
CREATE FUNCTION H1 ()
RETURNS INT
DETERMINISTIC
NO EXTERNAL ACTION
NOT FENCED
BEGIN
  DECLARE RES INT;
  INCLUDE SQL INCLUDE(COMMONCOND);
  SET RES = AFUNCTION();
  RETURN RES;
END;

COMMONCOND in file SQLINCLUDE in the library list contains the following.
The condition handler calls an SQL procedure named ERR_PROC for a specific
not found condition. As part of the message handling, it uses the
ROUTINE_SCHEMA and ROUTINE_SPECIFIC_NAME built-in global variables
to indicate the source of the error.
DECLARE NO_FUNC CONDITION FOR SQLSTATE '42704';
DECLARE CONTINUE HANDLER FOR NO_FUNC
BEGIN
  CALL ERR_PROC(SYSIBM.ROUTINE_SCHEMA CONCAT '.' CONCAT
               SYSIBM.ROUTINE_SPECIFIC_NAME CONCAT
               ': Function not found');
END;

- Use the INCLUDE statement to embed a call to a C function. It will use the
  Qp0zLprintf interface to print the input parameter.
CREATE PROCEDURE LPRINTF(P1 VARCHAR(1000))
BEGIN
  IF P1 IS NOT NULL THEN
    INCLUDE QGPL/CINCLUDE(MYLPRINTF);
  END IF;
END;

Member MYLPRINTF in file CINCLUDE in library QGPL contains the following
code. Note that this include has a reference to the function’s input parameter.
You need to examine the generated C code to determine what the names are.
{
  /* declare prototype for Qp0zLprintf */
  extern int Qp0zLprintf (char *format, ...);

  /* print input parameter to job log */
  Qp0zLprintf("%.s\n", LPRINTF.P1.LEN, LPRINTF.P1.DAT);
}
ITERATE statement

The ITERATE statement causes the flow of control to return to the beginning of a labelled loop.

Syntax

```
ITERATE target-label
```

Description

**label**

Specifies the label for the ITERATE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

**target-label**

Specifies the label of the FOR, LOOP, REPEAT, or WHILE statement to which the flow of control is passed. `target-label` must be defined as a label for a FOR, LOOP, REPEAT, or WHILE statement. The ITERATE statement must be in that FOR, LOOP, REPEAT, or WHILE statement, or in the block of code that is directly or indirectly nested within that statement, subject to the following restrictions:

- If the ITERATE statement is in a condition handler, `target-label` must be defined in that condition handler.
- If the ITERATE statement is not in a condition handler, `target-label` must not be defined in a condition handler.
- If the ITERATE statement is in a FOR statement, `target-label` must be that label on that FOR statement, or the label must be defined inside that FOR statement.

Notes

**Considerations for SQLSTATE and SQLCODE variables**: The ITERATE statement does not affect the SQLSTATE and SQLCODE SQL variables. At the end of the ITERATE statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last statement executed before that ITERATE statement.

Example

This example uses a cursor to return information for a new department. If the `not_found` condition handler was invoked, the flow of control passes out of the loop. If the value of `v_dept` is 'D11', an ITERATE statement passes the flow of control back to the top of the LOOP statement. Otherwise, a new row is inserted into the DEPARTMENT table.

```sql
CREATE PROCEDURE ITERATOR ()
    LANGUAGE SQL
    MODIFIES SQL DATA
BEGIN
    DECLARE v_dept CHAR(3);
    DECLARE v_deptname VARCHAR(29);
    DECLARE v_admdept CHAR(3);
    DECLARE at_end INTEGER DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT deptno,deptname,admrdept
```
FROM department
ORDER BY deptno;
DECLARE CONTINUE HANDLER FOR not_found
SET at_end = 1;
OPEN c1;
ins_loop:
LOOP
  FETCH c1 INTO v_dept, v_deptname, v_admdept;
  IF at_end = 1 THEN
    LEAVE ins_loop;
  ELSEIF v_dept = 'D11' THEN
    ITERATE ins_loop;
  END IF;
  INSERT INTO department (deptno,deptname,admdept)
    VALUES ('NEW', v_deptname, v_admdept);
END LOOP;
CLOSE c1;
END
The LEAVE statement continues execution by leaving a block or loop.

Syntax

```
label1: LEAVE label2
```

Description

- **label1**: Specifies the label for the LEAVE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

- **label2**: Specifies the label of the compound, FOR, LOOP, REPEAT, or WHILE statement to exit.

The LEAVE statement cannot be used to leave a handler.

Notes

**Effect on open cursors**: When a LEAVE statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contains the LEAVE statement are closed, unless they are declared to return result sets or unless *ENDACTGRP* is specified.

**Considerations for SQLSTATE and SQLCODE variables**: The LEAVE statement does not affect the SQLSTATE and SQLCODE SQL variables. At the end of the LEAVE statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last statement executed before that LEAVE statement.

Examples

The example contains a loop that fetches data for cursor *c1*. If the value of SQL variable *at_end* is not zero, the LEAVE statement transfers control out of the loop.

```
CREATE PROCEDURE LEAVE_LOOP (OUT COUNTER INTEGER)
LANGUAGE SQL
BEGIN

DECLARE v_counter INTEGER;
DECLARE v_firstname VARCHAR(12);
DECLARE v_midinit CHAR(1);
DECLARE v_lastname VARCHAR(15);
DECLARE at_end SMALLINT DEFAULT 0;
DECLARE not_found CONDITION FOR SQLSTATE '02000';
DECLARE c1 CURSOR FOR
    SELECT firstname, midinit, lastname
    FROM employee;
DECLARE CONTINUE HANDLER FOR not_found
    SET at_end = 1;
SET v_counter = 0;
OPEN c1;
fetch_loop:
    LOOP
        FETCH c1 INTO v_firstname, v_midinit, v_lastname;
        IF at_end <> 0 THEN
            LEAVE fetch_loop;
        END IF;
```
LEAVE statement

SET v_counter = v_counter + 1;
END LOOP fetch_loop;
SET counter = v_counter;
CLOSE c1;
END
LOOP statement

The LOOP statement repeats the execution of a statement or a group of statements.

Syntax

```sql
label: LOOP SQL-procedure-statement ; END LOOP label
```

Description

**label**

Specifies the label for the LOOP statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

**SQL-procedure statement**

Specifies an SQL statement to be executed in the loop.

Notes

**Considerations for the diagnostics area**: At the beginning of the first iteration of the LOOP statement, and with every subsequent iteration, the diagnostics area is cleared.

**Considerations for SQLSTATE and SQLCODE variables**: Prior to executing the first SQL-procedure statement within that LOOP statement, the SQLSTATE and SQLCODE values reflect the last values that were set prior to the LOOP statement. If the loop is terminated with a GOTO or a LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. When the LOOP statement iterates, the SQLSTATE and SQLCODE values reflect the result of the last SQL statement executed within the LOOP statement.

Examples

This procedure uses a LOOP statement to fetch values from the employee table. Each time the loop iterates, the OUT parameter **counter** is incremented and the value of **v_midinit** is checked to ensure that the value is not a single space (' '). If **v_midinit** is a single space, the LEAVE statement passes the flow of control outside of the loop.

```sql
CREATE PROCEDURE LOOP_UNTIL_SPACE (OUT COUNTER INTEGER)
  LANGUAGE SQL
BEGIN
  DECLARE v_counter INTEGER DEFAULT 0;
  DECLARE v_firstnme VARCHAR(12);
  DECLARE v_midinit CHAR(1);
  DECLARE v_lastname VARCHAR(15);
  DECLARE c1 CURSOR FOR
    SELECT firstnme, midinit, lastname
    FROM employee;
  DECLARE CONTINUE HANDLER FOR NOT FOUND
    SET counter = -1;
  OPEN c1;
  fetch_loop:
    LOOP
      ... statements...
      IF v_midinit = ' ' THEN
        LEAVE fetch_loop;
      END IF;
    END LOOP;
  END LOOP;
END;
```

IBM i: Db2 for i SQL Reference
FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
IF v_midinit = ' ' THEN
    LEAVE fetch_loop;
END IF;
SET v_counter = v_counter + 1;
END LOOP fetch_loop;
SET counter = v_counter;
CLOSE c1;
END
The PIPE statement returns one row from a table function. An SQL table function that uses a PIPE statement is referred to as a pipelined function.

**Syntax**

```
PIPE
label: (expression, NULL)
(NULL, row-fullselect)
(expression)
```

**Description**

`label`  
Specifies the label for the PIPE statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

`(expression, ...)`  
Specifies a row value is returned from the function. The number of expressions or NULL keywords in the list must match the number of columns in the function result. The data types of each expression must be assignable to the data type of the corresponding column defined for the function result, using the storage assignment rules as described in "Assignments and comparisons" on page 99.

`row-fullselect`  
Specifies a fullselect that returns a single row. The number of columns in the fullselect must match the number of columns in the function result. The data types of the result table columns of the fullselect must be assignable to the data types of the columns defined for the function result, using the storage assignment rules as described in "Assignments and comparisons" on page 99. If the result of the row fullselect is no rows, a null value is returned for each column. An error is returned if there is more than one row in the result.

`expression`  
Specifies a scalar value is returned from the function. The table function must return a single column and the value of the expression must be assignable to that column.

`NULL`  
Specifies that a null value is returned from the function. If there is more than one result column, a null value is returned for each column.

**Example**

Use a PIPE statement to return rows from an SQL table function.

```
CREATE FUNCTION TRANSFORM() RETURNS TABLE ( EMPLOYEE_NAME CHAR(20), UNIQUE# INT )
BEGIN
    DECLARE EMPNAME VARCHAR(15);
    DECLARE MYRECNUM INTEGER DEFAULT 1;
    DECLARE AT_END INTEGER DEFAULT 0;
    DECLARE EMP_CURSOR CURSOR FOR SELECT lastname FROM employee;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '02000'
        SET AT_END = 1;
```

IBM i: Db2 for i SQL Reference
OPEN EMP_CURSOR;
MYLOOP: LOOP
   FETCH EMP_CURSOR INTO EMPNAME;
   IF AT_END = 1 THEN
      LEAVE MYLOOP;
   END IF;
   PIPE (EMPNAME, MYRECNUM); -- return single row
   SET MYRECNUM = MYRECNUM + 1;
END LOOP;

CLOSE EMP_CURSOR;
RETURN;
END;
The REPEAT statement executes a statement or group of statements until a search condition is true.

Syntax

```
REPEAT
  label:
  SQL-procedure-statement
  ;
UNTIL
  search-condition
END
REPEAT
```

Description

- **label**: Specifies the label for the REPEAT statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

- **SQL-procedure-statement**: Specifies an SQL statement to be executed in the REPEAT loop.

- **search-condition**: The search-condition is evaluated after each execution of the REPEAT loop. If the condition is true, the REPEAT loop will exit. If the condition is unknown or false, the looping continues.

Notes

- **Considerations for the diagnostics area**: At the beginning of the first iteration of the REPEAT statement, and with every subsequent iteration, the diagnostics area is cleared.

- **Considerations for SQLSTATE and SQLCODE SQL variables**: With each iteration of the REPEAT statement, the SQLSTATE and SQLCODE SQL variables are cleared prior to executing the first SQL-procedure-statement within the REPEAT statement. At the beginning of the first iteration of the REPEAT statement, the SQLSTATE and SQLCODE values reflect the last values that were set prior to the REPEAT statement. At the beginning of iterations 2 through n of the REPEAT statement, the SQLSTATE and SQLCODE values reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT statement. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END REPEAT of the REPEAT statement completes, the SQLSTATE and SQLCODE values reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT statement.

Example

A REPEAT statement fetches rows from a table until the not_found condition handler is invoked.
CREATE PROCEDURE REPEAT_STMT (OUT COUNTER INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstnme VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE at_end SMALLINT DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT firstnme, midinit, lastname
      FROM employee;
    DECLARE CONTINUE HANDLER FOR not_found
      SET at_end = 1;
    OPEN c1;
    fetch_loop:
      REPEAT
        FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
        SET v_counter = v_counter + 1;
        UNTIL at_end > 0
      END REPEAT fetch_loop;
    SET counter = v_counter;
    CLOSE c1;
  END
RESIGNAL statement

The RESIGNAL statement is used within a condition handler to re-raise the current condition, or raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned, along with optional message text.

Issuing the RESIGNAL statement without an operand causes the current condition to be passed outwards.

Syntax

```
RESIGNAL label: VALUE SQLSTATE sqlstate-string
  signal-information
```

```
signal-information:
  SET MESSAGE_TEXT = SQL-variable-name
  CONSTRAINT_CATALOG SQL-parameter-name
  CONSTRAINT_SCHEMA diagnostic-string-constant
  CONSTRAINT_NAME CONSTRAINT_ORIGIN
  CATALOG_NAME SUBCLASS_ORIGIN
  SCHEMA_NAME CLASS_ORIGIN
  TABLE_NAME CURSOR_NAME
  COLUMN_NAME CLASS_ORIGIN
```

Description

**label**

Specifies the label for the RESIGNAL statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

**SQLSTATE VALUE**

Specifies the SQLSTATE that will be resignaled. Any valid SQLSTATE value can be used. The specified value must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00' since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is returned.

**sqlstate-string-constant**

The sqlstate-string-constant must be a character string constant with exactly 5 characters.

**sqlstate-string-variable**

The sqlstate-string-variable must be a character or Unicode graphic variable. The actual length of the contents of the sqlstate-string-variable must be 5.
**SQL-condition-name**

Specifies the name of the condition that will be returned. The
*SQL-condition-name* must be declared within the *compound-statement*.

**SET**

Introduces the assignment of values to *condition-information-items*. The
*condition-information-item* values can be accessed using the GET DIAGNOSTICS
statement. The only *condition-information-item* that can be accessed in the
SQLCA is MESSAGE_TEXT.

**MESSAGE_TEXT**

Specifies a string that describes the error or warning.

If an SQLCA is used,

- the string is returned in the SQLERRMC field of the SQLCA
- if the actual length of the string is longer than 1000 bytes, it is truncated
  without a warning.

**CONSTRAINT_CATALOG**

Specifies a string that indicates the name of the database that contains a
constraint related to the signalled error or warning.

**CONSTRAINT_SCHEMA**

Specifies a string that indicates the name of the schema that contains a
constraint related to the signalled error or warning.

**CONSTRAINT_NAME**

Specifies a string that indicates the name of a constraint related to the
signalled error or warning.

**CATALOG_NAME**

Specifies a string that indicates the name of the database that contains a
table or view related to the signalled error or warning.

**SCHEMA_NAME**

Specifies a string that indicates the name of the schema that contains a
table or view related to the signalled error or warning.

**TABLE_NAME**

Specifies a string that indicates the name of a table or view related to the
signalled error or warning.

**COLUMN_NAME**

Specifies a string that indicates the name of a column in the table or view
related to the signalled error or warning.

**CURSOR_NAME**

Specifies a string that indicates the name of a cursor related to the
signalled error or warning.

**CLASS_ORIGIN**

Specifies a string that indicates the origin of the SQLSTATE class related to
the signalled error or warning.

**SUBCLASS_ORIGIN**

Specifies a string that indicates the origin of the SQLSTATE subclass
related to the signalled error or warning.

**SQL-variable-name**

Identifies an SQL variable declared within the *compound-statement*, that
RESIGNAL statement

contains the value to be assigned to the condition-information-item. The SQL variable must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

SQL-parameter-name
Identifies an SQL parameter declared within the compound-statement, that contains the value to be assigned to the condition-information-item. The SQL parameter must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

diagnostic-string-constant
Specifies a character string constant that contains the value to be assigned to the condition-information-item.

Notes

SQLSTATE values: Any valid SQLSTATE value can be used in the RESIGNAL statement. However, it is recommended that programmers define new SQLSTATEs based on ranges reserved for applications. This prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

For more information about SQLSTATEs, see the SQL Messages and Codes topic collection.

Assignment: When the RESIGNAL statement is executed, the value of each of the specified string-constants and variables is assigned to the corresponding condition-information-item. However, if the length of a string-constant or variable is longer than the maximum length of the corresponding condition-information-item, it is truncated without a warning. For details on the assignment rules, see "Assignments and comparisons" on page 99. For details on the maximum length of specific condition-information-items, see "GET DIAGNOSTICS" on page 1388.

Processing a RESIGNAL statement:

- If the RESIGNAL statement is specified without a SQLSTATE clause or a SQL-condition-name, the SQL function, SQL procedure, or SQL trigger resinals the identical condition that invoked the handler and the SQLCODE is not changed.
- When a RESIGNAL statement is issued and an SQLSTATE or SQL-condition-name is specified, the SQLCODE is based on the SQLSTATE value as follows:
  - If the specified SQLSTATE class is either '01' or '02', a warning or not found is signalled and the SQLCODE is set to +438.
  - Otherwise, an exception is returned and the SQLCODE is set to −438.

If the SQLSTATE or condition indicates that an exception is signalled (SQLSTATE class other than '01' or '02'),

- If a handler exists in the same compound statement as the RESIGNAL statement, and the compound-statement contains a handler for SQLEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.
- If the compound-statement is nested and an outer level compound-statement has a handler for SQLEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.
If the SQLSTATE or condition indicates that a warning (SQLSTATE class '01') or not found (SQLSTATE class '02') is signalled:

- If a handler exists in the same compound statement as the RESIGNAL statement, and the compound-statement contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is handled and control is transferred to that handler.

- If the compound-statement is nested and an outer level compound statement contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is not handled and processing continues with the next statement.

- Otherwise, the warning is not handled and processing continues with the next statement.

Considerations for the diagnostics area: The RESIGNAL statement might modify the contents of the current diagnostics area. If an SQLSTATE or SQL-condition-name is specified as part of the RESIGNAL statement, the RESIGNAL statement starts with a clear of the diagnostics area and sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or SQL-condition-name. If any signal-information is specified, the corresponding items in the condition area are assigned the specified values. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or SQL-condition-name.

Example

This example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the overflow condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE value to the client application.

```
CREATE PROCEDURE divide ( IN numerator INTEGER,
                          IN denominator INTEGER,
                          OUT divide_result INTEGER )

BEGIN
  DECLARE overflow CONDITION FOR '22003';
  DECLARE CONTINUE HANDLER FOR overflow;
  RESIGNAL SQLSTATE '22375';
  IF denominator = 0 THEN
    SIGNAL overflow;
  ELSE
    SET divide_result = numerator / denominator;
  END IF;
END
```

RESIGNAL statement
The RETURN statement returns from a routine. For SQL scalar functions, it returns the result of the function. For SQL non-pipelined table functions, it returns a table as the result of the function. For SQL pipelined table functions, it indicates the end of the result table has been reached. For an SQL procedure, it optionally returns an integer status value.

Syntax

```
RETURN
```

**Description**

**label**

Specifies the label for the RETURN statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see "References to SQL labels" on page 1651.

**expression**

Specifies a value that is returned from the routine:

- If the routine is a scalar function, the data type of the result must be assignable to the data type defined for the function result, using the storage assignment rules as described in "Assignments and comparisons" on page 99. An aggregate function, or user-defined function that is sourced on an aggregate function must not be specified for a RETURN statement in an SQL scalar function.
- If the routine is a table function, a scalar expression (other than a scalar fullselect) cannot be specified.
- If the routine is a procedure, the data type of expression must be INTEGER. If the expression evaluates to the null value, a value of zero is returned.

**NULL**

Specifies that the null value is returned from the routine.

- If the routine is a scalar function, the null value is returned.
- If the routine is a table function, NULL must not be specified.
- If the routine is a procedure, NULL must not be specified.

**WITH common-table-expression**

Specifies one or more common table expressions to be used in the fullselect.

**fullselect**

Specifies the row or rows to be returned for the routine.

- If the routine is a scalar function, the fullselect must return one column and, at most, one row. The data type of the result column must be assignable to
the data type defined for the function result, using the storage assignment rules as described in "Assignments and comparisons" on page 99.

- If the routine is a table function, the fullselect can return zero or more rows with one or more columns. The number of columns in the fullselect must match the number of columns in the function result. In addition, the data types of the result table columns of the fullselect must be assignable to the data types of the columns defined for the function result, using the storage assignment rules as described in "Assignments and comparisons" on page 99.

- If the routine is a procedure, fullselect must not be specified.

Notes

Returning from a table function:
- The last statement executed in the SQL-routine-body must be a RETURN statement.
- For a non-pipelined table function, the RETURN statement indicates the rows to be returned. Exactly one RETURN statement must be specified and it must contain a fullselect.
- For a pipelined table function, one or more RETURN statements must be specified and they must contain no return values.

Returning from a procedure:
- If a RETURN statement with a specified return value is used to return from a procedure then the SQLCODE, SQLSTATE, and message length in the SQLCA or diagnostics area are initialized to zeros, and message text is set to blanks. An error is not returned to the caller.
- If a RETURN statement is not used to return from a procedure or if a value is not specified on the RETURN statement,
  - if the procedure returns with an SQLCODE that is greater than or equal to zero, the specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS statement will be set to a value of 0
  - if the procedure returns with an SQLCODE that is less than zero, the specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS statement will be set to a value of -1.
- When a value is returned from a procedure, the caller may access the value using:
  - the GET DIAGNOSTICS statement to retrieve the DB2_RETURN_STATUS when the SQL procedure was called from another SQL procedure
  - the parameter bound for the return value parameter marker in the escape clause CALL syntax (?=CALL...) in a ODBC or JDBC application
  - directly from the SQLCA returned from processing the CALL of an SQL procedure by retrieving the value of sqllerr[0] when the SQLCODE is not less than zero. When the SQLCODE is less than zero, the sqllerr[0] value is not set and the application should assume a return status value of -1.

RETURN restrictions:
- RETURN is not allowed in SQL triggers.
- In a compound(dynamic) statement, RETURN cannot specify a return value.
Example

Example 1: Use a RETURN statement to return from an SQL procedure with a status value of zero if successful, and –200 if not.

```
BEGIN
  ...
  GOTO fail;
  ...
  success: RETURN 0
  fail: RETURN -200
  ...
END
```

Example 2: Define a scalar function that returns the tangent of a value using the existing sine and cosine functions.

```
CREATE FUNCTION mytan (x DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(x)/COS(x)
```
**SIGNAL statement**

The SIGNAL statement signals an error or warning condition. It causes an error or warning to be returned with the specified SQLSTATE and optional condition-information-items. The syntax of SIGNAL in an SQL function, SQL procedure, or SQL trigger is similar to what is supported as a SIGNAL statement in other contexts.

See “SIGNAL” on page 1615 for details.

### Syntax

```
label: SIGNAL SQLSTATE VALUE sqlstate-string-constant 
     SQL-condition-name sqlstate-string-variable 
     signal-information 
```

**signal-information:**

```
SET MESSAGE_TEXT = SQL-variable-name 
    CONSTRAINT_CATALOG SQL-parameter-name 
    CONSTRAINT_SCHEMA diagnostic-string-constant 
    CONSTRAINT_NAME 
    CATALOG_NAME 
    SCHEMA_NAME 
    TABLE_NAME 
    COLUMN_NAME 
    CURSOR_NAME 
    CLASS_ORIGIN 
    SUBCLASS_ORIGIN 
```

### Description

**label**

Specifies the label for the SIGNAL statement. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

**SQLSTATE VALUE**

Specifies the SQLSTATE that will be signalled. The specified value must not be null and must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00' since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is returned.

**sqlstate-string-constant**

The sqlstate-string-constant must be a character string constant with exactly 5 characters.
SIGNAL statement

sqlstate-string-variable
The sqlstate-string-variable must be a character or Unicode graphic variable.
The actual length of the contents of the variable must be 5.

SQL-condition-name
Specifies the name of the condition that will be signalled. The
SQL-condition-name must be declared within the compound-statement.

SET
Introduces the assignment of values to condition-information-items. The
condition-information-item values can be accessed using the GET DIAGNOSTICS
statement. The only condition-information-item that can be accessed in the
SQLCA is MESSAGE_TEXT.

MESSAGE_TEXT
Specifies a string that describes the error or warning.
If an SQLCA is used,
• the string is returned in the SQLERRMC field of the SQLCA
• if the actual length of the string is longer than 1000 bytes, it is truncated
  without a warning.

CONSTRAINT_CATALOG
Specifies a string that indicates the name of the database that contains a
constraint related to the signalled error or warning.

CONSTRAINT_SCHEMA
Specifies a string that indicates the name of the schema that contains a
constraint related to the signalled error or warning.

CONSTRAINT_NAME
Specifies a string that indicates the name of a constraint related to the
signalled error or warning.

CATALOG_NAME
Specifies a string that indicates the name of the database that contains a
table or view related to the signalled error or warning.

SCHEMA_NAME
Specifies a string that indicates the name of the schema that contains a
table or view related to the signalled error or warning.

TABLE_NAME
Specifies a string that indicates the name of a table or view related to the
signalled error or warning.

COLUMN_NAME
Specifies a string that indicates the name of a column in the table or view
related to the signalled error or warning.

CURSOR_NAME
Specifies a string that indicates the name of a cursor related to the
signalled error or warning.

CLASS_ORIGIN
Specifies a string that indicates the origin of the SQLSTATE class related to
the signalled error or warning.

SUBCLASS_ORIGIN
Specifies a string that indicates the origin of the SQLSTATE subclass
related to the signalled error or warning.
**SQL-variable-name**
Identifies an SQL variable declared within the compound-statement, that contains the value to be assigned to the condition-information-item. The SQL variable must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

**SQL-parameter-name**
Identifies an SQL parameter declared within the compound-statement, that contains the value to be assigned to the condition-information-item. The SQL parameter must be defined as CHAR, VARCHAR, Unicode GRAPHIC, or Unicode VARGRAPHIC variable.

**diagnostic-string-constant**
Specifies a character string constant that contains the value to be assigned to the condition-information-item.

( diagnostic-string-constant )
Specifies a character string constant that contains the message text.

This form is only allowed in the triggered action of a CREATE TRIGGER statement.

To conform with the ANS and ISO standards, this form should not be used. It is provided for compatibility with other products.

**Notes**

**SQLSTATE values:** Any valid SQLSTATE value can be used in the SIGNAL statement. However, it is recommended that programmers define new SQLSTATEs based on ranges reserved for applications. This prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

For more information about SQLSTATEs, see the [SQL Messages and Codes](#) topic collection.

**Assignment:** When the SIGNAL statement is executed, the value of each of the specified string-constants and variables is assigned to the corresponding condition-information-item. However, if the length of a string-constant or variable is longer than the maximum length of the corresponding condition-information-item, it is truncated without a warning. For details on the assignment rules, see “Assignments and comparisons” on page 99. For details on the maximum length of specific condition-information-items, see “GET DIAGNOSTICS” on page 1388.

**Processing a SIGNAL statement:** When a SIGNAL statement is issued, the SQLCODE returned in the SQLCA is based on the SQLSTATE value as follows:

- If the specified SQLSTATE class is either '01' or '02', a warning or not found is signalled and the SQLCODE is set to +438.
- Otherwise, an exception is signalled and the SQLCODE is set to –438.

If the SQLSTATE or condition indicates that an exception (SQLSTATE class other than '01' or '02') is signalled,

- If a handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a handler for SQLEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.
SIGNAL statement

- If the compound-statement is nested and an outer level compound-statement has a handler for SQLEXCEPTION or the specified SQLSTATE or condition; the exception is handled and control is transferred to that handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If the SQLSTATE or condition indicates that a warning (SQLSTATE class '01') or not found (SQLSTATE class '02') is signalled,
- If a handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is handled and control is transferred to that handler.
- If the compound-statement is nested and an outer level compound statement contains a handler for SQLWARNING (if the SQLSTATE class is '01'), NOT FOUND (if the SQLSTATE class is '02'), or the specified SQLSTATE or condition; the warning or not found condition is not handled and processing continues with the next statement.
- Otherwise, the warning is not handled and processing continues with the next statement.

Considerations for the diagnostics area: The SIGNAL statement starts with a clear of the diagnostics area and then sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or SQL-condition-name. If any signal-information is specified, the corresponding items in the condition area are assigned the specified values. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or SQL-condition-name.

Example

An SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

```sql
CREATE PROCEDURE SUBMIT_ORDER
  (IN ONUM INTEGER, IN CNUM INTEGER,
   IN PNUM INTEGER, IN QNUM INTEGER)
  LANGUAGE SQL
  MODIFIES SQL DATA
BEGIN
  DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'
  SIGNAL SQLSTATE '75002'
  SET MESSAGE_TEXT = 'Customer number is not known';
  INSERT INTO ORDERS (ORDERNO, CUSTNO, PARTNO, QUANTITY) VALUES (ONUM, CNUM, PNUM, QNUM);
END
```
WHILE statement

The WHILE statement repeats the execution of a statement while a specified condition is true.

Syntax

```
label: WHILE search-condition DO SQL-procedure-statement ;
```

END WHILE label

Description

`label`

Specifies the label for the WHILE statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to SQL labels” on page 1651.

`search-condition`

Specifies a condition that is evaluated before each execution of the WHILE loop. If the condition is true, the `SQL-procedure-statements` in the WHILE loop are executed.

`SQL-procedure-statement`

Specifies an SQL statement or statements to execute within the WHILE loop.

Notes

Considerations for the diagnostics area: At the beginning of the first iteration of the WHILE statement, and with every subsequent iteration, the diagnostics area is cleared.

Considerations for SQLSTATE and SQLCODE SQL variables: With each iteration of the WHILE statement, when the first `SQL-procedure-statement` is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search condition of that WHILE statement. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END WHILE of the WHILE statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating the search condition of that WHILE statement.

Example

This example uses a WHILE statement to iterate through FETCH and SET statements. While the value of SQL variable `v_counter` is less than half of number of employees in the department identified by the IN parameter `deptNumber`, the WHILE statement continues to perform the FETCH and SET statements. When the condition is no longer true, the flow of control leaves the WHILE statement and closes the cursor.
CREATE PROCEDURE dept_median
  (IN deptNumber SMALLINT,
   OUT medianSalary DECIMAL(7,2))
LANGUAGE SQL
BEGIN
  DECLARE v_numRecords INTEGER DEFAULT 1;
  DECLARE v_counter INTEGER DEFAULT 0;
  DECLARE c1 CURSOR FOR
    SELECT salary
    FROM staff
    WHERE dept = deptNumber
    ORDER BY salary;
  DECLARE EXIT HANDLER FOR NOT FOUND
    SET medianSalary = 6666;
  SET medianSalary = 0;
  SELECT COUNT(*) INTO v_numRecords
  FROM staff
  WHERE dept = deptNumber;
  OPEN c1;
  WHILE v_counter < (v_numRecords/2 + 1) DO
    FETCH c1 INTO medianSalary;
    SET v_counter = v_counter + 1;
  END WHILE;
  CLOSE c1;
END
Appendix A. SQL limits

The following tables describe certain SQL and database limits imposed by the Db2 for i database manager.

Note:
- System storage limits may preclude the limits specified here. For example, see “Maximum row sizes” on page 1210.
- A limit of storage means that the limit is dependent on the amount of storage available.
- A limit of statement means that the limit is dependent on the limit for the maximum length of a statement.
### SQL limits

**Table 118. Identifier Length Limits**

<table>
<thead>
<tr>
<th>Identifier Limits</th>

<tr>
<td>Longest XML element name, attribute name, prefix name, or processing instruction name specified in XMLELEMENT, XMLFOREST, XMLATTRIBUTES, XMLNAMESPACEs or XMLPI</td>
<td>128</td>
</tr>
</tbody>
</table>
### Table 118. Identifier Length Limits (continued)

<table>
<thead>
<tr>
<th>Identifier Limits</th>
<th>Db2 for i Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Longest XML path name specified in XMTABLE</td>
<td>128</td>
</tr>
<tr>
<td>Longest XML element name, attribute name, prefix name, or processing instruction</td>
<td>1000</td>
</tr>
<tr>
<td>name for a parsed XML document</td>
<td></td>
</tr>
<tr>
<td>Longest XML schema location uniform resource identifier (URI)</td>
<td>1000</td>
</tr>
<tr>
<td>Longest JSON path name</td>
<td>128</td>
</tr>
</tbody>
</table>

---

131. As an application requester, Db2 for i can send an authorization name of up to 255 bytes.
132. For REXX procedures, the limit is 33.
133. For an RPG, COBOL, or REXX program, the limit is 64.
### Table 119. Numeric Limits

<table>
<thead>
<tr>
<th>Numeric Limits</th>
<th>Db2 for i Limit</th>

<td>38</td>
</tr>
<tr>
<td>Smallest REAL value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>-3.4x10&lt;sup&gt;38&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest REAL value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>+3.4x10&lt;sup&gt;38&lt;/sup&gt;</td>
</tr>
<tr>
<td>Minimum exponent (E&lt;sub&gt;min&lt;/sub&gt;) for REAL values</td>
<td>-38</td>
</tr>
<tr>
<td>Smallest positive REAL value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>+1.18x10&lt;sup&gt;-38&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest negative REAL value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>-1.18x10&lt;sup&gt;-38&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum exponent (E&lt;sub&gt;max&lt;/sub&gt;) for DOUBLE values</td>
<td>308</td>
</tr>
<tr>
<td>Smallest DOUBLE value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>-1.79x10&lt;sup&gt;308&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest DOUBLE value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>+1.79x10&lt;sup&gt;308&lt;/sup&gt;</td>
</tr>
<tr>
<td>Minimum exponent (E&lt;sub&gt;min&lt;/sub&gt;) for DOUBLE values</td>
<td>-308</td>
</tr>
<tr>
<td>Smallest positive DOUBLE value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>+2.23x10&lt;sup&gt;-308&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest negative DOUBLE value&lt;sup&gt;134&lt;/sup&gt;</td>
<td>-2.23x10&lt;sup&gt;-308&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum exponent (E&lt;sub&gt;max&lt;/sub&gt;) for DECFLOAT(16) values</td>
<td>384</td>
</tr>
<tr>
<td>Smallest DECFLOAT(16) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>-9.999999999999999x10&lt;sup&gt;384&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest DECFLOAT(16) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>9.999999999999999x10&lt;sup&gt;384&lt;/sup&gt;</td>
</tr>
<tr>
<td>Minimum exponent (E&lt;sub&gt;min&lt;/sub&gt;) for DECFLOAT(16) values</td>
<td>-383</td>
</tr>
<tr>
<td>Smallest positive DECFLOAT(16) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>1x10&lt;sup&gt;-383&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest negative DECFLOAT(16) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>-1x10&lt;sup&gt;-383&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum exponent (E&lt;sub&gt;max&lt;/sub&gt;) for DECFLOAT(34) values</td>
<td>6144</td>
</tr>
<tr>
<td>Smallest DECFLOAT(34) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>-9.9999999999999999999999x10&lt;sup&gt;6144&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest DECFLOAT(34) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>9.9999999999999999999999x10&lt;sup&gt;6144&lt;/sup&gt;</td>
</tr>
<tr>
<td>Minimum exponent (E&lt;sub&gt;min&lt;/sub&gt;) for DECFLOAT(34) values</td>
<td>-6143</td>
</tr>
<tr>
<td>Smallest positive DECFLOAT(34) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>1x10&lt;sup&gt;6143&lt;/sup&gt;</td>
</tr>
<tr>
<td>Largest negative DECFLOAT(34) value&lt;sup&gt;135&lt;/sup&gt;</td>
<td>-1x10&lt;sup&gt;6143&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

134. The values shown are approximate.
135. These are the limits for normal numbers in DECFLOAT. DECFLOAT also contains special values such as NaN and Infinity that are also valid. DECFLOAT also supports subnormal numbers that are outside of the documented range.
### Table 120. String Limits

<table>
<thead>
<tr>
<th>String Limits</th>
<th>Db2 for i Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of CHAR (in bytes)</td>
<td>32765&lt;sup&gt;136&lt;/sup&gt;</td>

<tr>
<td>Maximum length of BINARY (in bytes)</td>
<td>32765&lt;sup&gt;136&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum length of VARBINARY (in bytes)</td>
<td>32739&lt;sup&gt;136&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum length of BLOB (in bytes)</td>
<td>2 147 483 647</td>
</tr>
<tr>
<td>Maximum length of serialized XML (in bytes)</td>
<td>2 147 483 647</td>
</tr>
<tr>
<td>Maximum length of character constant</td>
<td>32740</td>
</tr>
<tr>
<td>Maximum length of a graphic constant</td>
<td>16370</td>
</tr>
<tr>
<td>Maximum length of binary constant</td>
<td>32740</td>
</tr>
<tr>
<td>Maximum length of concatenated character string</td>
<td>2 147 483 647</td>
</tr>
<tr>
<td>Maximum length of concatenated graphic string</td>
<td>1 073 741 823</td>
</tr>
<tr>
<td>Maximum length of concatenated binary string</td>
<td>2 147 483 647</td>
</tr>
<tr>
<td>Maximum number of hexadecimal constant digits</td>
<td>32 762</td>
</tr>
<tr>
<td>Maximum length of catalog comments</td>
<td>2000&lt;sup&gt;137&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum length of column label (in bytes)</td>
<td>60</td>
</tr>
<tr>
<td>Maximum length of SQL routine label</td>
<td>128</td>
</tr>
<tr>
<td>Maximum length of table, package, or alias label</td>
<td>50</td>
</tr>
<tr>
<td>Maximum length of C NUL-terminated</td>
<td>32739&lt;sup&gt;136&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum length of C NUL-terminated graphic</td>
<td>16369&lt;sup&gt;136&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

### Table 121. XML Limits

<table>
<thead>
<tr>
<th>XML Limits</th>
<th>Db2 for i Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of an XML schema document (in bytes)</td>
<td>2 147 483 647</td>
</tr>
<tr>
<td>Maximum length of a parsed XML entity</td>
<td>2 147 483 647</td>
</tr>
<tr>
<td>Maximum depth of an internal XML tree</td>
<td>128</td>
</tr>
</tbody>
</table>

### Table 122. JSON Limits

<table>
<thead>
<tr>
<th>JSON Limits</th>
<th>Db2 for i Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of an JSON document (in bytes)</td>
<td>2 147 483 647</td>
</tr>
</tbody>
</table>

<sup>136</sup>. If the column is NOT NULL, the maximum is one more.  
<sup>137</sup>. For sequences the limit is 500.
### SQL limits

**Table 123. Datetime Limits**

<table>
<thead>
<tr>
<th>Datetime Limits</th>
<th>Db2 for i Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smallest DATE value</td>
<td>0001-01-01</td>
</tr>
<tr>
<td>Largest DATE value</td>
<td>9999-12-31</td>
</tr>
<tr>
<td>Smallest TIME value</td>
<td>00:00:00</td>
</tr>
<tr>
<td>Largest TIME value</td>
<td>24:00:00</td>
</tr>
<tr>
<td>Smallest TIMESTAMP value</td>
<td>0001-01-01-00.00.00.0000000000000</td>
</tr>
<tr>
<td>Largest TIMESTAMP value</td>
<td>9999-12-31-24.00.00.0000000000000</td>
</tr>
<tr>
<td>Smallest timestamp precision</td>
<td>0</td>
</tr>
<tr>
<td>Largest timestamp precision</td>
<td>12</td>
</tr>
</tbody>
</table>

**Table 124. DataLink Limits**

<table>
<thead>
<tr>
<th>DataLink Limits</th>
<th>Db2 for i Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of DATALINK</td>
<td>32718</td>
</tr>
<tr>
<td>Maximum length of DATALINK comment</td>
<td>254</td>
</tr>

<tr>
<td>Maximum total length of columns in an ORDER BY clause</td>
<td>3.5 Gigabytes&lt;sup&gt;141&lt;/sup&gt;</td>
</tr>
<tr>
<td>Maximum levels of recursion for hierarchical query</td>
<td>250</td>
</tr>
<tr>
<td>Maximum levels allowed for a subquery</td>
<td>256</td>
</tr>
<tr>
<td>Maximum number of values in an insert operation</td>
<td>8000</td>
</tr>
<tr>
<td>Maximum number of SET clauses in a single update operation</td>
<td>8000</td>
</tr>
</tbody>
</table>

#### Routines

| Maximum number of parameters in a procedure | 2000<sup>142</sup> |
| Maximum number of parameters in a function | 2000<sup>142</sup> |
| Maximum number of return columns in a table function | 8000 |
| Maximum number of nested levels for routines | storage |

#### Types

| Maximum cardinality of an array type | 2 147 483 647 |

#### Applications

| Maximum number of host variable declarations in a precompiled program | storage<sup>143</sup> |
| Maximum length of a host variable value (in bytes) | 2 147 483 647 |
| Maximum length of an MQ message CLOB value (in bytes) | 2M |
| Maximum length of an MQ message varying length value (in bytes) | 32000 |
| Maximum number of declared cursors in a program | storage |
| Maximum number of cursors opened at one time | storage<sup>144</sup> |
| Maximum number of rows locked in a unit of work | 500 000 000 |
| Maximum number of DDL statements in a unit of work | 131 036 |
| Maximum number of locators in a transaction | 16 000 000<sup>145</sup> |
| Maximum size of an SQLDA (in bytes) | 16 777 215 |
| Maximum number of prepared statements | storage |
| Maximum number of savepoints active at one time | storage |
| Maximum number of simultaneously allocated CLI handles in a process | 160 000<sup>146</sup> |
| Maximum size of a package | 1008 megabytes<sup>147</sup> |
| Maximum length of a path | 8843 |
| Maximum number of schemas in a path | 268 |
| Maximum length of a password | 127 |
| Maximum length of a hint | 32 |
| Maximum size of a program, service program, or module associated space (in bytes) | 16 777 216 |
### Table 125. Database Manager Limits (continued)

<tbody>
<tr>
<td>Maximum size of the diagnostics area</td>
<td>90K</td>
</tr>
<tr>
<td>Maximum size of an array variable</td>
<td>4GB</td>
</tr>
</tbody>
</table>
Appendix B. Characteristics of SQL statements

This appendix contains information on the characteristics of SQL statements pertaining to the various places where they are used.

- “Actions allowed on SQL statements” on page 1726 shows whether an SQL statement can be executed, prepared interactively or dynamically, and whether the statement is processed by the requester, the server or the precompiler.
- “SQL statement data access classification for routines” on page 1729 shows the level of SQL data access that must be specified to use the SQL statement in a routine.
- “Considerations for using distributed relational database” on page 1732 provides information about the use of SQL statements when the application server is not the same as the application requester.

138. The maximum number of members (and partitions) referenced is also 1000. In DELETE and UPDATE statements the maximum number is 256.

139. The limit is restricted by internal structures and may be less depending on how the constants are used in the statement and if very large string constants or variables are used.

140. The limit is based on the size of internal structures generated for the parsed SQL statement.

141. The limit is 32766 if CQE processed the select statement. The limit will be less if an ICU collating sequence or ALWCPYDTA(‘NO) is used.

142. SQL procedures and SQL functions can have up to 2000 parameters. The number of parameters for external procedures and external functions cannot exceed 2000 and is limited by the maximum number of parameters allowed by the language.

143. In RPG/400 and PL/I programs when the old parameter passing technique is used, the limit is approximately 4000. The limit is based on the number of pointers allowed in the program. In all other cases, the limit is based on operating system constraints.

144. The maximum number of cursors open at one time in a single job is approximately 20 473.

145. The maximum number of locators in a transaction in SQL Server mode is 209 000.

146. The maximum number of allocated handles per DRDA connection is 500.

147. The maximum size of a DRDA package can be increased from 500 megabytes to 1 gigabyte by using a QAQQINI option.

## Characteristics of SQL statements

### Actions allowed on SQL statements

Indicates whether an SQL statement can be executed, prepared interactively or dynamically, and whether the statement is processed by the requester, the server, or the precompiler.

The table below shows whether a specific Db2 statement can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler. The letter Y means yes.

**Table 126. Actions allowed on SQL statements**

**Notes:**

1. This statement can only be used in the triggered action of a trigger.
2. This statement can only be used in an SQL function, SQL procedure, or SQL trigger.
3. This statement can only be used in a procedure.
4. This statement is not applicable in a Java program.
5. This statement is not supported in a REXX program.
6. The target of the SET variable statement must be a global variable.
SQL statement data access classification for routines

Indicates the level of SQL data access that must be specified to use the SQL statement in a routine.

The following table indicates whether an SQL statement (specified in the first column) is allowed to execute in a function or procedure with the specified SQL data access classification. If an executable SQL statement is encountered in a function or procedure defined with NO SQL, SQLSTATE 38001 is returned. For other executions contexts, SQL statements that are not supported in any context return SQLSTATE 38003. For other SQL statements not allowed in a CONTAINS SQL context, SQLSTATE 38004 is returned and in a READS SQL DATA context, SQLSTATE 38002 is returned. During creation of an SQL function or SQL procedure, a statement that does not match the SQL data access classification will cause SQLSTATE 42895 to be returned.

<td>Y</td>
<td>Y</td>
<td>Y</td>
</tr>
</tbody>
</table>

**Note:**

1. Although the NO SQL option implies that no SQL statements can be specified, non-executable statements are not restricted.
2. It depends on the statement being executed. The statement specified for the EXECUTE statement or any statement executed within a compound (dynamic) statement must be a statement that is allowed in the context of the particular SQL access level in effect. For example, if the SQL access level in effect is READS SQL DATA, the statement must not be an INSERT, UPDATE, or DELETE.
3. Connection management and transaction statements are not allowed in a procedure running on a remote server. COMMIT and ROLLBACK are not allowed in an ATOMIC SQL procedure.
Considerations for using distributed relational database

This section contains information that may be useful in developing applications that use application servers which are not the same product as their application requesters.

All Db2 products support extensions to IBM SQL. Some of these extensions are product-specific, but many are already shared by more than one product or support is planned but not yet generally available.

For the most part, an application can use the statements and clauses that are supported by the database manager of the current server, even though that application might be running through the application requestor of a database manager that does not support some of those statements and clauses. Restrictions to this general rule are identified by application requestor:

- for Db2 for z/OS Application Server application requestor, see Table 128
- for Db2 for i Application Server application requestor, see Table 129 on page 1733
- for Db2 LUW application requestor, see Table 130 on page 1733

Note that an 'R' in the table indicates that this SQL function is not supported in the specified environment. An 'R' in every column of the same row means that the function is available only if the current server and requestor are the same product or that the statement is blocked by the application requestor from being processed at the application server.

<td></td>
</tr>
</tbody>
</table>

149. The Db2 LUW application requester application requester will process a ROWID data type at the application server using the compatible VARCHAR(40) FOR BIT DATA data type.
CONNECT (type 1) and CONNECT (type 2) differences

There are two types of CONNECT statements.

They have the same syntax, but they have different semantics:

- CONNECT (type 1) is used for remote unit of work. See “Remote unit of work” on page 43.
- CONNECT (type 2) is used for distributed unit of work. See “CONNECT (type 2)” on page 998.

The following table summarizes the differences between CONNECT (type 1) and CONNECT (type 2) rules:

<table>
<thead>
<tr>
<th>Table 131. CONNECT (type 1) and CONNECT (type 2) Differences</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type 1 Rules</strong></td>
</tr>
<tr>
<td>CONNECT statements can only be executed when the activation group is in the connectable state. No more than one CONNECT statement can be executed within the same unit of work.</td>
</tr>
<tr>
<td>If the CONNECT statement fails because the server name is not listed in the local directory, the connection state of the activation group is unchanged.</td>
</tr>
<tr>
<td>If a CONNECT statement fails because the activation group is not in the connectable state, the SQL connection status of the activation group is unchanged.</td>
</tr>
<tr>
<td>If a CONNECT statement fails for any other reason, the activation group is placed in the unconnected state.</td>
</tr>
<tr>
<td>CONNECT ends all existing connections of the activation group. Accordingly, CONNECT also closes any open cursors for that activation group.</td>
</tr>
<tr>
<td>A CONNECT to the current server is executed like any other CONNECT (type 1) statement.</td>
</tr>
</tbody>
</table>

Determining the CONNECT rules that apply

A program preparation option is used to specify the type of CONNECT that will be performed by a program. The program preparation option is specified using the RDBCNNMTH parameter on the CRSQL.xxx command.

Connecting to servers that only support remote unit of work

CONNECT (type 2) connections to application servers that only support remote unit of work might result in connections that are read-only.
Characteristics of SQL statements

If a CONNECT (type 2) is performed to an application server that only supports remote unit of work:

- The connection allows read-only operations if, at the time of the connect, there are any dormant connections that allow updates. In this case, the connection does not allow updates.
- Otherwise, the connection allows updates.

If a CONNECT (type 2) is performed to an application server that supports distributed unit of work:

- The connection allows read-only operations when there are dormant connections that allow updates to application servers that only support remote unit of work. In this case, the connection allows updates as soon as the dormant connection is ended.
- Otherwise, the connection allows updates.

150. Db2 for i using the initial DRDA support for native TCP/IP is an example of an application server that supports only remote unit of work.
Appendix C. SQLCA (SQL communication area)

An SQLCA is a set of variables that may be updated at the end of the execution of every SQL statement. A program that contains executable SQL statements may provide one, but no more than one SQLCA (unless a stand-alone SQLCODE or a stand-alone SQLSTATE variable is used instead), except in Java, where the SQLCA is not applicable.

Instead of using an SQLCA, the GET DIAGNOSTICS statement can be used in all languages to return return codes and other information about the previous SQL statement. For more information, see "GET DIAGNOSTICS" on page 1388.

The SQL INCLUDE statement can be used to provide the declaration of the SQLCA in all host languages except Java, RPG, or REXX. For information about the use of the SQLCA in a REXX procedure, see the Embedded SQL Programming topic collection. For information about how to access the information regarding errors and warnings in Java, refer to the IBM Developer Kit for Java topic collection.

In C, COBOL, and PL/I, the name of the storage area must be SQLCA. Every SQL statement must be within the scope of its declaration.

If a stand-alone SQLCODE or SQLSTATE is specified in the program, the SQLCA must not be included. For more information, see "SQL diagnostic information" on page 826.

The stand-alone SQLCODE and stand-alone SQLSTATE must not be specified in the Java or REXX language.

Field descriptions

The names in the following table are those provided by the SQL INCLUDE statement.

For the most part, C (and C++), COBOL, and PL/I use the same names. RPG names are different, because in RPG/400, they are limited to 6 characters. In ILE RPG, both a long name and the short 6 character name is supported. Note one instance where PL/I names differ from the COBOL names.

Table 132. Names Provided by the SQL INCLUDE Statement

<td>SQLCODE</td>
<td>SQLCODE</td>
<td>INTEGER</td>
<td>Contains an SQL return code.</td>
<td></td>
</tr>
</tbody>
</table>
| sqlerrp       | SQLERRP       | CHAR(8)       | Contains the name of the product and module returning the error or warning. The first three characters identify the product:  
|               |               |               | • ARI for Db2 for VM and VSE                                          |
|               |               |               | • DSN for Db2 for z/OS                                                |
|               |               |               | • QSQ for Db2 for i                                                   |
|               |               |               | • SQL for all other Db2 products                                      |
|               |               |               | See ["CONNECT (type 1)" on page 992] or ["CONNECT (type 2)" on page 998] for additional information. |
| SQLERRD       | SQLERRD       | Array         | Contains six INTEGER variables that provide diagnostic information, see [Table 134 on page 1739] for a description of the diagnostic information. |
| sqlwarn       | SQLWARN       | CHAR(11)      | A set of 11 CHAR(1) warning indicators, each containing blank or 'W' or 'N'. |
| sqlstate      | SQLSTATE      | CHAR(5)       | A return code that indicates the outcome of the most recently executed SQL statement. |

**Notes:**

1. In COBOL, SQLERRM includes SQLERRML and SQLERRMC. In PL/1, the varying-length string SQLERRM is equivalent to SQLERRML prefixed to SQLERRMC.

2. In RPG/400, SQLERR is defined as 24 characters (not an array) that are redefined by the fields SQLER1 through SQLER6. The fields are full-word binary. In ILE RPG, SQLERR is also redefined as an array. The name of the array is SQLERRD.

3. In RPG/400, SQLWRN is defined as 11 characters (not an array) that are redefined by the fields SQLWN0 through SQLWNA. The fields are full-word binary. In ILE RPG, SQLWRN is also redefined as an array. The name of the array is SQLWARN.

<td></td>
<td></td>
<td></td>
<td>For a FETCH statement, SQLERRD(3) contains the number of rows fetched.</td>
</tr>
<tr>
<td></td>
<td>SQLERRD(4)</td>
<td>SQLERRD(4)</td>
<td>For the PREPARE statement, contains the estimated number of rows selected. If the number of rows is greater than 2 147 483 647, then 2 147 483 647 is returned.</td>
</tr>
<tr>
<td></td>
<td>sqlerrd[3]</td>
<td>SQLER4</td>
<td>For the PREPARE statement, contains a relative number estimate of the resources required for every execution. This number varies depending on the current availability of indexes, file sizes, CPU model, etc. It is an estimated cost for the access plan chosen by the Db2 for i Query Optimizer.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For a CONNECT and SET CONNECTION statement, SQLERRD(4) contains the type of conversation used and whether or not committable updates can be performed. See &quot;CONNECT (type 2)&quot; on page 998 for more information.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For a CALL statement, SQLERRD(4) contains the message key of the error that caused the procedure to fail. The QMHRTVFM API can be used to return the message description for the message key.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For a trigger error in a DELETE, INSERT MERGE, or UPDATE statement, SQLERRD(4) contains the message key of the error that was signaled from the trigger program. The QMHRTVFM API can be used to return the message description for the message key.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For a FETCH statement, if the result row does not contain a LOB, SQLERRD(4) contains the length of the row(s) retrieved.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For an OPEN statement, if the result row does not contain a LOB, SQLERRD(4) contains the length of a result row.</td>
</tr>
</tbody>
</table>

¹ For a CALL statement, SQLERRD(2) contains the number of result sets.
Table 134. SQLERRD Diagnostic Information (continued)

<table>
<thead>
<tr>
<th>C Name</th>
<th>COBOL Name</th>
<th>ILE RPG Name</th>
<th>RPG/400 Name</th>
<th>Field Value</th>
</tr>
</thead>
</table>
| SQLERRD(5) | sqllerrd[4] | SQLERRD(5) | SQR5 | For a CONNECT or SET CONNECTION statement, SQLERRD(5) contains:  
  • -1 if the connection is unconnected  
  • 0 if the connection is local  
  • 1 if the connection is remote  
  For a DELETE, INSERT, MERGE, or UPDATE statement, shows the number of rows affected by referential constraints and triggers.  
  For an EXECUTE IMMEDIATE or PREPARE statement, may contain the position of a syntax error.  
  For a multiple-row FETCH statement, SQLERRD(5) contains +100 if the last row currently in the table has been fetched.  
  For a PREPARE statement, SQLERRD(5) contains the number of parameter markers in the prepared statement. |
| SQLERRD(6) | sqllerrd[5] | SQLERRD(6) | SQR6 | Contains the SQL completion message identifier when the SQLCODE is 0.  
  In all other cases, it is undefined. |

Note:

1 SQLERRD(1) and SQLERRD(2) are set only if appropriate and only if the current server is Db2 for i.

</table>
INCLUDE SQLCA declarations

This section shows the equivalent INCLUDE SQLCA declaration for C and C++, COBOL, PL/I, RPG/400, and ILE RPG.

In C and C++, INCLUDE SQLCA declarations are equivalent to the following:

```c
#ifndef SQLCODE
struct sqlca
{
    unsigned char sqlcaid[8];
    long sqlcabc;
    long sqlcode;
    short sqlerrml;
    unsigned char sqlerrmc[70];
    unsigned char sqlerrp[8];
    long sqlerrrd[6];
    unsigned char sqlwarn[11];
    unsigned char sqlstate[5];
};
#define SQLCODE sqlca.sqlcode
#define SQLWARN0 sqlca.sqlwarn[0]
#define SQLWARN1 sqlca.sqlwarn[1]
#define SQLWARN2 sqlca.sqlwarn[2]
#define SQLWARN3 sqlca.sqlwarn[3]
#define SQLWARN4 sqlca.sqlwarn[4]
#define SQLWARN5 sqlca.sqlwarn[5]
#define SQLWARN6 sqlca.sqlwarn[6]
#define SQLWARN7 sqlca.sqlwarn[7]
#define SQLWARN8 sqlca.sqlwarn[8]
#define SQLWARN9 sqlca.sqlwarn[9]
#define SQLWARRNA sqlca.sqlwarn[10]
#define SQLSTATE sqlca.sqlstate
#endif
struct sqlca sqlca;
```

In COBOL, INCLUDE SQLCA declarations are equivalent to the following:

```
01 SQLCA.
   05 SQLCAID    PIC X(8).
   05 SQLCABC    PIC S9(9) BINARY.
   05 SQLCODE    PIC S9(9) BINARY.
   05 SQLERRML   49 SQLERRML PIC S9(4) BINARY.
   49 SQLERRMC   PIC X(70).
   05 SQLERRP    PIC X(8).
   05 SQLERRRD   OCCURS 6 TIMES
                 PIC S9(9) BINARY.
   05 SQLWARN.
      10 SQLWARN0 PIC X(1).
      10 SQLWARN1 PIC X(1).
      10 SQLWARN2 PIC X(1).
      10 SQLWARN3 PIC X(1).
      10 SQLWARN4 PIC X(1).
      10 SQLWARN5 PIC X(1).
      10 SQLWARN6 PIC X(1).
      10 SQLWARN7 PIC X(1).
      10 SQLWARN8 PIC X(1).
      10 SQLWARN9 PIC X(1).
      10 SQLWARRNA PIC X(1).
   05 SQLSTATE   PIC X(5).
```

Note: In COBOL, INCLUDE SQLCA must not be specified outside the Working Storage Section.

In PL/I, INCLUDE SQLCA declarations are equivalent to the following:
DCL 1 SQLCA,
  2 SQLCAID  CHAR(8),
  2 SQLCABC  BIN FIXED(31),
  2 SQLCODE  BIN FIXED(31),
  2 SQLERRM  CHAR(70) VAR,
  2 SQLERRP  CHAR(8),
  2 SQLERRD(6) BIN FIXED(31),
  2 SQLWARN,
    3 SQLWARN0  CHAR(1),
    3 SQLWARN1  CHAR(1),
    3 SQLWARN2  CHAR(1),
    3 SQLWARN3  CHAR(1),
    3 SQLWARN4  CHAR(1),
    3 SQLWARN5  CHAR(1),
    3 SQLWARN6  CHAR(1),
    3 SQLWARN7  CHAR(1),
    3 SQLWARN8  CHAR(1),
    3 SQLWARN9  CHAR(1),
    3 SQLWARNA CHAR(1),
  2 SQLSTATE  CHAR(5);

In RPG/400; SQLCA declarations are equivalent to the following:

```
ISQLCA   DS
I       1  8 SQLCAID   SQL
I       B  9 120SQLABC SQL
I       B 13 160SQLCOD SQL
I       B 17 180SQLERL SQL
I       19 88 SQLERM  SQL
I       89 96 SQLERP  SQL
I       97 120 SQLERR  SQL
I       B 97 1000SQLER1 SQL
I       B 101 1040SQLER2 SQL
I       B 105 1080SQLER3 SQL
I       B 109 1120SQLER4 SQL
I       B 113 1160SQLER5 SQL
I       B 117 1200SQLER6 SQL
I       121 131 SQLRN  SQL
I       121 121 SQLRN0 SQL
I       122 122 SQLRN1 SQL
I       123 123 SQLRN2 SQL
I       124 124 SQLRN3 SQL
I       125 125 SQLRN4 SQL
I       126 126 SQLRN5 SQL
I       127 127 SQLRN6 SQL
I       128 128 SQLRN7 SQL
I       129 129 SQLRN8 SQL
I       130 130 SQLRN9 SQL
I       131 131 SQLRN/A SQL
I       132 136 SQLSTT SQL
```

In ILE RPG; SQLCA declarations are equivalent to the following:

```
// SQL COMMUNICATION AREA
DCL-DS SQLCA;
SQLCAID  CHAR(8)  INZ('X'0000000000000000');
SQLCAID  CHAR(8)  OVERLAY(SQLCAID);  
SQLCABC  INT(10);  
SQLCABC  BINDEC(9) OVERLAY(SQLCABC);  
SQLCODE  INT(10);  
SQLCODE  BINDEC(9) OVERLAY(SQLCODE);  
SQLERRM  INT(5);  
SQLERRM  BINDEC(4) OVERLAY(SQLERRM);  
SQLERRP  CHAR(70);  
SQLERRP  CHAR(8);  
SQLERRP  CHAR(8) OVERLAY(SQLERRP);  
SQLERR  CHAR(24);  
```
SQLCA

```sql
  SQLER1 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER2 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER3 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER4 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER5 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLER6 BINDEC(9) OVERLAY(SQLERR:*NEXT);
  SQLERD INT(10) DIM(6) OVERLAY(SQLERR);
  SQLWRN CHAR(11);
  SQLWN0 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN1 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN2 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN3 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN4 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN5 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN6 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN7 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN8 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWN9 CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWNA CHAR(1) OVERLAY(SQLWRN:*NEXT);
  SQLWARN CHAR(1) DIM(11) OVERLAY(SQLWRN);
  SQLSTATE CHAR(5);
  SQLSTT CHAR(5) OVERLAY(SQLSTATE);
END-DS SQLCA;
```
Appendix D. SQLDA (SQL descriptor area)

An SQLDA is a set of variables that is used for execution of the SQL DESCRIBE statement, and it may optionally be used by the PREPARE, OPEN, CALL, FETCH, and EXECUTE statements.

An SQLDA can be used in a DESCRIBE or PREPARE statement, altered with the addresses of storage areas\textsuperscript{151}, and then used again in a FETCH statement.

SQLDAs are supported for all languages, but predefined declarations are provided only for C (and C++), COBOL, ILE RPG, PL/I, and REXX. In REXX, the SQLDA is somewhat different than in the other languages; for information about the use of SQLDAs in REXX, see the Embedded SQL Programming topic collection.

The meaning of the information in an SQLDA depends on its use.

- When an SQLDA is used in a DESCRIBE or PREPARE statement, an SQLDA provides information to an application program about a prepared select-statement. Each column of the result table is described in an SQLVAR occurrence or set of related SQLVAR occurrences.
- In OPEN, EXECUTE, CALL, and FETCH, an SQLDA provides information to the database manager about storage areas for input or output data. Each storage area is described in the SQLVARs.
  - For OPEN and EXECUTE of a statement other than CALL, each SQLVAR occurrence or set of related SQLVAR occurrences describes a storage area that is used to contain an input value which is substituted for a parameter marker in the associated SQL statement that was previously prepared.
  - For FETCH, each SQLVAR occurrence or set of related SQLVAR occurrences describes a storage area that is used to contain an output value from a row of the result table.
  - For CALL and EXECUTE of a prepared CALL statement, each SQLVAR occurrence or set of related SQLVAR occurrences describes a storage area that is used to contain an input or output value (or both) that corresponds to an argument in the argument list for the procedure.

An SQLDA consists of four variables in a header followed by an arbitrary number of occurrences of a base SQLVAR. When the SQLDA describes either LOBs or distinct types the base SQLVARs are followed by the same number of occurrences of an extended SQLVAR.

**Base SQLVAR entry**

The base SQLVAR entry is always present. The fields of this entry contain the base information about the column or variable such as data type code, length attribute (except for LOBs), column name (or label), CCSID, variable address, and indicator variable address.

**Extended SQLVAR entry**

The extended SQLVAR entry is needed (for each column) if the result includes any LOB or distinct type columns. For distinct types, the extended SQLVAR contains the distinct type name. For LOBs, the extended SQLVAR contains the length attribute of the variable and a pointer to the buffer that

\textsuperscript{151} A storage area could be the storage for a variable defined in the program (that may also be a host variable) or an area of storage explicitly allocated by the application.

© Copyright IBM Corp. 1998, 2015
contains the actual length. If locators or file reference variables are used to represent LOBs, an extended SQLVAR is not necessary.

The extended SQLVAR entry is also needed for each column when:

- USING BOTH is specified, which indicates that column names and labels are returned.
- USING ALL is specified, which indicates that column names, labels, and system column names are returned.

The fields in the extended SQLVAR that return LOB and distinct type information do not overlap, and the fields that return LOB and label information do not overlap. Depending on the combination of labels, LOBs and distinct types, more than one extended SQLVAR entry per column may be required to return the information. See “Determining how many SQLVAR occurrences are needed” on page 1750.
Field descriptions in an SQLDA header

An SQLDA consists of four variables in a header structure followed by an arbitrary number of occurrences of a sequence of five variables collectively named SQLVAR. In OPEN, CALL, FETCH, and EXECUTE, each occurrence of SQLVAR describes a variable. In PREPARE and DESCRIBE, each occurrence describes a column of a result table.

The SQL INCLUDE statement provides the following field names:

**Table 136. Field Descriptions for an SQLDA Header**

<table>
<thead>
<tr>
<th>C Name</th>
<th>Field Data Type</th>
<th>Usage in DESCRIBE and PREPARE (set by the database manager except for SQLN)</th>
<th>Usage in FETCH, OPEN, CALL, or EXECUTE (set by the user prior to executing the statement)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqldaid</td>
<td>CHAR(8)</td>
<td>An ‘eye catcher’ for storage dumps, containing ‘SQLDA’. The 7th byte of the SQLDAID can be used to determine whether more than one SQLVAR entry is needed for each column. For details, see &quot;Determining how many SQLVAR occurrences are needed&quot; on page 1750.</td>
<td>A ’2’ in the 7th byte indicates that two SQLVAR entries were allocated for each column. A ’3’ in the 7th byte indicates that three SQLVAR entries were allocated for each column. A ’4’ in the 7th byte indicates that four SQLVAR entries were allocated for each column.</td>
</tr>
<tr>
<td>sqldabc</td>
<td>INTEGER</td>
<td>Length of the SQLDA.</td>
<td>Number of bytes of storage allocated for the SQLDA. Enough storage must be allocated to contain SQLN occurrences. SQLDABC must be set to a value greater than or equal to 16+SQLN*(80), where 80 is the length of an SQLVAR occurrence. If LOBs or distinct types are specified, there must be two SQLVAR entries for each parameter marker.</td>
</tr>
<tr>
<td>sqln</td>
<td>SMALLINT</td>
<td>Unchanged by the database manager. Must be set to a value greater than or equal to zero before the PREPARE or DESCRIBE statement is executed. It should be set to a value that is greater than or equal to the number of columns in the result or a multiple of the number of columns in the result when multiple sets of SQLVAR entries are necessary. Indicates the total number of occurrences of SQLVAR.</td>
<td>Total number of occurrences of SQLVAR provided in the SQLDA. SQLN must be set to a value greater than or equal to zero. If LOBs or distinct types are specified, there must be two SQLVAR entries for each parameter marker and SQLN must be set to two times the number of parameter markers.</td>
</tr>
<tr>
<td>sqld</td>
<td>SMALLINT</td>
<td>The number of columns described by occurrences of SQLVAR (zero if the statement being described is not a select-statement, CALL, or VALUES INTO).</td>
<td>Number of occurrences of SQLVAR entries in the SQLDA that are used when executing the statement. SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.</td>
</tr>
</tbody>
</table>

152. In this column, the lowercase name is the C Name. The uppercase name is the COBOL, PL/I, or RPG Name.
Determining how many SQLVAR occurrences are needed

The number of SQLVAR occurrences needed depends on the statement that the SQLDA was provided for and the data types of the columns or parameters being described. See the tables above for more information.

The 7th byte of SQLDAID is always set to the number of sets of SQLVARs necessary when LOBs or UDTs are in the result set.

If SQLD is not set to a sufficient number of SQLVAR occurrences:

- When LOBs and UDTs are not in the result set, SQLD is set to the total number of SQLVAR occurrences needed for all sets. When there are LOBs or UDTs in the result set, SQLD is set to the number of columns in the result table and the seventh byte of SQLDAID indicates the number of sets of SQLVAR entries needed. The number of required SQLVAR entries can always be determined by multiplying SQLD by the value in the seventh byte of SQLDAID.
- A warning (SQLSTATE 01594) is returned if at least enough SQLVARs were specified for the Base SQLVAR Entries. The Base SQLVAR entries are returned, but no extended SQLVARs are returned.
- A warning (SQLSTATE 01005) is returned if enough SQLVARs were not specified for even the Base SQLVAR Entries. No SQLVAR entries are returned.

Table 137, Table 138 on page 1751, and Table 139 on page 1751 show how to map the base and extended SQLVAR entries. For an SQLDA that contains both base and extended SQLVAR entries, the base SQLVAR entries are in the first block, followed by a block of extended SQLVAR entries, which if necessary, are followed by a second or third block of extended SQLVAR entries. In each block, the number of occurrences of the SQLVAR entry is equal to the value in SQLD even though many of the extended SQLVAR entries might be unused.

Field descriptions in an occurrence of SQLVAR

This section includes field descriptions in an occurrence of a base and secondary SQLVAR.

Fields in an occurrence of a base SQLVAR

<table>
<thead>
<tr>
<th>C Name</th>
<th>COBOL Name</th>
<th>PL/I Name</th>
<th>RPG Name</th>
<th>Field</th>
<th>Data Type</th>
<th>Usage in DESCRIBE and PREPARE (set by the database manager)</th>
<th>Usage in FETCH, OPEN, CALL, and EXECUTE (set by the user prior to executing the statement)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqltype</td>
<td>SQLTYPE</td>
<td>SMALLINT</td>
<td></td>
<td></td>
<td></td>
<td>Indicates the data type of the column and whether it can contain nulls. For a description of the type codes, see Table 142 on page 1756. For a distinct type, the data type on which the distinct type is based is placed in this field. The base SQLVAR contains no indication that this is part of the description of a distinct type.</td>
<td>Indicates the data type of the host variable and whether an indicator variable is provided. For a description of the type codes, see Table 142 on page 1756.</td>
</tr>
<tr>
<td>sqllen</td>
<td>SQLLEN</td>
<td>SMALLINT</td>
<td></td>
<td></td>
<td></td>
<td>The length attribute of the column. For datetime columns, the length of the string representation of the values. See Table 142 on page 1756. For a LOB, the value is 0 regardless of the length attribute of the LOB. For XML, the value is 0. Field SQLLONGLEN in the extended SQLVAR entry contains the length attribute of the LOB or XML.</td>
<td>The length attribute of the host variable. See Table 142 on page 1756. For a LOB, the value is 0 regardless of the length attribute of the LOB. Field SQLLONGLEN in the extended SQLVAR entry contains the length attribute of the LOB. For XML AS BLOB, CLOB, or DBCLOB, the value is 0.</td>
</tr>
<tr>
<td>sqires</td>
<td>SQLRES</td>
<td>CHAR(12)</td>
<td></td>
<td></td>
<td></td>
<td>Reserved. Provides boundary alignment for SQLDATA.</td>
<td>Reserved. Provides boundary alignment for SQLDATA.</td>
</tr>
<tr>
<td>sqldata</td>
<td>SQLDATA</td>
<td>pointer</td>
<td></td>
<td></td>
<td></td>
<td>The CCSID of a string column or XML column as described in Table 143 on page 1758. Contains the address of the host variable. For LOB host variables, if the SQLDATALEN field in the extended SQLVAR is null, this points to the four-byte LOB length, followed immediately by the LOB data. If the SQLDATALEN field in the extended SQLVAR is not null, this points to the LOB data and the SQLDATALEN field points to the four-byte LOB length.</td>
<td></td>
</tr>
</tbody>
</table>

154. In this column, the lowercase name is the C Name. The uppercase name is the PL/I, COBOL, and RPG Name.
Table 140. Field Descriptions for an SQLVAR (continued)

<table>
<thead>
<tr>
<th>C Name</th>
<th>COBOL Name</th>
<th>PL/I Name</th>
<th>RPG Name</th>
<th>Field Data Type</th>
<th>Usage in DESCRIBE and PREPARE (set by the database manager)</th>
<th>Usage in FETCH, OPEN, CALL, and EXECUTE (set by the user prior to executing the statement)</th>
</tr>
</thead>
</table>
| sqlind | SQLIND     |           |          | pointer         | For a select-statement, indicates whether the column was added as a result of using the WITH ROW CHANGE COLUMNS attribute:  
  • -1 ROW CHANGE TOKEN (distinct)  
  • -2 ROW CHANGE TOKEN (not distinct)  
  • -3 RID  
  • -4 RID_BIT  
  Otherwise, reserved. | Contains the address of the indicator variable. Not used if there is no indicator variable (as indicated by an even value of SQLTYPE). |
| sqlname| SQLNAME    |           |          | VARCHAR(30)     | The unqualified name of the column. If the column does not have a name, a string is constructed from the expression and returned.  
  The name is case sensitive and does not contain surrounding delimiters. | Contains the CCSID of the host variable as described in Table 143 on page 1758  
  For XML data, sqlname can be set as follows to indicate as XML subtype:  
  The length of sqlname is 8  
  Bytes 1 and 2: Must be X'0000'.  
  Bytes 3 and 4: May contain a CCSID.  
  Bytes 5 and 6 X'0100' XML host variable  
  (XML AS CLOB, XML AS DBCLOB,  
  XML AS BLOB, XML AS CLOB_FILE,  
  XML AS DBCLOB_FILE, XML AS  
  BLOB_FILE)  
  Bytes 7 and 8: Must be X'0000'. |
## Fields in an occurrence of a secondary SQLVAR

### Table 141. Field Descriptions for an Extended SQLVAR

<table>
<thead>
<tr>
<th>C Name</th>
<th>COBOL Name</th>
<th>PL/I Name</th>
<th>RPG Name</th>
<th>Field</th>
<th>Data Type</th>
<th>Usage in DESCRIBE and PREPARE (set by the database manager)</th>
<th>Usage in FETCH, OPEN, CALL, and EXECUTE (set by the user prior to executing the statement)</th>
</tr>
</thead>
<tbody>
<tr>
<td>len.sqllonglen</td>
<td>SQLLONGLEN</td>
<td>SQLLONGLEN</td>
<td>SQLLONGLEN</td>
<td>INTEGER</td>
<td>The length attribute of a LOB column. For XML, the value is 0.</td>
<td>The length attribute of a LOB or XML host variable. The database manager ignores the SQLLEN field in the base SQLVAR for these data types. The length attribute indicates the number of bytes for a BLOB, and the number of characters for a CLOB, DBCLOB, or for XML.</td>
<td></td>
</tr>
<tr>
<td>*</td>
<td>CHAR(12)</td>
<td>Pointer</td>
<td>Pointer</td>
<td>Pointer</td>
<td>Reserved. Provides boundary alignment for SQLDATALEN</td>

<td></td>
</tr>
<tr>
<td>sqldatalen</td>
<td>SQLDATAL</td>
<td>SQLDATAL</td>
<td>SQLDATAL</td>
<td>POINTER</td>
<td>Not used.</td>
<td>Used only for LOB host variables.</td>
<td></td>
</tr>
</tbody>
</table>

If the value of this field is not null, this field points to a four-byte long buffer that contains the actual length of the LOB in bytes (even for DBCLOBs). The SQLDATA field in the matching base SQLVAR then points to the LOB data.

If the value of this field is null, the actual length of the LOB is stored in the first four bytes pointed to by the SQLDATA field in the matching base SQLVAR, and the LOB data immediately follows the four-byte length. The actual length indicates the number of bytes for a BLOB or CLOB and the number of double-byte characters for a DBCLOB.

Regardless of whether this field is used, field SQLLONGLEN must be set.

---

155. In this column, the lowercase name is the C Name. The first uppercase name is the PL/I and RPG Name. The second uppercase name is the COBOL Name.

SQLDA

SQLTYPE and SQLLEN

The following table shows the values that may appear in the SQLTYPE and SQLLEN fields of the SQLDA. In PREPARE and DESCRIBE, an even value of SQLTYPE means the column does not allow nulls, and an odd value means the column does allow nulls.

**Note:** In an SQLDA used in DESCRIBE or PREPARE statements, an odd value is returned for an expression if one operand is nullable or if the expression may result in a -2 mapping-error null value.

In FETCH, OPEN, CALL, and EXECUTE, an even value of SQLTYPE means no indicator variable is provided, and an odd value means that SQLIND contains the address of an indicator variable.

Table 142. SQLTYPE and SQLLEN values for PREPARE, DESCRIBE, FETCH, OPEN, CALL, or EXECUTE

156. Binary numbers can be represented in the SQLDA with a length of 2, 4, or 8, or with the precision in byte 1 and the scale in byte 2. If the first byte is greater than x'00', it indicates precision and scale.

157. Field SQLLONGLEN in the extended SQLVAR contains the length attribute of the column.

158. Less for *JUL, *YMD, *DMY, and *MDY formats. For more information, see Table 8 on page 85.
CCSID values in SQLDATA or SQLNAME

In the OPEN, FETCH, CALL, and EXECUTE statements, the SQLNAME field of the SQLVAR element can be used to specify a CCSID for string host variables. If the SQLNAME field is used to specify a CCSID, the SQLNAME length must be set to 8. In addition, the first 4 bytes of SQLNAME must be set as described in the table below. If no CCSID is specified, the job CCSID is used.

In the DESCRIBE, DESCRIBE TABLE, and PREPARE statements, the SQLDATA field of the SQLVAR element contains the CCSID of the column of the result table if that column is a string column. The CCSID is located in bytes 3 and 4 as described in [Table 143].

Unrecognized and unsupported SQLTYPES

The values that appear in the SQLTYPE field of the SQLDA are dependent on the level of data type support available at the sender as well as the receiver of the data. This is particularly important as new data types are added to the product.

New data types may or may not be supported by the sender or receiver of the data and may or may not even be recognized by the sender or receiver of the data. Depending on the situation, the new data type may be returned, or a compatible data type agreed upon by both the sender and receiver of the data may be returned or an error may result.

When the sender and receiver agree to use a compatible data type, the following indicates the mapping that will take place. This mapping will take place when at least one of the sender or receiver does not support the data type provided. The unsupported data type can be provided by either the application or the database manager.

Table 144. Compatible Data Types for Unsupported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Compatible Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>DECIMAL(19,0)</td>
</tr>
<tr>
<td>ROWID</td>
<td>VARCHAR(40) FOR BIT DATA</td>
</tr>
<tr>
<td>TIMESTAMP(n)</td>
<td>TIMESTAMP(6)</td>
</tr>
</tbody>
</table>

159. Db2 does not internally store DECFLOAT(7) numbers, but it will support DECFLOAT(7) numbers from applications. A DECFLOAT(7) variable referenced in an SQL statement will be converted to DECFLOAT(16).
**INCLUDE SQLDA declarations**

This section shows the equivalent INCLUDE SQLDA declaration for C and C++, COBOL, ILE COBOL, PL/I, and ILE RPG.

**For C and C++**

In C and C++, INCLUDE SQLDA declarations are equivalent to the following:

```c
#ifndef SQLDASIZE
struct sqlda
{
    unsigned char sqldaid[8];
    long sqldabc;
    short sqln;
    short sqld;
    struct sqlvar
    {
        short sqltype;
        short sqllen;
    union {
        unsigned char *sqldata;
        long long sqld_result_set_locator; }
    union {
        short *sqlind;
        long sqld_row_change;
        long sqld_result_set_rows; }
    struct sqlname
    {
        short length;
        unsigned char data[30];
    } sqlname;
    } sqlvar[1];
};
struct sqlvar2
    { struct
    { long sqllonglen;
    char reserve1[28];
    } len;
    char *sqldatalen;
    struct sqldistinct_type
    { short length;
    unsigned char data[30];
    } sqldatatypename;
    }; #define SQLDASIZE(n) (sizeof(struct sqlda)+(n-1) * sizeof(struct sqlvar))
#endif
```

*Figure 11. INCLUDE SQLDA Declarations for C and C++*
# define SQLDoubled '2'
# define SQLSingly '1'

/**************************************************************************/
/* GETSQLDoubled(daptr) returns 1 if the SQLDA pointed to by */
/* daptr has been doubled, or 0 if it has not been doubled. */
/**************************************************************************/
#define GETSQLDoubled(daptr) (((daptr)->sqlaid[6] == 
 (char) SQLDoubled) ? 
 (1) : 
 (0) )

/**************************************************************************/
/* SETSQLDoubled(daptr, SQLDoubled) sets the 7th byte of sqlaid */
/* to '2'. */
/* SETSQLDoubled(daptr, SQLSingly) sets the 7th byte of sqlaid */
/* to be a '1'. */
/**************************************************************************/
#define SETSQLDoubled(daptr, newvalue) 
 (( (daptr)->sqlaid[6] = (newvalue)) )

/**************************************************************************/
/* GETSQLDAlongLen(daptr,n) returns the data length of the nth */
/* entry in the sqlda pointed to by daptr. Use this only if the */
/* sqlda was doubled or tripled and the nth SQLVAR entry has a */
/* LOB datatype. */
/**************************************************************************/
#define GETSQLDAlongLen(daptr,n) ((long) (((struct sqlvar {*}

 ((daptr)->sqlaid[6])]); 
 var2ptr->sqldatalen = (char {*} ptr; 
 }

/**************************************************************************/
/* GETSQLDALENPtr(daptr,n) returns a pointer to the data length for */
/* the nth entry in the sqlda pointed to by daptr. Unlike the inline */
/* value (union sql8byteilen len), which is 8 bytes, the sqldatalen */
/* pointer field returns a pointer to a long (4 byte) integer. */
/* If the SQLDALEN pointer is zero, a NULL pointer is be returned. */
/* */
/* NOTE: Use this only if the sqlda has been doubled or tripled. */
/**************************************************************************/
#define GETSQLDALENPtr(daptr,n) 
 \ 
 (((struct sqlvar2 {*} &((daptr)->sqlvar[(n)+ 

For COBOL and ILE COBOL

In COBOL and ILE COBOL, INCLUDE SQLDA declarations are equivalent to the following:

```
1 SQLDA.
  05 SQLDAID PIC X(8).
  05 SQLDABC PIC S9(9) BINARY.
  05 SQLN PIC S9(4) BINARY.
  05 SQLD PIC S9(4) BINARY.
  05 SQLVAR OCCURS 0 TO 409 TIMES DEPENDING ON SQLD.
    10 SQLVAR1.
      15 SQLTYPE PIC S9(4) BINARY.
      15 SQLLEN PIC S9(4) BINARY.
      15 FILLER REDEFINES SQLLEN.
      20 SQLPRECISION PIC X.
      20 SQLSCALE PIC X.
      15 SQLRES PIC X(12).
      15 SQLDATA POINTER.
      15 SQL-RESULT-SET-LOCATOR-R REDEFINES SQLDATA.
      20 SQL-RESULT-SET-LOCATOR PIC S9(18) BINARY.
      15 SQLIND POINTER.
      15 SQL-ROW-CHANGE-SQL-R REDEFINES SQLIND.
      20 SQLD-ROW-CHANGE PIC S9(9) BINARY.
      15 SQLRESULT-SET-ROWS-R PIC REDEFINES SQLIND.
      20 SQLD-RESULT-SET-ROWS PIC S9(9) BINARY.
      15 SQLNAME.
        49 SQLNAMEL PIC S9(4) BINARY.
        49 SQLNAMEC PIC X(30).
    10 SQLVAR2 REDEFINES SQLVAR1.
      15 SQLVAR2-RESERVED-1 PIC S9(9) BINARY.
      15 SQLLONGLEN REDEFINEDS SQLVAR2-RESERVED-1
        PIC S9(9) BINARY.
      15 SQLVAR2-RESERVED-2 PIC X(28).
      15 SQLDATALEN POINTER.
      15 SQLDATATYPE-NAME.
        49 SQLDATATYPE_NAMEL PIC S9(4) BINARY.
        49 SQLDATATYPE_NAMEC PIC X(30).
```

Figure 12. INCLUDE SQLDA Declarations for COBOL

For PL/I

In PL/I, INCLUDE SQLDA declarations are equivalent to the following:
**SQLDA**

DCL 1 SQLDA BASED(SQLDAPTR),
    2 SQLDAID  CHAR(8),
    2 SQLABC   BIN FIXED(31),
    2 SQLN     BIN FIXED,
    2 SQLD     BIN FIXED,
    2 SQLVAR   (99),
    3 SQLTYPE  BIN FIXED,
    3 SQLLEN   BIN FIXED,
    3 SQLRES   CHAR(12),
    3 SQLDATA  PTR,
    3 SQLIND   PTR,
    3 SQLNAME  CHAR(30) VAR,

1 SQLDA2 BASED(SQLDAPTR),
    2 SQLDAID2 CHAR(8),
    2 SQLABC2  FIXED(31) BINARY,
    2 SQLN2    FIXED(15) BINARY,
    2 SQLD2    FIXED(15) BINARY,
    2 SQLVAR2  (99),
    3 SQLBIGLEN,
    4 SQLLONGL FIXED(31) BINARY,
    4 SQLRSVDL FIXED(31) BINARY,
    3 SQLDATAL POINTER,
    3 SQLTNAME CHAR(30) VAR;

DECLARE SQLSIZE FIXED(15) BINARY;
DECLARE SQLDAPTR PTR;
DECLARE SQLDOUBLED CHAR(1) INITIAL('2') STATIC;
DECLARE SQLSINGLED CHAR(1) INITIAL(' ') STATIC;

*Figure 13. INCLUDE SQLDA Declarations for PL/I*

**For ILE RPG**

In ILE RPG, INCLUDE SQLDA declarations are equivalent to the following:
The user is responsible for the definition of SQL\_NUM. SQL\_NUM must be defined as a numeric constant with the dimension required for SQL\_VAR.

Since RPG does not support structures within arrays, the SQLDA generates three data structures. The second and third data structures are used to setup/reference the part of the SQLDA which contains the field descriptions.

To set the field descriptions of the SQLDA the program sets up the field description in the subfields of SQLVAR (or SQLVAR2) and then does a MOVEA of SQLVAR (or SQLVAR2) to SQL\_VAR, n where n is the number of the field in the SQLDA. This is repeated until all the field descriptions are set.

When the SQLDA field descriptions are to be referenced the user does a MOVEA of SQL\_VAR, n to SQLVAR (or SQLVAR2) where n is the number of the field description to be processed.
Appendix E. CCSID values

The tables in this section describe the CCSIDs and conversions provided by the IBM relational database products.

For more information, see “Character conversion” on page 33.

The following list defines the symbols used in the Db2 product column in the following tables:

- **X** Indicates that the conversion tables exist to convert from or to that CCSID. This also implies that this CCSID can be used to tag local data.

- **C** Indicates that conversion tables exist to convert from that CCSID to another CCSID. This also implies that this CCSID cannot be used to tag local data, because the CCSID is in a foreign encoding scheme (for example, a PC-Data CCSID such as 850 cannot be used to tag local data in Db2 for i).

- **blank** Indicates that the specific product does not support the CCSID at all. Such a CCSID must not be used unless interoperability with the specific product is not necessary.

This information is current as of the publishing date of this book for the CCSIDs listed. Additional CCSIDs may have been added since the publishing date and are not in the lists below.

Appendix F. Db2 for i catalog views

The views contained in a Db2 for i catalog are described in this section.

The database manager maintains a set of tables containing information about the data in each relational database. These tables are collectively known as the catalog. The catalog tables contain information about tables, user-defined functions, distinct types, parameters, procedures, packages, views, indexes, aliases, sequences, variables, constraints, triggers, XSR objects, and languages supported by Db2 for i. The catalog also contains information about all relational databases that are accessible from this system.

There are three classes of catalog views:

- **IBM i catalog tables and views**
  The IBM i catalog tables and views are modeled after the ANS and ISO catalog views, but are not identical to the ANS and ISO catalog views. These tables and views are compatible with prior releases of Db2 for i.
  These tables and views exist in schemas QSYS and QSYS2.
  The catalog tables and views contain information about all tables, parameters, procedures, functions, distinct types, packages, XSR objects, views, indexes, aliases, sequences, variables, triggers, and constraints in the entire relational database. When an SQL schema is created, an additional subset of these views are created into the schema that only contain information about tables, packages, views, indexes, and constraints in that schema.

- **ODBC and JDBC catalog views**
  The ODBC and JDBC catalog views are designed to satisfy ODBC and JDBC metadata API requests. For example, SQLCOLUMNS. These views are compatible with views on Db2 LUW Version 8. These views will be modified as ODBC or JDBC enhances or modifies their metadata APIs.
  These views exist in schema SYSIBM.

- **ANS and ISO catalog views**
  The ANS and ISO catalog views are designed to comply with the ANS and ISO SQL standard (the Information Schema catalog views). These views will be modified as the ANS and ISO standard is enhanced or modified.
  There are several columns in these views that are reserved for future standard enhancements.
  There are two versions of these views:
  - The first version of these views exist in schema INFORMATION_SCHEMA\(^{160}\). Only rows associated with objects to which the user has some privilege are included in the views. This version is compatible with the ANS and ISO SQL standard.
    If you use of this set of catalog views to prevent users from seeing any information about objects to which they have no privilege, you should revoke privileges to the other catalog views from users and PUBLIC.
    - The second version of these views exist in schema SYSIBM. All rows are included in these views whether or not the user has some privilege to the

---

\(^{160}\) INFORMATION_SCHEMA is the ANS and ISO SQL standard schema name that contains catalog views. It is a synonym for QSYS2.

© Copyright IBM Corp. 1998, 2015
Catalog views

objects associated with rows in the views. These views are compatible with views on Db2 LUW Version 8 and will generally perform better than the ANS and ISO views in QSYS2.

For example, assume that a user has the SELECT privilege to the QSYS2.TABLES and SYSIBM.TABLES catalog views but does not have any privilege to a table called WORK.EMPLOYEE. The following SQL statement will not return a result row:

```sql
SELECT *
FROM QSYS2.TABLES
WHERE TABLE_SCHEMA = 'WORK' AND TABLE_NAME = 'EMPLOYEE'
```

However, the following SQL statement will return a result row:

```sql
SELECT *
FROM SYSIBM.TABLES
WHERE TABLE_SCHEMA = 'WORK' AND TABLE_NAME = 'EMPLOYEE'
```

**Note:** Some of these views use special catalog functions as part of the view definition. These functions exist in SYSIBM and QSYS2. If these functions are used directly in applications, care should be taken because they may be incompatibly changed in future releases or fix packs.

**Notes**

**Names in the Catalog:** In general, all names stored in columns of a catalog table are undelimited and case sensitive. For example, assume the following table was created:

```sql
CREATE TABLE "colname"/"long_table_name"
("long_column_name" CHAR(10),
 INTCOL INTEGER)
```

If the following select statement is used to return information about the mapping between SQL names and system names, the following select statement could be used:

```sql
SELECT TABLE_NAME, SYSTEM_TABLE_NAME, COLUMN_NAME, SYSTEM_COLUMN_NAME
FROM QSYS2/SYSCOLUMNS
WHERE TABLE_NAME = 'long_table_name' AND TABLE_SCHEMA = 'colname'
```

The following rows would be returned:

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>SYSTEM_TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>SYSTEM_COLUMN_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>long_table_name</td>
<td>&quot;long0001&quot;</td>
<td>long_column_name</td>
<td>LONG_0001</td>
</tr>
<tr>
<td>long_table_name</td>
<td>&quot;long0001&quot;</td>
<td>INTCOL</td>
<td>INTCOL</td>
</tr>
</tbody>
</table>

**System Names in the Catalog:** In general, the longer SQL column names should be used rather than the short system column names. The short system column names for IBM i catalog tables and views are explicitly maintained for compatibility with prior releases and other Db2 products. The short system column names for the ODBC and JDBC catalog views and the ANS and ISO catalog views are not explicitly maintained and may change between releases.

**Null Values in the Catalog:** If the information in a column is not applicable, the null value is returned. Using the table created above, the following select statement, which queries the NUMERIC_SCALE and the CHARACTER_MAXIMUM_LENGTH, would return the null value when the data was not applicable to the data type of the column.
SELECT COLUMN_NAME, NUMERIC_SCALE, CHARACTER_MAXIMUM_LENGTH
FROM QSYS2/SYSCOLUMNS
WHERE TABLE_NAME = 'long_table_name' AND TABLE_SCHEMA = 'colname'

The following rows would be returned:

<table>
<thead>
<tr>
<th>COLUMN_NAME</th>
<th>NUMERIC_SCALE</th>
<th>CHARACTER_MAXIMUM_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>long_column_name</td>
<td>?</td>
<td>10</td>
</tr>
<tr>
<td>INTCOL</td>
<td>0</td>
<td>?</td>
</tr>
</tbody>
</table>

Because numeric scale is not valid for a character column, the null value is returned for NUMERIC_SCALE for the 'long_column_name' column. Because character length is not valid for a numeric column, the null value is returned for CHARACTER_MAXIMUM_LENGTH for the INTCOL column.

Install and Backup Considerations: Certain catalog tables and any views created over the catalog tables and views should be regularly saved:

- The catalog table QSYS.QADBXRDBD contains relational database information. This table should be regularly saved.
- When an ILE external function or procedure or an SQL function or procedure is restored, information is automatically inserted into these catalog tables. This does not occur for non-ILE external functions and procedures. In order to back up the definitions of non-ILE external functions or procedures, ensure that the catalog tables SYSROUTINES and SYSPARMS are saved or ensure you have a back up of the SQL source statements that were used to create these functions and procedures.
- All catalog views in the QSYS2 or SYSIBM schemas are system objects. This means that any user views created over these catalog views must be deleted when the operating system is installed. All dependent objects must be deleted as well. To avoid this requirement, you can save views before installation and then restore them afterwards.
- Catalog tables in the QSYS library are also system objects. However, the catalog tables in the QSYS library are not deleted during installation. Hence, any views created over these tables are preserved throughout the installation process.

Granting Privileges to Catalog Views: Tables and views in the catalog are like any other database tables and views. If you have authorization, you can use SQL statements to look at data in the catalog views in the same way that you retrieve data from any other table. The tables and views in the catalogs are shipped with the SELECT privilege to PUBLIC. This privilege may be revoked and the SELECT privilege granted to individual users.

QSYS Catalog Tables: Most of the catalog views are based on the following tables in the QSYS library (sometimes called the database cross reference files). These tables are not shipped with the SELECT privilege to PUBLIC and should not be used directly:

QADBCCST  QADBPKG  QADBXSFLD
QADBFDEP  QADBXTLS  QADBXTRIGB
QADBFCST  QADBXTLSD  QADBXTRIGC
QADBIFLD  QADBXRDBD  QADBXTRIGD
QADBKFLD  QADBXREF
Catalog views

**Use of SELECT *:** New columns are likely to be added to tables and views in the catalog as new functionality is implemented and as the ISO/ANSI standards evolve. For this reason, it is recommended that SELECT * not be used when accessing catalog tables and views unless your application is prepared to tolerate these new columns.
## IBM i catalog tables and views

The IBM i catalog includes the views and tables in the QSYS2 schema displayed in this section.

</tr>
</tbody>
</table>
**SYSCOLAUTH**

The SYSCOLAUTH view contains one row for every privilege granted on a column. Note that this catalog view cannot be used to determine whether a user is authorized to a column because the privilege to use a column could be acquired through a group user profile or special authority (such as *ALLOBJ). Furthermore, the privilege to use a column is also acquired through privileges granted on the table.

The following table describes the columns in the SYSCOLAUTH view:

*Table 158. SYSCOLAUTH view*

The SYSCOLUMNS2 view contains one row for every column of each table and view in the SQL schema (including the columns of the SQL catalog).

For information related to a single table or view, a query that uses SYSCOLUMNS2 will typically perform better than querying SYSCOLUMNS. SYSCOLUMNS2 also contains a few more column attributes than SYSCOLUMNS.

The following table describes the columns in the SYSCOLUMNS2 view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLUMN_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the column. This will be the SQL column name if one exists; otherwise, it will be the system column name.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table or view that contains the column. This will be the SQL table or view name if one exists; otherwise, it will be the system table or view name.</td>
</tr>
<tr>
<td>TABLE_OWNER</td>
<td>TBCREATOR</td>
<td>VARCHAR(128)</td>
<td>The owner of the table or view.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>COLNO</td>
<td>INTEGER</td>
<td>Numeric place of the column in the table or view, ordered from left to right.</td>
</tr>
<tr>
<td>Column name</td>
<td>System Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>

</tbody>
</table>
The SYSCOLUMNSTAT view contains one row for every column in a table partition or table member that has a column statistics collection. If the table is a distributed table, the partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes. The following table describes the columns in the SYSCOLUMNSTAT view:

### Table 161. SYSCOLUMNSTAT view

<table>
<thead>

### SYSCST

The SYSCST view contains one row for each constraint in the SQL schema.

The following table describes the columns in the SYSCST view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>CDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>RELNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the constraint.</td>
</tr>
</tbody>
</table>
| CONSTRAINT_TYPE      | TYPE               | VARCHAR(11)      | Constraint Type  
|                      |                    |                  |   - CHECK  
|                      |                    |                  |   - UNIQUE  
|                      |                    |                  |   - PRIMARY KEY  
|                      |                    |                  |   - FOREIGN KEY  |
| TABLE_SCHEMA         | TDBNAME            | VARCHAR(128)     | Name of the schema containing the table. |
| TABLE_NAME           | TBNAME             | VARCHAR(128)     | Name of the table which the constraint is created over. This will be the SQL table name if it exists; otherwise, it will be the system table name. |
| IS_DEFERRABLE        | ISDEFER            | VARCHAR(3)       | Indicates whether the constraint checking can be deferred. Will always be 'NO'. |
| INITIALLY_DEFERRED   | INITDEFER          | VARCHAR(3)       | Indicates whether the constraint was defined as initially deferred. Will always be 'NO'. |
| SYSTEM_TABLE_NAME    | SYS_TNAME          | CHAR(10)         | System name of the table. |
| SYSTEM_TABLE_SCHEMA  | SYS_DNAME          | CHAR(10)         | System name of the schema containing the table. |
| CONSTRAINT_KEYS      | COLCOUNT           | SMALLINT         | Specifies the number of key columns if this is a UNIQUE, PRIMARY KEY, or FOREIGN KEY constraint.  
|                      |                    | Nullable         | Contains the null value if the constraint is a CHECK constraint. |
| IASP_NUMBER          | IASPNUMBER         | SMALLINT         | Specifies the independent auxiliary storage pool (IASP) number. |
| CONSTRAINT_STATE     | CST_STATE          | VARCHAR(11)      | Indicates whether the constraint is established or defined:  
|                      |                    |                  |   - ESTABLISHED  
|                      |                    |                  |       - The referential constraint is established.  
|                      |                    |                  |       - The parent table exists.  
|                      |                    |                  |   - DEFINED  
|                      |                    |                  |       - The referential constraint is defined.  
|                      |                    |                  |       - The parent table does not exist.  |
| ENABLED              | ENABLED            | VARCHAR(3)       | Indicates whether the constraint is enabled:  
|                      |                    | Nullable         | Contains the null value if the constraint is defined or is a unique constraint. |
| CHECK_PENDING        | CHECKFLAG          | VARCHAR(3)       | Indicates whether the constraint is in check pending state:  
|                      |                    | Nullable         | Contains the null value if the constraint is defined, disabled, or is a unique constraint. |
| CONSTRAINT_TEXT      | LABEL              | VARGRAPHIC(50) CCSID 1200 | A character string provided with the LABEL statement.  
|                      |                    | Nullable         | Contains the null value if there is no label. |
### Table 164. SYSCST view (continued)

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>CCSID 1200</td>
<td>Contains the null value if there is no long comment.</td>
</tr>
<tr>
<td></td>

<td>Nullable</td>
<td></td>
</tr>
<tr>
<td>SYSTEM_CONSTRAINT_SCHEMA</td>
<td>SYS_CDNAME</td>
<td>CHAR(10)</td>
<td>Name of the system schema containing the constraint.</td>
</tr>
</tbody>
</table>
SYSCSTCOL

The SYSCSTCOL view records the columns on which constraints are defined. There is one row for every column in a unique, primary key, and check constraint and the referencing columns of a referential constraint.

The following table describes the columns in the SYSCSTCOL view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>TDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table the constraint is dependent on.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table the constraint is dependent on.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>This is the SQL table name if it exists; otherwise, it is the system table name.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>COLUMN</td>
<td>VARCHAR(128)</td>
<td>Column that the constraint was created over.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>This is the SQL column name if it exists; otherwise, it is the system column name.</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>CDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the schema of the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>RELNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the constraint.</td>
</tr>
<tr>
<td>SYSTEM_COLUMN_NAME</td>
<td>SYS_CNAME</td>
<td>CHAR(10)</td>
<td>System name of the column.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_NAME</td>
<td>SYS_TNAME</td>
<td>CHAR(10)</td>
<td>System name of the table.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_SCHEMA</td>
<td>SYS_DNAME</td>
<td>CHAR(10)</td>
<td>System name of the schema containing the table.</td>
</tr>
<tr>
<td>SYSTEM_CONSTRAINT_SCHEMA</td>
<td>SYS_CDNAME</td>
<td>CHAR(10)</td>
<td>Name of the system schema containing the constraint.</td>
</tr>
</tbody>
</table>
SYSCSTDEP

The SYSCSTDEP view records the tables on which constraints are defined.

The following table describes the columns in the SYSCSTDEP view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>TDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table on which the constraint is dependent</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table on which the constraint is dependent. This is the SQL table name if it exists otherwise it is the system table name.</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>CDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the schema of the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>RELNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the constraint.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_NAME</td>
<td>SYS_TNAME</td>
<td>CHAR(10)</td>
<td>System name of the table.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_SCHEMA</td>
<td>SYS_DNAME</td>
<td>CHAR(10)</td>
<td>System name of the schema containing the table.</td>
</tr>
<tr>
<td>IASP_NUMBER</td>
<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Specifies the independent auxiliary storage pool (IASP) number.</td>
</tr>
<tr>
<td>SYSTEM_CONSTRAINT_SCHEMA</td>
<td>SYS_CDNAME</td>
<td>CHAR(10)</td>
<td>Name of the system schema containing the constraint.</td>
</tr>
</tbody>
</table>
**SYSFIELDS**

The SYSFIELDS view contains one row for every column that has a field procedure.

The column attributes in SYSFIELDS describe the internal column attributes defined by the field procedure. The following table describes the columns in the SYSFIELDS view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>DBNAME</td>
<td>VARCHAR(128)</td>
<td>The name of the SQL schema containing the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table that contains the column. This will be the SQL table name if one exists; otherwise, it will be the system table name.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the column. This will be the SQL column name if one exists; otherwise, it will be the system column name.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>COLNO</td>
<td>INTEGER</td>
<td>Numeric place of the column in the table, ordered from left to right.</td>
</tr>
</tbody>
</table>

### Table 167. SYSFIELDS view (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMERIC_PRECISION</td>
<td>PRECISION</td>
<td>INTEGER</td>
<td>The precision of all numeric columns. Note: This column supplies the precision of all numeric data types, including decimal floating-point and single- and double-precision floating point. The NUMERIC_PRECISION_RADIX column indicates if the value in this column is in binary or decimal digits. Contains the null value if the column is not numeric.</td>
</tr>
<tr>
<td>NUMERIC_PRECISION_RADIX</td>
<td>RADIX</td>
<td>INTEGER</td>
<td>Indicates if the precision specified in column NUMERIC_PRECISION is specified as a number of binary or decimal digits. The value can be 2 (binary), 10 (decimal), or null.</td>
</tr>
<tr>
<td>CCSID</td>
<td>CCSID</td>
<td>INTEGER</td>
<td>The CCSID value for CHAR, VARCHAR, CLOB, DATE, TIME, TIMESTAMP, GRAPHIC, VARGRAPHIC, DBCLOB, XML, and DATALINK columns. Contains 65535 if the column is a BINARY, VARBIN, BLOB, or ROWID.</td>
</tr>
<tr>
<td>DATETIME_PRECISION</td>
<td>DATPRC</td>
<td>INTEGER</td>
<td>The fractional part of a date, time, or timestamp. The value can be 0 (for DATE and TIME data types), 0-12 (for TIMESTAMP data types (number of fractional seconds)). Contains the null value if the column is not a date, time, or timestamp.</td>
</tr>
<tr>
<td>FIELD_PROC</td>
<td>FLDPROC</td>
<td>VARCHAR(279)</td>
<td>The name of the procedure.</td>

</table>
The SYSFUNCS view contains one row for each function created by the CREATE FUNCTION statement.

The following table describes the columns in the SYSFUNCS view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPECIFIC_SCHEMA</td>
<td>SPECSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Schema name of the routine (function) instance.</td>
</tr>
<tr>
<td>SPECIFIC_NAME</td>
<td>SPECNAME</td>
<td>VARCHAR(128)</td>
<td>Specific name of the routine instance.</td>
</tr>
<tr>
<td>ROUTINE_SCHEMA</td>
<td>FUNCSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema (schema) that contains the routine.</td>
</tr>
<tr>
<td>ROUTINE_NAME</td>
<td>FUNCNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the routine.</td>
</tr>
<tr>
<td>ROUTINE_CREATED</td>
<td>RTNCREATE</td>
<td>TIMESTAMP</td>
<td>Identifies the timestamp when the routine was created.</td>
</tr>
<tr>
<td>ROUTINE_DEFINER</td>
<td>DEFINER</td>
<td>VARCHAR(128)</td>
<td>Name of the user that defined the routine.</td>
</tr>
<tr>
<td>ROUTINE_BODY</td>
<td>BODY</td>
<td>VARCHAR(8)</td>
<td>The type of the routine body:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>EXTERNAL</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>SQL</td>
</tr>
<tr>
<td>EXTERNAL_NAME</td>
<td>EXTNAME</td>
<td>VARCHAR(279)</td>
<td>This column identifies the external program name.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>• For SQL functions or ILE service programs, the external program name is schema-name/service-program-name(entry-point-name).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• For Java programs, the external program name is an optional jar-id followed by a fully-qualified-class-name/method-name or fully-qualified-class-name.method-name.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• For all other languages, the external program name is schema-name/program-name.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Contains the null value if this is a system-generated function.</td>
</tr>
<tr>
<td>EXTERNAL_LANGUAGE</td>
<td>LANGUAGE</td>
<td>VARCHAR(8)</td>
<td>If this is an external routine, this column identifies the external program name.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>• C</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• C++</td>

</table>
**SYSINDEXES**

The SYSINDEXES view contains one row for every index in the SQL schema created using the SQL CREATE INDEX statement, including indexes on the SQL catalog.

The following table describes the columns in the SYSINDEXES view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEX_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the index. This will be the SQL index name if one exists; otherwise, it will be the system index name.</td>
</tr>
<tr>
<td>INDEX_OWNER</td>
<td>CREATOR</td>
<td>VARCHAR(128)</td>
<td>Owner of the index</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table on which the index is defined. This will be the SQL table name if one exists; otherwise, it will be the system table name.</td>
</tr>
<tr>
<td>TABLE_OWNER</td>
<td>TBCREATOR</td>
<td>VARCHAR(128)</td>
<td>Owner of the table</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>TBDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table on which the index is defined</td>
</tr>
<tr>
<td>IS_UNIQUE</td>
<td>UNIQUERULE</td>
<td>CHAR(1)</td>
<td>If the index is unique:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>D    No (duplicates are allowed)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>V    Yes (duplicate NULL values are allowed)</td>
</tr>
<tr>
<td></td>
<td></td>

The SYSINDEXSTAT view contains one row for every SQL index partition.

Use this view when you want to see information for a specific SQL index or set of SQL indexes. The information is similar to that returned via Show Indexes in System i Navigator.

The following table describes the columns in the SYSINDEXSTAT view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEX_SCHEMA</td>
<td>INDSHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the SQL index.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>INDNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL index.</td>
</tr>
<tr>
<td>INDEX_PARTITION</td>
<td>INDPART</td>
<td>VARCHAR(128)</td>
<td>Partition or member name of the SQL index.</td>
</tr>
<tr>
<td>INDEX_OWNER</td>
<td>INDOWNER</td>
<td>VARCHAR(128)</td>
<td>SQL index owner.</td>
</tr>
<tr>
<td>INDEX_TEXT</td>
<td>LABEL</td>
<td>VARCHARGRAPHIC(50) CCSID 1200</td>
<td>Text of the SQL index. Contains null if text does not exist for the SQL index.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TABNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>TABLE_PARTITION</td>
<td>TABPART</td>
<td>VARCHAR(128)</td>
<td>Name of the table partition or member.</td>
</tr>
<tr>
<td>INDEX_VALID</td>
<td>VALID</td>
<td>VARCHAR(3)</td>
<td>An indication or whether the SQL index is invalid and needs to be rebuilt:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NO The SQL index is invalid.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>YES The SQL index is valid.</td>
</tr>
<tr>
<td>INDEX_CREATE_TIMESTAMP</td>
<td>INDCREATED</td>
<td>TIMESTAMP</td>
<td>The timestamp when the SQL index was created.</td>
</tr>
<tr>
<td>CREATE_TIMESTAMP</td>
<td>CREATED</td>
<td>TIMESTAMP</td>
<td>The timestamp when the SQL index partition was created.</td>
</tr>
<tr>
<td>LAST_BUILD_TIMESTAMP</td>
<td>LASTBUILD</td>
<td>TIMESTAMP</td>
<td>The timestamp when the SQL index was last rebuilt. Contains null if the SQL index has never been built.</td>
</tr>
<tr>
<td>LAST_QUERY_USE</td>
<td>LASTQRYUSE</td>
<td>TIMESTAMP</td>
<td>The timestamp of the last time the SQL index was used in a query since the last time the usage statistics were reset. If the SQL index has never been used in a query since the last time the usage statistics were reset, contains null.</td>
</tr>
<tr>
<td>LAST_STATISTICS_USE</td>
<td>LASTSTUSE</td>
<td>TIMESTAMP</td>
<td>The timestamp of the last time the SQL index was used by the optimizer for statistics since the last time the usage statistics were reset. If the SQL index has never been used for statistics since the last time the usage statistics were reset, contains null.</td>
</tr>
<tr>
<td>QUERY_USE_COUNT</td>
<td>QRYUSECNT</td>
<td>BIGINT</td>
<td>The number of times the SQL index was used in a query since the last time the usage statistics were reset. If the SQL index has never been used in a query since the last time the usage statistics were reset, contains 0.</td>
</tr>
<tr>
<td>QUERY_STATISTICS_COUNT</td>
<td>QRYSTCNT</td>
<td>BIGINT</td>
<td>The number of times the SQL index was used by the optimizer for statistics since the last time the usage statistics were reset. If the SQL index has never been used for statistics since the last time the usage statistics were reset, contains 0.</td>
</tr>
<tr>
<td>LAST_USED_TIMESTAMP</td>
<td>LASTUSED</td>
<td>TIMESTAMP</td>
<td>The timestamp of the last time the SQL index was used directly by an application for native record I/O or SQL operations. If the SQL index has never been used, contains null.</td>
</tr>
</tbody>
</table>

<tr>
<td>LAST_RESET_TIMESTAMP</td>
<td>LASTRESET</td>
<td>TIMESTAMP</td>
<td>The timestamp of the last time the usage statistics were reset for the SQL index. For more information see the Change Object Description (CHGOBJD) command. If the SQL index’s last used timestamp has never been reset, contains null.</td>
</tr>
<tr>
<td>NUMBER_KEY_COLUMNS</td>
<td>INDEKS</td>
<td>BIGINT</td>
<td>Number of columns that define the SQL index key.</td>
</tr>
<tr>
<td>COLUMN_NAMES</td>
<td>COLNAMES</td>
<td>VARCHAR(1024)</td>
<td>A comma separated list of column names that define the SQL index key. If the length of all the column names exceeds 1024, ‘...’ is returned at the end of the column value.</td>
</tr>
<tr>
<td>NUMBER_KEYS</td>
<td>NUMRIDS</td>
<td>BIGINT</td>
<td>Number of keys in the SQL index. If the SQL index is invalid, -1 is returned.</td>
</tr>
<tr>
<td>INDEX_SIZE</td>
<td>SIZE</td>
<td>BIGINT</td>
<td>Size (in bytes) of the binary tree or encoded vector index of the SQL index.</td>
</tr>
<tr>
<td>NUMBER_PAGES</td>
<td>PAGES</td>
<td>BIGINT</td>
<td>Number of pages in the SQL index. If the SQL index is invalid or is an encoded vector index, contains null.</td>
</tr>
<tr>
<td>LOGICAL_PAGE_SIZE</td>
<td>PAGE_SIZE</td>
<td>INTEGER</td>
<td>The logical page size of the index. If the index is an encoded vector index, contains null.</td>
</tr>
<tr>
<td>UNIQUE</td>
<td>UNIQUE</td>
<td>VARCHAR(21)</td>
<td>Indicates whether an SQL index is unique:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>UNIQUE The SQL index is a UNIQUE index.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>UNIQUE WHERE NOT NULL The SQL index is a UNIQUE WHERE NOT NULL index.</td>

</tbody>
</table>
## SYSJARCONTENTS

The SYSJARCONTENTS table contains one row for each class defined by a jarid in the SQL schema.

The following table describes the columns in the SYSJARCONTENTS table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JARSCHEMA</td>
<td>JARSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the jar_id.</td>
</tr>
<tr>
<td>JAR_ID</td>
<td>JAR_ID</td>
<td>VARCHAR(128)</td>
<td>Name of the jar_id.</td>
</tr>
<tr>
<td>CLASS</td>
<td>CLASS</td>
<td>VARCHAR(128)</td>
<td>Name of the class.</td>
</tr>
<tr>
<td>CLASS_SOURCE</td>
<td>CLASSSRC</td>
<td>DBCLOB(10485760)</td>
<td>Reserved. Contains the null value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>CCSID 13488</td>
<td></td>
</tr>
<tr>
<td>IASP_NUMBER</td>
<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Specifies the independent auxiliary storage pool (IASP) number.</td>
</tr>
</tbody>
</table>
The SYSJAROBJECTS table contains one row for each jarid in the SQL schema.

The following table describes the columns in the SYSJAROBJECTS table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JARSCHEMA</td>
<td>JARSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the jar_id.</td>
</tr>
<tr>
<td>JAR_ID</td>
<td>JAR_ID</td>
<td>VARCHAR(128)</td>
<td>Name of the jar_id.</td>
</tr>
<tr>
<td>DEFINER</td>
<td>DEFINER</td>
<td>VARCHAR(128)</td>
<td>Name of the owner of the jarid.</td>
</tr>
<tr>
<td>JAR_DATA</td>
<td>JAR_DATA</td>
<td>BLOB(10485760)</td>
<td>Byte-codes for the jar.</td>
</tr>
<tr>
<td>IASP_NUMBER</td>
<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Specifies the independent auxiliary storage pool (IASP) number.</td>
</tr>
<tr>
<td>JAR_CREATED</td>
<td>CREATEDTS</td>
<td>TIMESTAMP</td>
<td>Jar created timestamp</td>
</tr>
<tr>
<td>LAST_ALTERED</td>
<td>ALTEREDTS</td>
<td>TIMESTAMP</td>
<td>Reserved. Contains the null value.</td>
</tr>
<tr>
<td>DEBUG_MODE</td>
<td>DEBUG_MODE</td>
<td>CHAR(1)</td>
<td>Identifies whether the routine is debuggable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>N</td>
</tr>
<tr>
<td>DEBUG_DATA</td>
<td>DEBUG_DATA</td>
<td>CLOB(1048576)</td>
<td>Reserved. Contains the null value.</td>
</tr>
</tbody>
</table>

Nullable
The SYSKEYCST view contains one or more rows for each UNIQUE KEY, PRIMARY KEY, or FOREIGN KEY in the SQL schema. There is one row for each column in every unique or primary key constraint and the referencing columns of a referential constraint.

The following table describes the columns in the SYSKEYCST view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>CDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>RELNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the constraint.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>TDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>COLNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the column.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>COLSEQ</td>
<td>INTEGER</td>
<td>The position of the column within the key</td>
</tr>
<tr>
<td>COLUMN_POSITION</td>
<td>COLNO</td>
<td>INTEGER</td>
<td>The position of the column within the row</td>
</tr>
<tr>
<td>TABLE_OWNER</td>
<td>CREATOR</td>
<td>VARCHAR(128)</td>
<td>Owner of the table.</td>
</tr>
<tr>
<td>SYSTEM_COLUMN_NAME</td>
<td>SYS_CNAME</td>
<td>CHAR(10)</td>
<td>System name of the column.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_NAME</td>
<td>SYS_TNAME</td>
<td>CHAR(10)</td>
<td>System name of the table.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_SCHEMA</td>
<td>SYS_DNAME</td>
<td>CHAR(10)</td>
<td>System name of the schema containing the schema table.</td>
</tr>
<tr>
<td>SYSTEM_CONSTRAINT_SCHEMA</td>
<td>SYS_CDNAME</td>
<td>CHAR(10)</td>
<td>Name of the system schema containing the constraint.</td>
</tr>
</tbody>
</table>
SYSKEYS

The SYSKEYS view contains one row for every column of an index in the SQL schema, including the keys for the indexes on the SQL catalog.

The following table describes the columns in the SYSKEYS view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEX_NAME</td>
<td>IXNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the index. This will be the SQL index name if one exists; otherwise, it will be the system index name.</td>
</tr>
<tr>
<td>INDEX_OWNER</td>
<td>IXCREATOR</td>
<td>VARCHAR(128)</td>
<td>Owner of the index</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>COLNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the column of the key. This will be the SQL column name if one exists; otherwise, it will be the system column name.</td>
</tr>
<tr>
<td>COLUMN_POSITION</td>
<td>COLNO</td>
<td>INTEGER</td>
<td>Numeric position of the column in the row. Contains the null value if the key column is an expression.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>COLSEQ</td>
<td>INTEGER</td>
<td>Numeric position of the column in the key</td>
</tr>
<tr>
<td>ORDERING</td>
<td>ORDERING</td>
<td>CHAR(1)</td>
<td>Order of the column in the key: A Ascending D Descending</td>
</tr>
<tr>
<td>INDEX_SCHEMA</td>
<td>IXDBNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the index</td>
</tr>
<tr>
<td>SYSTEM_COLUMN_NAME</td>
<td>SYS_CNAME</td>
<td>CHAR(10)</td>
<td>System name of the column</td>
</tr>
<tr>
<td>SYSTEM_INDEX_NAME</td>
<td>SYS_IXNAME</td>
<td>CHAR(10)</td>
<td>System name of the index</td>
</tr>
<tr>
<td>SYSTEM_INDEX_SCHEMA</td>
<td>SYS_IDNAME</td>
<td>CHAR(10)</td>
<td>System name of the schema containing the index</td>
</tr>
<tr>
<td>COLUMN_IS_EXPRESSION</td>
<td>IXISEXP</td>
<td>CHAR(1)</td>
<td>If the key column is an expression: Y The key column is not an expression. N The key column is an expression.</td>
</tr>
<tr>
<td>EXPRESSION_HAS_UDF</td>
<td>IXEXPUDF</td>
<td>CHAR(1)</td>
<td>If the key column is an expression and the expression contains a user-defined function: N The key column is not an expression or the expression does not contain a user-defined function. Y The key column is an expression and the expression contains a UDF.</td>
</tr>
<tr>
<td>KEY_EXPRESSION</td>
<td>IXKEYEXP</td>
<td>DBCLOB(2097152)</td>
<td>If the key column is an expression, contains the expression. Contains the column name if the key column is not an expression.</td>
</tr>
</tbody>
</table>
The SYSMQTSTAT view contains one row for every materialized table partition.

Use this view when you want to see information about a specified materialized query table or set of materialized query tables. The information is similar to that returned via Show Materialized Query Tables in System i Navigator.

The following table describes the columns in the SYSMQTSTAT view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MQT_SCHEMA</td>
<td>MQTSHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the materialized query table.</td>
</tr>
<tr>
<td>MQT_NAME</td>
<td>MQTNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the materialized query table.</td>
</tr>
<tr>
<td>MQT_PARTITION</td>
<td>MQTMEMBER</td>
<td>VARCHAR(128)</td>
<td>Partition or member name of the materialized query table.</td>
</tr>
<tr>
<td>MQT_OWNER</td>
<td>MQTOWNER</td>
<td>VARCHAR(128)</td>
<td>Materialized query table owner.</td>
</tr>
<tr>
<td>MQT_TEXT</td>
<td>LABEL</td>
<td>VARCHARGRAPHIC(50) CCSID 1200</td>
<td>Text of the materialized query table. Contains null if text does not exist for the materialized query table.</td>
</tr>
<tr>
<td>ENABLED</td>
<td>ENABLED</td>
<td>VARCHAR(3)</td>
<td>An indication of whether the materialized query table is enabled:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NO The materialized query table is not enabled for use.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>YES The materialized query table is enabled for use by the database manager.</td>
</tr>
<tr>
<td>CREATE_TIMESTAMP</td>
<td>CREATED</td>
<td>TIMESTAMP</td>
<td>The timestamp when the materialized query table was created.</td>
</tr>
<tr>
<td>REFRESH_TIME</td>
<td>REFRESHDTS</td>
<td>TIMESTAMP</td>
<td>The timestamp when the materialized query table was last refreshed. Contains null if the materialized query table has never been refreshed.</td>
</tr>
<tr>
<td>LAST_QUERY_USE</td>
<td>LASTQRYUSE</td>
<td>TIMESTAMP</td>
<td>The timestamp of the last time the materialized query table was used in a query since the last time the usage statistics were reset. If the materialized query table has never been used in a query since the last time the usage statistics were reset, contains null.</td>
</tr>
<tr>
<td>LAST_STATISTICS_USE</td>
<td>LASTSTUSE</td>
<td>TIMESTAMP</td>
<td>The timestamp of the last time the materialized query table was used by the optimizer for statistics since the last time the usage statistics were reset. If the materialized query table has never been used for statistics since the last time the usage statistics were reset, contains null.</td>
</tr>
<tr>
<td>QUERY_USE_COUNT</td>
<td>QRYUSECNT</td>
<td>BIGINT</td>
<td>The number of times the materialized query table was used in a query since the last time the usage statistics were reset. If the materialized query table has never been used in a query since the last time the usage statistics were reset, contains 0.</td>
</tr>
<tr>
<td>QUERY_STATISTICS_COUNT</td>
<td>QRYSTCNT</td>

</tbody>
</table>
The SYSPARTITIONINDEXES view contains one row for every index built over a table partition or table member. If the table is a distributed table, the indexes over partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

Use this view when you want to see index information for indexes built on a specified table or set of tables. The information is similar to that returned via Show Indexes in System i Navigator.

The following table describes the columns in the SYSPARTITIONINDEXES view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TABNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>TABLE_PARTITION</td>
<td>TABPART</td>
<td>VARCHAR(128)</td>
<td>Name of the table partition or member.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>INDNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the index, logical file, or constraint. If the index type indicates one or more temporary indexes, INDEX_NAME contains the number of maintained temporary indexes that currently exist on the table followed by the string 'MAINTAINED TEMPORARY INDEXES'.</td>
</tr>
<tr>
<td>INDEX_TYPE</td>
<td>INDTYPE</td>
<td>VARCHAR(11)</td>
<td>The type of the index:</td>
</tr>
<tr>
<td></td>

## SYSPARTITIONINDEXSTAT

The SYSPARTITIONINDEXSTAT view contains one row for every index built over a table partition or table member. Indexes that share another index’s binary tree are not included. If the table is a distributed table, the indexes over partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSPARTITIONINDEXSTAT view:

### Table 185. SYSPARTITIONINDEXSTAT view

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</table>
The SYSPARTITIONMQTS view contains one row for every materialized table built over a table partition or table member. If the table is a distributed table, the materialized tables over partitions that reside on other database nodes are not contained in this catalog view. They are contained in the catalog views of the other database nodes.

Use this view when you want to see materialized query table information for materialized tables built on a specified table or set of tables. The information is similar to that returned via Show Materialized Query Tables in System i Navigator.

The following table describes the columns in the SYSPARTITIONMQTS view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table.</td>

The SYSPROGRAMSTAT view contains one row for each program, service program, and module that contains SQL statements.

The following table describes the columns in the SYSPROGRAMSTAT view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM_SCHEMA</td>
<td>COLLID</td>
<td>VARCHAR(128)</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>PROGRAM_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the program, service program, or module. For an SQL procedure, function, or trigger, this is the SQL object name.</td>
</tr>
<tr>
<td>PROGRAM_TYPE</td>
<td>PGMTYPE</td>
<td>VARCHAR(128)</td>
<td>Type of the object</td>
</tr>
<tr>
<td>MODULE_NAME</td>
<td>MODNAME</td>
<td>VARCHAR(10)</td>
<td>Module name for ILE program or service program. Contains the null value if this is not an ILE program or service program.</td>
</tr>
<tr>
<td>PROGRAM_OWNER</td>
<td>OWNER</td>
<td>VARCHAR(128)</td>
<td>Owner of the program, service program, or module</td>
</tr>
<tr>
<td>PROGRAM_CREATOR</td>
<td>CREATOR</td>
<td>VARCHAR(128)</td>
<td>Creator of the program, service program, or module</td>
</tr>
<tr>
<td>CREATION_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Timestamp of when the program, service program, or module was created</td>
</tr>
<tr>
<td>DEFAULT_SCHEMA</td>
<td>QUALIFIER</td>
<td>VARCHAR(128)</td>
<td>Implicit name for unqualified tables, views, and indexes. Contains null if a default schema was not specified (DFTRDBCOL) or if the program is an external procedure without SQL statements.</td>
</tr>
<tr>
<td>ISOLATION</td>
<td>ISOLATION</td>
<td>CHAR(2)</td>
<td>Isolation option specification:</td>
</tr>
<tr>
<td>CONCURRENTACCESSRESOLUTION</td>
<td>CONCURRENT</td>
<td>CHAR(1)</td>
<td>Specifies the concurrent access resolution:</td>
</tr>
<tr>
<td>NUMBER_STATEMENTS</td>
<td>NBRSTMTS</td>
<td>INTEGER</td>
<td>Number of SQL statements in the program, service program or module</td>
</tr>
<tr>
<td>PROGRAM_USED_SIZE</td>
<td>PGMSIZE</td>
<td>INTEGER</td>
<td>Number of bytes that are used for SQL statements and access plans in the program, service program or module.</td>
</tr>
<tr>
<td>NUMBER_COMPRESSIONS</td>
<td>PGM_CMP</td>
<td>INTEGER</td>
<td>Number of times the program or service program has been compressed. Contains null for modules or if the program is an external procedure without SQL statements.</td>
</tr>
</tbody>
</table>

The SYSPROGRAMSTMTSTAT view contains one row for each embedded SQL statement in a program, module, or service program.

The following table describes the columns in the SYSPROGRAMSTMTSTAT view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM_SCHEMA</td>
<td>COLLID</td>
<td>VARCHAR(128)</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>PROGRAM_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the program, service program, or module. For an SQL procedure, function, or trigger, this is the SQL object name.</td>
</tr>
<tr>
<td>PROGRAM_TYPE</td>
<td>PGMTYPE</td>
<td>VARCHAR(128)</td>
<td>Type of the object:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>*PGM  The object is a program.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>*MODULE The object is a module.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>*SRVPGM The object is a service program.</td>
</tr>
<tr>
<td>MODULE_NAME</td>
<td>MODNAME</td>
<td>VARCHAR(10)</td>
<td>Module name for ILE program or service program. Nullable Contains the null value if this is not an ILE program or service program.</td>
</tr>
<tr>
<td>STATEMENT_NUMBER</td>
<td>STMTNBR</td>
<td>INTEGER</td>
<td>Statement number in program.</td>
</tr>
<tr>
<td>NUMBER_TIMES_EXECUTED</td>
<td>NBRREXEC</td>
<td>INTEGER</td>
<td>Number of times this statement has been executed. This value is not maintained for CALL, SET, or VALUES INTO statements. Will contain 0 for a SET or VALUES INTO statement that is not implemented using a cursor.</td>
</tr>
<tr>
<td>ROWS_AFFECTED</td>
<td>ROWCNT</td>
<td>INTEGER</td>
<td>Total rows fetched, updated, inserted, or deleted for all executions of the statement. Contains 0 if the statement is not a FETCH, SET, VALUES INTO, UPDATE, INSERT, DELETE, or MERGE. Will contain 0 for a SET or VALUES INTO statement that is not implemented using a cursor.</td>
</tr>
<tr>
<td>NUMBER_HOST_VARIABLES</td>
<td>NBRHV</td>
<td>INTEGER</td>
<td>Total number of host variables specified in the statement. This includes input and output host variables.</td>
</tr>
<tr>
<td>NUMBER_INPUT_HOST_VARIABLES</td>
<td>NBRRIHV</td>
<td>INTEGER</td>
<td>Number of input host variables specified in the statement.</td>
</tr>
<tr>
<td>WITH_HOLD</td>
<td>WITHHOLD</td>
<td>CHAR(3)</td>
<td>Specifies the WITH HOLD option for statement:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>YES WITH HOLD clause specified. Contains the null value if the clause was not specified.</td>
</tr>
<tr>
<td>FETCH_ONLY</td>
<td>FETCHONLY</td>
<td>CHAR(3)</td>
<td>Specifies the FOR READ ONLY option for statement:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>YES FOR READ ONLY clause specified. Contains the null value if the clause was not specified.</td>
</tr>
<tr>
<td>CONCURRENTACCESSRESOLUTION</td>
<td>CONCURRENT</td>
<td>CHAR(1)</td>
<td>Specifies the concurrent access resolution for the statement:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>W Wait for outcome</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>U Use currently committed</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>S Skip locked data</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Contains the null value if concurrent access was not specified at the statement level.</td>
</tr>
<tr>
<td>NUMBER_REBUILDS</td>
<td>NBRREBLD</td>
<td>INTEGER</td>
<td>Number of times QDT or access plan has been rebuilt.</td>
</tr>
<tr>
<td>Column Name</td>
<td>System Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>--------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>

<tr>
<td>SYSTEM_PROGRAM_SCHEMA</td>
<td>SYS_DNAME</td>
<td>CHAR(10)</td>
<td>System name of the schema containing the program.</td>
</tr>
<tr>
<td>ACCESS_PLAN_LENGTH</td>
<td>AP_LENGTH</td>
<td>INTEGER</td>
<td>Number of bytes that are used for the QDT and access plan for the statement.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EARLIEST_POSSIBLE_RELEASE</td>
<td>MINRLS</td>
<td>VARCHAR(6)</td>
<td>The earliest IBM i release that supports this SQL statement (VxRxMs).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ANY  The statement is valid on any supported IBM i release.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>VxRxMs The statement is valid on IBM i VxRxMx release or later.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Contains the null value if the earliest release is not known.</td>
</tr>
<tr>
<td>SQL_DB2_GROUP_LEVEL</td>
<td>SQL_LEVEL</td>
<td>INTEGER</td>
<td>The latest Db2 PTF Group level that SQL language syntax used in this statement is dependent on.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>Contains the null value if no SQL syntax in this statement was identified as being dependent on a Db2 PTF Group.</td>
</tr>
<tr>
<td>SERVICES_DB2_GROUP_LEVEL</td>
<td>SERV_LEVEL</td>
<td>INTEGER</td>
<td>The latest Db2 PTF Group level that a service referenced in this statement might be dependent on. This column contains a value if the SQL statement references an IBM i provided service or Db2 for i built-in function or built-in global variable. If the SQL statement includes unqualified references to objects whose names match IBM i provided services, this column considers the unqualified name as the IBM i service.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>Contains the null value if no built-in function, built-in global variable, or IBM i provided service in this statement was identified as being dependent on a Db2 PTF Group.</td>
</tr>
</tbody>
</table>
The SYSREFCST view contains one row for each foreign key in the SQL schema.

The following table describes the columns in the SYSREFCST view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_SCHEMA</td>

</tbody>
</table>
The SYSSCHEMMAUTH view contains one row for every privilege granted on a schema. Note that this catalog view cannot be used to determine whether a user is authorized to a schema because the privilege to use a schema could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSSCHEMMAUTH view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTOR</td>
<td>GRANTOR</td>
<td>VARCHAR(128)</td>
<td>Reserved. Contains the null value.</td>
</tr>
<tr>
<td>GRANTEE</td>
<td>GRANTEE</td>
<td>VARCHAR(128)</td>
<td>The user profile to which the privilege is granted.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the schema</td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td>PRIVTYPE</td>
<td>VARCHAR(10)</td>
<td>The privilege granted:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>CREATEIN</td>

<tr>
<td></td>
<td></td>
<td></td>
<td>USAGE</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>IS_GRANTABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NO</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>YES</td>
</tr>
<tr>
<td>AUTHORIZATION_LIST</td>
<td>AUTL</td>
<td>VARCHAR(10)</td>
<td>If the privilege is granted through an authorization, contains the name of</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>the authorization list.</td>
</tr>
<tr>
<td>SYSTEM_SCHEMA_NAME</td>
<td>SYS_NAME</td>
<td>CHAR(10)</td>
<td>System name of the schema</td>
</tr>
</tbody>
</table>
The SYSSCHEMAS view contains one row for every schema in the relational database.

For information related to a single schema, a query that uses table function OBJECT_STATISTICS will perform much better than querying SYSSCHEMAS. For example:

```sql
SELECT *
FROM TABLE (QSYS2.OBJECT_STATISTICS('MJATST', 'LIB')) AS A
```

The following table describes the columns in the SYSSCHEMAS view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema.</td>
</tr>
<tr>
<td>SCHEMA_OWNER</td>
<td>OWNER</td>
<td>VARCHAR(128)</td>
<td>Owner of the schema.</td>
</tr>
<tr>
<td>SCHEMA_CREATOR</td>
<td>CREATOR</td>
<td>VARCHAR(128)</td>
<td>Name of the user that created the schema.</td>
</tr>
<tr>
<td>CREATION_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Timestamp when the schema was created.</td>
</tr>
<tr>
<td>SCHEMA_SIZE</td>
<td>SIZE</td>
<td>DECIMAL(15,0)</td>
<td>Size of the schema (in bytes).</td>
</tr>
<tr>
<td>SCHEMA_TEXT</td>
<td>LABEL</td>
<td>VARGRAPHIC(50) CCSID 1200</td>
<td>A character string supplied with the LABEL statement. Contains the null value if the schema has no text.</td>
</tr>
<tr>
<td>SYSTEM_SCHEMA_NAME</td>
<td>SYS_NAME</td>
<td>CHAR(10)</td>
<td>System schema name.</td>
</tr>
<tr>
<td>IASP_NUMBER</td>
<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Specifies the independent auxiliary storage pool (IASP) number.</td>
</tr>
</tbody>
</table>
**SYSSEQUENCEAUTH**

The SYSSEQUENCEAUTH view contains one row for every privilege granted on a sequence. Note that this catalog view cannot be used to determine whether a user is authorized to a sequence because the privilege to use a sequence could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the SYSSEQUENCEAUTH view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTOR</td>
<td>GRANTOR</td>
<td>VARCHAR(128)</td>
<td>Reserved. Contains the null value.</td>
</tr>
<tr>
<td>GRANTEE</td>
<td>GRANTEE</td>
<td>VARCHAR(128)</td>
<td>The user profile to which the privilege is granted.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
SYSTABLEDEP

The SYSTABLEDEP view records the dependencies of materialized query tables.

The following table describes the columns in the SYSTABLEDEP view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table, view or alias</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TABNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table, view or alias. This is the SQL table, view or alias name if it exists; otherwise, it is the system table, view or alias name.</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>BSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the object.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>BNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the object the materialized query table is dependent on.</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>BTYPE</td>
<td>CHAR(24)</td>
<td>Indicates the object type of the object referenced in the materialized query table:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>FUNCTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The object is a function.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The object is a table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>TYPE</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The object is a distinct type.</td>

<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Specifies the independent auxiliary storage pool (IASP) number of the object.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_SCHEMA</td>
<td>SYS_DNAME</td>
<td>CHAR(10)</td>
<td>System schema name</td>
</tr>
<tr>
<td>SYSTEM_TABLE_NAME</td>
<td>SYS_TNAME</td>
<td>CHAR(10)</td>
<td>System table name</td>
</tr>
<tr>
<td>PARM_SIGNATURE</td>
<td>SIGNATURE</td>
<td>BLOB(3M)</td>
<td>This column identifies the routine signature.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td>Contains the null value if the object is not a routine.</td>
</tr>
</tbody>
</table>

Appendix F. Db2 for i catalog views  1913
SYSTABLEINDEXSTAT

The SYSTABLEINDEXSTAT view contains one row for every index that has at least one partition or member built over a table. If the index is over more than one partition or member, the statistics include all those partitions and members. If the table is a distributed table, the partitions that reside on other database nodes are not included. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSTABLEINDEXSTAT view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TABNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>PARTITION_TYPE</td>
<td>PARTTYPE</td>
<td>CHAR(1)</td>
<td>The type of the table partitioning:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>blank The table is not partitioned.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>H This is data hash partitioning.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>R This is data range partitioning.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>D This is distributed database hash partitioning.</td>
</tr>
<tr>
<td>NUMBER_PARTITIONS</td>
<td>NBRPARTS</td>
<td>INTEGER</td>
<td>Number of partitions or members of the table.</td>
</tr>
<tr>
<td>NUMBER_DISTRIBUTED_PARTITIONS</td>
<td>DSTPARTS</td>
<td>INTEGER</td>
<td>If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.</td>
</tr>
<tr>
<td>INDEX_SCHEMA</td>
<td>INDSHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the index, logical file, or constraint.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>INDNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the index, logical file, or constraint.</td>
</tr>
<tr>
<td>INDEX_TYPE</td>
<td>INDTYPE</td>
<td>VARCHAR(11)</td>
<td>The type of the index:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>INDEX The index is an SQL index.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>LOGICAL The index is part of a logical file.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>PRIMARY KEY The index is a primary key constraint.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>UNIQUE The index is a unique constraint.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>REFERENTIAL The index is a foreign key constraint.</td>
</tr>
<tr>
<td>NUMBER_KEY_COLUMNS</td>
<td>INDKEYS</td>
<td>BIGINT</td>
<td>Number of columns that define the index key.</td>
</tr>
<tr>
<td>COLUMN_NAMES</td>
<td>COLNAMES</td>
<td>VARCHAR(1024)</td>
<td>A comma separated list of column names that define the index key. If the length of all the column names exceeds 1024, ‘...’ is returned at the end of the column value.</td>
</tr>
<tr>
<td>NUMBER_LEAF_PAGES</td>
<td>NLEAF</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td></td>
<td>NLEVELS</td>
<td>SMALLINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>FIRSTKEYCARD</td>
<td>KEYCARD1</td>
<td>BIGINT</td>
<td>The total number of distinct first key values for all index partitions. If the index is an encoded vector index, this is the total number of unique values for the entire index key.</td>
</tr>
<tr>
<td>FIRST2KEYCARD</td>
<td>KEYCARD2</td>
<td>BIGINT</td>
<td>The total number of distinct keys using the first two columns for all index partitions. If the index is an encoded vector index, -1 is returned.</td>
</tr>
<tr>
<td>FIRST3KEYCARD</td>
<td>KEYCARD3</td>
<td>BIGINT</td>
<td>The total number of distinct keys using the first three columns for all index partitions. If the index is an encoded vector index, -1 is returned.</td>
</tr>
<tr>
<td>FIRST4KEYCARD</td>
<td>KEYCARD4</td>
<td>BIGINT</td>
<td>The total number of distinct keys using the first four columns for all index partitions. If the index is an encoded vector index, -1 is returned.</td>
</tr>
<tr>
<td>Column name</td>
<td>System Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FULLKEYCARD</td>
<td>KEYCARD</td>
<td>BIGINT</td>
<td>The total number of distinct full key values for all index partitions. If the index has more than 4 key columns or is an encoded vector index, -1 is returned.</td>
</tr>
<tr>
<td>CLUSTERRATIO</td>
<td>CLSRATIO</td>
<td>SMALLINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>CLUSTERFACTOR</td>
<td>CLSFACCTOR</td>
<td>DOUBLE</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>

<td>SEQUENTIAL_PAGES</td>
<td>SEQPAGES</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>DENSITY</td>
<td>DENSITY</td>
<td>INTEGER</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>PAGE_FETCH_PAIRS</td>
<td>FETCHPAIRS</td>
<td>VARCHAR(520)</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>NUMBER_KEYS</td>
<td>NUMRIDS</td>
<td>BIGINT</td>
<td>The total number of keys for all index partitions. If the index is invalid or is an encoded vector index, -1 is returned.</td>
</tr>
<tr>
<td>NUMRIDS_DELETED</td>
<td>NUMRIDS DLT</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be 0.</td>
</tr>
<tr>
<td>NUM_EMPTY_LEAFS</td>
<td>EMPTYLEAFS</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be 0.</td>
</tr>
<tr>
<td>AVERAGE_RANDOM_FETCH_PAGES</td>
<td>AVGRNDFTCH</td>
<td>DOUBLE</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVERAGE_RANDOM_PAGES</td>
<td>AVGRNDPAGE</td>
<td>DOUBLE</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVERAGE_SEQUENCE_GAP</td>
<td>AVGSEQGAP</td>
<td>DOUBLE</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVERAGE_SEQUENCE_FETCH_GAP</td>
<td>AVGSEQFGAP</td>
<td>DOUBLE</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVERAGE_SEQUENCE_FETCH_PAGES</td>
<td>AVGSEQFPAG</td>
<td>DOUBLE</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVGPARTITION_CLUSTERRATIO</td>
<td>PCLSFACTOR</td>
<td>SMALLINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVGPARTITION_CLUSTERFACTOR</td>
<td>PCLSFACTOR</td>
<td>DOUBLE</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVGPARTITION_PAGE_FETCH_PAIRS</td>
<td>PPFETCHPAIR</td>
<td>VARCHAR(520)</td>
<td>Not applicable for Db2 for i. Will always be an empty string.</td>
</tr>
<tr>
<td>DATAPARTITION_CLUSTERFACTOR</td>
<td>DCLSFACTOR</td>
<td>DOUBLE</td>
<td>A statistic measuring the “clustering” of the index keys with regard to data partitions. It is a number between 0 and 1, with 1 representing perfect clustering and 0 representing no clustering.</td>
</tr>
<tr>
<td>INDCARD</td>
<td>INDCARD</td>
<td>BIGINT</td>
<td>Number of keys in the index. If the index is invalid or is an encoded vector index, -1 is returned.</td>
</tr>
<tr>
<td>INDEX_VALID</td>
<td>VALID</td>
<td>CHAR(1)</td>
<td>An indication of whether any index is invalid and needs to be rebuilt:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0 At least one partition or member for the index is invalid.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 All partitions or members for the index are valid.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2 The index was saved with STG(*FREE).</td>
</tr>
<tr>
<td>INDEX_Held</td>
<td>HELD</td>
<td>CHAR(1)</td>
<td>An indication of whether a pending rebuild of the index is currently held by the user:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0 No rebuilds are pending or held for any partition or member of the index.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 A pending rebuild for at least one partition or member for the index is held.</td>
</tr>
<tr>
<td>CREATE_TIMESTAMP</td>
<td>CREATED</td>
<td>TIMESTAMP</td>
<td>Maximum timestamp when any partition or member of the index was created.</td>
</tr>
<tr>
<td>LAST_BUILD_TIMESTAMP</td>
<td>LASTBUILD</td>
<td>TIMESTAMP</td>
<td>Maximum timestamp when any partition or member of the index was last rebuilt.</td>
</tr>
<tr>
<td>LAST_QUERY_USE</td>
<td>LASTQRYUSE</td>
<td>TIMESTAMP</td>
<td>Maximum timestamp of the last time any partition or member of the index was used in a query since the last time the usage statistics were reset. If no partition or member of the index has ever been used in a query since the last time the usage statistics were reset, contains null.</td>
</tr>
</tbody>
</table>
### Table 202. SYSTABLEINDEXSTAT view (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>

SYSTABLES

The SYSTABLES view contains one row for every table, view or alias in the SQL schema, including the tables and views of the SQL catalog.

The following table describes the columns in the SYSTABLES view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_NAME</td>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table, view or alias. This is the SQL table, view or alias name if it exists; otherwise, it is the system table, view or alias name.</td>
</tr>
<tr>
<td>TABLE_OWNER</td>
<td>CREATOR</td>
<td>VARCHAR(128)</td>
<td>Owner of the table, view or alias.</td>
</tr>
<tr>
<td>TABLE_TYPE</td>
<td>TYPE</td>
<td>CHAR(1)</td>
<td>If the row describes a table, view, or alias:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>A</td>

</table>

Appendix F. Db2 for i catalog views 1921
The SYSTABLESTAT view contains one row for every table. If the table has more than one partition or member, the statistics include all partitions and members. If the table is a distributed table, the partitions that reside on other database nodes are not included. They are contained in the catalog views of the other database nodes.

The following table describes the columns in the SYSTABLESTAT view:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TABNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>PARTITION_TYPE</td>
<td>PARTTYPE</td>
<td>CHAR(1)</td>
<td>The type of the table partitioning:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>blank The table is not partitioned.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>H This is data hash partitioning.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>R This is data range partitioning.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>D This is distributed database hash partitioning.</td>
</tr>
<tr>
<td>NUMBER_PARTITIONS</td>
<td>NBRPARTS</td>
<td>INTEGER</td>
<td>The partition number of this partition. If the table is a distributed table, contains null.</td>
</tr>
<tr>
<td>NUMBER_DISTRIBUTED_PARTITIONS</td>
<td>DSTPARTS</td>
<td>INTEGER</td>
<td>If the table is a distributed table, contains the total number of partitions. If the table is not a distributed table, contains null.</td>
</tr>
<tr>
<td>NUMBER_ROWS</td>
<td>CARD</td>
<td>BIGINT</td>
<td>Number of valid rows in all partitions or members of the table.</td>
</tr>
<tr>
<td>NUMBER_ROW_PAGES</td>
<td>NPages</td>
<td>BIGINT</td>
<td>Number of 64K pages in all partitions or members of the table.</td>
</tr>
<tr>
<td>NUMBER_PAGES</td>
<td>FPages</td>
<td>BIGINT</td>
<td>Same as NUMBER_ROW_PAGES.</td>
</tr>
<tr>
<td>OVERFLOW</td>
<td>OVERFLOW</td>
<td>BIGINT</td>
<td>The estimated number of rows that have overflowed to variable length segments. If the table does not contain variable length or LOB columns, contains 0.</td>
</tr>
<tr>
<td>CLUSTERED</td>
<td>CLUSTERED</td>
<td>CHAR(1)</td>
<td>Not applicable for Db2 for i. Will always be null.</td>
</tr>
<tr>
<td>ACTIVE_BLOCKS</td>
<td>ACTBLOCKS</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVERAGECOMPRESSEDROWSIZE</td>
<td>ACROWSIZE</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVGROWCOMPRESSIORATIO</td>
<td>ACROWRATIO</td>
<td>REAL</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>AVERAGE_SIZE</td>
<td>AVGROWSIZE</td>
<td>BIGINT</td>
<td>Average length (in bytes) of a row in this table. If the table has variable length or LOB columns, contains -1.</td>
</tr>
<tr>
<td>PCTROWSCOMPRESSED</td>
<td>PCTCROWS</td>
<td>REAL</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>PCTPGSAVED</td>
<td>PCTPGSAVED</td>
<td>SMALLINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>NUMBER_DELETED_ROWS</td>
<td>DELETED</td>
<td>BIGINT</td>
<td>Number of deleted rows in all partitions or members of the table.</td>
</tr>
<tr>
<td>DATA_SIZE</td>
<td>SIZE</td>
<td>BIGINT</td>
<td>Total size (in bytes) of the data spaces in all partitions or members of the table.</td>
</tr>
<tr>
<td>VARIABLE_LENGTH_SIZE</td>
<td>VLSIZE</td>
<td>BIGINT</td>
<td>Size (in bytes) of the variable-length data space segments in all partitions or members of the table.</td>
</tr>
<tr>
<td>FIXED_LENGTH_EXTENTS</td>
<td>FLEXTENTS</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
<tr>
<td>VARIABLE_LENGTH_EXTENTS</td>
<td>VLEXTENTS</td>
<td>BIGINT</td>
<td>Not applicable for Db2 for i. Will always be -1.</td>
</tr>
</tbody>
</table>

161. The length is the number of bytes passed in database buffers, not the internal storage length.

SYSTRIGGERS

The SYSTRIGGERS view contains one row for each trigger in an SQL schema.

The following table describes the columns in the SYSTRIGGERS view:

Table 207. SYSTRIGGERS view

<table>
<thead>
<tr>
<th>Column Name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRIGGER_SCHEMA</td>
<td>TRIGSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the trigger.</td>
</tr>
<tr>
<td>TRIGGER_NAME</td>
<td>TRIGNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the trigger.</td>
</tr>
<tr>
<td>EVENT_MANIPULATION</td>
<td>TRIGEVENT</td>
<td>VARCHAR(6)</td>
<td>Indicates the event that causes the trigger to fire:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DELETE  Trigger fires on a DELETE.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>INSERT   Trigger fires on a INSERT.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>UPDATE   Trigger fires on a UPDATE.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>READ      Trigger fires when a row is read. This is only valid for triggers created via the ADDPFTRG command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>MULTI     Trigger fires for multiple events. The EVENTUPDATE, EVENTDELETE, and EVENTINSERT columns define the events.</td>
</tr>
<tr>
<td>EVENT_OBJECT_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the subject table or view of the trigger.</td>
</tr>
<tr>
<td>EVENT_OBJECT_TABLE</td>
<td>TABNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the subject table or view of the trigger.</td>

<tr>
<td>SYSTEM_XSR_SCHEMA</td>
<td>SYSXSHEMA</td>
<td>CHAR(10)</td>
<td>System name of the schema</td>
</tr>
<tr>
<td>SYSTEM_XSR_NAME</td>
<td>SYSXNAME</td>
<td>CHAR(10)</td>
<td>System name of the XML schema</td>
</tr>
</tbody>
</table>
The XSRANNOTATIONINFO table contains one row for each annotation in an XML schema to record the table and column information about the annotation.

The following table describes the columns in the XSRANNOTATIONINFO table:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSROBJECTID</td>
<td>OBJECTID</td>
<td>BIGINT</td>
<td>Internal identifier of the XML schema.</td>
</tr>
<tr>
<td>ANNOTATION_ID</td>
<td>ANNOID</td>
<td>INTEGER</td>
<td>Internal identifier of the XML schema annotation.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>TABSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Schema of the table to insert the data into.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>TABNAME</td>
<td>VARCHAR(128)</td>
<td>Table to insert the data into.</td>
</tr>
<tr>
<td>ROWSET</td>
<td>ROWSET</td>
<td>VARCHAR(1000)</td>
<td>Name of the rowset for this annotation.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>COLNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the column for this annotation.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>COLTYPE</td>
<td>INTEGER</td>
<td>Data type of the column for this annotation.</td>
</tr>
<tr>
<td>INSTANCE_TYPE</td>
<td>INSTTYPE</td>
<td>INTEGER</td>
<td>Type of data that will be provided by parser during decomposition:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>4</td>
</tr>
<tr>

<tr>
<td></td>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>EXPRESSION</td>
<td>EXPRESSION</td>
<td>VARCHAR(1024)</td>
<td>Expression to be applied to data on insert by Db2.</td>
</tr>
<tr>
<td>CONDITION</td>
<td>CONDITION</td>
<td>VARCHAR(1024)</td>
<td>Condition to be applied before data is inserted by Db2.</td>
</tr>
<tr>
<td>CAST_EXPRESSION</td>
<td>CASTEXP</td>
<td>VARCHAR(20)</td>
<td>Cast expression to be applied when the column data is inserted by Db2 during decomposition.</td>
</tr>
<tr>
<td>IASP_NUMBER</td>
<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Specifies the independent auxiliary storage pool (IASP) number.</td>
</tr>
<tr>
<td>ROWSET_ORDER</td>
<td>ORDER</td>
<td>INTEGER</td>
<td>RowSet order sequence. Default is 1.</td>
</tr>
</tbody>
</table>
The XSROBJECTCOMPONENTS table contains one row for each component (document) in an XML schema.

The following table describes the columns in the XSROBJECTCOMPONENTS table:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSRCOMPONENTID</td>
<td>COMPID</td>
<td>BIGINT</td>
<td>Internal identifier of the XML schema document.</td>
</tr>
<tr>
<td>TARGETNAMESPACE</td>
<td>TGTNAMESPACE</td>
<td>VARCHAR(1000)</td>
<td>String identifier for the target namespace.</td>
</tr>
<tr>
<td>SCHEMALOCATION</td>
<td>SCHEMALOC</td>
<td>VARCHAR(1000)</td>
<td>String identifier for the schema location.</td>
</tr>
<tr>
<td>COMPONENT</td>
<td>COMPONENT</td>
<td>BLOB(30M)</td>
<td>Contents of the XML schema document.</td>
</tr>
<tr>
<td>PROPERTIES</td>
<td>PROPERTIES</td>
<td>BLOB(5M)</td>
<td>Additional document property information for the XML schema document.</td>
</tr>
<tr>
<td>CREATED</td>
<td>CREATEDTS</td>
<td>TIMESTAMP</td>
<td>The time when the XSR_REGISTER stored procedure was executed for the XML schema.</td>
</tr>
<tr>
<td>STATUS</td>
<td>STATUS</td>
<td>CHAR(1)</td>
<td>Registration status of the XML schema:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>C Complete</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>I Incomplete</td>
</tr>
<tr>
<td>IASP_NUMBER</td>
<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Indicates the IASP where the catalog table is located.</td>
</tr>
</tbody>
</table>
XSROBJECTHIERARCHIES

The XSROBJECTHIERARCHIES table contains one row for each component (document) in an XML schema to record the XML schema document hierarchy relationship.

The following table describes the columns in the XSROBJECTHIERARCHIES table:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSROBJECTID</td>
<td>OBJECTID</td>
<td>BIGINT</td>
<td>Internal identifier of the XML schema.</td>
</tr>
<tr>
<td>XSRCOMPONENTID</td>
<td>COMPID</td>
<td>BIGINT</td>
<td>Internal identifier of the XML schema document.</td>
</tr>
<tr>
<td>HTYPE</td>
<td>HTYPE</td>
<td>CHAR(1)</td>
<td>Hierarchy type:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>D       Document</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>P       Primary document</td>
</tr>
<tr>
<td>TARGETNAMESPACE</td>
<td>TGTNAMESPACE</td>
<td>VARCHAR(1000)</td>
<td>String identifier for the target namespace.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td></td>
</tr>
<tr>
<td>SCHEMALLOCATION</td>
<td>SCHEMALOC</td>
<td>VARCHAR(1000)</td>
<td>String identifier for the schema location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nullable</td>
<td></td>
</tr>
<tr>
<td>IASP_NUMBER</td>
<td>IASPNUMBER</td>
<td>SMALLINT</td>
<td>Specifies the independent auxiliary storage pool (IASP) number.</td>
</tr>
</tbody>
</table>

IBM i: Db2 for i SQL Reference
The XSROBJECTS table contains one row for each registered XML schema.

The following table describes the columns in the XSROBJECTS table:

<table>
<thead>
<tr>
<th>Column name</th>
<th>System Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSROBJECTID</td>
<td>OBJECTID</td>
<td>BIGINT</td>
<td>Internal identifier of the XML schema.</td>
</tr>
<tr>
<td>XSROBJECTSCHEMA</td>
<td>XSRSCHEMA</td>
<td>VARCHAR(128)</td>
<td>Qualifier of the XML schema name.</td>
</tr>
<tr>
<td>XSROBJECTNAME</td>
<td>XSRNAME</td>
<td>VARCHAR(128)</td>
<td>Name of the XML schema.</td>
</tr>
<tr>
<td>SYSTEM_XSR_SCHEMA</td>
<td>SYSXSCHEMA</td>
<td>CHAR(10)</td>
<td>System library name corresponding to the qualifier of the XML schema.</td>
</tr>
<tr>
<td>SYSTEM_XSR_NAME</td>
<td>SYSXNAME</td>
<td>CHAR(10)</td>
<td>System name of the XSROBJECT that correlates to the XML schema.</td>
</tr>
<tr>
<td>TARGETNAMESPACE</td>
<td>TGTNAMESPACE</td>
<td>VARCHAR(1000)</td>
<td>String identifier for the target namespace.</td>
</tr>
<tr>
<td>SCHEMALOCATION</td>
<td>SCHEMALLOCATION</td>
<td>VARCHAR(1000)</td>
<td>String identifier for the schema location.</td>
</tr>
<tr>
<td>XSR_OBJECT_TEXT</td>
<td>LABEL</td>
<td>VARCHARGRAPHIC(50)</td>
<td>A character string supplied with the LABEL statement.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>CCSID 1200</td>
<td>Contains the null value if there is no label.</td>
</tr>
<tr>
<td>GRAMMAR</td>
<td>GRAMMAR</td>
<td>BLOB(250M)</td>
<td>The internal binary representation of the XML schema as the result of an XML_COMPLETE.</td>
</tr>
<tr>
<td>PROPERTIES</td>
<td>PROPERTIES</td>
<td>BLOB(5M)</td>
<td>Additional document property information for the XML schema document.</td>
</tr>
<tr>
<td>XSR_SCHEMA_DEFINER</td>
<td>DEFINER</td>
<td>VARCHAR(128)</td>
<td>Authorization ID under which the XML schema was created.</td>
</tr>
<tr>
<td>XSR_SCHEMA_OWNER</td>
<td>OWNER</td>
<td>VARCHAR(128)</td>
<td>Authorization ID that owns the XML schema.</td>
</tr>
<tr>
<td>XSR_SCHEMA_CREATED</td>
<td>CREATEDTS</td>
<td>TIMESTAMP</td>
<td>The time when the XML schema document was registered.</td>
</tr>
<tr>
<td>STATUS</td>
<td>STATUS</td>
<td>CHAR(1)</td>
<td>Registration status of the XML schema:</td>
</tr>

</tbody>
</table>
SQLCOLPRIVILEGES

The SQLCOLPRIVILEGES view contains one row for every privilege granted on a column or a privilege granted on the column's table. Note that this catalog view cannot be used to determine whether a user is authorized to a column because the privilege to use a column could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CAT</td>
<td>VARCHAR(128)</td>
<td>Relational database name.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the SQL schema that contains the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(128)</td>
<td>Table name.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR(128)</td>
<td>Column name.</td>
</tr>
<tr>
<td>GRANTOR</td>
<td>VARCHAR(128)</td>
<td>Reserved. Contains the null value.</td>
</tr>
<tr>
<td>GRANTEE</td>
<td>VARCHAR(128)</td>
<td>The user profile to which the privilege is granted.</td>
</tr>
<tr>
<td>PRIVILEGE</td>
<td>VARCHAR(10)</td>
<td>The privilege granted:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>UPDATE</strong> The privilege to update the column.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>REFERENCES</strong> The privilege to reference the column in a referential constraint.</td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td>VARCHAR(3)</td>
<td>Indicates whether the privilege is grantable to other users.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NO</strong> The privilege is not grantable.</td>
</tr>
<tr>

</table>
SQLFUNCTIONCOLS

The SQLFUNCTIONCOLS view contains one row for every parameter of a function. The result of a scalar function and the result columns of a table function are also returned.

The following table describes the columns in the view:

Table 224. SQLFUNCTIONCOLS view

SQLTABLEPRIVILEGES

SQLTABLEPRIVILEGES

The SQLTABLEPRIVILEGES view contains one row for every privilege granted on a table. Note that this catalog view cannot be used to determine whether a user is authorized to a table or view because the privilege to use a table or view could be acquired through a group user profile or special authority (such as *ALLOBJ).

The following table describes the columns in the view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CAT</td>
<td>VARCHAR(128)</td>
<td>Relational database name</td>
</tr>
<tr>
<td>TABLE_SCHEM</td>
<td>VARCHAR(128)</td>

ANS and ISO catalog views

There are two versions of some of the ANS and ISO catalog views. The version documented is the normal set of ANS and ISO views. A second set of views have names that are limited to no more than 18 characters and other than the view names are not documented in this book.

The ANS and ISO catalog includes the following tables in the QSYS2 library:

<table>
<thead>
<tr>
<th>View Name</th>
<th>Shorter View Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;SQL_FEA_TURES&quot; on page 2024</td>
<td></td>
<td>Information about features supported by the database manager</td>
</tr>
<tr>
<td>&quot;SQL_LANGUAGES&quot; on page 2025</td>
<td>SQL_LANGUAGES_S</td>
<td>Information about the supported languages</td>
</tr>
<tr>
<td>&quot;SQL_SIZING&quot; on page 2026</td>
<td></td>
<td>Information about the limits supported by the database manager</td>
</tr>
</tbody>
</table>

The ANS and ISO catalog includes the following views and tables in the SYSIBM and QSYS2 libraries:

<table>
<thead>
<tr>
<th>View Name</th>
<th>Shorter View Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;AUTHORIZATIONS&quot; on page 1996</td>
<td></td>
<td>Information about authorization IDs</td>
</tr>
<tr>
<td>&quot;CHARACTER_SETS&quot; on page 1997</td>
<td>CHARACTER_SETS_S</td>
<td>Information about supported CCSIDs</td>
</tr>
<tr>
<td>&quot;CHECK_CONSTRAINTS&quot; on page 1998</td>
<td></td>
<td>Information about check constraints</td>
</tr>
<tr>
<td>&quot;COLUMN_PRIVILEGES&quot; on page 1999</td>
<td></td>
<td>Information about column privileges</td>
</tr>
<tr>
<td>&quot;COLUMNS&quot; on page 2000</td>
<td>COLUMNS_S</td>
<td>Information about columns</td>
</tr>
<tr>
<td>&quot;INFORMATION_SCHEMA_CATALOG_NAME&quot; on page 2005</td>
<td>CATALOG_NAME</td>
<td>Information about the relational database</td>
</tr>
<tr>
<td>&quot;PARAMETERS&quot; on page 2006</td>
<td>PARAMETERS_S</td>
<td>Information about procedure parameters</td>
</tr>
<tr>
<td>&quot;REFERENTIAL_CONSTRAINTS&quot; on page 2010</td>
<td>REF_CONSTRAINTS</td>
<td>Information about referential constraints</td>
</tr>
<tr>
<td>&quot;ROUTINE_PRIVILEGES&quot; on page 2021</td>
<td>RTNPRIV</td>
<td>Information about routine privileges</td>
</tr>
<tr>
<td>&quot;ROUTINES&quot; on page 2011</td>
<td>ROUTINES_S</td>
<td>Information about routines</td>
</tr>
<tr>
<td>&quot;SCHEMATA&quot; on page 2022</td>
<td>SCHEMATA_S</td>
<td>Statistical information about schemas</td>
</tr>
<tr>
<td>&quot;SEQUENCES&quot; on page 2023</td>
<td></td>
<td>Information about sequences</td>
</tr>
<tr>
<td>&quot;TABLE_CONSTRAINTS&quot; on page 2027</td>
<td></td>
<td>Information about constraints</td>
</tr>
<tr>
<td>&quot;TABLE_PRIVILEGES&quot; on page 2028</td>
<td></td>
<td>Information about table privileges</td>
</tr>
<tr>
<td>&quot;TABLES&quot; on page 2029</td>
<td>TABLES_S</td>
<td>Information about tables</td>
</tr>
<tr>
<td>&quot;UDT_PRIVILEGES&quot; on page 2030</td>
<td>UDP_PRIV</td>
<td>Information about type privileges</td>
</tr>
<tr>
<td>&quot;USAGE_PRIVILEGES&quot; on page 2031</td>
<td>USAGE_PRIV</td>
<td>Information about sequence and XML schema privileges</td>
</tr>
<tr>
<td>&quot;USER_DEFINED_TYPES&quot; on page 2032</td>
<td>UDT_S</td>
<td>Information about types</td>
</tr>
<tr>
<td>&quot;VARIABLE_PRIVILEGES&quot; on page 2036</td>
<td>VAR_PRIV</td>
<td>Information about global variable privileges</td>
</tr>
<tr>
<td>&quot;VIEWS&quot; on page 2037</td>
<td></td>
<td>Information about views</td>
</tr>
</tbody>
</table>
The AUTHORIZATIONS view contains one row for every authorization ID.

The following table describes the columns in the view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTHORIZATION_NAME</td>
<td>VARCHAR(128)</td>
<td>Authorization ID name</td>
</tr>
<tr>
<td>AUTHORIZATION_TYPE</td>
<td>VARCHAR(4)</td>
<td>The type of authorization ID. Contains 'USER'.</td>
</tr>
<tr>
<td>AUTHORIZATION_ATTR</td>
<td>VARCHAR(5)</td>
<td>The type of user profile. Contains 'USER' or 'GROUP'.</td>
</tr>
<tr>
<td>AUTHORIZATION_TEXT</td>
<td>VARCHAR(50)</td>
<td>The text description for the profile.</td>
</tr>
</tbody>
</table>
CHARACTER_SETS

The CHARACTER_SETS view contains one row for every CCSID supported.

The following table describes the columns in the view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER_SET_CATALOG</td>
<td>VARCHAR(128)</td>
<td>Relational database name</td>
</tr>
<tr>
<td>CHARACTER_SET_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>The schema name of the character set. Contains SYSIBM.</td>
</tr>
<tr>
<td>CHARACTER_SET_NAME</td>
<td>VARCHAR(128)</td>
<td>The character set name.</td>
</tr>
<tr>
<td>FORM_OF_USE</td>
<td>VARCHAR(128)</td>
<td>Reserved. Contains the null value.</td>
</tr>
<tr>
<td>NUMBER_OF_CHARACTERS</td>
<td>INTEGER</td>
<td>Reserved. Contains the null value.</td>
</tr>
<tr>
<td>DEFAULT_COLLATE_CATALOG</td>
<td>VARCHAR(128)</td>
<td>Reserved.</td>
</tr>
<tr>
<td>DEFAULT_COLLATE_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>Reserved.</td>
</tr>
<tr>
<td>DEFAULT_COLLATE_NAME</td>
<td>VARCHAR(128)</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>
The CHECK_CONSTRAINTS view contains one row for every check constraint.

The following table describes the columns in the view:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>VARCHAR(128)</td>
<td>Relational database name</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the schema containing the constraint</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the constraint</td>
</tr>
<tr>
<td>CHECK_CLAUSE</td>
<td>VARGRAPHIC(2000)</td>
<td>Text of the check constraint clause</td>
</tr>
<tr>
<td></td>
<td>CCSID 1200</td>
<td>Contains the null value if the check clause cannot be contained in the</td>
</tr>
<tr>
<td></td>
<td>Nullable</td>
<td>column without truncation.</td>
</tr>
</tbody>
</table>
**COLUMN_PRIVILEGES**

The COLUMN_PRIVILEGES view contains one row for every privilege granted on a column. Note that this catalog view cannot be used to determine whether a user is authorized to a column because the privilege to use a column could be acquired through a group user profile or special authority (such as *ALLOBJ). Furthermore, the privilege to use a column is also acquired through privileges granted on the table.

The following table describes the columns in the view:

*Table 239. COLUMN_PRIVILEGES view*

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTOR</td>
<td>VARCHAR(128)</td>

Appendix F. Db2 for i catalog views 2037
Appendix G. Text search argument syntax

A text search argument is specified when searching for terms in text documents. It consists of search parameters and one or more search terms. The SQL scalar text search functions that use text search arguments are CONTAINS and SCORE.

For information on CONTAINS and SCORE, see “CONTAINS” on page 365 and “SCORE” on page 580.

For more information on text search, see OmniFind Text Search Server for DB2 for

Syntax

```
qualified-clause—operator—qualified-clause
```

operator:

```
AND
OR
```

qualified-clause:

```
modifier—clause—boost
```

modifier:

```
+—-—NOT
```

clause:

```
unqualified-term—opaque-term
```

boost:

```
^—number
```

Description

A search argument is a term or sequence of terms, separated by white space, specified when searching in text documents. It consists of one or more search
terms and various optional search parameters.

To perform a simple search, you can enter one or more terms. The search engine returns documents that contain all of those terms or variations of those terms. For example, if you perform a search on the term king, documents containing king are returned. By default, the search engine also returns variants of the search term. Thus, documents containing kings are also returned. Similarly, when you search on two terms, the search engine returns documents containing both terms. If you want the terms to be searched as an exact phrase, simply add quotation marks.

The more specific the search term you use, the more precise the results. However, you may also want to refine your searches by using one or more of the following options:

**operator**

Specifies whether the search for either or both qualified clauses on either side of the operator must be satisfied.

**AND**

The search for both qualified clauses on either side of the operator must be satisfied.

**OR**

The search for at least one of the qualified clauses on either side of the operator must be satisfied.

Similar to search conditions in SQL, parentheses can be used to determine which qualified clauses and operators are evaluated first. If parentheses are not specified, AND is applied before OR.

**modifier**

Each clause can have an occurrence modifier. If a modifier is not specified for a clause, the default is plus (+).

+ The clause is required in the document.

- or NOT

The clause must not be specified in the document.

? The clause is optional in the document.

**clause**

Specifies a search string. In the search string, the question mark and asterisk have special meanings. Use a question mark (?) to represent any single character, and an asterisk (*) to represent a string of zero or more characters. If the search string contains multiple words that should be treated as a phrase, include quotation marks (") around the search string. Blanks within a clause are ignored.

**unqualified-term**

An unqualified term is simply a term or a phrase. A term can be a word, such as king; an exact word, such as "king"; or a word that includes a question mark (?) to represent any single character, and an asterisk (*) to represent a string of zero or more characters, such as king* or king?.

Similarly, a phrase can be a group of words, such as cabbages and kings; an exact phrase, such as "The King and I"; or a phrase that includes a wildcard, such as "all the king's ho*ses" or "all the king's ?".

If a character in clause is one of the characters that has a special meaning in the syntax of the search argument, an escape character (\) can be used to indicate that the subsequent character should be treated as a regular character in the clause.
opaque-term

An opaque query term is so called because it is not parsed by the linguistic query parser; opaque terms are identified by their syntax. The opaque term used for text search queries that include XML markup is @xmlxp,, for example: @xmlxp:/TagA/TagB[. contains("king")]

boost

boost can be specified for each clause. boost provides a higher or lower importance to occurrences of the clause.

number

Specifies a decimal or integer constant that is greater than 0. If boost is not specified for a clause, the default boost value is 1.

Notes

Case sensitivity: Searches are not case sensitive, so a search in Spanish for the exact term "DOS" could return documents containing DOS or dos.

Examples: Simple text search

The CONTAINS and SCORE functions can be used to perform a simple text search for a single word or multiple words in a text search index.

The search engine ignores white space between characters. An empty search argument, or one that contains only blanks, does not match anything.

The following table shows some examples of simple text search requests.

<table>
<thead>
<tr>
<th>Search word types</th>
<th>Examples</th>
<th>Search results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single word</td>
<td>king</td>
<td>Returns all documents that contain the word king or kings. The search is not case-sensitive.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Multiple words</td>
<td>king lear</td>
<td>Returns all documents that contain king and lear. The default operator is the logical operator AND.</td>
</tr>
</tbody>
</table>

The operators AND and + (plus sign) are implicit in every text search. For example, the text search for King Lear returns the same results as King AND Lear or King + Lear.

You must enter the logical operators NOT, AND, and OR in all uppercase.

Advanced text search operators

You can use advanced text search operators to refine the search results for the CONTAINS function and the SCORE function.

In the following table, the first column describes the operator that you can use in a text search. (You must enter the logical operators NOT, AND, and OR in all uppercase letters.) The second column shows a sample text search that you might enter. The third column describes the types of results that you might see from the example text search.
### Advanced text search operators

#### Table 260. Advanced search operators and complex text search examples

<table>
<thead>
<tr>
<th>Operators</th>
<th>Examples</th>
<th>Search results</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AND</strong></td>
<td>&quot;King Lear&quot; AND &quot;Othello&quot;</td>
<td>Either text search returns documents that contain both terms King Lear and Othello. The AND operator is the default conjunction operator. If no logical operator is between the two terms, the AND operator is used. For example, the text search King Lear is the same as the text search King AND Lear.</td>
</tr>
<tr>
<td><strong>OR</strong></td>
<td>&quot;King Lear&quot; OR Lear</td>
<td>Returns documents that contain either King Lear or just Lear. The OR operator links the two terms and finds a matching document if either of the terms exist in a document.</td>
</tr>
<tr>
<td><strong>NOT</strong></td>
<td>&quot;King Lear&quot; NOT &quot;Norman Lear&quot;</td>
<td>Returns documents that contain King Lear but not Norman Lear. The NOT operator cannot be used with only one term. For example, the following search will return no results: NOT &quot;King Lear&quot;.</td>
</tr>
<tr>
<td><strong>&quot; &quot;</strong></td>
<td>First text search: &quot;King Lear&quot; Second text search: &quot;king&quot;</td>
<td>The first text search returns the exact phrase King Lear. The second text search returns only the word king and no other forms, such as kings or kingly.</td>
</tr>
<tr>
<td><strong>(Exact match)</strong></td>
<td>test* text</td>
<td>Returns documents that can match possible combinations, such as test, tests, and tester, or test and text.</td>
</tr>
<tr>
<td><strong>?</strong></td>
<td>test? te?t</td>
<td>Returns documents that can match possible combinations, such as tests, or test and text.</td>
</tr>
<tr>
<td><strong>^</strong></td>
<td>First text search: &quot;King Lear&quot;^4 &quot;Richard III&quot; Second text search: title: (software download)^5 pdf viewer -shipping</td>
<td>The first text search forces documents with the phrase King Lear to appear higher in the list of search results. The second text search forces a document titled software download to appear higher in the list of results. Although a boost factor must be positive, the boost factor can be less than 1. For example, 0.2. The boost factor number has no limit.</td>
</tr>
<tr>
<td><strong>+</strong></td>
<td>+Lear King</td>
<td>Returns all documents that contain Lear and King, which is the same as the text search Lear AND King.</td>
</tr>
<tr>
<td><strong>-</strong></td>
<td>&quot;King Lear&quot; -&quot;Lear Jet&quot;</td>
<td>Returns documents that contain King Lear but not Lear Jet.</td>
</tr>
<tr>
<td><strong>()</strong></td>
<td>(King OR Lear) AND plays</td>
<td>Returns documents that contain either King or Lear and plays. The parentheses ensure that plays is found and either term King or Lear is present.</td>
</tr>
</tbody>
</table>

---

2042  IBM i: Db2 for i SQL Reference
Table 260. Advanced search operators and complex text search examples (continued)

<table>
<thead>
<tr>
<th>Operators</th>
<th>Examples</th>
<th>Search results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\</td>
<td>{(1+1)}:2</td>
<td>Returns documents that contain {(1+1):2. Use the \ to clear special characters that</td>
</tr>
<tr>
<td></td>
<td></td>
<td>are part of the text search syntax. Special characters are + - &amp;&amp;</td>
</tr>
<tr>
<td>(Escape character)</td>
<td></td>
<td>? : . If a special character is cleared, the special character is analyzed as part of</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the text search.</td>
</tr>
</tbody>
</table>

Example: Using the CONTAINS function and SCORE function

You can use the CONTAINS function or the SCORE function in the same query to search a text search index and to return if and how frequently the text document matches the search argument criteria.

The example in the following table uses data from the base table BOOKS with the columns ISBN (VARCHAR(20)), ABSTRACT (VARCHAR(10000)), and PRICE (INTEGER).

Table 261. The base table BOOKS

<table>
<thead>
<tr>
<th>ISBN</th>
<th>ABSTRACT</th>
<th>PRICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>&quot;a b c&quot;</td>
<td>7</td>
</tr>
<tr>
<td>i2</td>
<td>&quot;a b d&quot;</td>
<td>10</td>
</tr>
<tr>
<td>i3</td>
<td>&quot;a e a&quot;</td>
<td>8</td>
</tr>
</tbody>
</table>

You run the following query:

```sql
SELECT ISBN, SCORE(ABSTRACT,"b")
FROM BOOKS
WHERE CONTAINS (ABSTRACT,"b") = 1
```

This query returns the following two rows:

11, 0.3
13, 0.4

The score values might differ depending on the content of the text column.
XML text search

Based on a subset of the XPath language with extensions for text search, XML text search allows you to index and search XML documents so that structural elements can be used separately or can be combined with free text in queries.

Structural elements are tag names, attribute names, and attribute values.

The following list highlights the key features of XML search:

XML structural search
By including special opaque terms in queries, you can search XML documents for structural elements (tag names, attribute names, and attribute values) and text that is scoped by those elements.

XML query tokenization
Free text in XML query terms is tokenized the same way that text in non-XML query terms is tokenized, except that (nested) opaque terms are not supported. Synonyms, wildcard characters, phrases, and lemmatization are supported.

Numeric values
Predicates that compare attribute values to number, date, or dateTime data types are supported.

Complete match
The = (equal sign) operator with a string argument in a predicate calls for an exact match of all tokens in the string with all tokens in the identified text span. The order is NOT significant.

No UIMA access
Unstructured Information Management Architecture (UIMA) is used for tokenization in XML search, but user-written annotators are not supported.

XML text search grammar
A subset of the XPath language, which is defined by an Extended Backus-Naur Form (EBNF) grammar, is supported by the XML search query parser. Queries that do not conform to the supported grammar are rejected by the query parser, which throws an exception.

The EBNF grammar has been simplified in the following ways by:
• Removing the largest-scale structures for specifying iteration and ranges
• Eliminating filter expressions
• Disallowing absolute pathnames in predicate expressions
• Recognizing only one axis (tag) and only in the forward direction

The following table shows the supported grammar in EBNF notation.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLQuery ::=</td>
<td>QueryPrefix NameSpaceDeclaration QueryString</td>

For more information about QName, see http://www.w3.org/TR/REC-xml-names/#NT-QName

The following information about XML search queries that use XPath notation might not be obvious from the EBNF grammar notations:

- **Names not normalized**: XML tag and attribute names are not normalized when they are indexed. The names are not changed to lowercase or modified in any way. Case is significant in XML tag and attribute names to get a match. Therefore, the strings that are used for XML tag and attribute names in queries must match exactly the names that appear in the source documents.

- **Free text normalization**: Free text in XML documents (text between tags, not inside a tag itself) and attribute values are normalized before indexing. Text in XML search queries (in contains or excludes operators, or in strings that are surrounded by quotation marks) is normalized, too. Features such as phrases, synonyms, wildcard characters, and lemmas are supported.

- **Operator precedence**: In XML search predicates, containment operators and comparison operators take precedence over logical operators, and all logical operators have the same precedence. Containment operators are contains and
excludes. Comparison operators are =, !, <, >, <= and >=. Logical operators are "and" and "or." You can use parentheses to ensure the desired precedence.

- **Semantics:** In XML search predicates, the comparison operators can be applied only to attribute values and not to tags.

### Examples: XPath text search

All valid XPath queries that are sent to the XML parser must be written in a subset of the XPath language using opaque terms. Opaque terms are not parsed by the linguistic text search parser.

The text search parser recognizes an opaque term by the syntax that is used in the text search. For example:

```
@xpath: 'query'
```

where *query* is the text shown in the examples in the following table.

**Table 263. Examples of valid XPath queries**

<table>
<thead>
<tr>
<th>Query</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/sentences</code></td>
<td>Any document with a top-level tag called <em>sentences</em>.</td>
</tr>
<tr>
<td><code>//sentences</code></td>
<td>Any document with a tag at any level called <em>sentences</em>.</td>
</tr>
<tr>
<td><code>/sentence/paragraph</code></td>
<td>Any document with a top-level tag <em>sentence</em> having a direct child tag <em>paragraph</em>.</td>
</tr>
<tr>
<td><code>/sentence/paragraph/</code></td>
<td>Any document with a top-level tag <em>sentence</em> having a direct child tag <em>paragraph</em>.</td>
</tr>
<tr>
<td><code>/book/@author</code></td>
<td>Any document with a top-level <em>book</em> tag having an attribute <em>author</em>.</td>
</tr>
<tr>
<td><code>/book//@author</code></td>
<td>Any document with a top-level <em>book</em> tag having a descendant tag at any level with the attribute <em>author</em>.</td>
</tr>
<tr>
<td><code>/book[@author contains(&quot;barnes&quot;) and @title = &quot;the lemon table&quot;]</code></td>
<td>Any document with a top-level <em>book</em> tag with an <em>author</em> attribute containing &quot;barnes&quot; (normalized) and a <em>title</em> attribute that only contains the words &quot;the,&quot; &quot;lemon&quot; and &quot;table&quot; (normalized in that order).</td>
</tr>
<tr>
<td><code>/book[@author contains(&quot;barnes&quot;) and (@title contains(&quot;lemon&quot;) or @title contains(&quot;flaubert&quot;))]</code></td>
<td>Any document with a top-level <em>book</em> tag with the specified <em>author</em> attribute and either of the two specified <em>title</em> attributes.</td>
</tr>
<tr>
<td><code>/book[@publishDate &gt; xs:date(&quot;2000-01-01&quot;)</code></td>
<td>Top level tag is <em>book</em> and <em>book</em> has an attribute <em>PublishDate</em> that is greater than the date of 2000-01-01.</td>
</tr>
<tr>
<td><code>/book[purchaseTime &gt; xs:dateTime(&quot;2009-05-20T13:00:00&quot;)]</code></td>
<td>Top level tag is <em>book</em>. <em>book</em> has a direct child <em>purchaseTime</em> that is a DateTime expression greater than 2009-05-20T13:00:00.</td>
</tr>
<tr>
<td><code>/program\. contains(&quot;hello, world.&quot;&quot;)</code></td>
<td>Any document with a top-level <em>program</em> tag containing both the tokens <em>hello</em> and <em>world</em> (normalized) in that order and in consecutive positions.</td>
</tr>
</tbody>
</table>
Table 263. Examples of valid XPath queries  (continued)

<table>
<thead>
<tr>
<th>Query</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/book[paragraph contains(&quot;foo&quot;)]/sentence</td>
<td>Any document with a top-level book tag with a direct child tag paragraph containing &quot;foo&quot; and, referring to the book tag, having a descendant tag sentence at any level.</td>
</tr>
<tr>
<td>/auto[@price &lt; 30000.]</td>
<td>Any document with a top-level auto tag having an attribute price with a numeric value that is less than 30000.</td>
</tr>
<tr>
<td>//microbe[@size &lt; 3.0e-06]</td>
<td>Any document containing a microbe tag at any level with a size attribute with a value that is less than .000003.</td>
</tr>
</tbody>
</table>
## Text search language options

The text search language option specifies which language rules to use when performing a text search.

If QUERYLEANUAGE is not specified, the default is the language value of the text search index that is used when the CONTAINS or SCORE function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLEANUAGE is en_US. The following table shows the valid language codes that may be used in the QUERYLEANUAGE option.

<table>
<thead>
<tr>
<th>Language code</th>

Appendix I. Reserved schema names and reserved words

This topic describes the restrictions of certain names used by the database manager. In some cases, names are reserved and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs though not prevented by the database manager.

Reserved schema names

This is the list of reserved schema names.

The following schema names are reserved:
• QSYS2
• SYSCAT
• SYSFUN
• SYSIBM
• SYSIBMADM
• SYSPROC
• SYSPUBLIC
• SYSSTAT
• SYSTEM

In addition, it is strongly recommended that schema names never begin with the Q prefix or SYS prefix, as Q and SYS are by convention used to indicate an area reserved by the system.

It is also recommended not to use SESSION as a schema name.
Reserved words

This is the list of currently reserved Db2 for i words.

Words may be added at any time. For a list of additional words that may become reserved in the future, see the IBM SQL and ANSI reserved words in the SQL Reference for Cross-Platform Development (http://www.ibm.com/developerworks/data/library/techarticle/0206sqlref/0206sqlref.html).

Appendix J. Related information

The publications listed here provide additional information about topics described or referred to in this guide.

These manuals are listed with their full titles and order numbers. When these manuals are referred to in this guide, a shortened version of the title is used.

- **Backup and recovery**
  The manual contains information about planning a backup and recovery strategy, the different types of media available to save and restore procedures, and disk recovery procedures. It also describes how to install the system again from backup.

- **ILE COBOL Programmer's Guide**
  This guide provides information needed to design, write, test, and maintain COBOL programs on the IBM i products.

- **ILE RPG Programmer's Guide**
  This guide provides information you need to design, write, test, and maintain ILE RPG programs on the IBM i products.

- **REXX/400 Programmer's Guide**
  This guide provides information you need to design, write, test, and maintain REXX/400 programs on the IBM i products.

- **CL programming**
  This guide provides a wide-ranging discussion of the programming topics, including a general discussion of objects and libraries, CL programming, controlling flow and communicating between programs, working with objects in CL programs, and creating CL programs. Other topics include predefined and impromptu messages and handling, defining and creating user-defined commands and menus, application testing, including debug mode, breakpoints, traces, and display functions.

- **Database file management**
  This book provides information about using files in application programs.

- **Database programming**
  This book provides a detailed description of the IBM i database organization, including information about how to create, describe, and update database files on the system.

- **Distributed database programming**
  Provides information about preparing and managing an IBM i product in a distributed relational database using the Distributed Relational Database Architecture (DRDA). Describes planning, setting up, programming, administering, and operating a distributed relational database on more than one IBM i product in a like-system environment.

- **Security reference**
  This guide provides information about system security concepts, planning for security, and setting up security on the system. It also gives information about protecting the system and data from being used by people who do not have the
proper authorization, protecting the data from intentional or unintentional
damage or destruction, keeping security up-to-date, and setting up security on
the system.

- **SQL programming**
  This book provides an overview of how to design, write, run, and test Db2 for i
  statements. It also describes interactive Structured Query Language (SQL).

- **SQL XML programming**
  This book provides information about using the XML data type with SQL. It
  includes examples of using functions and procedures to generate XML and to
  retrieve all or part of an XML document.

- **Embedded SQL programming**
  This book provides examples of how to write SQL statements in ILE C, ILE C++,
  COBOL, ILE COBOL, RPG, ILE RPG, REXX, and PL/I programs.

- **Database performance and query optimization**
  This book provides information about optimizing the performance of your
  queries using available tools and techniques.

- **IDDU Use**
  This book describes how to use IBM i interactive data definition utility (IDDU)
  to describe data dictionaries, files, and records to the system.

- **SQL call level interfaces (ODBC)**
  This book describes how to use X/Open SQL Call Level Interface to access SQL
  functions directly through procedure calls to a service program provided by Db2
  for i.

- **IBM i Access** category in the IBM i Information Center
  This information describes how to set up and run ODBC applications on a client
  using IBM i Access ODBC. Included in this document are chapters on
  performance, examples, and configuring specific applications to run with IBM i
  Access ODBC.

- **IBM Toolbox for Java**
  This book describes how to set up and run JDBC applications on a client using
  IBM Toolbox for Java. Included in this document are chapters on performance,
  examples, and configuring specific applications to run with IBM Toolbox for
  Java.

- **IBM Developer Kit for Java**
  This information provides the details you need to design, write, test, and
  maintain JAVA programs on the IBM i product. The book also contains
  information about the IBM Developer Kit for Java JDBC driver.

- **DB2 Multisystem**
  This book describes the fundamental concepts of distributed relational database
  files, nodegroups, and partitioning. The book provides the information you need
  to create and use database files that are partitioned across multiple systems.
  Information is provided on how to configure the systems, how to create the files,
  and how the files can be used in applications.
Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user’s responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.
1623-14, Shimotsuruma, Yamato-shi
Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.
IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation
Software Interoperability Coordinator, Department YBWA
3605 Highway 52 N
Rochester, MN 55901
U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM’s future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating
platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:

© (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs.

### Programming interface information

This Db2 for i SQL Reference publication documents intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM i.

### Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at www.ibm.com/legal/copytrade.shtml.

Adobe, the Adobe logo, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

Java and all Java-based trademarks and logos are trademarks of Oracle, Inc. in the United States, other countries, or both.

Other product and service names might be trademarks of IBM or other companies.

### Terms and conditions

Permissions for the use of these publications is granted subject to the following terms and conditions.

**Personal Use:** You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative works of these publications, or any portion thereof, without the express consent of IBM.

**Commercial Use:** You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved.
You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM makes no guarantee about the content of these publications. The publications are provided "AS-IS" and without warranty of any kind, either expressed or implied, including but not limited to implied warranties of merchantability, non-infringement, and fitness for a particular purpose.
