     `maxItems` and `minItems`, like in the example\nbelow.\n\n```\nLimited:\n  type: array\n  maxItems: 10\n  items:\n
     type: string\n    format: date\n```\n\nYou should ensure that the schema referenced in  `items` is constrained
     too.\n\nIf you delegate input validation to a library or framework,\nbe sure to test it thoroughly and ensure that it
     verifies `maxItems`.",
             "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
             "formats": [
               "oas3"
             ],
             "severity": "warn",
             "recommended": true,
             "given": [
               "$..[?(@.type==\"array\")]"
             ],
             "then": [
               {
                 "field": "maxItems",
                 "function": "defined"
               }
     ```

```
        ]
      }
    ]
  }
```

The following JSON shows the contents of an example product document ruleset file:

```
{
  "type": "ruleset",
  "ruleset_type": "custom",
  "api_version": "2.0.0",
  "id": "dbb5f400-e707-412e-b081-ac36f5afbbb9",
  "name": "test-product",
  "title": "Test Product",
  "description": "",
  "ruleset_version": "1.0.0",
  "ruleset_state": "draft",
  "ruleset_format_type": "2",
  "rule_urls": [
    "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b"
  ],
  "created_at": "2024-05-22T17:19:02.820Z",
  "updated_at": "2024-05-22T17:24:59.000Z",
  "url": "https://my.manager.com/governance/orgs/myorg/rulesets/dbb5f400-e707-412e-b081-ac36f5afbbb9",
  "rules": [
    {
      "api_version": "2.0.0",
      "id": "ca6ef7d9-a503-498e-8f53-4e3aa35d086b",
      "name": "subscribe",
      "version": "1.0.0",
      "title": "subscribe",
      "description": "subscribe enabled",
      "message": "subscribe not enabled",
      "given": [
        "$.visibility.subscribe.enabled"
      ],
      "severity": "error",
      "created_at": "2024-05-22T17:19:02.000Z",
      "updated_at": "2024-05-22T17:24:59.000Z",
      "url": "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b",
      "then": [
        {
          "function": "pattern",
          "functionOptions": {
            "notMatch": "/true"
          }
        }
      ]
    }
  ]
}
```

2. Log in to the toolkit as an Admin.
   For example:

   ```
   apic login --server mgmt_endpoint_url --username admin --password password --realm admin/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

3. Run the `rulesets:create` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:create --org <target_org> --server <server_url> RULESET_FILE
   ```

   Where:
   - `<target_org>` is the name of the organization that owns the new ruleset.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and file name of the JSON file that contains the ruleset.

Results

Your draft API or product ruleset is now listed in the table of Global rulesets.

What to do next

When you finish editing your ruleset, you can publish it to your provider organizations. Click the options menu icon ⋮ either next to the ruleset that you want to publish, or from within the ruleset viewer. Select Publish, and then click Publish again to confirm. The status of your ruleset changes from Draft to Published, and can now be used to validate API and product documents. For more information, see Validating an API document by using governance.

You can also use a published ruleset to validate an API or product document in the Cloud Manager. Click Validate, upload a document file to validate, and then select the rulesets and rules that you want to use for the validation. If the API that you want to validate includes a tag that has a matching tag in one or more rulesets, then those rulesets are automatically selected for the scan. However, you can edit the ruleset selection to your requirements. The results of the validation are displayed in a scorecard.

Note:

- After a ruleset is published, the ruleset information and rules can no longer be edited. If you need to update this information, you must create a new version by clicking the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer, and selecting Save as new ruleset.
- By default, rulesets are published to all of your provider organizations. If you want to change which provider organizations can use your rulesets, you must edit the visibility after publishing.

If you want to change the visibility of your ruleset, click the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer. Then click Edit visibility, and select from the following visibility options:

- Private - the ruleset is not visible and cannot be used by any provider organization.
- Public - the ruleset is visible and can be used by all provider organizations.
- Custom - the ruleset is visible to and can be used by only the provider organizations that are designated by you.

Click Save to confirm your visibility option.

- **The governance ruleset lifecycle in the Cloud Manager**
  When you manage your custom governance rulesets in the Cloud Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.
- **Updating rulesets and rules with the toolkit CLI**
  Use the API Connect toolkit CLI to update a ruleset or individual rules.

The governance ruleset lifecycle in the Cloud Manager

When you manage your custom governance rulesets in the Cloud Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

The following sections describe the various lifecycle states for a custom governance ruleset.

Note:

- Approval is not required for any of the lifecycle state transitions.
- Default rulesets are built-in to API Connect, and contain pre-configured rules that are available to all of your provider organizations, and cannot be edited. These rulesets are always in the Published state, and their visibility cannot be changed.

Draft

The draft state for a ruleset is when the ruleset is not published, and isn't visible any provider organization. The ruleset can continue to be edited, and its Status is shown as Draft.

Published

When you publish a ruleset, it is made visible to all of your provider organizations, and cannot be changed. The ruleset Status is shown as Published, and the ruleset visibility is shown as Public. If you want to change which provider organizations can use your rulesets, you must edit the visibility after publishing. You can select from the following visibility options:

- Private - the ruleset is not visible and cannot be used by any provider organization.
- Public - the ruleset is visible and can be used by all provider organizations.
- Custom - the ruleset is visible to and can be used by only the provider organizations that are designated by you.

Any other changes require a new version of the ruleset to be created by using the Save as new ruleset option.

Archived

When you archive a ruleset, it becomes a ready-only, fixed version of the ruleset that cannot be used for validation by any provider organization. The ruleset Status is shown as Archived.
Note: If you cannot see your Archived ruleset, ensure that the Edit filters option on the ruleset table is set to include Archived.
You can restore archived rulesets by using the Restore option, after which the Status returns to Published.

Also, you can delete Archived rulesets by using the Delete option.

Updating rulesets and rules with the toolkit CLI

Use the API Connect toolkit CLI to update a ruleset or individual rules.

Updating a ruleset

1. Create a JSON file that defines the updated ruleset.
   The following example shows an updated ruleset:

   ```
   {
       "title": "custom-ruleset-2",
       "description": "short ruleset updated",
       "ruleset_type": "custom"
   }
   ```

   where:
   - `title` is updated to a new title for the ruleset.
   - `description` is updated to a new description for the ruleset.
   - `ruleset_type` is updated to be custom for the ruleset.
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the ruleset.
3. Run the `rulesets:update` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:update --org <target_org> --server <server_url> RULESET RULESET_FILE
   ```

   where:
   - `<target_org>` is the name of the organization that owns the ruleset.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and filename of the JSON file that contains the updated ruleset.
   - `RULESET` is the name or the unique ID of the updated ruleset.
     To determine the ID of a ruleset, run the following command:

     ```
     apic -m governance rulesets:list --org <target_org> --server <server_url>
     ```

Updating a rule

1. Create a JSON file that defines the updated rule.
   The following example shows an updated rule in a file called:

   ```
   {
     "description": "Updated the rule",
     "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
     "formats": [
       "oas3"
     ],
     "severity": "warn",
     "recommended": true,
     "given": [
       "$..[?(@.type==\"array\")]"
     ]
   }
   ```

   where:
   - `description` is updated to a new title for the rule
   - `message` is updated to a new message for the rule
   - `formats` array is replaced to have only the format oas3 for the rule
   - `severity` is updated to the warn value for the rule
   - `recommended` is updated to have a new value for the rule
   - `given` array is replaced to have new values for the rule
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the rule.
3. Run the `rules:update` toolkit command in `governance` mode.
   There are two ways to specify the updated rule in the command, depending on whether you provide the rule name and version, or the rule ID:

   Specify the rule name and version in the update command

   ```
   apic -m governance rules:update --org <target_org> --server <server_url> --ruleset <ruleset_name or ruleset_id>
   NAME:VERSION RULE_FILE
   ```

   where:
   - `<target_org>` is the name of the organization that owns the rule.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `<ruleset_name or ruleset_id>` is the name or the unique ID of the ruleset to which the updated rule belongs.
   - `NAME` is the name of the updated rule.
   - `VERSION` is the version of the updated rule; increase the version when you update the rule, using the `major.minor.patch` format as in "1.0.1".
   - `RULE_FILE` is the path and filename of the JSON file that contains the updated rule.

   Specify the rule ID in the update command

   Instead of providing the rule's name and version, you can provide its unique ID instead by running the following command:

   ```
   apic -m governance rules:update --org <target_org> --server <server_url> --ruleset <ruleset_name or ruleset_id> --id
   <rule_id> RULE_FILE
   ```

   where:
   - `<target_org>` is the name of the organization that owns the rule.
   - `<server_url>` is the management server URL that you specified when you logged in to the toolkit.
   - `<ruleset_name or ruleset_id>` is the name or the unique ID of the ruleset to which the update rule belongs.
   - `RULE_FILE` is the path and filename of the JSON file that contains the updated rule.
   - `<rule_id>` is the value of the updated rule's unique ID.

To determine the ID of a rule, run the following command:

```
apic -m governance rules:list --org <target_org> --server <server_url> --ruleset <ruleset_name> RULE_NAME
```

Administering provider organizations

Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.

About this task

Perform these tasks to manage your provider organizations:

- **Creating a provider organization**
  For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.
- **Editing a provider organization**
  You can edit the title of a provider organization, and also transfer ownership to a new organization owner.
- **Deleting a provider organization**
  You can delete a provider organization. All Catalogs and Spaces are also removed.
- **Viewing current provider organizations**
  View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.
- **Sending messages to provider organization owners**
  You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Related tasks

- Creating a provider organization
- Editing a provider organization
- Deleting a provider organization
- Viewing current provider organizations

Creating a provider organization

For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.

Before you begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications

About this task

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

There are two options for creating a provider organization account, as follows:

- Option 1: Create a provider organization and send an email invitation to a new user to register and become the organization owner. Choose the Add > Invite organization owner option.
- Option 2: Create a provider organization and specify the user who will be the organization owner. Choose the Add > Create organization option.

Procedure

- **Option 1:** To create a provider organization and invite a new user to register as the owner, complete the following steps:
  1. In the Cloud Manager, click  Provider Organizations.
  2. Click Add > Invite organization owner
  3. Enter a valid email address and click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Activation Link and click Copy in the pop up window.
     To configure email server, see Configuring an email server for notifications.

     The new provider organization is placed in Pending status, and is changed to Enabled status after the owner completes the registration form to activate their account. The owner can then log in to the API Manager user interface with the API Connect user name that they specified during account activation.

Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously provider organization owners but whose organization was deleted.

- **Option 2:** To create a provider organization and specify the user who will be the organization owner, complete the followings steps:

  1. In the Cloud Manager, click  Provider Organizations.
  2. Click Add > Create organization.
  3. In the Title field, enter a title for the provider organization. If desired, the title can be edited after the provider organization is created.
  4. The internal Name is automatically generated for you by the system. The Name field contains the string that is included in the organization segment of the URL for API calls. For more information, see Calling an API.
     Tip: The Name field is auto-generated to ensure its validity in the URL.
     The value in the Name field is also used to identify the provider organization in developer toolkit CLI commands. To view the CLI commands to manage provider organizations, see the toolkit CLI reference documentation.
  5. Select the user registry for the provider organization owner.
     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Click Create. The user account is created, and the provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with the specified user name and password; the user interface open in the new provider organization.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with their LDAP user name. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must use the invitation mechanism described in Option 1.
       - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.

What to do next

For details of how an invited organization owner activates their account see Activating your API Manager user account. For details of how to log in to the API Manager user interface, see Accessing the API Manager user interface.

Editing a provider organization

You can edit the title of a provider organization, and also transfer ownership to a new organization owner.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

If you transfer ownership, the new organization owner can be an existing user, or you can create a new user. When the ownership changes, the new owner is assigned administration privileges for the organization, and the previous owner has their administration privileges removed. Optionally, you can also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner. If required, you can restore the privileges to the previous owner as described in Administering members and roles.

Procedure

To update a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Click the name of the provider organization that you want to update.
3. To change the title, enter a new title in the Title field, then click Save.

4. To transfer ownership, select the user registry for the provider organization owner you want to transfer ownership to.
   The remaining procedure varies according to the type of the selected user registry, as follows:
   - Local User Registry
     - Select whether the user is an Existing user or a New User.
       - For an existing user, complete the following steps:
         - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
         - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
         - Click Save.
       - For a new user, complete the following steps:
         - Enter a unique user name for the new user.
         - Supply an email address, name details, and a password.
         - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
         - Click Save.
   - LDAP
     - Enter the name of a user that exists in the selected user registry.
     - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
     - Click Save.
   - Authentication URL and OIDC
     - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must ensure they have been invited to the organization first.
     - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
     - Click Save.

Deleting a provider organization

You can delete a provider organization. All Catalogs and Spaces are also removed.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

The user account for the owner of the deleted provider organization remains in the associated API Connect user registry. The user can still log in to the API Manager user interface; if they are a member of one or more other provider organizations then those organizations are accessible, otherwise only information links are available, with no access to view or manage any resources.
The user can be added again as a provider organization owner at a later time; see Creating a provider organization.

Procedure

To delete a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Navigate to the provider organization that you want to delete in the list and select Delete from the Actions menu.
3. Confirm that you want to delete the provider organization.
   The provider organization is deleted and removed from the Provider Organizations list.

Results

The provider organization, and its Catalogs and Spaces, are deleted.

Viewing current provider organizations

View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.

Before you begin

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications

- Creating a provider organization

This task can be completed by users who are assigned one of the following roles:

- All roles
- Custom role with the `Provider-org:Manage` or the `Provider-org:View` permissions

About this task

All roles can view the list of provider organizations. Use the provider organization list screen to manage your provider organizations.

Procedure

1. In the Cloud Manager, click  Provider Organizations.
2. View the list of provider organizations and their status. The statuses are as follows:
   - **Pending**: A provider organization is in `Pending` status until the invited owner successfully completes the registration form.
   - **Enabled**: A provider organization is in `Enabled` status if the owner is an existing user with an account in a user registry.
3. The Actions menu performs different functions depending on the organization's status.
   - For an Enabled organization, you can Edit or Delete the organization or you can send a message to the provider organization owner by clicking Message owner.
   - For a Pending organization, you can resend the invitation by clicking Resend invite, or Delete the request.
4. Add new provider organizations using the Add menu. See Creating a provider organization

Related tasks

- Creating a provider organization
- Editing a provider organization
- Deleting a provider organization

Sending messages to provider organization owners

You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

Note: You can also send email messages by using the developer toolkit CLI, or by using the API Connect REST APIs. See Cloud administration commands, or API Connect REST APIs, for more information.

Procedure

To send a message, complete the following steps:

1. In the Cloud Manager, click  Provider Organizations.
2. Click the options icon ⋮ alongside the provider organization that you want to work with, then click Message owner.
   The Send message window opens, and the email address of the provider organization owner is displayed as the recipient.
3. Enter the subject of the message in the Subject field.
4. Select the Content type that you want to use for the entering the content of the message, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 1. List of allowed HTML tags and their attributes

HTML tag	Attribute
`<a>`	`"class", "href", "hreflang", "style"`
`<em>`	`"class", "style"`
`<strong>`	`"class", "style"`
`<cite>`	`"class", "style"`
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`

HTML tag	Attribute
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`

`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **`<img src="https://path/to/image.png"/>`** tag in the template. The **`src`** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

5. Enter the content of the message.
6. Click Send.

Administering members and roles

Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.

About this task

To manage roles, add members, and assign roles to member, perform the following tasks:

- **Creating roles in the admin organization**
  Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.
- **Editing roles in the admin organization**
  As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.
- **Configuring LDAP group mappings on Cloud Manager user roles**
  As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.
- **Deleting roles in the admin organization**
  Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.
- **Viewing members and roles**
  Use the Members page to view the current members of the Admin organization and manage the role assignments.
- **Adding members to the admin organization**
  As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.
- **Assigning roles to members**
  As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.
- **Deleting a member**
  As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.
- **Role Defaults overview**
  Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Creating roles in the admin organization

Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.

About this task

If you are assigned a role that has the `Settings: manage` permission, you can create custom roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.
One of the following roles is required to add custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Procedure

Perform the following steps to add custom roles to the Admin Organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Click Add to add a new role.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the custom role.

Results

The custom role appears in the list of roles and can be assigned to members.

What to do next

Assign the role to a member in the Members list. See Assigning roles to members

Related tasks

- Editing roles in the admin organization

Editing roles in the admin organization

As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.

About this task

You can customize the per-configured roles (except for the Owner, Viewer, and Member roles) to reflect your business needs.

If you are assigned a role that has the `Settings: manage` permission, you can edit the roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Following are the edits you can perform for a role:

- Change the title
- Add or delete permissions

Procedure

Perform the following steps to edit roles in the Admin organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Locate the Role you want to edit, and select Edit from the overflow menu.
4. Enter the desired Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the updated role.

Results

The Role will be updated with a new name and/or permissions. An updated role will affect the members who are assigned the role. If you change the name of a role, you will have to assign it to the members. If you change the permissions for a role, the way that members use the product may change.

Configuring LDAP group mappings on Cloud Manager user roles

As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.

Before you begin

You must have an LDAP user registry resource in the Cloud Manager that has the **external_group_mapping_enabled** configuration set to **true**. See Using the CLI to configure a shared LDAP user registry for information.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Note: The Admin organization roles apply only to Cloud Manager users. If you want to apply LDAP group mapping to API Manager users, see Configuring LDAP group mapping on API Manager user roles. LDAP group mapping cannot be applied to Developer Portal users.

About this task

You can map external LDAP groups to the API Connect preconfigured user roles (except for the Owner and Member roles), as well as to any custom user roles, to reflect your business needs.

Notes:

- After LDAP group mapping is enabled on a role, user onboarding always honors the group mappings.
- Once on-boarded, user membership in API Connect is valid throughout the login period (**access_token_ttl**), irrespective of any changes in the external LDAP registry. Membership is updated only on the next login, when the LDAP information is fetched and refreshed.
- One or more API Connect roles can be mapped to one or more LDAP groups, and one or more LDAP groups can be mapped to a role.
- When multiple LDAP groups are mapped to a single role, it means that a user from any one of the LDAP groups can log in to API Connect.
- If a user is removed from the external LDAP user registry, then to ensure quick removal from API Connect you must also delete the user membership in API Connect.

You can configure LDAP group mappings using one of the following methods:

- Using the UI to configure LDAP group mappings
- Using the CLI to configure LDAP group mappings

Using the UI to configure LDAP group mappings

Use the Cloud Manager UI to configure LDAP group mappings.

Procedure

1. Login to the Cloud Manager UI as a user with the appropriate permissions.
2. Click Settings > Roles > Add a new Role or edit existing role .
3. Select the following settings:
   - Enable external group mapping - select to enable external group mapping for this role.
   - LDAP user Registry - LDAP user registry list which has external group mapping enabled. User must select one of the LDAP user registry from this list.
   - LDAP group names - add one or more LDAP group names that you want to map to the user role.
   - User group prefix - add the prefix for the LDAP user group.
   - User group suffix - add the suffix for the LDAP user group.
4. Save your changes.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Using the CLI to configure LDAP group mappings

Use the toolkit CLI to configure LDAP group mappings.

About this task

For detailed information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Procedure

Perform the following steps to map external LDAP groups to Cloud Manager user roles.

1. Log in to the management server CLI.
   Before you can update the role configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   where ***mgmt_endpoint_url*** is the platform API endpoint URL.
   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
   ```

```
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
For full details of the login command, see Logging in to a management server.

2. Run the following command to get the URL of the LDAP user registry resource in the Cloud Manager that you want to map the user roles to:

```
apic user-registries:get  ldap_user_registry --org admin --server mgmt_endpoint_url --output -
```

where:
- *`ldap_user_registry`* is the name or ID of your LDAP user registry resource.
- `--org admin` means that the registry details are retrieved from the admin organization.
- *`mgmt_endpoint_url`* is the platform API endpoint URL.

This command outputs the configuration details of your LDAP user registry, and the `url:` is shown at the end of the list, for example:

```
type: user_registry
api_version: 2.0.0
id: 35e75bad-1d89-4a65-a70f-xxxxxx
name: ldap
title: LDAP
integration_url: >-
  https://server.com/api/cloud/integrations/user-registry/147b5fb1-e88e-41e3-90e9-xxxxxx
registry_type: ldap
user_managed: false
user_registry_managed: false
external_group_mapping_enabled: true
...
url: >-
  https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
```

3. Create a role yaml file that contains the following LDAP group mapping configuration properties:

```
external_group_mapping:
  user_registry_url: https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
  ldap_groups:
    - 'cn=apic-administrators,ou=ibmgroups,o=ibm.com'
    - 'cn=apic-developers,ou=ibmgroups,o=ibm.com'
  user_group_filter_prefix: (&(uniquemember=
  user_group_filter_suffix: )(objectClass=groupOfUniqueNames))
```

Where:
- `user_registry_url` is the URL of your LDAP user registry resource from Step 2.
- `ldap_groups` is a list of the LDAP group names that you want to map to the user role.
- `user_group_filter_prefix` is the prefix for the LDAP user group.
- `user_group_filter_suffix` is the suffix for the LDAP user group.

4. Run the following command to update the user role with the `external_group_mapping` configuration properties:

```
apic roles:update role_name --scope org --org admin --server mgmt_endpoint_url mapping_properties_file
```

Where:
- *`role_name`* is the name of the user role that you want to add the LDAP group mapping to.
- `--scope` is the organization scope that you want the update to apply to. For this task, the value must be `org`.
- `--org admin` means that the user role is updated on the admin organization.
- *`mgmt_endpoint_url`* is the platform API endpoint URL.
- *`mapping_properties_file`* is the name of your mapping properties file from Step 3, for example `role_mapping_file.yaml`.

If you prefer to enter the configuration properties interactively on the command line, you can substitute the *`mapping_properties_file`* for a terminating hyphen character `-`, and enter the information manually, followed by pressing `CTRL D` to terminate the input.
If you want to create a custom role that includes LDAP group mapping, you can include the `external_group_mapping` configuration section in the `role_file`, and then create the new role by using the `apic roles:create` command.

For more information about the `apic roles` commands, see the toolkit CLI reference documentation.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Deleting roles in the admin organization

Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.

About this task

All custom roles may be deleted. Pre-configured roles can also be deleted, except for the Owner, Viewer, and Member roles. Owner, viewer, and Member role cannot be deleted or edited. Members who are assigned a deleted role are given the most limited role, Viewer, with View-only privileges. These members will need to be assigned a new role if they require any other privileges.

If you are assigned a role that has the `Settings: manage` permission, you can delete roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.
One of the following roles is required to delete custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Procedure

Perform the following steps to delete roles in the Admin organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Locate the Role you want to delete, and select Delete from the overflow menu.
4. Confirm that you want to proceed with deleting the role.

Results

The Role will be deleted. Members who had been assigned the role are given the Viewer role.

Viewing members and roles

Use the Members page to view the current members of the Admin organization and manage the role assignments.

Procedure

To view the members of the Admin organization and their roles in Cloud Manager, follow these steps:

1. In the Cloud Manager, click Members.
2. From the Members list, you can scroll through the list of users to see their current roles and their status.
   - **Pending** - The invitation with the activation link has been sent to the user, but they have not yet completed the registration form.
   - **Enabled** - The user has completed the registration form and is now able to login and access the features associated with their role.

   Note: If your role has the proper permissions, you can assign roles, add, and delete members from this list.

What to do next

- To add members, see Adding members to the admin organization
- To change the roles assigned to members see Assigning roles to members
- To delete a member, see Deleting a member

Adding members to the admin organization

As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.

About this task

Membership in the Admin organization is required to use Cloud Manager to view and manage the topology of the API Connect cloud, to set up and manage provider organizations, and to manage other features of the cloud. There are two ways to add a member:

- Invite member - send an email invitation to a new user to register as a member of the Admin organization.
- Add member - specify the user and add them as a member of the Admin organization immediately.

One of the following roles is required to add members:

- Administrator
- Owner

Procedure

- To send an email invitation to a new user to register as a member of the Admin organization, complete the following steps:
  1. In the Cloud Manager, click Members.
     The list of current members for the Admin organization is displayed. You can view the owner of the Admin organization by expanding View Owners.
  2. Click Add > Invite member.
  3. Enter a valid email address.
  4. Select the roles that you want to assign to the user.
  5. Click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window.

Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See Configuring an email server for notifications.

The user is placed in Pending status, and is changed to Enabled status after they complete the registration form to activate their account. They can then log in to the Cloud Manager user interface with the API Connect user name that they specified during account activation.
Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously members but were deleted from the admin organization.

- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:
  1. In the Cloud Manager, click  Members.
     The list of current members for the Admin organization is displayed. You can view the owner of the Admin organization by expanding View Owners.
  2. Click Add > Add member.
  3. Select the required user registry
     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Select the roles that you want to assign to the user, then click Add. The user is added and their membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Select the roles that you want to assign to the user, then click Add. The user account is created, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface with their LDAP user name.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.

What to do next

The new member can log in and work in Cloud Manager. The member's authorization is defined by the roles assigned to them.
For instructions on assigning roles, see Assigning roles to members. The list of roles and permissions can be viewed at User roles and permissions in the Cloud Manager UI.

Assigning roles to members

As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.

About this task

Members in the Admin organization use Cloud Manager to view and manage the topology of the Cloud, to set up and manage provider organizations, and to work with other features of the API Connect Cloud. The member's role determines what tasks they are authorized to perform.
When assigning roles, you need to be aware that all members always have a basic set of permissions, which are contained in the **Member** role. The Member role is automatically granted to all members and cannot be removed. For this reason, you do not explicitly assign the Member role. You can grant additional permissions by selecting one or more roles. If additional roles are not assigned, then the user will have only the basic Member role.

One of the following roles is required to assign roles to members:

- Administrator
- Owner

Procedure

Perform the following steps to assign one or more roles to a member:

1. In the Cloud Manager, click  Members.
2. The list of current members for the Admin organization is displayed.
3. To change the roles assigned to a member, select the roles by marking the check boxes next to their name. The roles will be updated instantly. The list of roles and permissions can be viewed at User roles and permissions in the Cloud Manager UI

Results

The member will be assigned the permissions for the role(s).

What to do next

The new member can work in Cloud Manager. The member's authorization is defined by the roles assigned to them.

Deleting a member

As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.

About this task

One of the following roles is required to delete a member:

- Administrator
- Owner

Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the Cloud Manager user interface but only information links are available; there is no access to view or manage any resources.
The user can be added again as a member at a later time; see Adding members to the admin organization.

Procedure

To delete a member of the cloud administration organization, complete the following steps:

1. In the Cloud Manager, click  Members.
2. Choose Delete from the overflow menu that is adjacent to the member you want to delete.
3. Confirm the deletion.

Results

The member is deleted and removed from the Members list in Cloud Manager.

Role Defaults overview

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Role Defaults concepts

Role Defaults determine the base roles applied to either Provider or Consumer Organizations. The Role Defaults for the Admin organization are not configurable. Role Defaults help to standardize base roles for all organizations. Roles and permissions may be added or modified in the Role Defaults to customize the base roles as needed. Role Defaults are a "point-in-time" configuration, which effects only new organizations. You can add, delete, or modify roles (except for the Owner, Member, and Viewer roles) in the organization to customize the permissions for each organization.

Rules for editing Role Defaults:

- Edits to Role Defaults are not applied retroactively to existing organizations. Edits apply only to new organizations created after the changes are made.
- Role Defaults apply to all new organizations; roles can then be edited at the organization, catalog, and space level.
- Edits made to roles in an organization do not affect the Role Defaults. Role Defaults are the "parent" and organization roles are the "child". The child inherits from the parent, but changes do not filter up from the organization to the Role Default.

- **Managing role defaults for provider organizations**
  Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Related tasks

- Managing role defaults for provider organizations

Related information

- Creating custom roles

Managing role defaults for provider organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

About this task

If you are assigned a role that has permissions to manage Cloud Settings, you can create manage the Role Defaults for the provider organizations.
One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the Roles Defaults for provider organizations:

Procedure

1. In the Cloud Manager, click Settings.
2. Select Role Defaults.
3. Click Add to add a new role.
   a. To edit a role, select Edit from the overflow menu for the role.
   b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted.
   Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the role.

Results

The role appears in the list of roles for the provider organization Role Defaults. It will be included in the roles that can be assigned to members for all new provider organizations. The roles can be edited for individual organizations.

Monitoring the cloud

API Connect generates events to monitor the status of your cloud.

About this task

You can monitor your API Connect cloud and configure destination targets for your analytics data by using the following tasks:

- **Accessing and configuring analytics**
  Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.
- **Configuring audit logging to monitor user operations**
  Configure auditing in IBM API Connect to monitor user operations such as who published which product and when.
- **Reviewing processing status and downloading gateway logs**
  View and download the processing status information for the Gateway services that are enabled in your API Connect.

Accessing and configuring analytics

Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.

From the analytics view of the Cloud Manager UI, you can monitor the usage of your published APIs. API events from all catalogs, spaces, and organizations are captured and displayed together in the Cloud Manager analytics view. For more information about the features of the analytics view, see Viewing analytics data in Cloud Manager.

API event records

An API event is logged each time an API operation is invoked on the gateway. The API event record contains information about the API call. When an analytics service is associated with a gateway, all API invocations on that gateway are captured as API event records and sent to the analytics service. The content of the record depends on the logging policy that is set for the operation. For more information about the fields that are displayed in an API event record, see API event record fields.

Analytics configuration options

API Connect offers many configuration options to customize data collection, storage, and retention. For example, you can define filters that refine data to add or remove fields before they are stored. You can choose to offload some, or all, of the data to a third-party storage system. For more information about the analytics configuration options, see Advanced configuration options

Configuring audit logging to monitor user operations

Configure auditing in IBM® API Connect to monitor user operations such as who published which product and when.

Audit logging is useful when you want to monitor the create, read, update, delete, log-in, and log-out activity in your deployment; for example, who made changes, when, and what they changed.

Note: Actions that are performed by Portal administrators are not captured by the audit feature.

What events are audited?

All create, update, delete, log-in, and log-out operations that are performed by users in the Admin UI, Manager UI, Toolkit, and REST API are captured by this feature. For Portal users, all create, update, and delete operations involving applications are captured.

Beginning in API Connect 10.0.5.3, read operations can also be audited when the **audit_reads** setting is also enabled (by using the toolkit CLI).

Attention: If you choose to enable auditing of read operations for an HTTP endpoint, be aware of that the response might return large payloads, and might contain sensitive information.
Internal calls and calls between system components are not audited because they are part of the product functionality and are not run by users.

How are audit events logged?

Audit events are logged by sending the information about operations to one or more endpoints of the following types: HTTP, Syslog UDP, Syslog TCP, Syslog TLS or Analytics service.

- HTTP endpoints:
  Audit logging messages are sent as HTTP/HTTPS requests and use the payload format that is defined by the Cloud Auditing Data Federation (CADF). If the endpoint requires authentication, you can configure a header that is included in the audit logging request. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not resent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

  There are two modes that control how the auditing is sent to an endpoint: blocking and nonblocking. In nonblocking mode (the default), an audit event is sent to the endpoint and the system does not wait for a response from the endpoint. Nonblocking mode provides the best performance. Blocking mode should be used with caution: when an audit event is sent, the system pauses and waits for a response from the endpoint. Blocking mode has a negative impact on performance.

- Syslog endpoints:
  Audit logging messages are sent as syslog messages. If the endpoint requires mutual TLS, you can configure a TLS profile to send the required client certificates. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not resent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

  All syslog messages are sent as nonblocking regardless of the auditing mode because syslog messages are designed to be fire and forget (syslog was originally a UDP protocol, which by its nature does not have any acknowledgment). Blocking is only used for HTTP endpoints .

- Analytics service:
  Audit logging messages are sent through HTTPS to the configured analytics service in blocking or nonblocking mode.

  You can use audit data in the following ways:

  - Offload audit data to destinations that are supported by current audit export options. For more information, see Offload to third-party systems.
  - Use audit events in Engagement. Engagement includes a new audit data source that lets you define rules that are triggered by specific audit events. For more information, see Engagement datasource.
  - Store audit events temporarily for internal processing. For more information, see Analytics REST API.

Note:

- With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.
- You can currently access audit data in analytics through the Analytics API. UI support will be available in a future release.

What's included in the audit logging request?

- HTTP endpoints:
  The payload containing the audit logging record includes information about the user who ran the operation, the date and time of the call, the resource affected by the call, the operation performed, and the payload. If you enabled audit logging for read operations, the payload might also contain the properties from the response (based on your configuration settings).

  To see the most recent set of fields that are included in the payload, refer to the OpenAPI schema for the audit logging request in the Provider API, which you can download at https://us-south.functions.cloud.ibm.com/api/v1/web/API%20Connect%20Native_apic-on-prem/default/v10-index.http.

  HTTP example 1: sample payload for an audit logging message that is directed to an HTTP endpoint (IDs and users are not real):

```

```

- Analytics service endpoints:
  Analytics service endpoints receive the same **CADF** formatted payloads as **HTTP** endpoints, along with **orgId**, **catalogId**, and **spaceId**, if those fields are applicable to the event. Also, the attachments object in the payload includes the scope and component of the event.

  To retrieve audit data, run the following command:

  ```
  GET <apim-platformapi-hostname>/analytics/<analytics-service>/cloud/audit
  ```

- Syslog endpoints:
  The nature of syslog messaging means that the information logged is less structured and shorter than information logged that uses structured HTTP endpoints. With Syslog, the information is more of a summary.

  The following sample response shows payloads for an audit logging message that is directed to a syslog endpoint (IDs and users are not real):

  ```
  The user admin:default-idp-1/admin has deleted the resource Org 'alpha (Alpha title)', id 19cf81c7-7cb3-43de-b5e5-
  d92cdfb26214 and url https://localhost:3003/api/orgs/19cf81c7-7cb3-43de-b5e5-d92cdfb26214
  The user admin:default-idp-1/admin has deleted the resource Gateway Service 'webhook-gw-v5 (Webhook Gateway Service (v5)
  title)', id 08b87e25-616d-451e-8766-bad1c7b82a42 and url https://localhost:3003/api/orgs/69c878db-4f11-4c3e-9499-
  10daa25f04de/availability-zones/cb2caa3d-d619-4c2e-85f8-709956495a7b/gateway-services/08b87e25-616d-451e-8766-bad1c7b82a42
  The user provider:default-idp-2/steve@example.com has created the resource Catalog 'climbon:1.0.1 (The climbon product
  description)', id 665036df-28ad-447e-b8de-fe9d6967b66d and url https://localhost:3003/api/catalogs/19cf81c7-7cb3-43de-
  b5e5-d92cdfb26214/8641fda7-43f8-4e59-b405-58a4844016c9/products/665036df-28ad-447e-b8de-fe9d6967b66d
  The user admin:default-idp-1/admin has read the resource Cloud Setting 'cloud-setting', id settings and url
  https://localhost:3003/api/cloud/settings
  ```

Verifying that the endpoint is receiving audit logging messages

Note: The analytics service does not support a test connection option in the UI or the toolkit CLI.
By default, auditing operates in **non_block** mode to ensure best performance. In **non_block** mode, each audit logging message is sent immediately without waiting to ensure that the previous message was received. If you suspect that audit logging messages are not being received by the endpoint, download the server logs from the Kubernetes console and examine the apim microservices file for messages that are related to the connection state. Review the messages to validate that the connection was successful or to further diagnose issues.

For HTTP endpoints (not available for Syslog endpoints), you can test the connection by issuing a "test-connection" call that uses either the toolkit or a REST API. A response status of **204** indicates that the call was successful and the endpoint is available. The following example contains the payload from a connection test (IDs and users are not real):

```
{
  "id": "8d8eaaa2-1b46-4dcb-cadf-639d7d1f7f20",

      }
    }
  ]
}
```

Tip: To ensure that audit logging messages are not lost due to an unavailable endpoint, verify each endpoint periodically.

- **Configuring the audit settings**
  Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

Configuring the audit settings

Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

About this task

The audit feature tracks platform-level changes in API Connect through the use of platform APIs, CLI, and Web UI. For information on tracking run-time API execution, see API Analytics.

You can configure audit settings using either the Cloud Manager UI, or the Toolkit CLI.

Using the Cloud Manager UI to configure audit settings

Use the Cloud Manager user interface to enable auditing of customer API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in Configuring audit logging to monitor user operations.

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Note: Auditing for read operations can only be enabled and configured using the CLI.

Procedure

1. In the Cloud Manager, click Settings > Audit Setting > Edit.
2. Click Enable to enable the audit feature, or Disable to disable it.
3. Select an audit mode:
   - Non-blocking - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
   - Blocking - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
     Note: Blocking mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.
4. Click Add and select the type of endpoint that you want to add (you must add at least one endpoint).
   Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, Syslog TLS, or Analytics service.
5. In the Endpoints section, fill in the fields to describe the new endpoint:

   HTTP
   - URL - Required, must not be empty. The URL of the server where audit logging messages will be sent.
     If you previously saved the audit settings with an empty URL and experienced problems, you can edit the URL to correct it.
   - TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.

- Header name and Header value - Optional. Multiple headers are allowed (click Add to add another header). For each header, specify the header name and the header value.

Syslog UDP
- Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com. Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
- Port - Optional. The port number where audit logging messages should be directed.

Syslog TCP
- Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com. Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
- Port - Optional. The port number where audit logging messages should be directed.

Syslog TLS
- Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com. Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
- Port - Optional. The port number where audit logging messages should be directed.
- TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.

Analytics service

No additional fields are required for analytics service endpoints. You can select any registered analytics service. For more information about registering analytics service, see Registering an analytics service.
Note: You can select only one analytics service in the Cloud Manager UI. To specify multiple analytics services to receive audit messages, use the Toolkit CLI.

6. Verify that you can reach the endpoint by clicking Test.
7. To specify another endpoint, click Add at the beginning of the "Endpoints" section.
8. When you finish adding endpoints, click Save to save your settings.

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see Verifying that the endpoint is receiving audit logging messages for information on validating the connection.

Using the CLI to configure audit settings

Use the IBM API Connect toolkit CLI to enable auditing of API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in Configuring audit logging to monitor user operations.

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Use the following **`audit_setting`** options to enable auditing with the CLI toolkit:

- **`enable`** - Boolean, defaults to **`false`** (no audit). Set to **`true`** if you want to enable auditing.
- **`mode`** - Enumerated, defaults to **`non_block`**. The audit mode determines how audit requests are timed when they are sent to the endpoint:
  - **`non_block`** - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
  - **`block`** - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
    Note: Block mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.
- **`audit_reads`** - Use this setting to enable auditing of read operations:
  - **`enable`** - Boolean, defaults to **`false`** and no audit events are sent to the endpoint for read operations. Set to **`true`** if you want to enable audit logging for read operations.
  - **`response_data_to_http_endpoints`** - Configure additional settings for HTTP endpoints only (the settings do not apply to Syslog endpoints).
    - **`enable`** - Boolean, defaults to **`false`** and audit events for GET operations are sent to the HTTP endpoint with no response data in the event. Set to **`true`** if you want to include the response data.
      Attention: If you choose to include the response data, be aware that the response might return large payloads, and might contain sensitive information.
    - **`list_results_limit`** - Integer, must be 0 or larger. Use this setting to specify the maximum number of results of **`GET list`** operations to include in the audit message (default is 0 results).

      If **`audit_reads`** is enabled, then the audit message for a **`GET`** of *a single object* (for example, **`GET /orgs/admin`**) always includes all of the properties of the response object.

      If the **`list_results_limit`** is set to 0, then the audit message for a **`GET`** to *list objects* (for example, **`GET /orgs`**) does not include any objects from the GET response. If you set the **`list_results_limit`** to a value greater than 0, then the audit message includes all properties from the first **`list_results_limit`** number of objects from the **`GET /orgs`** response.
- **`endpoints`** - Array of strings. You must specify at least one endpoint where the audit logging messages are sent. Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, Syslog TLS .

For HTTP and Syslog TLS endpoints, you can optionally include a TLS client profile URL. For HTTP endpoints, you can additionally include one or more optional headers. For example, if the endpoint requires an authorization header, you can include it in the endpoint setting.

  - **`endpoint_type`** - String. Required. Allowed values are: **`http`**, **`syslog_udp`**, **`syslog_tcp`** or **`syslog_tls`**.
  - **`endpoint`** - String. Required, must not be empty or blank. The URL of the server where audit logging messages will be sent. Include the protocol (**`http://`** or **`syslog://`**) and the port, if applicable. For example, **`syslog://<hostname>:<port>`**.
  - **`tls_client_profile_url`** - String. Optional; supported only for HTTP and Syslog TLS endpoints. The URL of the server where the endpoint's TLS client profile is stored.
  - **`headers`** - String. Optional; supported only for HTTP endpoints. Multiple headers are allowed. For each header, specify the header name and the header value using the format shown in the example.

- **`analytics_service_urls`** - Array of strings. You can specify one or more registered analytics services to receive audit messages. If you specify **`analytics_service_urls`**, the **`endpoints`** list is optional. When auditing is enabled, you must include either **`analytics_service_urls`** or **`endpoints`**.

The endpoint setting can be lengthy, so uploading the settings in a file helps to avoid errors. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example enables auditing in non-blocking mode with multiple endpoints to demonstrate how the settings should be formatted.

```
audit_setting:
  enabled: true
  mode: non_block
  audit_reads:
    enabled: true
    response_data_to_http_endpoints:
      enabled: true
      list_results_limit: 0
  endpoints:
    - endpoint_type: syslog_udp
      endpoint:
        endpoint: syslog://syslog-audit-endpoint.example_1.com:514
    - endpoint_type: syslog_tls
      endpoint:
        endpoint: syslog://syslog-tls-audit-endpoint.example_1.com:1601
        tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
    - endpoint_type: http
      endpoint:
        endpoint: https://mutt-audit-endpoint.example_1.com/auditing
    - endpoint_type: http
      endpoint:
        endpoint: https://auditing-endpoint.example_1.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
        tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
      headers:
        authorization: Basic c3Bvb246c2ltb25rYXRpZXVtYQ==
    - endpoint_type: http
      endpoint:
        endpoint: https://auditing-endpoint.example_2.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
      headers:
        authorization: Basic c3Bvb246c2ltb24=
        x-header: ForYourEyeOnly
   analytics_service_urls:
    - https://<analytics_service_url>
```

Procedure

1. Create a YAML file with the audit settings as shown in the example.
   For information on using input files with the toolkit CLI, see Reading input from the command line.

2. Run the following command to log in to a management server as a member of the cloud administration organization:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **`default-idp-1`**.
   For more information on logging in, see Logging in to a management server.

3. Upload the YAML file with the auditing settings by running the following command:

   ```
   apic cloud-settings:update --server mgmt_endpoint_url my_audit_settings.yaml
   ```

4. Run the following command to log out of the management server:

```
apic logout --server mgmt_endpoint_url
```

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see Verifying that the endpoint is receiving audit logging messages for information on validating the connection.

API Gateway only

Reviewing processing status and downloading gateway logs

View and download the processing status information for the Gateway services that are enabled in your API Connect.

About this task

Check the status of API events processed by the gateway, and download gateway logs as needed. For example, you might want to check whether a Product was published and is available on the gateway before using one of its APIs. Or you might notice that API events are processing slowly and want to see if all events for a specific gateway service are affected.

When a user performs an action in API Manager, such as publishing, deprecating, or retiring a product. At this point, the status changes to an `in-progress` state:

- `published-in-progress`
- `deprecated-in-progress`
- `retired-in-progress`

API Manager then generates an event that corresponds to the action and sends it to the Gateway. Communication between API Manager and the Gateway is event-based and asynchronous.

After receiving the event, the Gateway attempts to apply the requested change:

- If the Gateway successfully applies the change, it sends a confirmation to API Manager. The product status then updates to a success state, such as `published-success`.
- If the Gateway fails to apply the change, it reports the failure to API Manager. The product status then updates to a failed state, such as `published-failed`.

For more information about the different statuses of a product compatible with DataPower® API Gateway, see Publishing a draft Product.
You can review or download a gateway's processing status in the Cloud Manager user interface, or by using the toolkit CLI to retrieve the information.

Notes: You can only obtain processing status information for the DataPower API Gateway. This feature is not supported for the DataPower Gateway (v5 compatible) service or the Event Gateway service.

Using the UI to view the gateway processing status

About this task

Use the Cloud Manager user interface to view or download the processing status information for all the DataPower API Gateway.

Procedure

To check the status of API events processed by the gateway and download gateway logs, complete the following steps:

a. Log in to Cloud Manager.

b. In the navigation pane, click Configure topology.

c. On the topology page, you can view the processing status and download the gateway logs.

- To view the processing status, complete the following steps:
  - Click ⋮ next to the gateway service and select View status.
    The View status page displays a list of the events that were sent to the gateway.

    A status icon displays for each service name to provide a quick indication of that service's status:

    - Normal: Between 0 and 10 events are waiting to be processed
    - Increased: Between 10 and 20 events are waiting to be processed
    - High: More than 20 events are waiting to be processed

    In addition, for each event, you can see the following information:

    - Event type: The action performed by the event; for example, subscribing to a product, deleting an application, or creating a new consumer organization.
    - Category: The feature area affected by the event; for example, subscriptions, applications, or consumer organizations.
    - Time: The time when the event was processed by the gateway service.
    - Status: The current event's processing status; for example, Queued (not yet sent for processing), Sent (but not processed yet), Processed (complete), or Failed (processing failed). For more information about the different statuses of a product compatible with DataPower API Gateway, see Publishing a draft Product.
      The number of events in the Queued and Sent states determine the status level for the service.

The display includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

- To download gateway logs, complete the following steps:
  - Click ⋮ next to the gateway service and select Download logs.
  - Downloads a compressed file to your computer with a name that uses the format *<gateway-name>*.zip for example v6gw.zip.

Using the CLI to obtain a gateway's processing status

About this task

You can use the developer toolkit CLI to obtain information about the processing status for the Gateway services that are enabled in your Catalogs and Spaces.

The processing status information is returned in the following fields:

Field	Description
`service_up_to_date`	If `true` then all outstanding events have been processed by the Gateway service.
`service_state`	An overall status summary of the various states of events and processing by the Gateway service: • `green` indicates normal status with between 0 and 10 events waiting to be processed • `orange` indicates that between 10 and 20 events are waiting to be processed • `red` indicates that more than 20 events are waiting to be processed
`last_processed_event`	Details of the last event that was processed by the Gateway service, helping to provide a timeline of when the last event was processed, and some statistics about how long ago it was and how long the processing took.
`last_sent_event`	Details of the last event that was sent to the gateway service
`number_of_outstanding_sent_events`	The number of events that have been sent but not yet processed by the Gateway service.
`number_of_outstanding_queued_events`	The number of events that have been queued but not yet sent to the Gateway service.
`first_failed_event`	This is the first event for which the gateway sent a failed status.

The following example shows a "green" response that includes the status information and the list of sent events:

```
gateway_processing_status:
  service_up_to_date: false
  service_state: green
  last_processed_event:
    event_id: 40e1a564-2aea-429b-9d35-f588218688a1

  queued_events: []
```

The following example shows a "red" response:

```
gateway_processing_status:
  service_up_to_date: false
  service_state: red
  last_processed_event:
    event_id: 07387d98-dbfc-494b-af12-d7db91208e4c
    title: >-
      Update Product (name-version:lts-cat0-product-49:1.0.0, id:
      25eba540-0cb1-4808-be3d-f22f65540cb2) by user shavon0
    processed_at: '2020-06-02 22:32:10.838+00'
    generated_at: '2020-06-02 22:31:43.38615+00'
    filter: product_del
    event_processing_time: 22597
    elapsed_time_since_last_processed_event: 18427
  last_sent_event:
    event_id: 93d0bf8f-ebfb-4a8b-aa22-7f805719d5c8
    title: >-
      Update Product (name-version:lts-cat0-product-11:1.0.0, id:
      d0bf799f-7f3a-4546-b267-a85c6a7f4b10) by user shavon0
    sent_at: '2020-06-02 22:32:28.426+00'
    generated_at: '2020-06-02 22:32:25.505109+00'
  number_of_outstanding_sent_events: 37
  number_of_outstanding_queued_events: 1
```

The result includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

Procedure

To obtain processing status information for a Gateway service, complete the following steps:

1. Log in to your API Connect Management server as a provider organization member, by using the following command:

   ```
   apic login --server api_platform_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   where:
   - *api_platform_endpoint_url* is the platform API endpoint URL.
   - *user_ID* is the user ID of your provider organization account, and is the same as the user ID that you use to log in to the API Manager user interface.
   - *password* is the password for your administrator account.
   - *identity_provider* is the identity provider that is used to authenticate API Manager users.

   For example:

   ```
   apic login --server platform-api.myserver.com --username myuser --password password --realm provider/myldap
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you need to be logged in to an admin real to use this command):

   ```
   apic identity-providers:list --scope provider --server api_platform_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope admin --server api_platform_endpoint_url  --fields title,realm
   total_results: 1
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details on how to log in to your management server from the CLI, see Logging in to the management server.

2. Obtain the Gateway processing status for a Gateway service that is enabled in a catalog by running the following command:

   ```
   apic gateway-services:get --server mgmt_endpoint_url --org organization_name  gateway_service_name --fields
   "add(gateway_processing_status,events,webhook_state)" --output -
   ```

   where:

   - *mgmt_endpoint_url* is the platform API endpoint URL.
   - *organization_name* is the name of the provider organization that contains the catalog.
   - *gateway_service_name* is the name of the Gateway service whose processing status you want to obtain.
   - The `--fields "add(arguments)"` parameter can include either, or both, of the following arguments (separated with a comma):
     - `gateway_processing_status`: returns the total number of sent events, queued events, and processed events
     - `events`: returns lists of sent events with details about each event
     - `webhook_state`: this is the current state of the webhook subscription between API Manager and the gateway

   For example:

   ```
   apic gateway-services:get --server platform-api.myserver.com --org myorg my-gateway-service --fields
   "add(gateway_processing_status,events,webhook_state)" --output -
   ```

Changing your Cloud Manager password and profile information

You can change your Cloud Manager password and update your profile information.

Procedure

To change your password or profile information, follow these steps:

1. Log in to the Cloud Manager user interface.
2. Click the User icon  , and then select My Account.
3. In the Profile section, enter a new email address and First Name and Last Name for the account owner.
4. Click Save.
5. In the Change password section, enter your current password and your new password, and confirm the new password.
   The password must contain six characters at a minimum. It must contain at least three of the following types of characters:
   - Lowercase letters
   - Uppercase letters
   - Numbers
   - Characters from the following list of allowed punctuation and special characters:

     ```
     !
     \"
     #
     $
     %
     &
     \
     (
     )
     *
     +
     ,(comma)
     - (dash/hyphen)
     .(period)
     /
     :(colon)
     ;(semi-colon)
     <
     =
     >
     ?
     @
     [
     \\
     ]
     ^
     _ (underscore)
     ` (back quote/grave accent)
     {
     | (pipe)
     }
     ~ (tilde)
     ```

   The password cannot contain more than two consecutive repeating characters.
6. Click Save.

Results

Your profile information and password are changed.

- Configuring and managing your server environment

Resolving login problems by increasing HTTP header size

You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.

About this task

Login attempts to the user interface might fail with error `502 (Bad Gateway)`. This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaround this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

Procedure

1. `SSH` to your management system or appliance.

2. Enter the following commands:

```
kubectl get deployment -n namespace  | grep apim
kubectl edit deployment -n namespace management-apim
```

3. In the **env** section of the deployment configuration, change **--max-http-header-size=12000** to a larger value that works for your environment. For example:

```
 - name: NODE_OPTIONS
          value: --max-old-space-size=8094 --max-http-header-size=16000
```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `management-apim` pods are up and running.

Onboarding a new admin for Cloud Pak for Integration

Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.

About this task

If you changed the local admin account for Cloud Pak for Integration, you must create a new admin user in API Connect to ensure that the new Cloud Pak for Integration admin can log in to API Connect with the Common Services User Registry.

Procedure

1. Download and install the API Connect toolkit CLI and credentials file as explained in Installing the toolkit.
2. Log in to the toolkit CLI.
   Logging in to the toolkit CLI requires the endpoint URL for your API Connect management server. In Cloud Pak for Integration, the URL indicates the location of the management server within the Cloud Pak for Integration deployment.

   a. Determine the URL to the API Connect management server by running the following command:

   ```
   oc -n APIC_namespace get mgmt APIC_instance -o jsonpath="{.status.zenRoute}" && echo ""
   ```

   The response looks like the following example URL:

   ```
   apic-mgmt-admin-apic.deve-cip-hlag-8e86d3798137c73f524cf9-0000.eu-de.containers.appdomain.cloud
   ```

   b. Log in to the API Connect toolkit CLI by running the following command:

   ```
   apic -s API_Connect_URL login -u admin -p <password> -r admin/default-idp-1
   ```

   where ***API_Connect_URL*** is the URL of the management server in your API Connect instance.

3. Create a new admin account by completing the following steps.
   Use the toolkit CLI to create an admin account in the Common Services User Registry and then add the new admin to the API Connect **administrator** role.

   a. Create a YAML file called newCp4iAdmin.yaml with the following information for the new admin account.

   ```
   username: <new_cp4i_admin_username>
   first_name: CP4I
   last_name: Administrator
   ```

   b. Create the CP4i admin account by running the following command:

   ```
   apic -s API_Connect_URL users:create -o admin --user-registry common-services newCp4iAdmin.yaml
   ```

   c. Verify that the account was created by running the following command:

   ```
   apic -s API_Connect_URL users:get -o admin --user-registry common-services <new_cp4i_admin_username> --output -
   ```

   d. Get the new admin account's URL by running the following command:

   ```
   apic -s API_Connect_URL users:list -o admin --user-registry common-services | grep <new_cp4i_admin_username> | awk
   '{print $4}'
   ```

   e. Get the URL of the API Connect **administrator** role by running the following command:

   ```
   apic -s API_Connect_URL roles:list --scope org -o admin | grep -w administrator | grep -v topology | awk '{print $2}'
   ```

   f. Create a YAML file called newcp4iadminmember.yaml with the following content:

   ```
   name: <new_cp4i_admin_username>
   user:
     url: <user_URL>
   role_urls:
     - <role_URL>
   ```

   g. Use the newcp4iadminmember.yaml file to add the new admin as a member of the API Connect instance's admin organization.
   Create the new member by running the following command:

   ```
   apic -s API_Connect_URL members:create --scope org -o admin newcp4iadminmember.yaml
   ```

   h. Verify that the new admin account works by using it to log in to the Cloud Manager interface in your API Connect instance.
4. Remove the old Cloud Pak for Integration admin user from API Connect.

After you verify that the new Cloud Pak for Integration admin can log into the API Connect Cloud Manager interface, delete the previous Cloud Pak for Integration admin account.

a. Remove the previous admin from the membership of the API Connect admin organization by running the following command:

```
apic -s API_Connect_URL members:delete --scope org -o admin cs-admin
```

When you initially deployed API Connect as a component of Cloud Pak for Integration, the admin username was **admin** and the member in the API Connect admin organization was **cs-admin**. If the **cs-admin** member does not exist in the admin organization, then the Cloud Pak for Integration admin user was changed after deployment. In this case, the member uses the same name as admin account's user name. Delete the member with that name:

```
apic -s API_Connect_URL members:delete --scope org -o admin <old_cp4i_admin_username>
```

b. Delete the previous Cloud Pack for Integration admin user account from the Common Services User Registry by running the following command:

```
apic -s API_Connect_URL users:delete -o admin --user-registry common-services <old_cp4i_admin_username>
```

Extending the Gateway server behavior

To support your enterprise requirements, you can extend the Gateway servers within IBM® API Connect to provide extra enforcement behavior.

API Connect Gateway servers uses a subset of DataPower® enforcement capabilities. You can supply DataPower® Extensions to customize these enforcement capabilities further.

The DataPower extensibility function can be used to perform actions that include schema validation, antivirus scanning, message filtering, authentication, and authorization, token translation, message enrichment, encryption & decryption, digital signing, and validation and message transformation. For more information, see IBM DataPower documentation.

For information on the different types of gateway, see API Connect gateway types.

Important: Gateway server extensions must not be used to modify objects that cause the **apic-gw-service** object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the **apic-gw-service** object to restart, lead to unpredictable behavior in the Gateway service.

- **Gateway extension guidelines - DataPower Gateway (v5 compatible)**
  Before you develop your extensions to the DataPower Gateway (v5 compatible), consider these guidelines.
- **Gateway extension guidelines - DataPower API Gateway**
  Use API Gateway extensions to customize and configure the DataPower application domain in ways that are not possible from the API Manager UI.
- **Configuring your Gateway server extensions**
  You can add extra DataPower enforcement capabilities to a gateway service by uploading a .zip file that defines the required extension behavior, and then enabling the extension in DataPower.

DataPower Gateway (v5 compatible)

Gateway extension guidelines - DataPower Gateway (v5 compatible)

Before you develop your extensions to the DataPower Gateway (v5 compatible), consider these guidelines.

Note: These guidelines apply to the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Gateway extension guidelines - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

You can download sample gateway extensions from https://github.com/ibm-apiconnect/dp-extensions.

You can create DataPower Processing Rules that can extend the enforcement behavior of the IBM® API Connect Gateway server at the following locations:

- **pre-request** extension:
  - Before the Gateway server begins to use the policies in the assembly to process the request.
- **post-request** extension:
  - After the Gateway server processes all of the policies in the assembly up to the proxy policy, if a proxy policy is used.
  - After the Gateway server processes all policies in the assembly, but before any catch logic is processed, if a proxy policy is not used.
- **post-response** extension:
  - After the Gateway server processes all of the remaining policies in the assembly after the proxy policy (including catch logic), but before the response is returned to the client application, if a proxy policy is used.
  - After the Gateway server processes the catch logic, but before the response is returned to the client application, if a proxy policy is not used.
- **post-error** extension:
  - If an error occurs, then before the Gateway server returns the error response to the client application.

To configure the Gateway server to call your extension Processing Rule, you must create an XML file that indicates the extension location and Processing Rule name. For example,

```
<extensions>
<extension location="pre-request">CustomRule1</extension>
<extension location="post-request">CustomRule2</extension>
<extension location="post-response">CustomRule3</extension>
<extension location="post-error">CustomRule4</extension>
</extensions>
```

The **<extension>** element entries are optional for any of the locations. Refer to the Gateway server Extension schema for the XML file syntax.

An extension Processing Rule can be applied to a specific organization or to all of the organizations and Catalogs. If the **<extension>** element does not have a tenant attribute, then the **<extension>** element is applied to all of the organizations. The following example shows an **<extension>** element without a tenant attribute.

```
<extension location="post-error">gen_error_handling</extension>
```

To apply an extension Processing Rule to a specific organization, enter the organization name as the value for the tenant attribute in the **<extension>** element. The following example shows an <extension> element with a tenant attribute value of *organization1*.

```
<extension location="post-error" tenant="organization1">organization1_error_handling</extension>
```

If you want to exclude a specific organization in an extension Processing Rule, enter the organization name as the value for the tenant attribute in an empty **<extension>** element. Add the empty **<extension>** element immediately after the custom rule **<extension>** element that you want to exclude the organization from. The following example shows an empty <extension> element with a tenant attribute value of *organization1*.

```
<extension location="pre-request">a_specified_CustomRule</extension>
<extension location="pre-request" tenant="organization1"></extension>
```

Important: An extension Processing Rule with a specified tenant attribute takes precedence over an **<extension>** element that applies to all of the organizations. Also, only one extension Processing Rule is applied to each extension location.
This XML file must be saved to the following location and included in your DataPower exported configuration .zip file:

```
local:///ext/extensions.xml
```

There can be only one DataPower exported configuration .zip file added to a Gateway server in API Connect.

CAUTION:

- Do not modify these files directly in the DataPower API Gateway file system, use the gateway extension mechanism described on this page.
- Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.
- Do not use Gateway server extensions to modify objects that cause the **apic-gw-service** object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the **apic-gw-service** object to restart, lead to unpredictable behavior in the Gateway service.

DataPower configuration restrictions

All Processing Rules have read access to the INPUT context.

Processing Rules must not rely on context variables that are created by the IBM Gateway server enforcement configuration, because those configuration variables might change in the future.

All Processing Rules except Before Request can transform or alter the message flowing through the Gateway server. Ensure that the Processing Rule returns the desired message output context back to the Gateway server at the end of processing.

To avoid name conflicts, all DataPower configuration object names prefixed with **webapi** are reserved for IBM use.

The following folders cannot be modified:

- **local:///isp/***
- **local:///gwapi/***

As a best practice, avoid adding asynchronous actions in your custom Processing Rules because they increase the use of memory per transaction.

Gateway extension guidelines - DataPower API Gateway

Use API Gateway extensions to customize and configure the DataPower application domain in ways that are not possible from the API Manager UI.

Note: These guidelines apply to the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Gateway extension guidelines - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Some common uses of API Gateway extensions are:

- Adding other DataPower services to the application domain.
- Deploying user defined policies.
- Deploying v5 emulation policies.

The extension structure is a zip file that contains a manifest file and one or more extension implementation files that the manifest file references. See Gateway extensions manifest for details on the manifest file JSON structure as well as the supported implementation types.

- gateway_extension.zip
  - manifest.json
  - extension_implementation_1.zip
  - extension_implementation_2.zip

You upload the extension .zip file to an API Connect Gateway service, and enable the extension, as described in Configuring your Gateway server extensions. Gateway server extensions can be deployed without having to restart the DataPower API Gateway.

Gateway extension limitations

This section details the limitations of the extensions to the DataPower API Gateway.

- If you use an extension to create a user-defined policy and then delete the extension, the extension is removed from the filesystem, but the configuration sequence is not triggered to clean up related files. For the policy to be cleaned up, you must send a modified extension that explicitly removes the user-defined policy from

`apic-gw-service`, as in the following example.

```
apic-gw-service
    no user-defined-policies udp-basic_1.0.0
exit
```

Note: This limitation does not apply only to user-defined policies, but any object customization that adds a reference to another object.

- `user-defined-policy-yaml` policies that use or reference another policy can be deployed only after the referenced policy has been advertised to API Manager. The deploy type must be set to `deferred` and the Gateway Service must be restarted.
- v5 policies that contain files outside of the `/policy` directory are not supported. If multiple v5 policies reference the same file outside the `/policy` directory, the last applied policy will overwrite the file and will be used by all policies that reference it. Removing any policy that contains the file will cause the file to be deleted and may cause errors for the remaining policies that use it.
- If an extension contains or references objects and files that are also referenced by other objects outside of the extension, deleting the extension can cause errors that are difficult to troubleshoot.
- It is possible to delete an extension that is referenced by published APIs. This may cause those API requests to return errors.
- For an extension type of `user-defined-policy`, extra assembly functions may be present in the DataPower import `.zip` file, even if there is no `.yaml` file to indicate their presence. Using these functions without declaring them using a `.yaml` file is not supported. A policy `.yaml` file is required for each policy you want to advertise to API Manager.
- Extension type `user-defined-policy-yaml` may leak generated Gateway script `.js` files in temporary:/js/ or `.xslt` files when deleted.
- Extension types that use SOMA imports must use new objects with no overrides. If you override a singleton or shared object using an extension of this type, then the object will not be restored to its previous state when the extension is deleted, and those objects may be missing after the extension is deleted. You must then restore any needed objects.
- The file names of file entries in the manifest.json file cannot be changed during an extension update. If the file name is changed, the system treats the new name as a separate extension entry and considers the previous file as removed. This change can cause parts of the original extension to be unintentionally deleted during the update.
- For the extension types `user-defined-policy`, `dp-import`, `policy-v5` or `v5_extension`, if you want to modify the extension, use the DataPower export feature to generate a new .zip file whenever possible. If manual modification of a DataPower extension .zip file is necessary, you must also update the export.xml file. This file is used by the Gateway to detect changes, and if the hash attributes remain unchanged, the Gateway might not apply the updates. To ensure that changes are recognized, either remove or update the hash attribute for each modified file in the files section in the export.xml file.

- **Gateway extensions manifest**
  The gateway extensions manifest controls how gateway extensions are applied to the DataPower API Gateway.
- **v5 policy emulation limitations**
  This page details the limitations of v5 policy emulation for the current release.

API Gateway

Gateway extensions manifest

The gateway extensions manifest controls how gateway extensions are applied to the DataPower® API Gateway.

The gateway extensions manifest enables you to deploy multiple extension implementations in a single package. The manifest is a JSON file that lists the extensions `.zip` files to be applied and when they are to be deployed. You can also use the manifest to enable v5 policy emulation for the API Connect gateway service. V5 policy emulation enables you to deploy supported v5 built-in policies and custom policies, and manage them from API Manager without having to rewrite them for DataPower API Gateway. V5 policy emulation is supported only for policies that are applied to the Gateway service scope.

The `manifest.json` file must be at the root level of the extensions `.zip` file, along with the gateway extension files specified in the manifest. For example:

```
manifest.json
jws-sign-policy.zip
add_udp.zip
```

The `manifest.json` file contains the following sections.

`properties` section

The properties section determines whether to enable the v5 framework to deploy supported v5 built-in policies and custom policies and manage them from API Manager without having to rewrite them for DataPower API Gateway.

Table 1. `properties` section properties

Property	Description
`deploy-policy-emulator`	Determines whether to enable v5 framework emulation. Valid values are `true` and `false`. v5 framework emulation is enabled for the API Connect Gateway service if `deploy-policy-emulator` set to `true`, if a v5 policy is detected in the files list, or if a `deploy-policies` entry is specified.
`deploy-policies`	Contains a list of built-in policies to advertise for v5 emulation. The following policies are supported. • `activity-log_1.5.0` • `gatewayscript_1.0.0` • `if_1.5.0` • `invoke_1.5.0` • `proxy_1.5.0` • `redact_1.5.0` • `switch_1.5.0` • `validate-usernametoken_1.0.0` • `xslt_1.0.0`
`defer-all-override`	An override toggle to force the deployment property of all extension entries (including V5E) to be deferred. When enabled, the user must restart the `apic-gw-service` object to apply any extension events.

`files` section

The **`files`** section is an array of file entries that reference extension implementations. Each entry must reference a file that is in the **`extension.zip`** file (or the extension is rejected).

Table 2. **`files`** section properties

Property	Description
`filename`	The name of the file that contains the extension implementation. This property is required and cannot be changed while the extension is deployed as part of an update. If the file name is changed, the system treats the new name as a separate extension entry and considers the previous file as removed. This change can cause parts of the original extension to be unintentionally deleted during the update.
`type`	The type of extension implementation to be deployed. This property is required. The following types are supported. **`dp-import`** A DataPower import used to add additional configuration and/or services to a gateway. Like the extension type, but **`dp-import`** persists the configuration on physical or virtual DataPowers. Note: A **`dp-import`** file cannot be used to change the **`apic-gw-service`** object. If it is configured for this purpose, the extension is rejected. **`extension`** A legacy API Gateway extension that can be used to add additional configuration to a gateway. **`Extension`** should not be used to modify objects created by the gateway service, see gwd_extension for that use case. For more information, see CLI command file extensions. **`gwd_extension`** A JSON file that allows users to customize objects created by the API Connect gateway service. Only one **`gwd_extension`** is allowed in the manifest. For more information about the **`gwd_extension`**, see GWD extension type. **`policy-v5`** A complete, valid v5 policy implementation. For more information, see Authoring policies for the DataPower Gateway (v5 compatible). **`user-defined-policy`** A native API Gateway policy packaged in a DataPower import zip. Using a DataPower import to apply the policy implementations allows the configuration to persist through restarts and upgrades on virtual and physical forms. The import might contain one or more policy implementations. This policy type is always global scoped. For more information, see Defining, packaging, and publishing a global-scoped policy for the API Gateway. **`user-defined-policy-yaml`** A YAML file that includes an assembly. This policy type is always global scope. If the assembly references another user-defined policy, that policy must already be advertised to the API Manager before it can be deployed. For more information, see Working with global policies. **`v5_extension`** A migrated v5 extension that the migration utility generates. Only certain parts of v5 extensions are usable in API Gateway. For more information, see Migrating gateway extensions. **`v5_extension`** is reserved for v5 extensions that the migration utility creates. Do not manually create this type of extension. Note: V5E is intended to allow users to migrate from V5 without editing their APIs. V5E type policies cause known performances degradations in the API gateway. To improve performance of V5E policies, it is recommended to convert them to native policies.
`deploy`	When to process manifest file entry events such as create, update, and delete. **`immediate`** Process entry event as soon as the extension is received by the API Connect gateway service. All gateway nodes apply the extension in parallel. Warning: **`immediate`** can cause an outage across the cluster, dependent on what the extension does. **`deferred`** Process event after the API Connect gateway service is restarted. This value is the default setting and allows users to roll outage causing extensions events to one node at a time. When a DRR occurs this property is ignored, and all entries are deployed immediately.
`catalog`	Indicates that a v5 policy is to be used only by certain catalogs and should not be advertised as a gateway service-level user policy. This property is valid only if the file type is **`policy-v5`**. The **`catalog`** value must be in the format ***`orgname_catalogname`***.

Example `manifest.json`

The following example **`manifest.json`** file enables v5 policy emulation and specifies two built-in v5 policies to deploy. The files section lists two v5 policy implementation files and two extension files.

```
{
   "extension":{
      "properties":{
         "deploy-policy-emulator":true,
         "deploy-policies":[
            "invoke_1.5.0"
         ]
      },
      "files":[
         {
            "filename":"proxy_service.zip",
            "deploy":"immediate",
            "type":"dp-import"
         },
         {
            "filename":"add_udp.zip",
            "deploy":"deferred",
            "type":"extension"
         },
         {
            "filename":"override-parse-defaults.json",
            "type":"gwd_extension"
         },
         {
```

```
            "filename":"jws-sign-policy.zip",
            "deploy":"immediate",
            "type":"policy-v5"
         },
         {
            "filename":"jwe-decrypt-policy.zip",
            "deploy":"deferred",
            "type":"policy-v5",
            "catalog":"extension-org_ext-cat-2"
         },
         {
            "filename":"mypolicy.zip",
            "deploy":"immediate",
            "type":"user-defined-policy"
         },
         {
            "filename":"Invoke-Private-Backend-policy.yaml",
            "deploy":"immediate",
            "type":"user-defined-policy-yaml"
         }
      ]
   }
}
```

- **CLI command file extensions**
  Extend DataPower API Gateway behavior with CLI commands in .cfg files.

GWD extension type

The **gwd_extension** type is a JSON map that is used to apply user customizations to objects generated by the gateway service.

The **gwd_extension** map contains an array of user-defined CLI commands to be run on one or more objects. Only one **gwd_extension** is allowed in the manifest. When deployment is set to deferred, restarting the API Connect gateway service object is required to apply, update, or remove the overrides.

Key features of the **gwd_extension** type:

- The **gwd_extension** type can be used to define overrides at various scope-levels, which means a single array of override commands can be applied to one or more objects of a particular type.
- With some object mappings, you can define instances within a scope so that you can apply the custom CLI commands to all objects in that scope that match a particular name or criteria. For example, you can apply overrides to all catalog instances with the name **MyCatalog** regardless of which organization it belongs to.
- By default, the overrides are applied in order of scope granularity (global → organization → catalog → product → instance).
- Add **"@exclusive": true** to the object at any scope level to signal not to apply the previous scopes. Similarly, using an empty override array in a scope is a signal to not apply all previous scope overrides for that mapping, see tls-client for an example.

The supported scopes are:

- **_global**: Applies customizations to all objects of a particular type. For example, add one or more custom assembly-rate-limits to all **api-collections**.
  - **_instance**: Applies customizations to all objects that match a name or criteria. For example, add one or more custom **assembly-rate-limits** to all **api-collections** with the name **my-restricted-catalog** regardless which organization it belongs to.
- **_organization**: Applies customizations to all objects used in an organization. For example, apply a customization to all TLS client profiles that are used in the organization called **provorg**.
  - **_instance**: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all TLS client profiles with a particular name and version regardless of which catalog is using it.
- **_catalog**: Applies customizations to all objects used in a catalog. For example, apply a customization to all TLS client profiles used in the catalog **myCat** of organization **myOrg**.
  - **_instance**: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all plans in a catalog with a particular name regardless of which product it comes from.
- **_product**: Applies customizations to all objects of a type used in a product. For example, apply a customization to all plans in **product my-prod:1.0.0** published in catalog **myCat** of organization **myOrg**. The product scope is only used by the api-plan **gwd_extension** extension type.
- **_instance**: Applies customizations to a single instance. For example, apply a customization to TLS client profile **my-profile:1.0.0** in catalog **myCat** of organization **myOrg**.

Example **gwd_extension** that shows multiple types of overrides:

```
{
  "parse-settings":{
     "_global":{
        "override":[
           "document-size 4194304"
        ]
     }
  },
  "apigw":{
     "_global":{
        "override":[
           "assembly-rate-limit ratelimit-reject-ALL 10000 5 second on on on off off off \"\" \"1\"",
           "assembly-rate-limit ratelimit-alert-ALL 7500 5 second off on on off off off \"\" \"1\""
        ]
     }
  }
}
```

For more information, read the blog post: What is a gwd_extension

The **gwd_extension** type supports the following objects:

- **config-sequence**
  The config-sequence object created by `apic-gw-service`, which is used to create all API gateway objects.
- **parse-settings**
  Parse settings used by the API Gateway.
- **analytics-endpoint**
- **front-side-handler**
  FSH and associated SNI Server profiles and objects that are used by the API Gateway.
- **apigw**
  API Gateway object.
- **tls-client**
- **api-collection**
  Catalog objects.
- **api-plan**
  API Plan objects that are created from published products.
- **registry**
  Registry objects used in a catalog.
- **oauth-provider**
  Oauth objects used in a catalog.
- **api-definition**
  The API objects that are published to one or more catalogs.
- **assembly**
  The assembly objects and their associated actions that are used by APIs and global policies.

config-sequence

The config-sequence object created by `apic-gw-service`, which is used to create all API gateway objects.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "config-sequence":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

parse-settings

Parse settings used by the API Gateway.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "parse-settings":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

analytics-endpoint

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "analytics-endpoint":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

front-side-handler

FSH and associated SNI Server profiles and objects that are used by the API Gateway.

- Override Key: `source-https`
- Child Objects:
  - `ssl-sni-server`
  - `ssl-sni-map`
  - `ssl-server`
    - Override Key: profile
    - _instance: SNI hostname key
    - Child Objects:
      - `valcred`
      - `idcred`
- Scopes:
  - _global
- Example:

```
{
   "front-side-handler":{
      "_global":{
         "source-https":[
            "summary global my-fsh-override"
         ],
         "ssl-sni-server":[
            "summary global my-sni-server-override"
         ],
         "ssl-sni-map":[
            "summary global my-sni-map-override"
         ],
         "ssl-server":{
            "_instance":{
               "*.myhost.com":{
                  "profile":[
                     "summary sni-host-instance-my-profile-override"
                  ],
                  "valcred":[
                     "summary sni-host-instance-my-valcred-override"
                  ],
                  "idcred":[
                     "summary sni-host-instance-my-idcread-override"
                  ]
               }
            },
            "profile":[
               "summary my-profile-override"
            ],
            "valcred":[
               "summary my-valcred-override"
            ],
            "idcred":[
               "summary my-idcread-override"
            ]
         }
      }
   }
}
```

apigw

API Gateway object.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "apigw":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

tls-client

Profiles that are attached to catalogs.

- Override Key: profile
- Child Objects:
  - Valcred
  - Idcred
- Scopes:
  - _global
    - _instance: *<profileName>*V*<profileVersion>*
  - _organization
    - _instance: *<profileName>*V*<profileVersion>*
  - _catalog
  - _instance: *<profileName>*V*<profileVersion>*
- Example: In this example, an empty array for **`valcred`** in catalog scope is used. The use of any empty array means the **`valcreds`** for TLS profiles in that catalog do not get the global or organizational overrides.

```
{
   "tls-client":{
      "_global":{
         "_instance":{
            "my-profileV1.0.0":{
               "profile":[
                  "summary global-instance-profile-override"
               ],
               "valcred":[
                  "summary global-instance-valcred-override"
               ],
               "idcred":[
                  "summary global-instance-idcred-override"
               ]
            }
         },

            }
         }
      }
   }
}
```

api-collection

Catalog objects.

- Override Key: collection
- Child Objects:
  - **`preflow-assembly-function`**
  - **`preflow-assembly-function-call`**
  - **`postflow-assembly-function`**
  - **`postflow-assembly-function-call`**
  - **`global-assembly-rule`**
  - **`global-assembly`**

    - `global-assembly-function`
    - `global-assembly-function-call`
    - `assembly-function-rule`
- Scopes:
    - _global
        - _instance: *<catalogName>*
    - _organization
    - _catalog
- Example: In the example, global instance is used to apply override to all `api-collections` that have the name `my-catalog`, regardless of what organization they belong to.

```
{
   "api-collection":{
      "_global":{
         "_instance":{
            "my-catalog":{
               "collection":[
                  "summary hello my-catalog"
               ]
            }
         },
         "preflow-assembly-function":[
            "summary hello preflow-assembly-function global scope"
         ],
         "preflow-assembly-function-call":[
            "summary hello preflow-assembly-function-call global scope"
         ],
         "postflow-assembly-function":[
            "summary hello postflow-assembly-function global scope"
         ],
         "postflow-assembly-function-call":[
            "summary hello postflow-assembly-function-call global scope"
         ],
         "global-assembly-rule":[
            "summary hello global-assembly-rule global scope"
         ],
         "global-assembly":[
            "summary hello global-assembly global scope"
         ],
         "global-assembly-function":[
            "summary hello global-assembly-function global scope"
         ],
         "global-assembly-function-call":[
            "summary hello global-assembly-function-call global scope"
         ],
         "assembly-function-rule":[
            "summary hello assembly-function-rule global scope"
         ],
         "collection":[
            "summary hello collection global scope"
         ]
      },
      "_organization":{
         "my-org":{
            "collection":[
               "summary hello collection org scope"
            ]
         }
      },
      "_catalog":{
         "my-org":{
            "my-catalog":{
               "collection":[
                  "summary hello collection cat scope"
               ]
            }
         }
      }
   }
}
```

api-plan

API Plan objects that are created from published products.

- Override Key: override
- Child Objects:
    - `graphql-schema-options`
        - Override Key: override
        - Child Objects:
            - `visibility-list`
    - `rate-limit`
        - Child Object:
            - `rate-limit-definition`
                - Override Key: override
    - `burst-limit`
        - Child Object:

        - **rate-limit-definition**
            - Override Key: override
    - **rate-limit-group**
        - Override Key: override
    - **api-operation-rate-limit**
        - Override Key: override
        - Child Objects:
            - **rate-limit-group**
            - **rate-limit-definition**
    - **assembly-limit**
        - Child Objects:
            - **rate-limit**
            - **burst-limit**
            - **count-limit**
- Scopes:
    - global
        - _instance: *<planName>*.
    - organization
        - _instance: *<planName>*.
    - catalog
        - _instance: *<planName>*.
    - product: *<name>*:*<version>*
    - _instance: *<planName>*.
- Example:

```
{
   "api-plan":{
      "_global":{
         "graphql-schema-options":{
            "visibility-list":[
               "echo hello graphql-schema-options visibility _global"
            ],
            "override":[
               "echo hello graphql-schema-options _global"
            ]
         },
         "rate-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello rate-limit _global"
               ]
            }
         },
         "burst-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello burst-limit _global"
               ]
            }
         },
         "rate-limit-group":{
            "override":[
               "echo hello rate-limit-group _global"
            ]
         },
         "api-operation-rate-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello api-operation-rate-limit _global"

               }
            }
         }
      }
   }
}
```

registry

Registry objects used in a catalog.

- Registry types:
  - LDAP
    - Override Key: override
    - Child object: `ldap-search-parameters`
  - AuthUrl
    - Override Key: override
- Scopes:
  - _global
  - _organization
  - _catalog
  - _instance: APIM name
- Example:

```
{
   "registry":{
      "ldap":{
         "_global":{
            "override":[
               "ldap-readtimeout 120"
            ],
            "ldap-search-parameters":[
               "summary override parameters global"
            ],
            "_instance":{
               "my-ldap-registry":{
                  "ldap-search-parameters":[
                     "summary override parameters global instance"
                  ],
                  "override":[
                     "ldap-port 636",
                     "ssl-client ldap-ssl-client"
                  ]
               }
            }
         },
         "_organization":{
```

```
            "my-org":{

         }
```

```
            }
        }
    }
}
```

oauth-provider

Oauth objects used in a catalog.

- Oauth Types
  - Native
    - Override Key: override
  - Third-party
    - Override Key: override
- Scopes:
  - _global
    - _instance: APIM name
  - _organization
    - _instance: APIM name
  - _catalog
  - _instance: APIM name
- Example

```
{
   "oauth-provider":{
      "native":{
         "_global":{
            "override":[
               "apic-access-token-ttl 86400"
            ],
            "_instance":{
               "my-native-oauth":{
                  "override":[
                     "scopes-allowed cmcscope1",
                     "enable-debug-mode on"
                  ]
               }
            }
         },
         "_organization":{
            "my-org-2":{
               "override":[

               ]
            }
         },
         "_instance":{
            "my-org":{
               "my-catalog":{
                  "my-native-oauth-2":{
                     "override":[
                        "apic-enable-introspection on",
                        "apic-auth-code-ttl 600",
                        "apic-enable-refresh-token on "
                     ]
                  }
               }
            }
         }
      },
      "third-party":{
         "_organization":{
            "my-org":{
               "_instance":{
                  "my-third-party-oauth":{
                     "override":[
                        "third-party-introspect-url https://someaddress.com"
                     ]
                  }
               }
            }
         }
      }
   }
}
```

api-definition

The API objects that are published to one or more catalogs.

- Override Key: api-definition
- Child Objects
  - api-schema
  - Security-definition

        - oauth2
            - api-sec-oauth
            - _instance: swagger name
        - apiKey
            - api-sec-apikey
            - _instance: swagger name
        - http
            - api-sec-http-scheme
            - _instance: swagger name
        - basic

- Scopes:
    - _global
        - _instance: name:version
    - _organization
        - _instance: name:version
    - _catalog
    - _instance: name:version
- Example: In this example, the **`@exclusive`** flag is used on the instance nick-limits:1.0.0 in my-catalog of my-organization. The **`@exclusive`** flag means that only the CLI commands at the instance level are applied for that API while all other APIs in that catalog still have the global, organization, and catalog CLI commands applied to them.

            - Override Key: api-rule
            - _instance: Error Name
        - default
        - finally
- Scopes:
    - _global
        - _instance: swagger name:version
    - _organization
        - _instance: swagger name:version

- _catalog
- _instance: swagger name:version

- Example: In this example, 2 instances are included within the global scope mapping. First is, **my-global-policy:1.0.0**, which is a global-policy that is used in some catalogs. Since it is defined at the global scope, the overrides apply anytime an assembly is built from a swagger with the name and version of **my-global-policy:1.0.0**. Second is, **complex-switch:1.0.0**, which is an API that is published to various catalogs. Similarly, since it is defined as an instance with in the global scope the overrides apply anytime that the assembly is built from a swagger with the name and version of **complex-switch:1.0.0**. Also see the **set-var** example within global scope for an example of overriding assembly action instances based on the title that is given in APIM or the DataPower object name.

```

   }
}
```

certificateIgnoreExpiration

Allows users to ignore certificate expiration dates to prevent gateway objects from failing due to expired certificates.

- Override Key: source-https
- Scopes:
  - _global
- Example:

```
{
   "front-side-handler":{
      "_global":{
         "ssl-server":[
            "certificateIgnoreExpiration": true
         ]
      }
   }
}
```

CLI command file extensions

Extend DataPower® API Gateway behavior with CLI commands in .cfg files.

You apply an extension to a DataPower API Gateway by uploading one or more .cfg files that define the required extension behavior. These .cfg files contain DataPower API Gateway CLI commands. For details of the full set of CLI commands that are available, see the DataPower API Gateway CLI command documentation.

You package the .cfg files in a .zip file, together with any additional required files that are referenced from CLI commands; for example, a .json file that contains the OpenAPI definition for an API. The .cfg files are processed in alphanumeric order by file name.
Note:

- All the .cfg files must be at the root of the .zip file. If you are attempting to use an API Connect Version 2018 gateway extension that has files in sub-directories, see Gateway extensions manifest for information on how to deploy multiple extensions in a single package.
- On macOS, run the `zip` command on the command line with the following flags:

  ```
  -x ".DS_Store" -x "__MACOSX"
  ```

  Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

You upload the extension .zip file to an API Connect Gateway service, and enable the extension, as described in Configuring your Gateway server extensions. Gateway server extensions can be deployed without having to restart the DataPower API Gateway.

To control how gateway extensions are applied to the DataPower API Gateway, you can include a Gateway extensions manifest as a manifest.json file. The manifest allows you to deploy multiple extensions of different types in a single package. For more information, see Gateway extensions manifest.

Using CLI commands in a Gateway extension

Although you can use any DataPower API Gateway CLI commands in your extension .cfg files, typically you use commands that modify API Connect objects that have previously been deployed to the DataPower API Gateway.

When API Connect objects are deployed to a DataPower API Gateway, .cfg are created on the Gateway that define the configuration of those objects. By examining those .cfg on the Gateway, you can determine the precise names of API Connect objects that you want to modify, and the current values of the properties of those objects. You can access these .cfg files by completing the following steps:

1. Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
2. Switch to the DataPower application domain for API Connect if necessary.

3. Under Files and Administration, click File Management.
4. Expand the temporary: folder to locate the .cfg files. The files for API Connect objects are named according to their containing provider organization and Catalog, as follows:

   `20.`*`provider-org-name_catalog-name`*`_collection.cfg`

   The prefix **`20`** controls the position of the file in the overall processing sequence, which is in alphanumeric order by file name.
   Restriction:
   - Do not modify these files directly in the DataPower API Gateway file system. Instead, use the gateway extension mechanism described on this page.
   - Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.
   - Do not use Gateway server extensions to modify objects that cause the **`apic-gw-service`** object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the **`apic-gw-service`** object to restart, lead to unpredictable behavior in the Gateway service.

Note: Modifying a .cfg file triggers the execution of all other .cfg files that run commands on the same object.

Config-Sequence tracks all of the objects that it manages through the .cfg files. Any change to a .cfg file that causes config-sequence to run commands on an object automatically executes all other .cfg files that run commands on the same object.

Example: If a new product is published to catalog A, then the .cfg file for that collection in temporary://config will be modified by the apic-gw-service to reflect the new product. Because that .cfg file was changed, config-sequence will execute every other .cfg file that also runs operations on catalog A, in the sequence of locations defined in the config-sequence object. If there are 2 .cfg files in the same location that run commands on catalog A, they run in alphabetical order.

Example 1 - change the scope of the rate limit for a Plan

Suppose the DataPower API Gateway configuration for a Plan has the following CLI command:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
```

The **api-plan** command has the following syntax:

`api-plan `*`plan_name`*

and creates a Plan of the specified name, or modifies a Plan of the same name if it already exists. By using the specified name, you can add **api-plan** commands in your Gateway extension .cfg files to modify the Plan.
Note: The names of API Connect objects in the DataPower API Gateway configuration are derived from their configuration in API Connect. For example, a Plan name has the following structure:

`provider-org-name_catalog-name_product-name_product-version_plan-name`

where:

- *provider-org-name* is the name of the provider organization.
- *catalog-name* is the name of the Catalog in that provider organization.
- *product-name* is the name of the Product that contains the Plan.
- *product-version* is the version of the Product.
- *plan-name* is the name of the Plan.

The default scope to which a Plan rate limit applies is per application. To change this setting on the Plan in this example, so that the rate limit scope is per client ID, add the following command to a .cfg in your Gateway extension:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
  rate-limit-scope per-client-id
exit
```

For more information on configuring Plans by using DataPower API Gateway CLI commands, see API Plan commands.

Example 2 - add a path to an API definition

The .cfg file in this example performs the following actions:

1. Uses the **top** and **configure terminal** commands to reset CLI processing.
2. Uses the **api-operation** command as follows:
   a. Creates a new operation called **`bank_branches_get_operation`**.
   b. Uses the **reset** command to set all properties to their default values.
   c. Sets the operation method to **`GET`**.
3. Uses the **api-path** command as follows:
   a. Creates a new path called **`bank_branches_path`**.
   b. Uses the **reset** command to set all properties to their default values.
   c. Sets the path URL segment to **`/details`**.
   d. Adds the previously created operation **`bank_branches_get_operation`** to the path.
4. Uses the **api-definition** command as follows:
   a. Modifies the existing API definition called **`myorg_sandbox_myapi_1.0.0`**.
      Note: The name of the API definition was derived from its configuration in API Connect when it was published to the DataPower API Gateway, and has the following structure:

      `provider-org-name_catalog-name_api-name_api-version`

      where:
      - *provider-org-name* is the name of the provider organization.
      - *catalog-name* is the name of the Catalog in that provider organization.
      - *api-name* is the name of the API definition in API Connect.
      - *api-version* is the version of the API.

   b. Adds the previously created path **`bank_branches_path`** to the API definition.

Note: The **reset** command is not used here because that would reset all the current settings on the `myorg_sandbox_myapi_1.0.0` API definition, whereas the requirement is to add a new path to the existing configuration of the API definition.

The .cfg file is as follows:

```
top; configure terminal

api-operation bank_branches_get_operation
  reset
  method GET
exit

api-path bank_branches_path
  reset
  path "/details"
  operation bank_branches_get_operation
exit

api-definition myorg_sandbox_myapi_1.0.0
  path bank_branches_path
exit
```

For more information on the DataPower API Gateway CLI commands used in this example, see the following pages:

- Initial login and common commands
- API Operation commands
- API Path commands
- API Definition commands

Gateway extension limitations

This section details the limitations of the extensions to the DataPower API Gateway.

- If you use an extension to create a user-defined policy and then delete the extension, the extension cfg's are removed from the filesystem, but the configuration sequence will not remove referenced objects created by the cfg's. For the policy objects to be cleaned up, you must first send an extension update that explicitly removes the user-defined policy from `apic-gw-service`, as in the following example.

  ```
  apic-gw-service
      no user-defined-policies udp-basic_1.0.0
  exit
  ```

  Note: This limitation does not apply only to user-defined policies, but any object customization that adds a reference to another object.
- `user-defined-policy-yaml` policies that use or reference another policy can be deployed only after the referenced policy has been advertised to API Manager. The deploy type must be set to `deferred` and the Gateway Service must be restarted.
- Deleting an extension that is used to create a user-defined policy using a .cfg file does not remove the policy reference in the `apic-gw-service` object. The policy is not removed from the assembly palette until a reboot or restart of the Gateway pod. To properly remove the policy, send an `apic extensions:update` command that explicitly removes the policy from the `apic-gw-service` prior to sending the `apic extensions:delete` command.
- v5 policies that contain files outside of the `/policy` directory are not supported. If multiple v5 policies reference the same file outside the `/policy` directory, the last applied policy will overwrite the file and will be used by all policies that reference it. Removing any policy that contains the file will cause the file to be deleted and may cause errors for the remaining policies that use it.
- If an extension contains or references objects and files that are also referenced by other objects outside of the extension, deleting the extension can cause errors that are difficult to troubleshoot.
- It is possible to delete an extension that is referenced by published APIs. This may cause those API requests to return errors.
- For an extension type of `user-defined-policy`, extra assembly functions may be present in the DataPower import `.zip` file, even if there is no `.yaml` file to indicate their presence. Using these functions without declaring them using a `.yaml` file is not supported. A policy `.yaml` file is required for each policy you want to advertise to API Manager.
- Extension type `user-defined-policy-yaml` may leak generated Gatewayscript `.js` files in temporary:/js/ or `.xslt` files when deleted.
- Extension types that use SOMA imports must use new objects with no overrides. If you override a singleton or shared object using an extension of this type, then the object will not be restored to its previous state when the extension is deleted, and those objects may be missing after the extension is deleted. You must then restore any needed objects.

v5 policy emulation limitations

This page details the limitations of v5 policy emulation for the current release.

- The reverse solidus character (\) might be removed from policy property values.
- The source parameter for XSLT and GatewayScript policies is base-64 encoded to preserve escaping. It cannot be easily viewed from the DataPower command line or the DataPower WebGUI.
- Some DataPower service variables (for example, `var://service/mpgw/skip-backside`) might not be applicable in API Gateway, depending on how the variables are used.
- User-defined policies that make any alterations to a DataPower context are not supported.
- Execution of a 1.0.0 policy may fail if a previous 2.0.0 policy updates the `message.body` content type (for example, from XML to JSON, or JSON to XML).
- A proxy 1.5.0 policy can return an incorrect response if it is the last action within a switch `case` or `otherwise` property. The response is parsed. The correct behavior is to not parse the response. To work around this issue, set the `final-action:true` parameter on the proxy.
- Proxy 1.5.0 and invoke 1.5.0 policies do not preserve the `gtid` header.
- The `cache-putpost-response` property is not included in the schema for invoke 1.5.0 and proxy 1.5.0 policies.
- Setting HTTP response headers in a v5 user-defined policy, GatewayScript policy, or XSLT policy is not supported.
- Non-UTF-8 characters are not supported.
- JSON data returned in the response of an API running in v10 with v5 emulation is formatted without spaces.

- The v5 user-defined policy emulation feature creates v5 compatible context. After running the user-defined policy, the emulation feature analyzes the context and converts it back to DataPower® API Gateway compatible context. The computations involved in this process might negatively impact the DataPower API Gateway performance. For better performance, use a non-emulated user-defined policy. For more information, see Authoring Policies for DataPower API Gateway.
- In the V5E framework, the maximum file size for parsing XML data is 4194304 bytes. Currently, users cannot modify parse settings for GatewayScript.

Configuring your Gateway server extensions

You can add extra DataPower enforcement capabilities to a gateway service by uploading a .zip file that defines the required extension behavior, and then enabling the extension in DataPower.

About this task

You can upload a Gateway server extension to a Gateway service in either of the following ways:

- Use the Cloud Manager user interface
- Use the developer toolkit CLI

Procedure

- To upload a Gateway server extension to a Gateway service by using the Cloud Manager user interface, complete the following steps:
  1. In the Cloud Manager user interface, click  Topology.
  2. Alongside the required Gateway service, click the options icon ⋮, then click Configure gateway extension.
  3. Click Add.
     Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If a Gateway server extension has previously been uploaded, the Add button is not available; you can replace the previous extension by clicking the options icon ⋮ alongside gateway-extension, then clicking Edit.
  4. Upload the extension as indicated, either by dragging and dropping the .zip file, or by browsing and selecting it.
  5. Click Save when done.
- To upload a Gateway server extension by using the developer toolkit CLI, complete the following steps:
  1. Log in to your API Connect Cloud Manager server as an administrator, using the following command:

     ```
     apic login --server <cloud-manager_endpoint_url> --username <admin_user_ID> --password <admin_password> --realm admin/<identity_provider>
     ```

     where:
     - *<cloud-manager_endpoint_url>* is the Cloud Manager endpoint URL; for example: `mgmt-admin.<myserver>.com`.
     - *<admin_user_ID>* is the user ID of your administrator account, and is the same as the user ID that you use to log in to the Cloud Manager user interface.
     - *<admin_password>* is the password for your administrator account.
     - *<identity_provider>* is the identity provider that is used to authenticate administrative users.

     For example:

     ```
     apic login --server mgmt-admin.myserver.com --username admin --password my-admin-password --realm admin/myldap
     ```

  2. Upload the Gateway extension .zip file by using the following command:

     ```
     apic gateway-extensions:create <extension_zip_file> --scope org --org admin --gateway-service <gateway_service> --availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
     ```

     where:
     - *<extension_zip_file>* is the Gateway extension .zip file that you want to upload.
     - *<gateway_service>* is the name of the Gateway service that you want add the extension to.
     - *<availability-zone>* is the name of the availability zone that contains the Gateway service.
     - *<cloud-manager_endpoint_url>* is the Cloud Manager endpoint URL.

     For example:

     ```
     apic gateway-extensions:create myextension.zip --scope org --org admin --gateway-service mygatewayservice --availability-zone availability-zone-default --server mgt-admin.myserver.com
     ```

     This example uses the default supplied availability zone name of `availability-zone-default`, which will be the required value if you have not configured your own availability zones. To check the names of the currently configured availability zones, use the following command:

     ```
     apic availability-zones:list --org admin --server <cloud-manager_endpoint_url>
     ```

     For details on configuring availability zones, see Creating an availability zone.
     To check the names of the currently configured gateway services, use the following command:

     ```
     apic gateway-services:list --org admin --availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
     ```

     You can confirm that the extension has been added to the Gateway service by using the `gateway-extensions:get` command; for example:

     ```
     apic gateway-extensions:get --scope org --org admin --gateway-service mygatewayservice --availability-zone availability-zone-default --server mgt-admin.myserver.com --output -
     ```

     (the parameter setting `--output -` writes the details of the Gateway extension object to the command window. You can specify the name of an existing folder to have the details written to a `.yaml` file in that folder.)
     For reference details of the `apic gateway-extensions` commands, see the toolkit CLI reference documentation.

     Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If you want add further extensions later, update the original .zip file, then use the `apic gateway-extensions:update` command to replace the previous gateway extensions file with the revised one; for example:

```
apic gateway-extensions:update mynewextension.zip --scope org --org admin --gateway-service mygatewayservice --
availability-zone myavailabilityzone --server mgt-admin.myserver.com
```

3. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:
   Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.
   a. Remove the Gateway server from the load balancing group.
   b. Disable, then enable the API Connect gateway service object. You can do this by using either the DataPower® administrative user interface in a web browser, or by using the DataPower CLI.
      - By using the administrative user interface:
        - Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
        - Switch to the DataPower application domain for API Connect if necessary.
        - Search for `Gateway Service`.
        - Set the Administrative State to disabled.
        - Apply the changes.
        - Set the Administrative State to enabled.
        - Apply the changes.
      - By using the CLI:
        - Enter configuration mode by entering the command `configure`.
        - Navigate to the DataPower application domain for API Connect by entering the command `switch api_connect_domain_name`, where *api_connect_domain_name* is the name of your API Connect application domain.
        - Disable the API Connect gateway service object by entering the following command:

          ```
          apic-gw-service; admin-state disabled; exit
          ```

        - Enable the API Connect gateway service object by entering the following command:

          ```
          apic-gw-service; admin-state enabled; exit
          ```

   c. Ensure that the gateway service object initialization has completed.
   d. Re-add the Gateway server to the load balancing group.
4. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:
   Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.

Results

The extension is uploaded and applied to each of the servers in the Gateway service, and the associated enforcement capabilities are applied to all incoming API resource requests.

Warning: DataPower Gateway (v5 compatible) only If you upload an extension to the DataPower Gateway (v5 compatible), a status file called extension_import_response.xml is written to the local:/ext folder in the gateway file system. Do not remove this file, otherwise if your gateway extension is subsequently removed then the referenced objects cannot be reverted to their original state automatically, and you will therefore have to either complete these clean up tasks manually, or re-add the gateway extension to regenerate the extension_import_response.xml file and then remove the gateway extension again. If the extension_import_response.xml exists and there is a cleanup failure for any object, a failure file is written to the local:/ext folder, with the failure details.

Cloud Manager Tutorials

Tutorials for using the Cloud Manager user interface in IBM® API Connect.

Prerequisites

To complete the following tutorials you must be the Cloud Administrator or Cloud Owner of an API Connect instance.

Overview

These tutorials guide you through common tasks performed to set up and maintain the configuration of a cloud.

- **Tutorial: Configuring the Cloud**
  This tutorial shows you how to create a basic cloud configuration, with DataPower® gateway, event gateway, analytics, and developer portal services.
- **Tutorial: Creating a Provider Organization**
  This tutorial shows you how to create a Provider Organization.

Tutorial: Configuring the Cloud

This tutorial shows you how to create a basic cloud configuration, with DataPower® gateway, event gateway, analytics, and developer portal services.

Before You Begin

One of the following roles is required to register and manage services in Cloud Manager:

- Administrator
- Topology Administrator

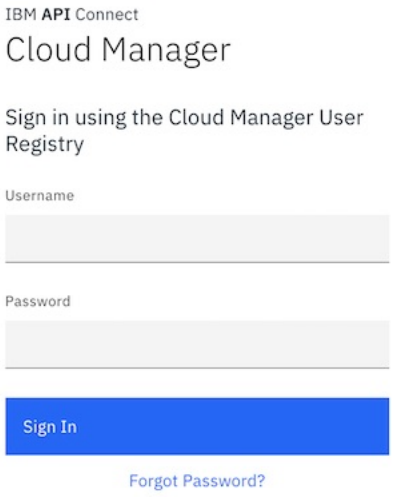
- Owner
- A custom role with the **`Topology:Manage`** permission

You will need the following information to complete this tutorial.

- The IP address or FQDN of the DataPower gateway, and the port assigned to accept API requests from clients.
- The IP address or FQDN of the DataPower gateway, and the port assigned to communicate with the management server. This cannot be the same as the port for API requests.
- The FQDN of the management endpoint on the event gateway to communicate with the API Connect management server.
- The FQDN of the client endpoint on the event gateway, and the port (**`443`**) assigned to accept API requests from clients.
- The FQDN of the developer portal service to accept requests from clients.
- The FQDN of the developer portal to communicate with the management server.
- The FQDN of the analytics service to accept requests from clients.
- The address, port, and optional login credentials for an SMTP email server.

Note: The port for the **`portal-www`**, **`portal-admin`**, and **`analytics-ingestion`** services is **`443`**, and is not configurable.

About this tutorial



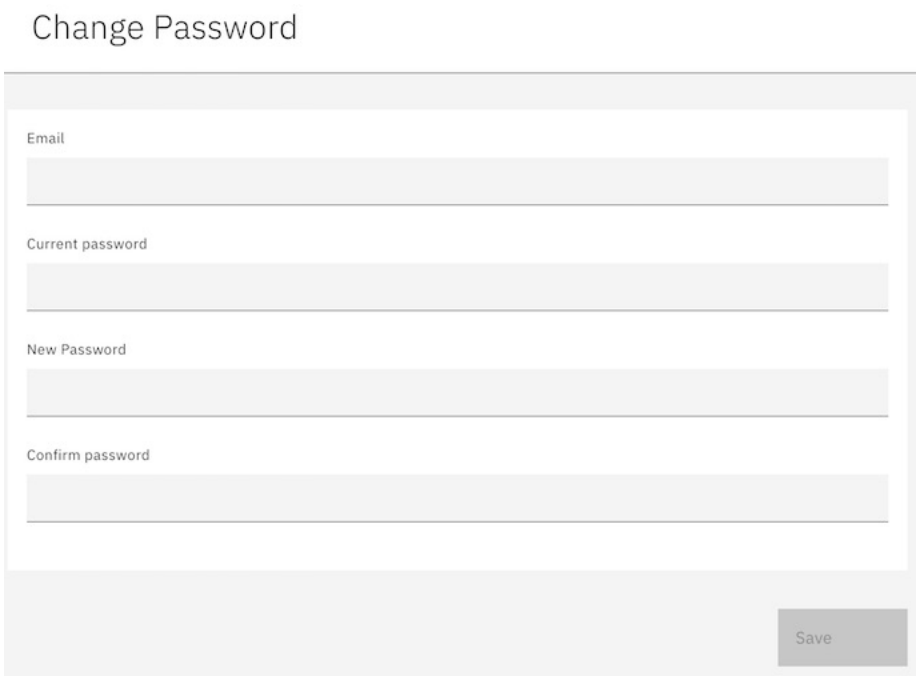
In this tutorial, you will complete the following lessons:

- Initial Cloud Manager Console login
- Configure an Email Server
- Register a DataPower Gateway Service
- Register an Event Gateway Service
- Register a Portal Service
- Register an Analytics Service
- Configure a Default DataPower Gateway Service

Initial Cloud Manager Console login

Take the following steps to log in to the Cloud Manager user interface for the first time.

1. In a web browser, enter the management service URL. For example, `https://ManagementService.domain/admin` where ManagementService.domain is the fully qualified host name or IP address of the Management service.



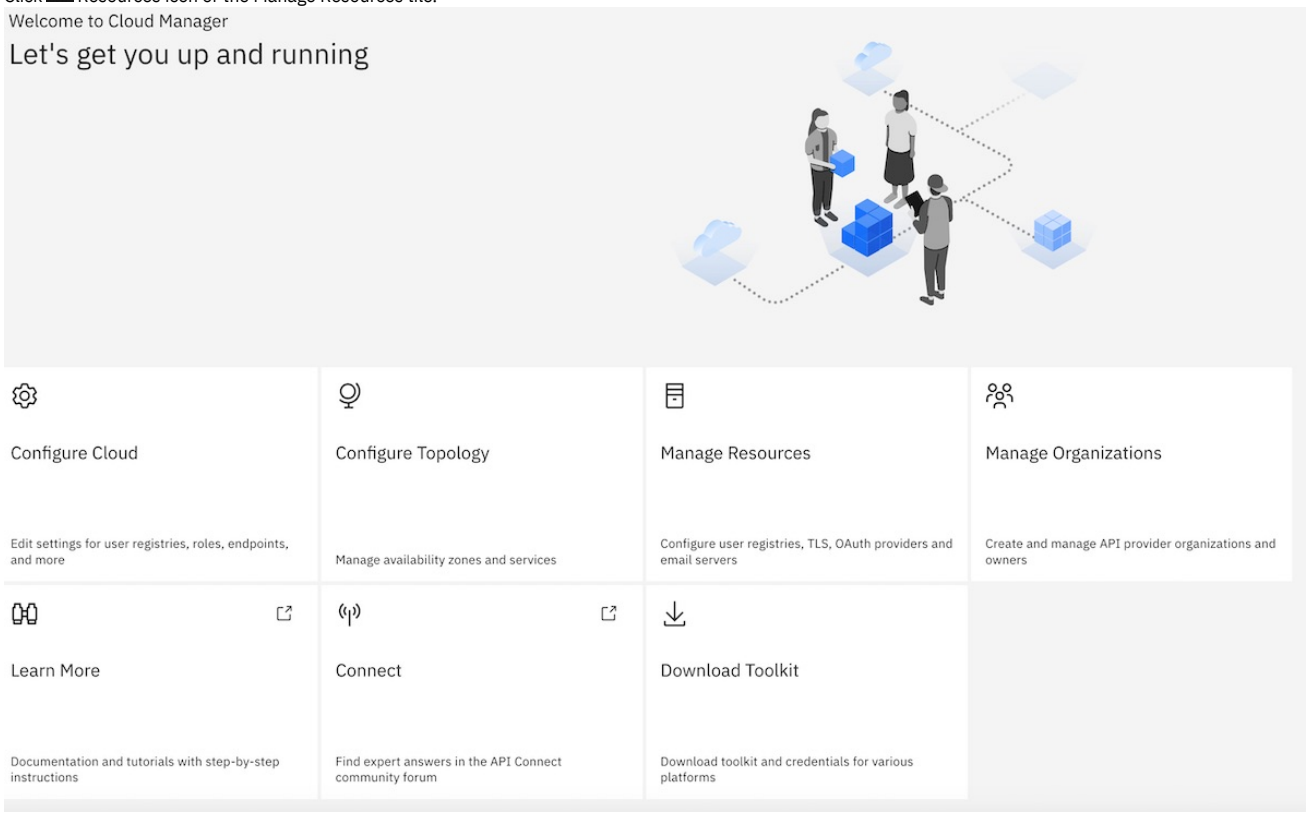
2. Enter the Cloud Administrator user name and password. The default values are `admin` for the user name and `7iron-hide` for the password.

   OpenShift top-level CR install

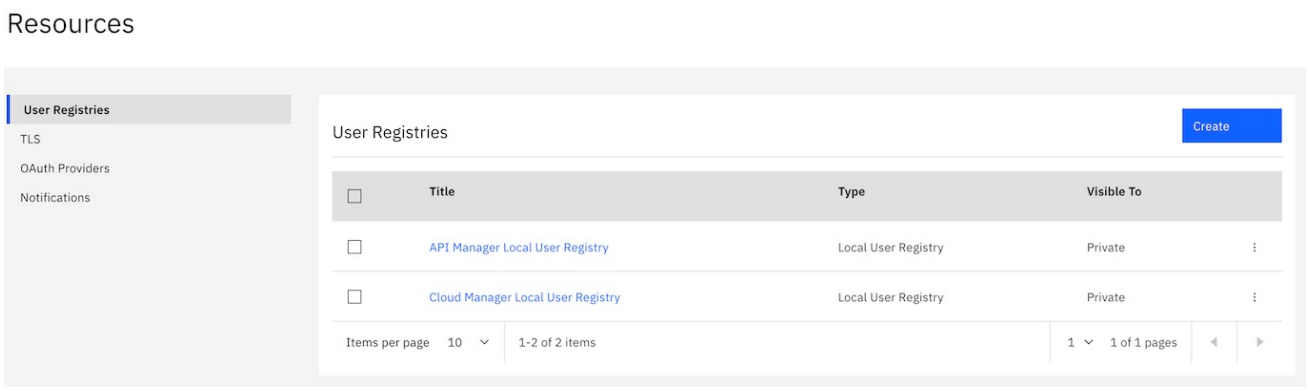
   If you installed API Connect on OpenShift using the top-level "API Connect Cluster" CR, the default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:

   ```
   oc get secret -n <namespace> | grep mgmt-admin-pass
   oc get secret -n <namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo ""
   ```

3. You are immediately required to change the admin password, as well as provide an email address for the cloud administrator. Enter the necessary information. Note: If you forget your password and request a password reset, the notification email is sent to this email address. This action will use the email server set in the Notifications section of the cloud Settings. This tutorial shows you how to set this configuration.

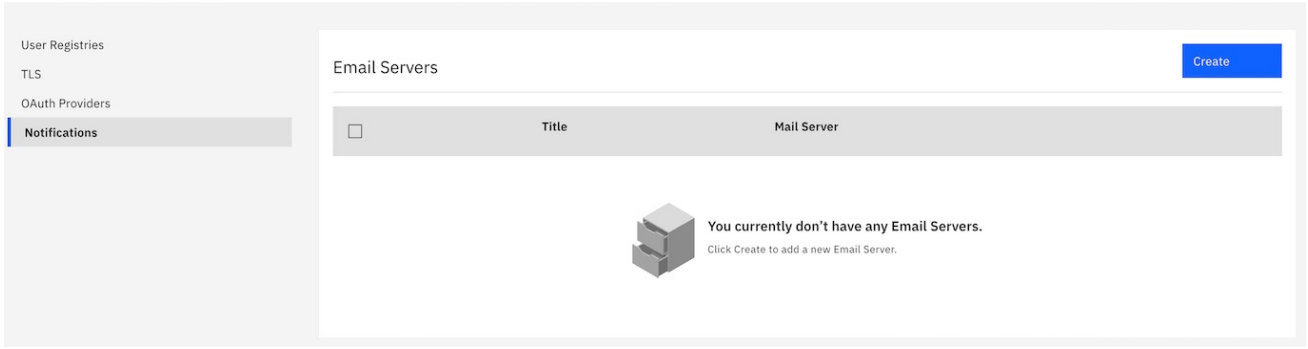


4. Click Save.
5. Log in using the new password.

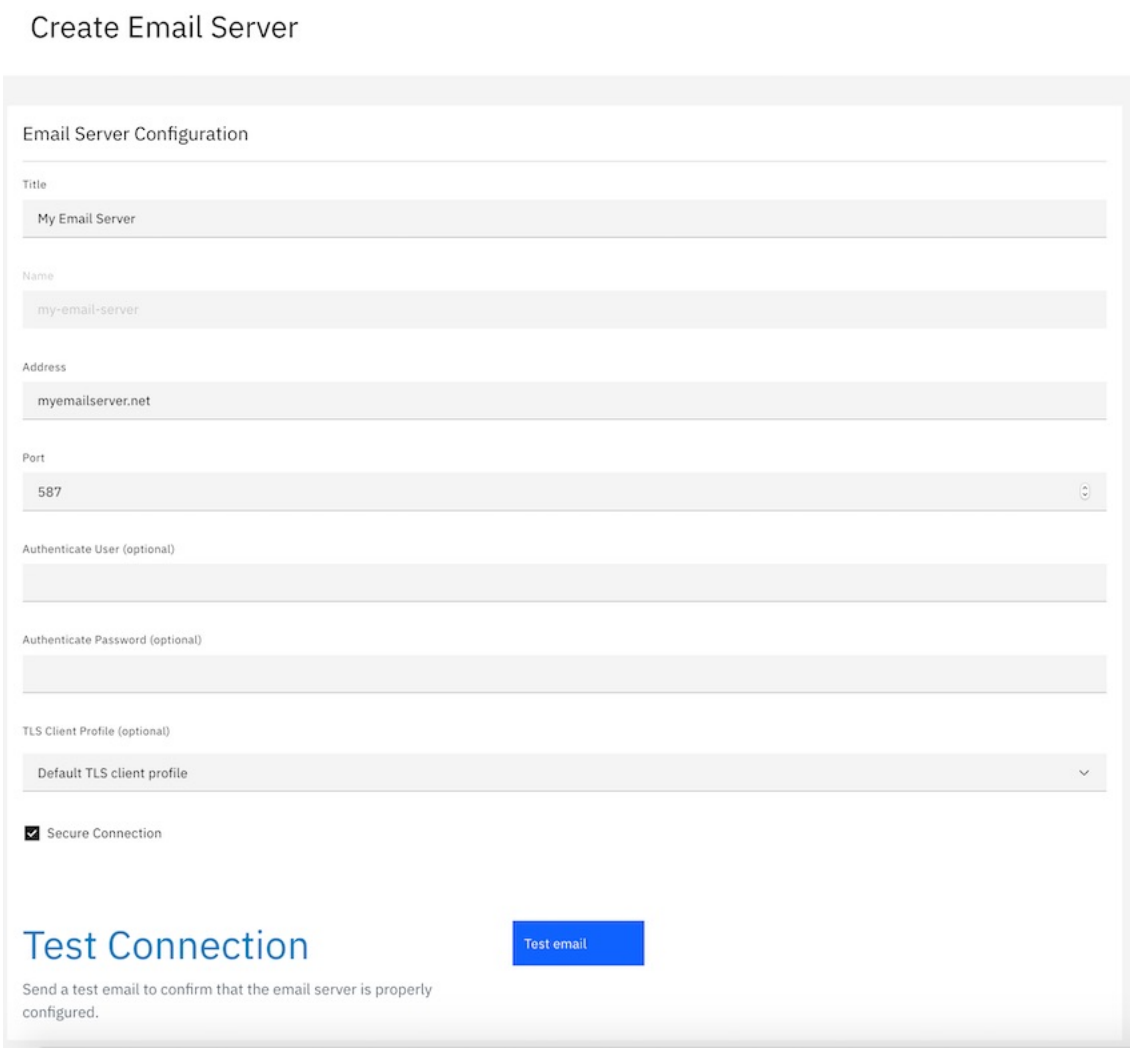


Configure an Email Server

Take the following steps to configure an email server. This configuration allows you to recover the admin password or receive other important notifications.



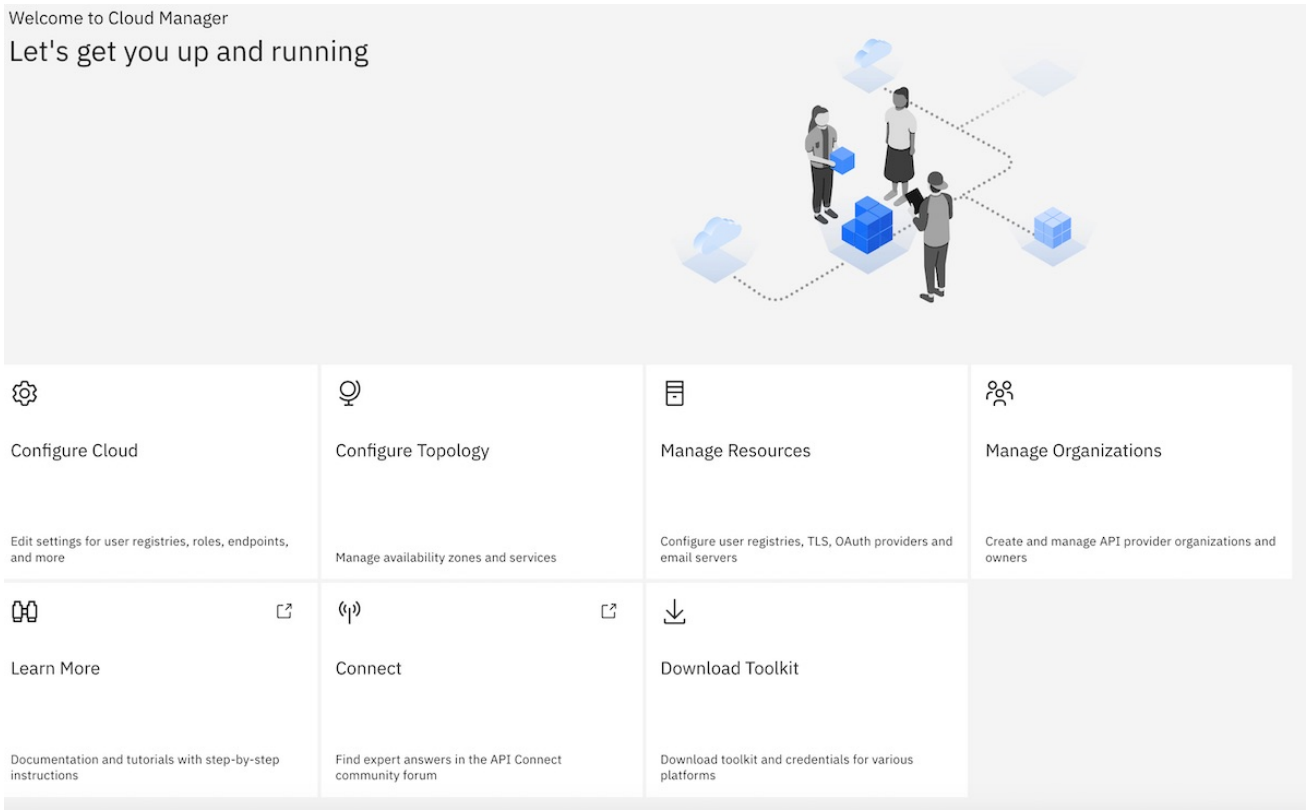
1. Click Resources icon or the Manage Resources tile.



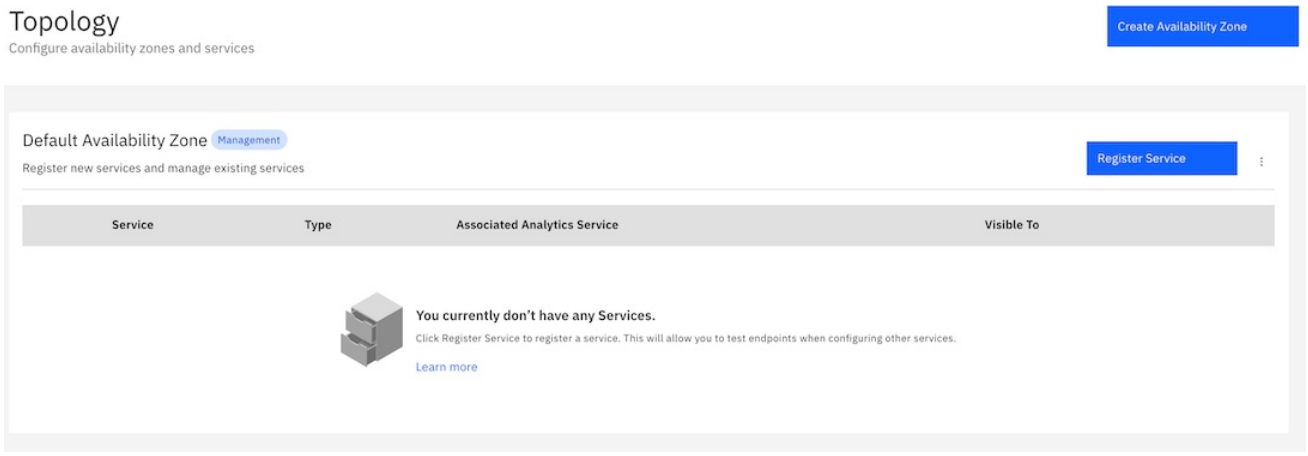
2. Click Notifications.

3. Click Create.

4. Enter the appropriate values in the fields These values vary depending on your site.
5. Click Save.

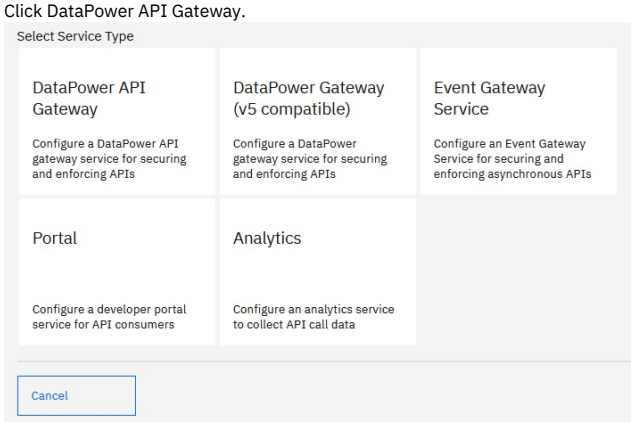


6. Click the Settings icon, then click Notifications > Edit.
7. Ensure your email server is selected, then click Save.
8. Click the Home icon.

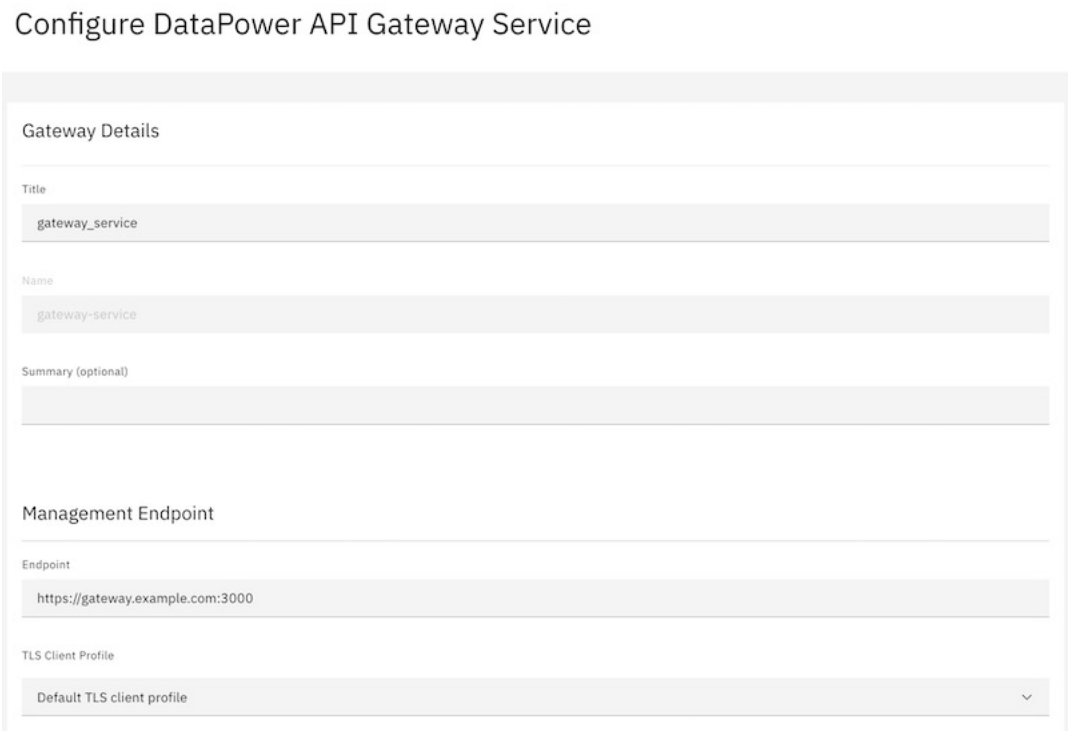


Register a DataPower Gateway Service

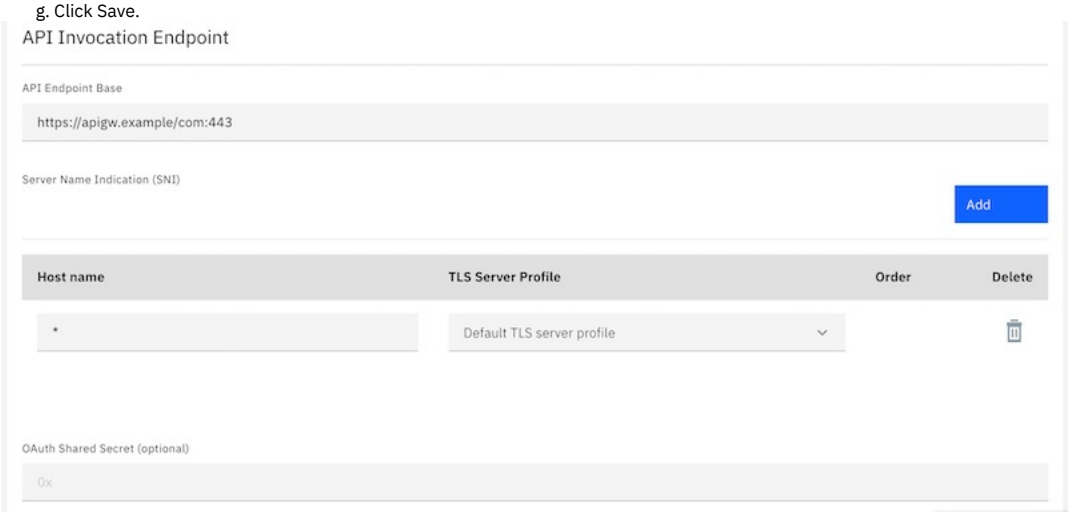
Take the following steps to register a gateway service.



1. Click the Configure Topology tile.

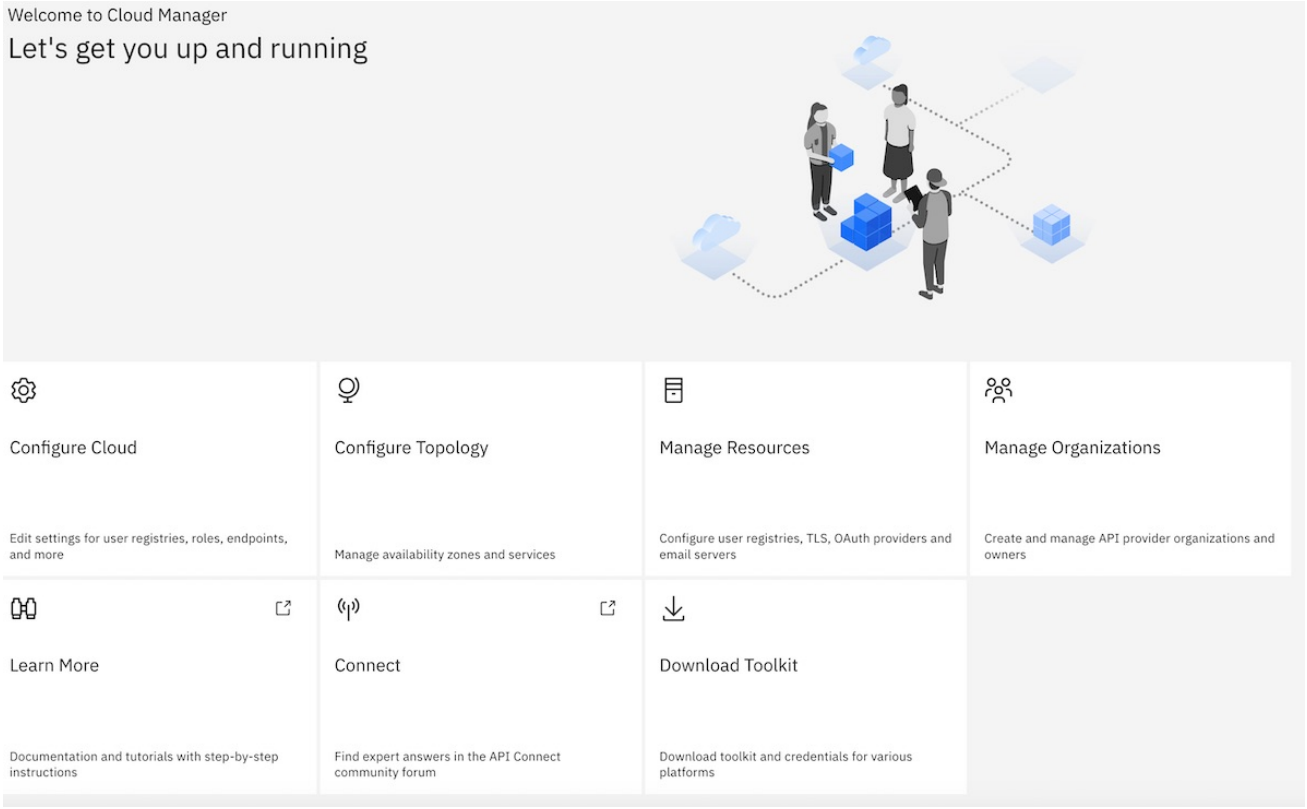


2. Click Register Service.

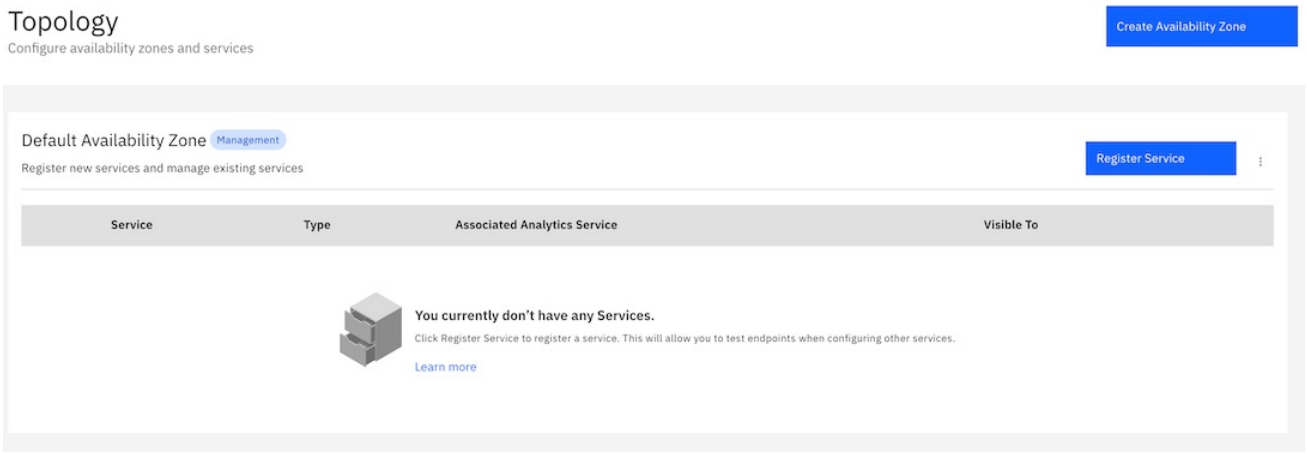


3. Click DataPower API Gateway.

4. Take the following steps.
   a. Enter `gateway_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the address and port assigned to the management endpoint in the Endpoint field. This is the port used by the API Management server to connect to the gateway.
   c. Leave the remaining values as given to set TLS profiles.



d. In the API Invocation Endpoint section, enter the URL of the gateway address and port assigned to accept API requests from clients in the API Endpoint Base field.
e. Do not change the defaults in the Server Name Indication (SNI) fields unless your topology requires different values.
f. Optionally enter a hex value in the OAuth Shared Secret field. This must be a 64-bit hex value that begins with "0x". Providing a shared secret value here enables gateways in a cluster to read the OAuth tokens generated by any member of the cluster using the same secret.
g. Click Save.



Register an Event Gateway Service

Take the following steps to register an event gateway service.

1. Click the Configure Topology tile.

2. Click Register Service.

3. Click Event Gateway Service.
4. Take the following steps.
   a. Enter `event_gateway_service` in the Title field.
   b. In the Management endpoint on the gateway service field, enter the URL of the event gateway management endpoint.
      To retrieve the URL, complete the following steps:
      i. Log in to your Kubernetes cluster as a cluster administrator by setting your **`kubectl`** context.
      ii. Set the context to the namespace where your Event Endpoint Management instance is installed:

      ```
      kubectl config set-context --current --namespace=<namespace>
      ```

      iii. List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in **`-apic`**:

      ```
      kubectl get ingress
      ```

      iv. Copy the URL for the ingress resource from the **`Host`** column.
   c. In the API endpoint base field, enter the URL and port of the event gateway client endpoint.
      To retrieve the URL and port, complete the following steps:
      i. Log in to your Kubernetes cluster as a cluster administrator by setting your **`kubectl`** context.
      ii. Set the context to the namespace where your Event Endpoint Management instance is installed:

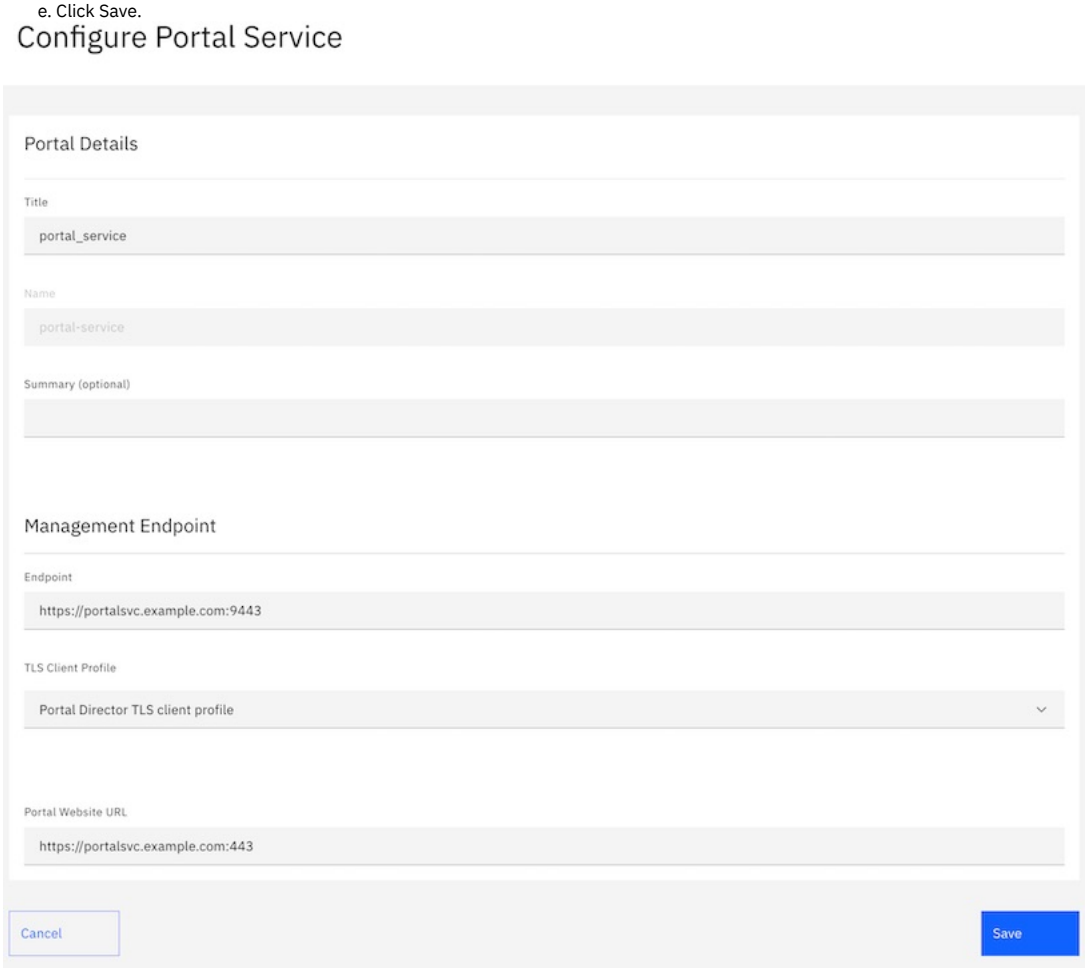
      ```
      kubectl config set-context --current --namespace=<namespace>
      ```

      iii. List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in **`-ibm-egw-rt`**:

      ```
      kubectl get ingress
      ```

iv. Copy the URL for the ingress resource from the **`Host`** column and append the port **`:443`**.

d. Leave the remaining values as given to set TLS profiles.

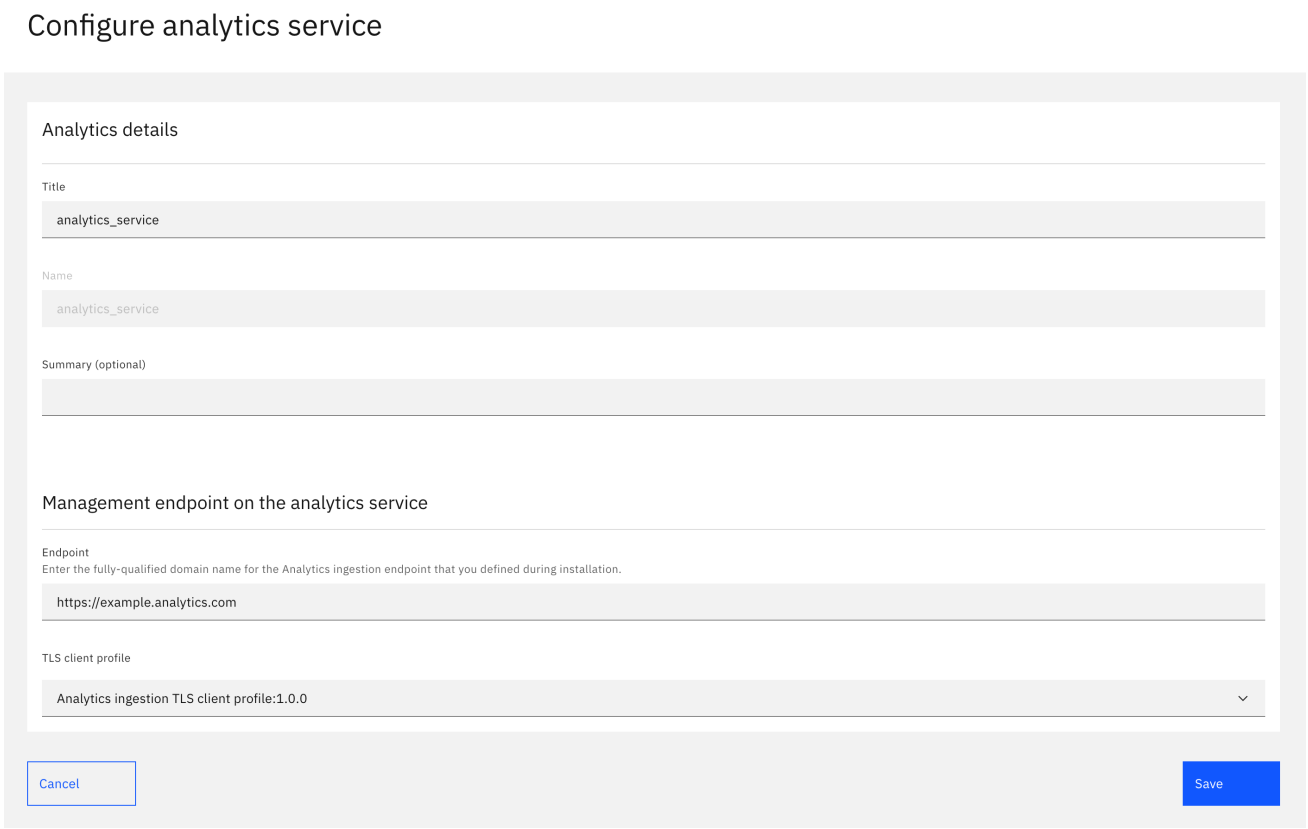


e. Do not change the defaults in the Server Name Indication (SNI) fields. unless your topology requires different values.

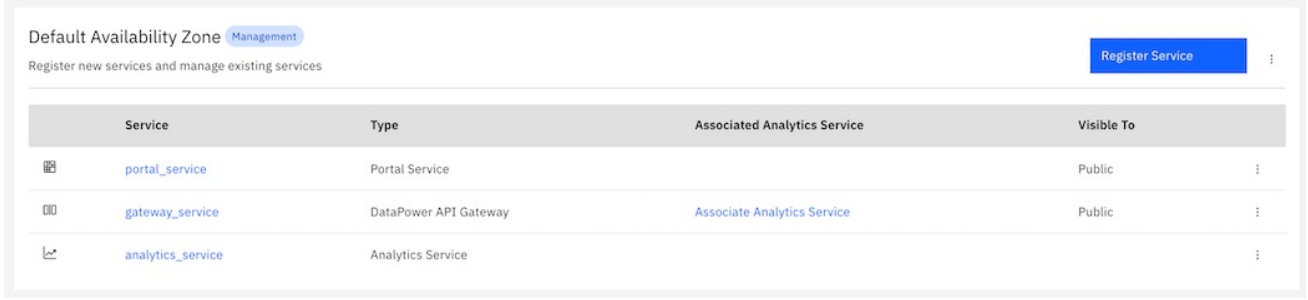
f. Click Save.

Register a Portal Service

Take the following steps to register a portal service.

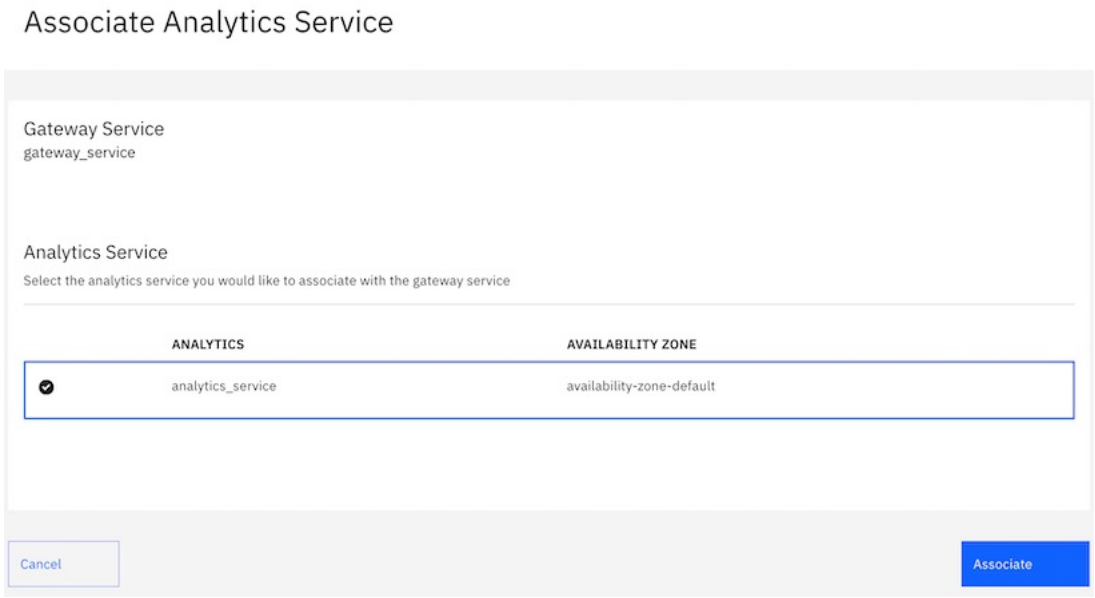


1. Click Register Service.
2. Click Portal.
3. Take the following steps.
   a. Enter `portal_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the portal address and port assigned to communicate with the management server in the Endpoint field.
   c. Enter the URL of the portal address and port assigned to accept requests from clients in the Portal Website URL field.
   d. Use the reconfigured profile in the TLS Client Profile field.
   e. Click Save.



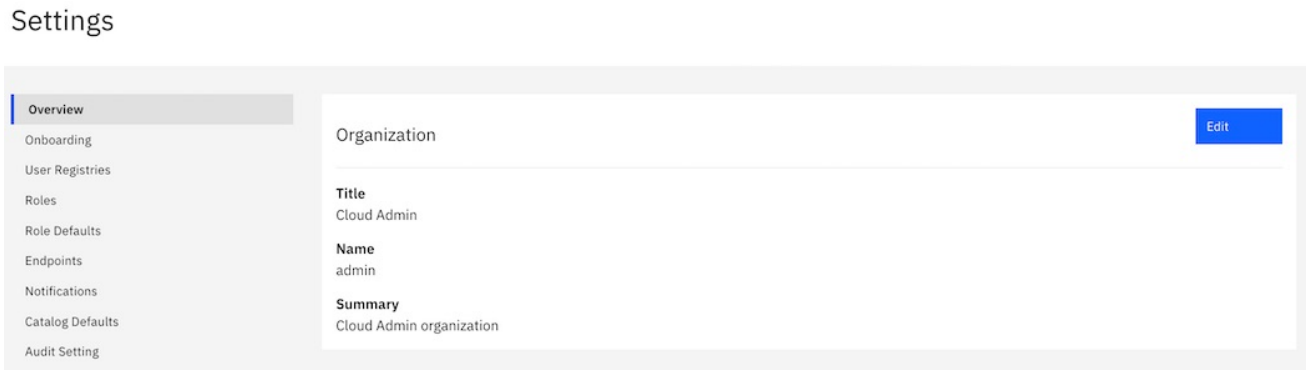
Register an Analytics Service

Take the following steps to register an analytics service.

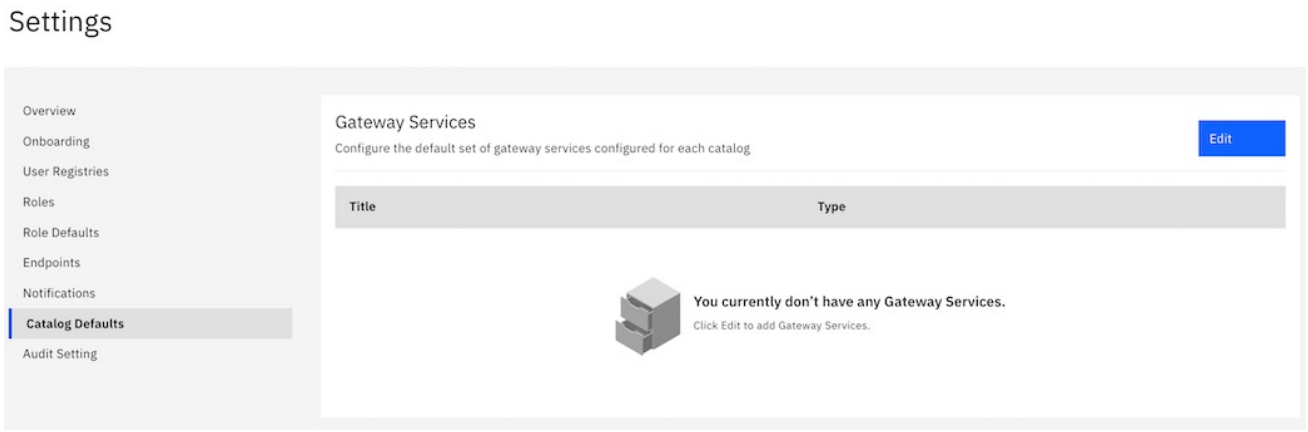


1. Click Register Service
2. Click Analytics.
3. Take the following steps.
   a. Enter `analytics_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the analytics server address and port assigned to accept requests from clients in the Endpoint field.
   c. Select `Analytics ingestion TLS client profile` in the TLS Client Profile field.
   d. Click Save.

4. Click Associate Analytics Service corresponding to the gateway service listing.

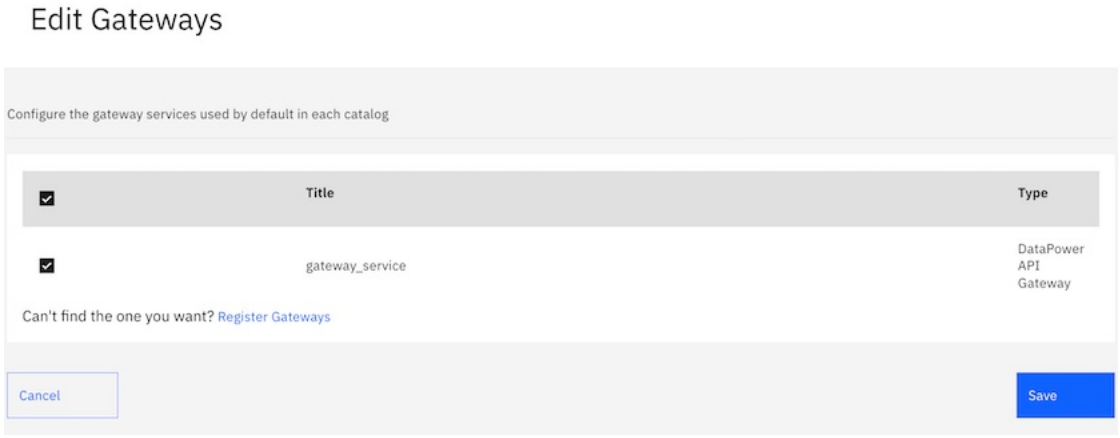


5. Select analytics_service. Click Associate.



Configure a Default DataPower Gateway Service

Take the following steps to configure a default DataPower gateway service for every catalog in the cloud.



1. Click Settings icon .
2. Click Catalog Defaults.

3. Click Edit.

4. Select an available gateway service.
5. Click Save.

What you did in this tutorial

- Set new Cloud Manager Console login password
- Configured a DataPower Gateway Service
- Configured an Event Gateway Service
- Configured a Developer Portal Service
- Configured an Analytics Service
- Configured a Notifications Email Server
- Configured a Catalog Default DataPower Gateway Service

Tutorial: Creating a Provider Organization

This tutorial shows you how to create a Provider Organization.

Before You Begin

This task can be completed by users who are assigned one of the following roles:

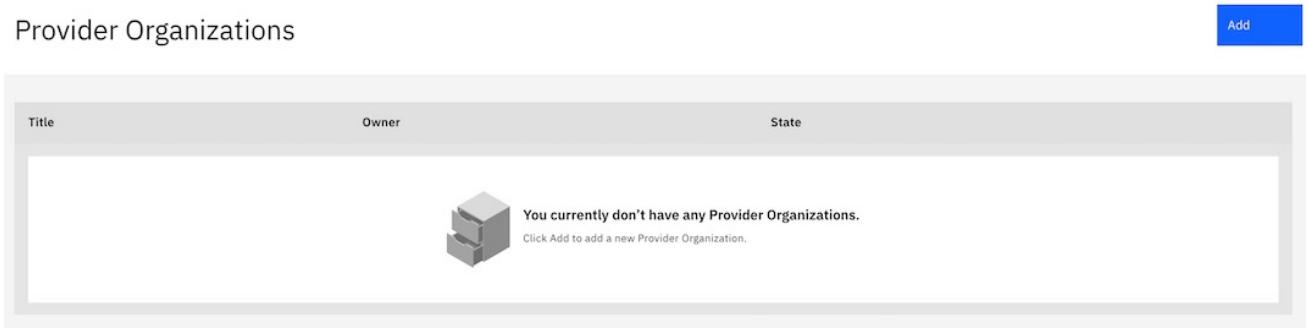
- Cloud Owner
- Cloud Administrator

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications

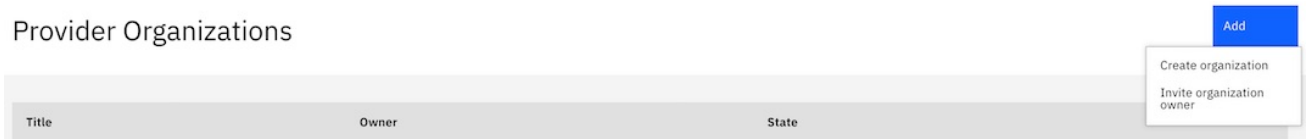
Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

About this tutorial



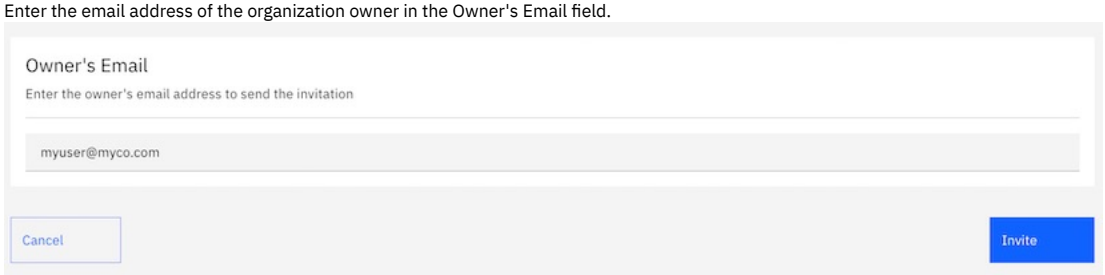
In this tutorial you are going to complete the following lessons:

- Create a Provider Organization

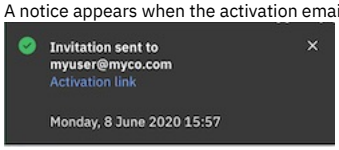


Create a Provider Organization

Take the following steps to create a new Provider Organization.

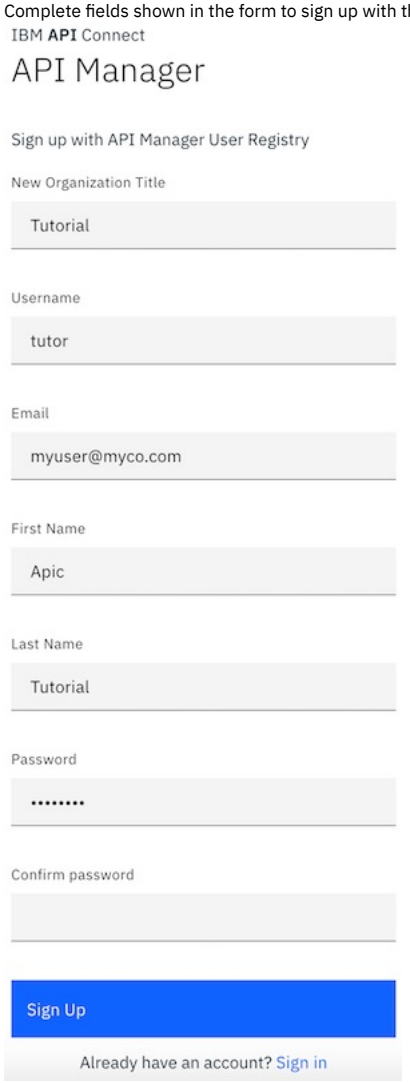


1. Log in to the Cloud Manager.
2. Click Provider Organizations.

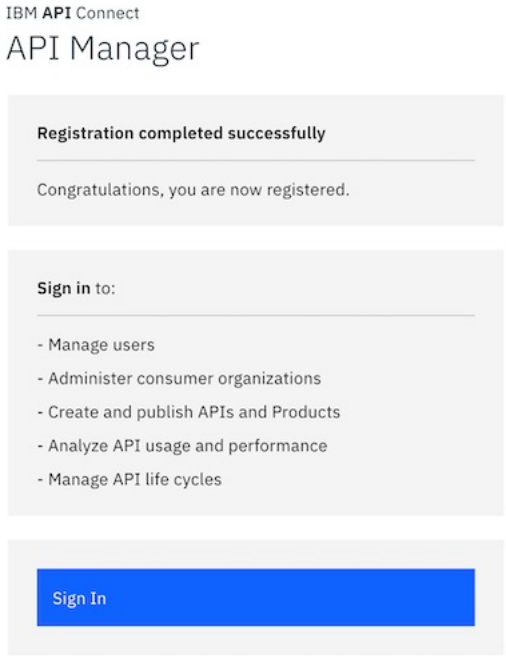


3. Click Add > Invite organization owner.

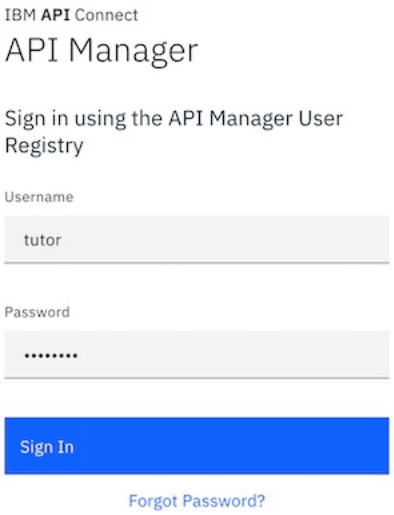
4. Enter the email address of the organization owner in the Owner's Email field.



5. Click Invite.
6. A notice appears when the activation email has been sent. Click Activation link..



7. A dialog box displays the activation link. Click the Copy to clipboard icon .



8. Open a new window in your browser. Paste the copied activation link into the Location bar. Optionally, you can click the activation link in the invitation email to open the registration form.
9. Complete fields shown in the form to sign up with the API Manager User Registry. Click Sign up.

10. You see a confirmation of registration. Click Sign in.

11. Enter the username and password you just created. Click Sign in to begin creating APIs and products.

12. Return to the original window of your browser. Click Provider Organizations to refresh the list. Your new organization is listed.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a new Provider Organization.

Creating, deploying, and publishing APIs using API Agent

API Agent is designed to accelerate the API journey with greater efficiency, speed, and confidence. This feature is built to work with the rapid evolution of large language models (LLMs) and AI agents, which are driving changes in the world of API consumption and creation.

This new feature enables developers and technical users to create APIs through a chat-based interface, allowing them to define, design, and deploy APIs using natural, conversational interactions.

Overview

API Agent is built on agentic framework so it can plan, understand, and execute user queries. Available as a Visual Studio Code (VS Code) plug-in, it simplifies and automates complex API management workflows. By intelligently translating user queries into actions, API Agent streamlines API discovery, creation, governance, and testing.

The API Agent uses an agentic framework that supports a variety of tools to automate tasks such as searching for APIs and tables, and generating code to interact with databases. For a comprehensive list of prompts, see Prompts library.

These tools include:

- Artifacts Searcher: Locates existing resources like APIs, database tables, or application source objects.
- OAS Creator: Automates the creation of APIs from database tables and IBM connector pack based applications.
- API Governance: Provides access to several key API governance capabilities of API Connect through the API Agent. With this tool, you can list rulesets, list rules in rulesets, validate an OpenAPI document using rulesets, and fix an OpenAPI document with supported rulesets.
- API Connect Tester: Facilitates API test generation and execution workflows.
- API Connect Task: Handles tasks related to IBM API Connect, such as publishing or securing APIs.
- OpenAPI Python Generator: Generates boilerplate or custom code from OpenAPI specifications using the FastAPI framework.
- OpenAPI Enhancer: Performs upgrading or modifying an input OpenAPI file or draft API with enhanced descriptions and examples, and automatically rectifies any OpenAPI file with validation problems or errors.
- OpenAPI Generator: Generates OpenAPI documents from a natural language description (NLP). The user provides a prompt to the API Agent, describing the intended functionality of the application. Based on this prompt, the API Agent generates an OpenAPI specification that represents the described API.
  The framework ensures that tasks are routed to the appropriate tool based on the user's query. In the initial version, API Agent confirms with the user whether the proposed plan of action is accurate before executing it, ensuring precision and user control.
- Code deployment: Streamlines the deployment of application source code to supported services, providing a flexible, and controlled way to manage deployments.

API Agent components

API Agent has the following components:

- API Agent sources
  The intelligence behind API Agent is powered by API Agent sources configured by administrators to integrate various sources that fuel the system's capabilities. Leveraging a robust Retrieval-Augmented Generation (RAG) pattern, this catalog crawls and indexes supported sources, including APIs and database tables, storing them as vector embeddings.
  Key capabilities:
  - Acting as a centralized hub for managing and configuring the resources required for API development.
  - Enabling seamless connection and configuration of data sources like databases, and APIs.
  - Providing immediate access to all configured resources for creating and managing APIs.
- Chat interface
  Using the Visual Studio Code, you can install API Agent that provides a chat interface through which you can enter different prompts. For example, `Search for available APIs` or `Create an openapi with the table purchaseorder`.
  The API Agent connects to API Agent sources, retrieves the necessary information, and provides actionable results.

The following topics provide full details for configuring and using API Agent.

- **API Agent user roles**
  The user roles and permissions for IBM® API Connect govern the actions that users can complete in API Agent.
- **Configuring**
  By default, API Agent is disabled and must be enabled before you can use its capabilities. To enable API Agent, you need to first enable the IBM managed watsonx.ai. After enabling watsonx.ai, you need to configure API Agent.

- **Using API Agent**
  You can use API Agent for end-to-end API publishing and testing. What follows here are sections with details about what to expect when using the API Agent plug-in and a sample end to end flow scenario, which you can walk through to get an understanding of how the agent works and the capabilities available in the agent.
- **API Agent tools**
  API Agent uses set of tools to automate and assist with API management tasks. Each tool is designed for a specific purpose, making it easier for users to build, test, govern, and enhance APIs efficiently.
- **Prompts library**
  The API Agent prompts library provides a comprehensive guide on using prompts to complete various tasks.
- **Troubleshooting**
  You can resolve common issues with API Agent in Visual Studio Code, such as authentication errors or missing source IDs.
- **Known limitations**
  During the public preview phase, API Agent has limitations for new chat sessions, chat interface settings, and login behavior.

API Agent user roles

The user roles and permissions for IBM® API Connect govern the actions that users can complete in API Agent.

The following roles and permissions are introduced to control who can use API Agent.

- The `Api-Agent` permission is introduced to enable the use of the Visual Studio Code plug-in.
- The `API Agent User` role is added with `Api-Agent` permission and all permissions from the `Viewer` role.
- The `Api-Agent` permission is also included in the `Owner` and `Administrator` roles, which contain all permissions.

User roles and permissions

The following tables describe the API Manager UI user permissions and roles.

Table 1. User permissions

Permission	Action	Permitted actions
Settings	View, Manage	View and configure the API Agent sources.
API Agent	API Agent	Use the Visual Studio Code plug-in.

Table 2. User roles

Role	Permission	Permitted actions
Owner and Administrator	All	Configure the API Agent sources and use the Visual Studio Code plug-in.
API Agent User	API Agent and Viewer	Use the Visual Studio Code plug-in.

Configuring

By default, API Agent is disabled and must be enabled before you can use its capabilities. To enable API Agent, you need to first enable the IBM managed watsonx.ai. After enabling watsonx.ai, you need to configure API Agent.

Setup and enablement

To streamline the experience, IBM manages various API Agent dependent services required for the API Agent functionality.

These include:

- watsonx.ai IBM Cloud settings for use of Granite models required by the API Agent
- IBM Code Engine for deployment of applications
- IBM connector pack runtime for running deployed applications

The following topics provide full details for configuring API Agent.

- **Watsonx.ai settings**
  The watsonx.ai service is required to support intelligent features across IBM® API Connect, including API Agent and other capabilities.
- **API Agent settings**
  The API Agent settings allow you to work with IBM Code Engine for deploying applications.
- **API Agent sources**
  You can manage API Agent sources such as catalogs and application sources.
- **Secure communication between Visual Studio Code plug-in and API Connect**
  Certificates are used by API Agent to establish a secure connection between the Visual Studio Code plug-in and API Connect. For API Connect installations using trusted CA-signed certificates, no additional certificate-related configuration is required. The steps in Option 1 and Option 2 apply only to API Connect deployments that use self-signed or non–publicly trusted CA certificates.
- **MTLS for connectivity pack applications**
  Enable Mutual Transport Layer Security (MTLS) for connectivity pack applications to ensure secure communication between the client and server using mutual authentication and encryption.

Watsonx.ai settings

The watsonx.ai service is required to support intelligent features across IBM® API Connect, including API Agent and other capabilities.

Before you begin

For software or on-premises installations, first enable API Agent on the management CR before you configure watsonx.ai settings. For more information about enabling API Agent, see Enabling API Agent settings.

About this task

Add your watsonx.ai credentials to enable the API Agent. Within API Agent, watsonx.ai provides access to a language model and is essential for enabling the agent to perform tasks such as tool selection, planning, and summarization, as well as powering tools that generate APIs and support design and development workflows.

Procedure

1. Log in to API Manager.
2. On the Settings page, select the AI tab and then click Add.
3. If you are configuring for the first time, click Add. If you previously configured, click Edit to modify the existing configuration.
4. In the Add watsonx.ai configuration dialog box, enter the details and then click Done:
   Note: You can enable watsonx.ai from the IBM Cloud and Software tabs.
   a. In the Name field, enter the configuration name.
   b. From the URL list, select the URL.
   c. In the Authentication field, enter an IBM Cloud API key or bearer token that has the correct permissions to use the foundation models that are provided by watsonx.ai.
   d. In the Environment field, enter your project ID or deployment space ID that is associated with your watsonx.ai service.
5. Optional: To verify the connection, click Test.
6. To use your watsonx.ai credentials as the default one for API Agent, select Set as default.
   Note: By default, Granite is selected as the large language model. If needed, you can switch to Llama.

API Agent settings

The API Agent settings allow you to work with IBM® Code Engine for deploying applications.

Before you begin

Enable API Agent on the management CR before you configure the API Agent settings. For more information about enabling API Agent, see Enabling API Agent for the management subsystem.

Procedure

To configure the API Agent settings, complete the following steps:

1. Log in to API Manager.
2. On the Settings page, click the API Agent tab, and then click Configuration.
3. If you are configuring API Agent sources for the first time, click Configure. If you previously configured API Agent sources, click Edit to modify the existing configuration.
4. To use your credential as the default credential for API Agent, from the API Agent Configuration dialog box, under the API Agent status section, set Disabled to Enabled, and then click Save.
5. Optional: Enable the Code Engine settings.
   a. In the API Agent Configuration dialog box, expand Code engine (Optional), and click Add. For more information about how the deployment works, see Code deployment tool.
   b. In the Add Code Engine dialog box, enter the following details:

      API key:
      : The IBM Cloud® IAM API key.

      Resource group:
      : The name of the resource group in which the Code Engine service is attached.

      Registry namespace
      : Create a namespace in the IBM cloud registry for the Code Engine service to push and retrieve build images.

   c. To use your API Agent credentials as the default credential for API Agent, set Enable user managed code engine to Enabled and then click Save.
   d. In the Configuration API Agent dialog box, click Save.
   e. To disable, update, or delete the Code engine settings, expand Code engine (Optional), and then select the Overflow menu.

API Agent sources

You can manage API Agent sources such as catalogs and application sources.

Overview

You can manage the API Agent sources in API Connect by clicking Settings > API AgentSources.

Sources that are added to the API Agent sources repository are indexed and stored as numerical representations of objects called **`embeddings`** in a vector database. You can search for APIs in the context of API Connect, and for schemas, tables, or columns in the context of application sources.

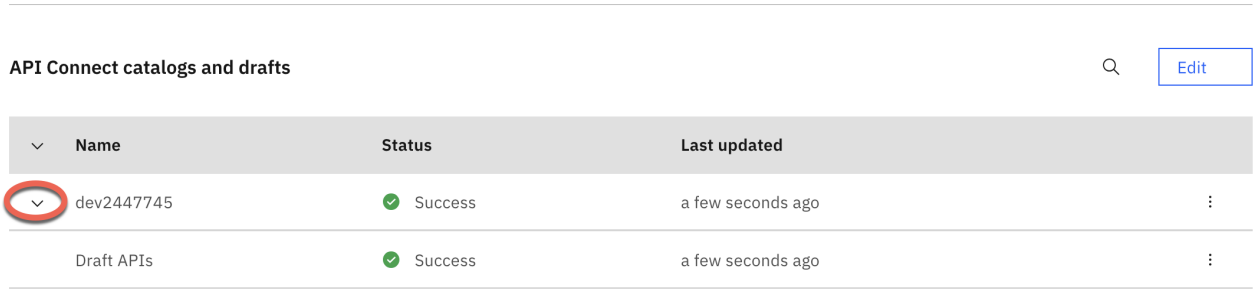
- The API Connect sources tab displays the list of API Connect catalogs and drafts of the provider organization that you are logged in to. Expand the provider organization name to view the list of catalogs that are added as API Agent sources. For more information, see API Connect catalogs and drafts.
- The Applications tab displays the list of application sources that are configured for API Agent. You can also edit the connection and application objects so that the users of the Visual Studio Code extension can search for schemas, tables, and application objects. For more information, see Application sources.
- Use the Documents tab to upload files in PDF or Markdown format. The uploaded documents help the API Agent search and provide relevant information in the chat interface.

The following topics provide details about how to add and remove sources such as catalogs and database tables for API Agent.

- **API Connect catalogs and drafts**
  You can configure catalogs and drafts for API Agent so that you can search for APIs.
- **Application sources**
  You can add, edit, or refresh application sources to store them in a vector database as embeddings so that the API Agent can search for APIs.

API Connect catalogs and drafts

You can configure catalogs and drafts for API Agent so that you can search for APIs.



About this task

The API Connect catalogs and drafts section shows the catalogs and drafts that are configured for API Agent use. By default, Drafts and Sandbox are added once the API Agent is enabled. Also, you can add more catalogs from your provider organization. You can search for APIs in the drafts and specified catalogs.

Procedure

To add a catalog, complete the following steps:

1. In API Manager, click Settings > API Agent > Sources.
2. In the API Connect sources tab, click Edit.
3. To add or remove a catalog, select or clear the checkbox against the respective catalog.
   Note: You cannot remove the Sandbox catalog.
4. Click Save, then expand the provider organization list to view the updated catalog list.

5. To edit the catalog, click the overflow menu, then click Edit catalog list.
6. To manually refresh the catalog list, click the overflow menu, then click Manaul Refresh.
7. To auto-refresh the catalog list, click the overflow menu, then click Auto refresh settings.
   Note: If search results do not update automatically, refresh the page manually.
8. To enable Discovery tool, set the switch to On.

Application sources

You can add, edit, or refresh application sources to store them in a vector database as embeddings so that the API Agent can search for APIs.

About this task

You must have administrator and API Agent user permissions to view the API Agent tab and access the API Agent sources page. For more information, see API Agent user roles .

You can do the following actions to configure the list of application sources under each application objects:

- Adding an application source
- Editing object list
- Manual refresh
- Auto refresh
- Editing connection
- Removing application sources

Procedure

- To add a application sources, you need to provide the necessary connection information for the application, including a name, location, and credentials. After you provide the connection information, the system add an application source to make available for use in your APIs. To add an application source, complete the

following steps:

1. In API Manager, click Settings > API Agent.
2. In the Application sources section, click Add.
   Note: API Agent now supports usage of multiple applications.
3. In the Application connection page, select the required application and enter the necessary details, and then click Next.
4. In the Application objects page, select the objects, and then click Next.
5. Optional: To create auto refresh settings, set Auto Refresh to On.
6. Select the required auto refresh frequency, and click Add.

- To modify the object list, complete the following steps:
  1. In API Manager, click Settings > API Agent.
  2. In the Application sources section, click overflow menu, then click Edit object list.
  3. In the Edit objects page, select the checkbox to add or remove the object.
  4. Click Save.
- To reflect any changes that were made in the backend, the Refresh option updates the application source. For example, if you added or deleted any fields in the object list, refresh the object to show the most recent updates. To refresh the application, click overflow menu, then click Refresh.
- To auto refresh, complete the following steps:click overflow menu, then click Auto refresh settings.
  1. Click overflow menu, then click Auto refresh settings.
  2. In the schedule refresh dialog box, set Auto Refresh to On.
  3. Select the refresh frequency, and then click Save.
- To edit the fields in the Application connection window, use the Edit connection option and complete the following steps:
  1. In API Manager, click Settings > API Agent.
  2. In the Application sources section, click overflow menu, then click Edit connection.
  3. In the Application connection page, update the connection details as necessary.
  4. Click Next.
- When you remove an application source, you remove it from the API Manager UI and from the backend, which means that the data is inaccessible. To remove an application source, complete the following steps:
  1. In API Manager, click Settings > API Agent.
  2. In the Application sources section, click overflow menu, then click Remove.

Secure communication between Visual Studio Code plug-in and API Connect

Certificates are used by API Agent to establish a secure connection between the Visual Studio Code plug-in and API Connect. For API Connect installations using trusted CA-signed certificates, no additional certificate-related configuration is required. The steps in Option 1 and Option 2 apply only to API Connect deployments that use self-signed or non–publicly trusted CA certificates.

Option 1: Ignore certificate errors

1. Run the following command to start the Visual Studio Code editor:

   ```
   code
   ```

2. Exit all existing open Visual Studio Code applications if any are open.
3. Open a terminal command prompt.
4. Go to the directory that you want to open in Visual Studio Code and run the following command:

   ```
   code . --ignore-certificate-errors
   ```

   This command opens the current directory in Visual Studio Code and ignores any certificate errors.

Option 2: Add the root CA certificate to the trusted list

1. In the settings for Visual Studio Code editor, set `http.systemCertificates: true`. The default value is true. Ensure that it is set to true.
2. Add the root CA certificate to the trusted list on the system that has the Visual Studio Code plug-in. The steps vary depending on the operating system.

- For macOS, complete the following steps:
  1. Copy the root CA certificate to the system.
  2. To open the Keychain Access application, press Command + Space.
  3. From the left side menu bar, select System.
  4. Drag the certificate to add the saved certificate to the system certificates. In the list of certificates, the root certificate that was added is displayed with a red error.
  5. Double-click the name of the certificate, which opens a new window. Expand the Trust section.
  6. In When using this certificate, select Always Trust.
  7. To add the certificate to the list of trusted certificates, close the window.
- For Linux®, complete the following steps:
  1. Copy the root CA certificate in PEM or DER format to the system.
  2. Run the following commands:

     ```
     sudo cp apic-dev-internal-root-ca.crt /etc/pki/ca-trust/source/anchors/
     ```

     ```
     sudo update-ca-trust
     ```

- For Ubuntu, complete the following steps:
  1. Copy the root CA certificate in the PEM or DER format to the system.
  2. Run the following command to create a directory:

     ```
     sudo mkdir -p /usr/local/share/ca-certificates
     ```

  3. Run the following command to copy the certificate file to the directory:

     ```
     sudo cp cert_file.crt /usr/local/share/ca-certificates
     ```

4. Run the following command to update the system's truststore :

   ```
   sudo update-ca-certificates
   ```

5. Verify that the certificate is in the `/etc/ssl/certs/ca-certificates.crt` file.

- For Windows, see the Windows documentation to use Microsoft Management Console (MMC) to add the certificate.

MTLS for connectivity pack applications

Enable Mutual Transport Layer Security (MTLS) for connectivity pack applications to ensure secure communication between the client and server using mutual authentication and encryption.

Before you begin

To enable MTLS, you are required to modify the generated Connectivity Pack code. Initially, you must adhere to the instructions outlined in the Enable MTLS, and upon completing these steps, you can proceed with the following steps.

Procedure

To enable MTLS, complete the following steps:

1. Run the following command to generate a FastAPI server for a connector pack application:

   ```
   Generate a FastAPI server for a connector pack application.
   ```

   Note: Use the OAS Creator tool to generate the input OpenAPI.
2. Extract the generated code file and open the client libraries configuration file. You can find the file in this path: `app-code/src/openapi_client/configuration.py`.
3. Add the following functions to the Configuration class:

   ```
   def set_ca_cert(self):
      filename = os.path.join(
         os.path.dirname(os.path.dirname(__file__)),
         "/tmp/certs/tls.crt",
      )
      return filename

   def set_tls_key(self):
      return os.path.join(
         os.path.dirname(os.path.dirname(__file__)),
         "/tmp/certs/tls.crt",
      )

   def set_tls_cert(self):
      return os.path.join(
         os.path.dirname(os.path.dirname(__file__)),
         "/tmp/certs/tls.crt",
      )
   ```

   The directories set for each of these functions must be pointed at the certificates you created earlier during secret creation, which you must download to your local file system, For more information, see Create secrets.

4. Update the following in the Configuration classes `__init__` definition:

   ```
   self.ssl_ca_cert = self.set_ca_cert()
   self.cert_file = self.set_tls_cert()
   self.key_file = self.set_tls_key()
   ```

Using API Agent

You can use API Agent for end-to-end API publishing and testing. What follows here are sections with details about what to expect when using the API Agent plug-in and a sample end to end flow scenario, which you can walk through to get an understanding of how the agent works and the capabilities available in the agent.

Administrators can assign appropriate roles to enable API Agent for specific developers within their organization. This selective enablement ensures that the tool is used effectively within the right context. After the admin configures the sources, developers can install the Visual Studio Code plug-in and start integrating it into their workspace. For more information, see the API Agent user roles section.

Best practices

The API Agent extension is a tool that is used in Visual Studio Code to assist with API management. To ensure proper functions, it is essential to have the extension window at full height and at least 1/3 width of the window.

Understanding prompts in the documentation

When you see a command in documentation, it's essential to understand how to use it correctly.

1. If a command contains a placeholder, such as `[apiName]`, you need to replace it with your own text. For example,

   - Command: `Run test cases for [apiName]:[version]`
   - Replacement: `Run test cases for bookshop-api-3:1.0`

   Note: Ensure that you replace `[apiName]` with the actual name of your API to run the command.

2. To populate the placeholder, such as `[@file]`:

    - The document might have the following prompt: `remediate api [@file] using spectral-owasp ruleset`. Replace it with `remediate api @bookstore.yaml using spectral-owasp ruleset`.

    To replace `[@file]`, you need to trigger the `@` symbol to access the files in your Visual Studio Code workspace. Then, select the wanted file to upload to the agent.

To start a new session

To keep the session active, you need to clear out any temporary or residual data that might be causing problems, and then refresh the system to ensure that it is in an updated state.

To keep the session active and refresh, complete the following steps:

1. Enter CMD + SHIFT + P to open the Visual Studio Code command palette.
2. In the command line, enter `Developer: Reload window`.
3. In the command line, enter `API Agent: Logout`.
   Note: This command removes your login session but you need to do the authentication process again. However, the login information (pOrg, login URL, and more) is still cached
4. To remove all cached login information after logout, in the command line, enter `API Agent: Clear session from workspace state and reload`.
   Note: When a plug-in is deleted or deactivated in Visual Studio Code, the cached login information persists. This means that when you again download the plug-in, the URL field is populated with your last used URL.

Debugging process

For debugging purposes, there are two areas to explore in the Visual Studio Code command palette.

To view the Visual Studio Code side of the extension, complete the following steps:

1. Enter CMD + SHIFT + P to open the Visual Studio Code command palette.
2. In the command line, enter `Show Output Channels`, and select the command from the list.
3. In the output channels list, select `API Agent Debug Logs`.
4. Visual Studio Code extension displays the following information:
    - Login and session data.
    - Reinitialization of the extension after changing tabs.

To view the chat webview side, complete the following steps:

1. Enter CMD + SHIFT + P to open the Visual Studio Code command palette.
2. In the command line, enter `Developer: Open Webview Developer Tools`, and select the command from the list.
3. You can view the webview developer tools, where you can access the following information:
    - Console tab: view logs and console output
    - Network tab: inspect REST calls being made

Attaching and downloading Files

To attach and download a file, complete the following steps:

1. To attach a file, you must trigger the file menu by typing `@` and then selecting the file.
   Note: The maximum file size is 1 GB, and the filename must not contain any spaces or special characters.
2. If you copied and pasted a command like `validate api @testapi.yaml`, delete back to the base command `validate api` and retype the `@` to trigger the file menu.
3. Select a file from the file menu that appears after typing `@`.
4. When a next action button includes a reference to a file, for example, `remediate api [@file] using spectral-owasp ruleset`, you must replace `[@file]` with a newly attached file by triggering the file menu with the `@` symbol.
5. To delete the file name in the command line, delete the command and reenter `validate api`.

API Agent reload and logout issues

- If you do not use your chat for a while, the token used with API Connect expires during this time and if you continue to have a conversation, it displays an `Error: Unauthorized` and auto log you out. You need to do the login process again.
- To properly clear out resources, you must use the logout option within the plug-in rather than the Visual Studio Code managed sign-out option.
  Important: The API Agent plug-in is renamed from API Assistant. If you have the old version, delete it before downloading the new one.

Using different stack or login with different user on the same stack

After logging out of one stack or user, clear the session from the workspace state, the API Agent might use outdated information when switching to another, resulting in persistence problems.

To resolve this problem, complete the following steps:

1. Log out of the current stack or user.
2. In the Command palette, run the following command:

   ```
   API Agent: Clear session from workspace state
   ```

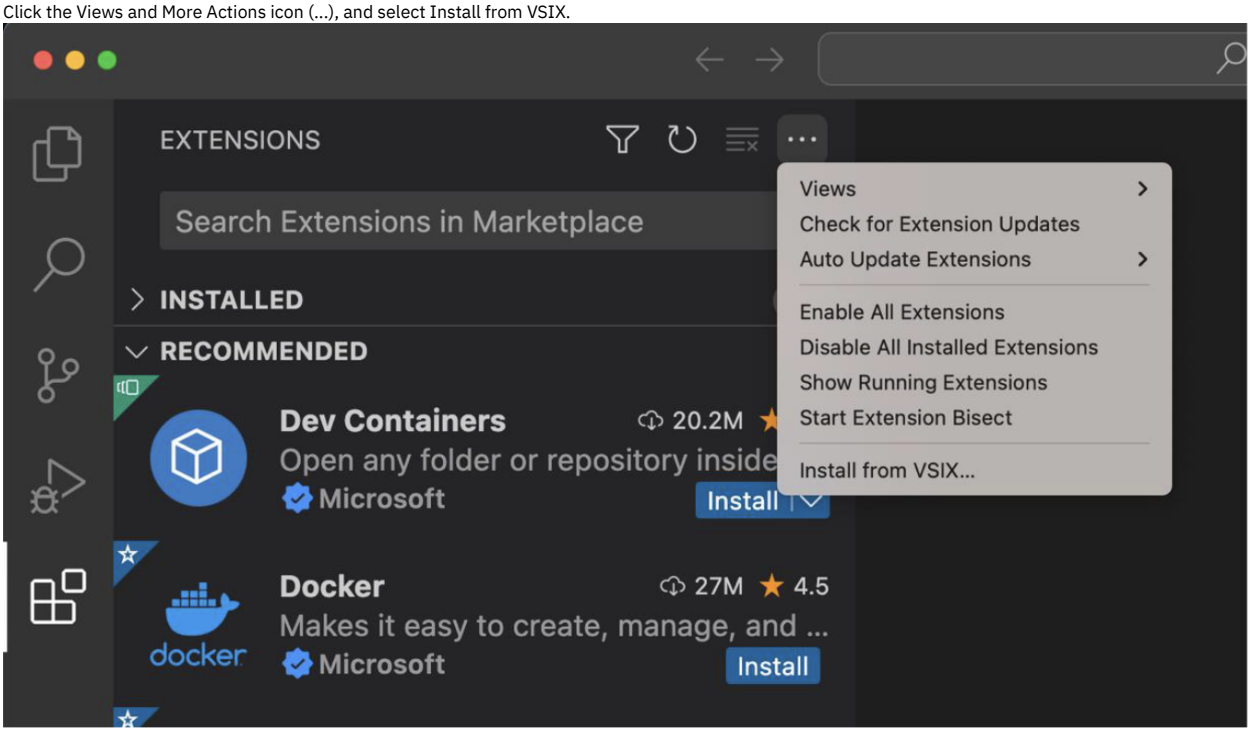
3. Reload the page.
4. Log in with the new stack or user.

- **Getting started**
  To install API Agent, download and install the Visual Studio Code plug-in. Then, you can log in to API Agent in Visual Studio Code using the URL for API Connect.
- **API Agent overview**
  An overview of the API Agent user interface and its key components.
- **Uninstalling API Agent**
  Uninstall API Agent from Visual Studio Code to remove it from your Extensions list.
- **Searching APIs and tables**
  Searches across API endpoints and database tables to return detailed metadata, including source location and specifications. Supports filtering by OpenAPI versions and API types, and presents results in clean, markdown-formatted tables for easy readability.

- **Creating an OpenAPI document from an existing source**
  You can use the API Agent to quickly generate an OpenAPI document from an existing database table or an IBM connector pack-based application. The generated OpenAPI document is in YAML format and can be used for API development, testing, and publishing.
- **Generating python code from an OpenAPI**
  API Agent helps you to generate Python code from an OpenAPI specification, deploy the generated code to IBM Code Engine, and update the source OpenAPI document to reflect the Code Engine application URL after deployment.
- **Deploying application to IBM Code Engine**
- **Creating, publishing, and testing a draft API**
  Use the API Agent to create, publish, and test a draft API from an existing OpenAPI document. The tool guides you through selecting a file, publishing to the Sandbox catalog, and running test cases, helping you validate your API before deployment.

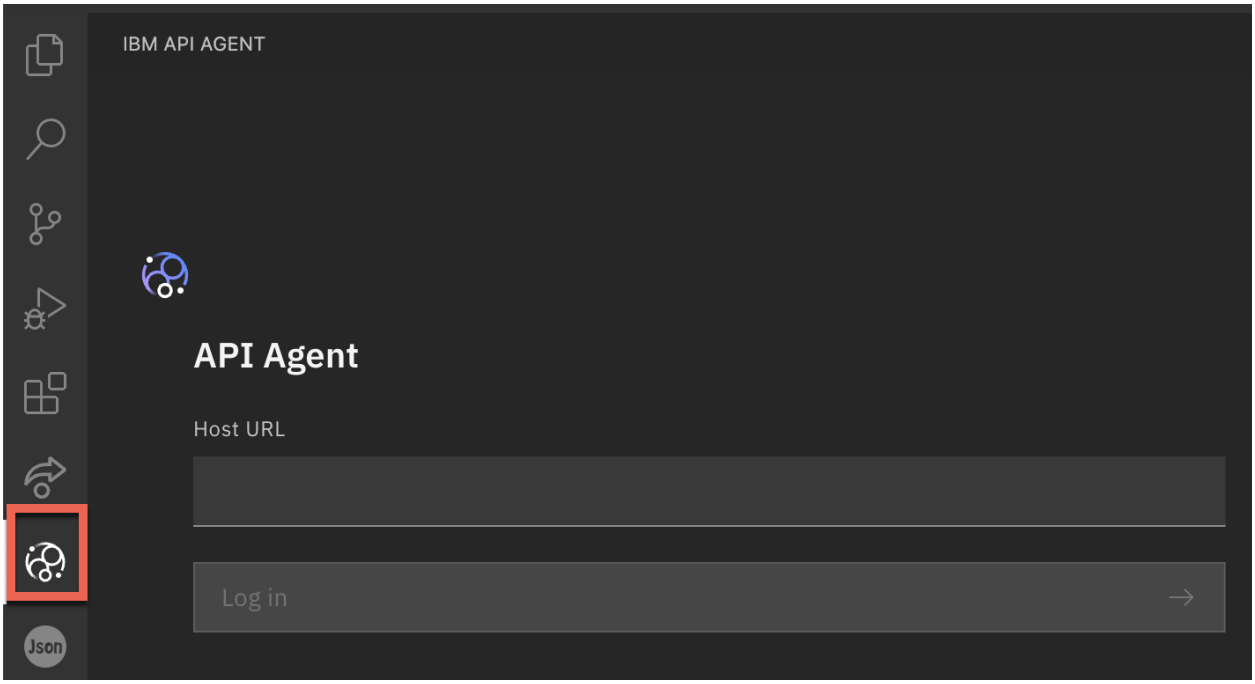
Getting started

To install API Agent, download and install the Visual Studio Code plug-in. Then, you can log in to API Agent in Visual Studio Code using the URL for API Connect.



Before you begin

Ensure that the following tools are installed on your system:

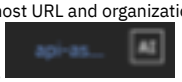


- Visual Studio Code
- Homebrew
- Python
- PostgresSQL

Procedure

- Install the API Agent plug-in in Visual Studio Code to automate tasks with natural language prompts. This setup helps you streamline API development by generating specs, tests, and code directly from API Agent. To install API Agent in Visual Studio Code, complete the following steps:
  1. Log in to API Manager
     Note: The `<environment short id>` value varies. Copy the value from the browser URL when you are logged in to your IBM® webMethods Hybrid Integration account.
  2. On the API Manager home page, click Tools for download in the More section.
  3. In the Tools for download window, click the API Agent tab.
  4. Click Download next to the Step 1: Download Visual Studio Code plug-in for API Agent.
     Note: Downloading the `.vsix` file might take a few minutes.
  5. Open Visual Studio Code.
  6. In the left panel, open Extensions.
  7. Click the Views and More Actions icon (...), and select Install from VSIX.

  8. Open the folder where you downloaded the plug-in, and select the api-agent-vscode-plugin-0.0.1-*<build_number>*.vsix file, and then click Install. You can view the API Agent icon on the left panel.



9. To upgrade the API Agent plug-in, repeat steps 1-8 and install the recent .vsix file.
   Note: Ensure that the .vsix file is the recent version.

- Log in to API Agent in Visual Studio Code to begin prompt-based automation for API development. To log in to API Agent, complete the following steps:
  1. Open Visual Studio Code.
  2. Click the API Agent icon.
  3. In the Host URL field, enter the API Manager URL and then click Log in.
     Note: The Host URL is the fully qualified hostname or IP address. Contact your administrator for the appropriate URL.
  4. Click Allow to sign in and then select Open when prompted.
  5. On the browser, if you are not automatically redirected, select use this link and then in the Visual Studio Code, click Open.
  6. Select a Provider organization, and click Continue.
  7. To start a new chat session or to logout, click the IBM API Agent menu and select one of the following options:

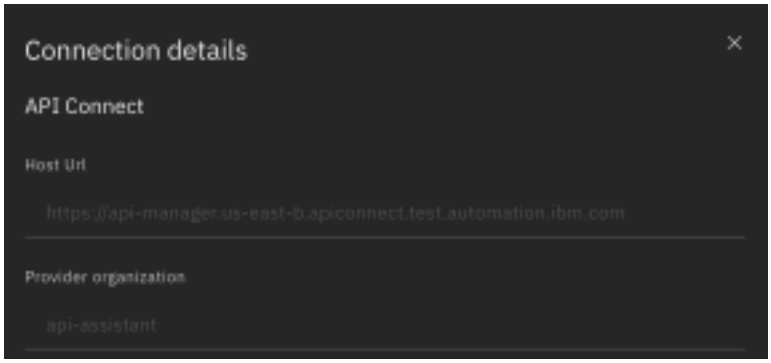
     New chat
     : Starts a new chat session. In this public preview, previous chat sessions are not accessible. For more details, see Limitations.

     Logout
     : Logout from API Agent.

  8. To view the host URL and organization information, in the upper-right corner of the window, select your organization.

     For example, 

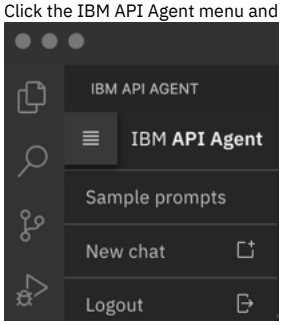
API Agent overview



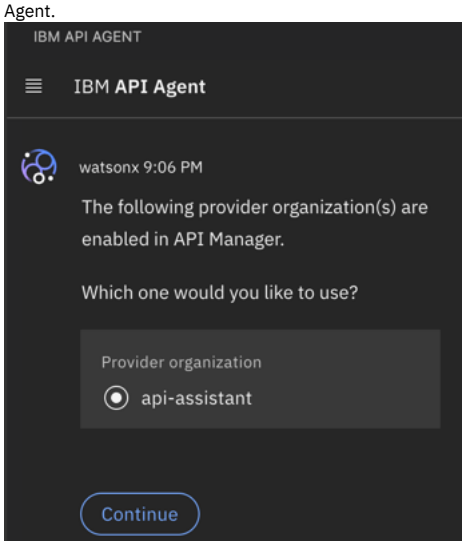
An overview of the API Agent user interface and its key components.

This page assumes you have already logged into API Agent. If you need help logging in, see Getting started.
Note: The actual look and feel of the images might differ slightly because updates are made regularly. Additionally, local Visual Studio Code themes and UI customizations can affect the appearance.

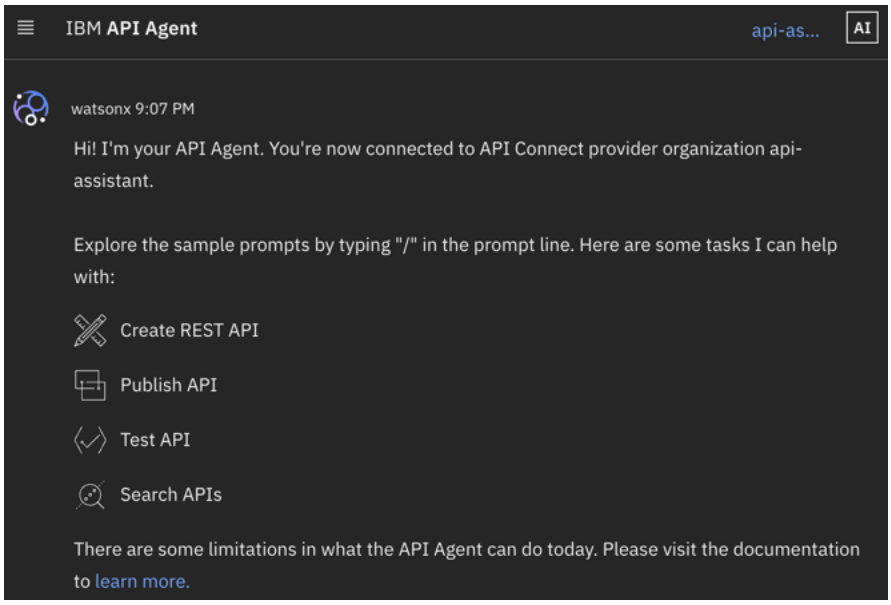
Connection details



After you log in, you can view your connection details at the upper-left bar. You can click on the text to the left of AI to access more specific information, which includes the API Connect management URL and your provider organization.



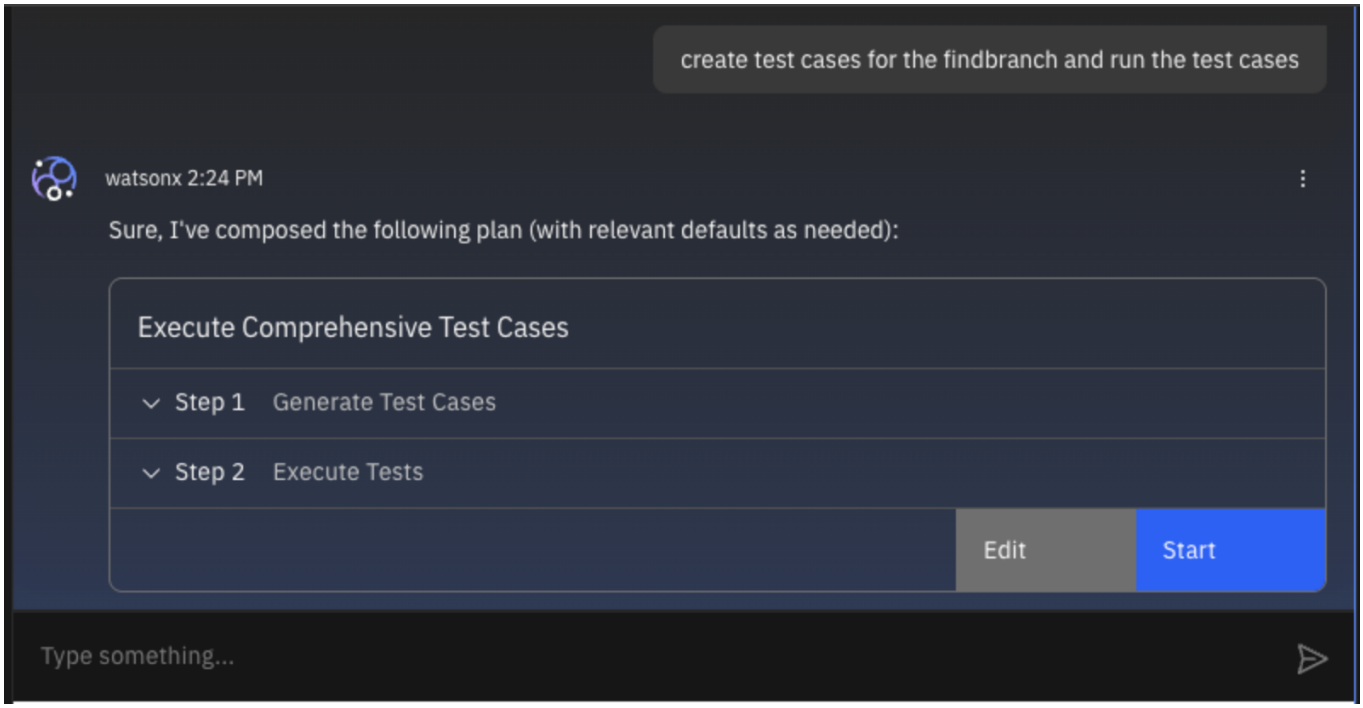
New chat



1. Click the IBM API Agent menu and select New chat to start a new session.

2. Select a provider organization. You must already be a member of this organization, and the API Agent must be enabled there for you. This allows you to use the API Agent.

3. Click Continue. A welcome message is displayed.

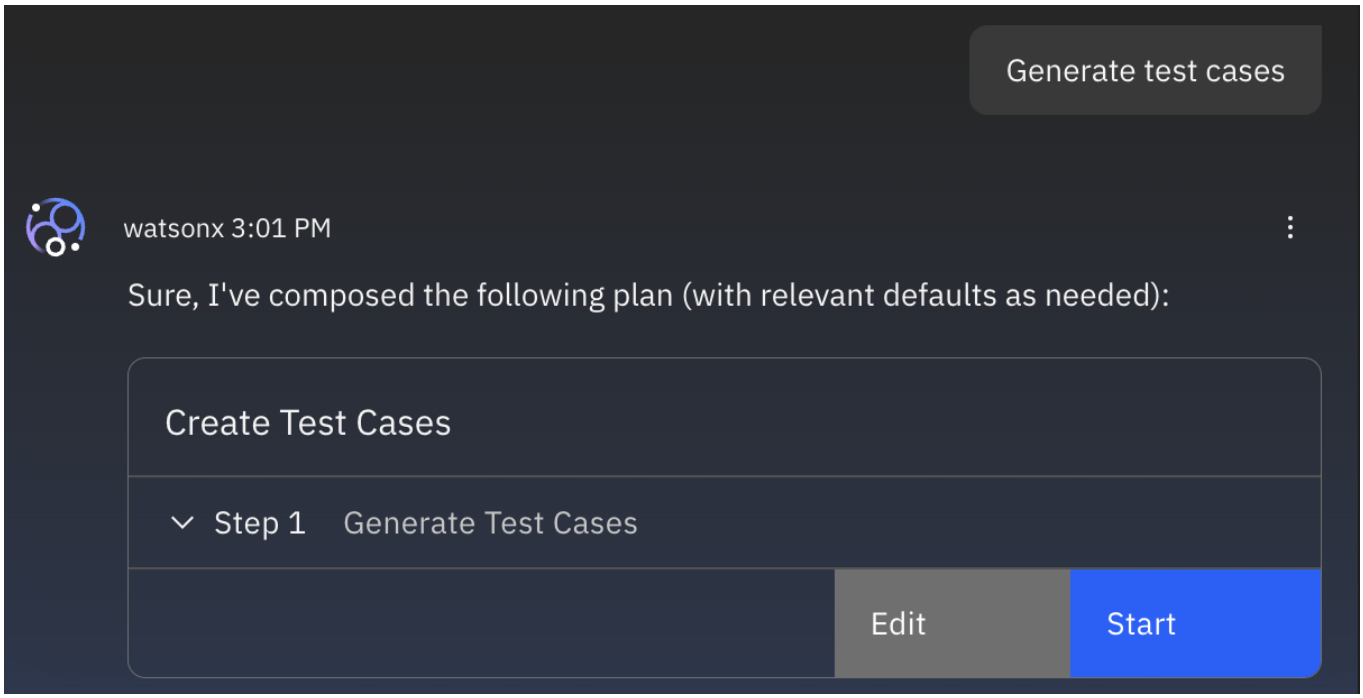


4. In the Type something field, enter text to start interacting with API Agent.

Plan

After you input a command, the API Agent displays or runs a plan, which is a series of tools each with its corresponding arguments, that is designed to fulfill the user request.

- Plans that do not modify the system (read-only operations) are executed automatically and do not require user approval.
- Plans that modify the system state (such as creating, updating, or deleting resources) requires explicit user approval before execution.



The following example shows the plan for user message of `create test cases for the petstore api and run the test cases`.

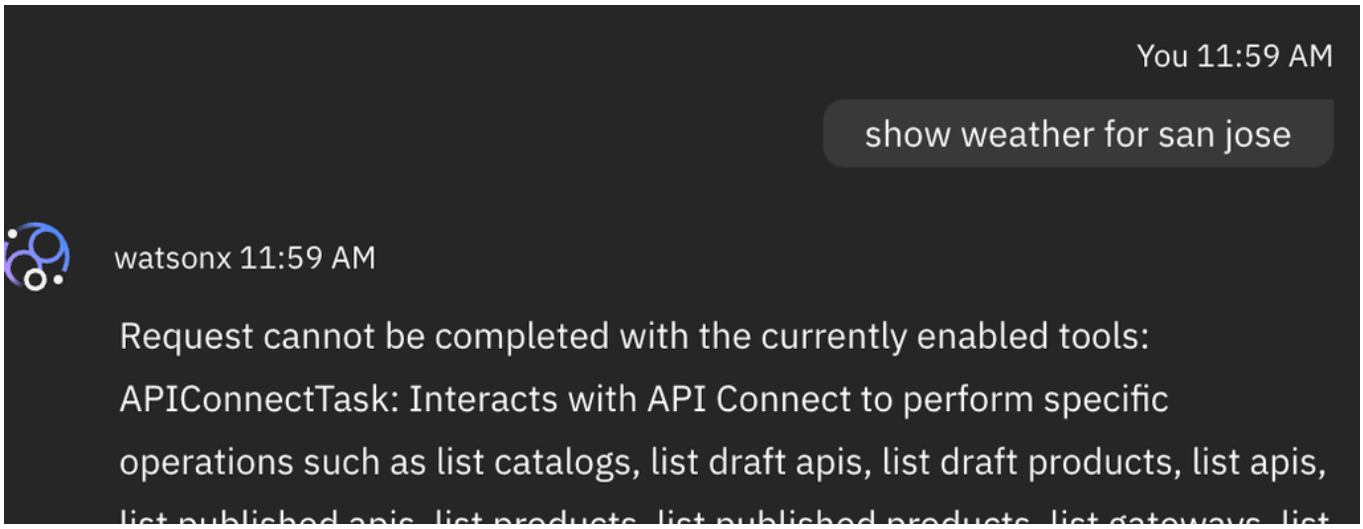
Viewing and editing the plan

After a plan is displayed, you can view and modify the suggestions for each tool. If the default suggestions that are provided by the API Agent are satisfactory, you can approve them and continue.

To make any changes, select Edit plan to open the Edit plan window, where you can make changes to the values.

Approval

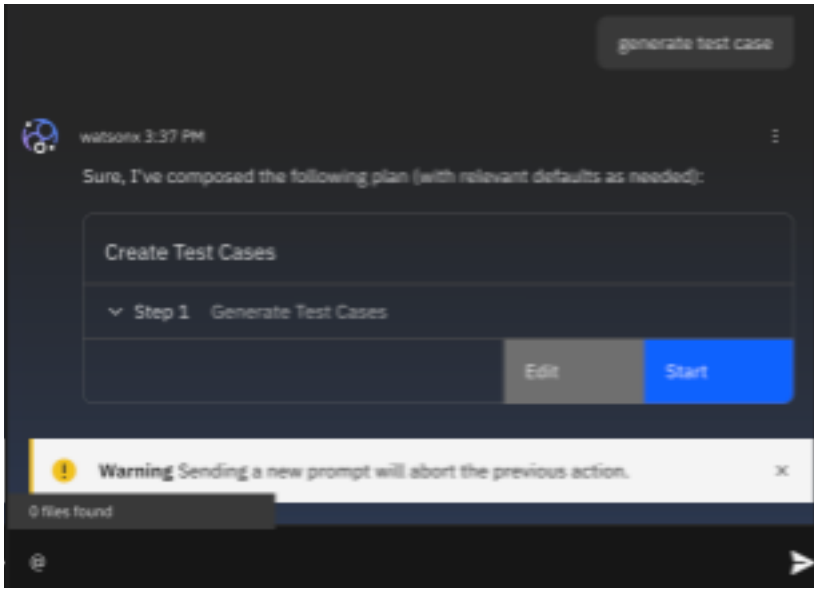
User approval is required to execute any tool that makes changes to the system state. These tools cannot be run without explicit user consent.



Understanding responses

Each response is a result that is displayed for the execution of a single tool. It includes a summary, expand the arrow option to view a detailed system response.

After you click Approve, the tool runs, and displays a response. The following is an example of a successful run.

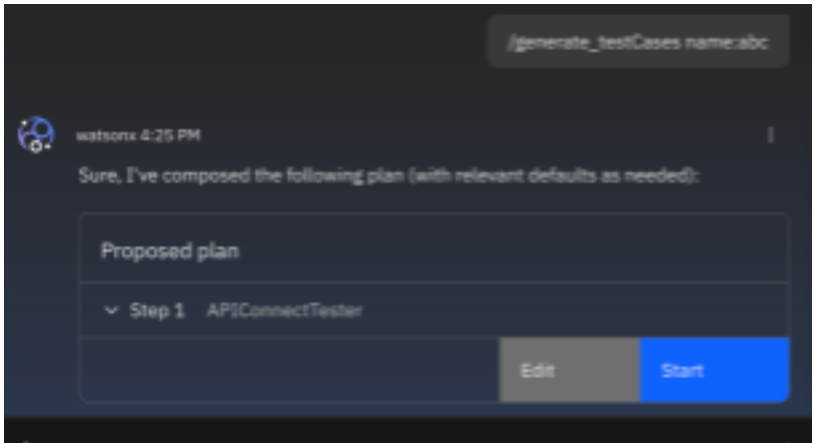


Errors

If your prompt requests an action that the API Agent cannot perform because the system lacks the appropriate set of tools for the request. The API Agent states that the request cannot be completed with the current tools. It will then list the available tools and their brief descriptions. Any other errors are execution errors of the tools. In such cases, the API Agent provides a summary of the error that was encountered during the tool's run time.

Aborting

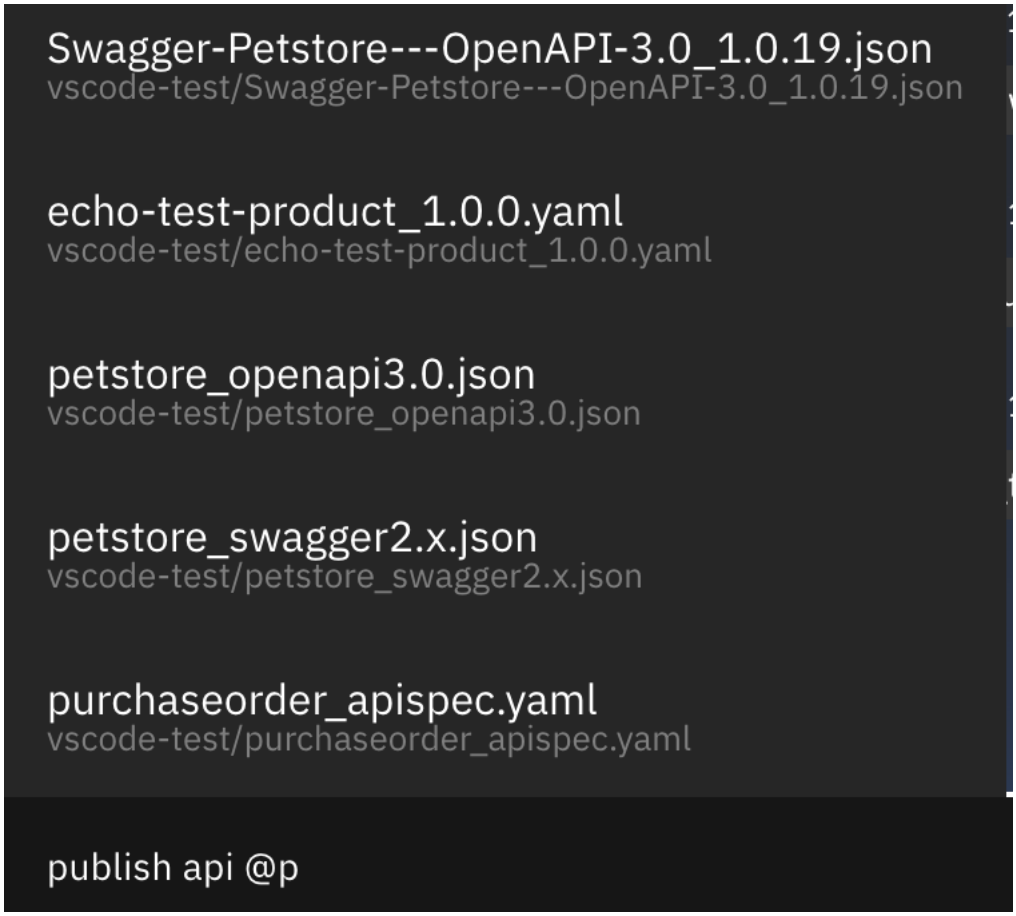
You have the option to disregard the generated plan and initiate another request. If you choose to do so, the previous prompt and action are disregarded.



Commands

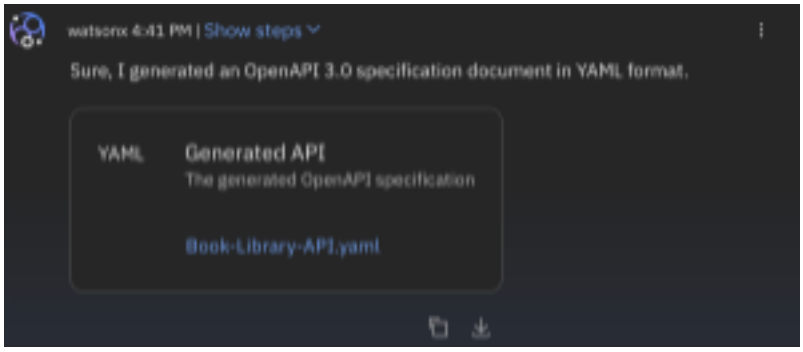
You can run some of the available tools directly by using ***/commands***. If you start typing forward slash (/), you can view the list of available commands.

To pass parameters, you have to give values in **`key:value`** format. Space is allowed before value, which makes it easier to specify file to upload. The following is an example of using /command.



Uploading and downloading files

Some commands need files to be uploaded. The file must be in your Visual Studio Code workspace for uploading.



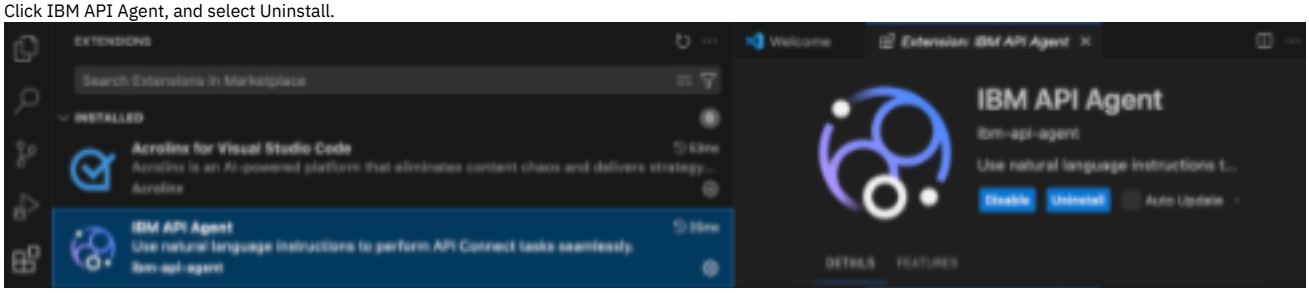
Entering `@` in the Type something field displays a list of available files. As you input characters, the list is filtered accordingly. You can select a file at any point during this process.

Where the **`@file name`** is listed, you can upload a file from the local workspace.

Whenever **`api_name`** is mentioned, you can use it with **`id`**, **`name:version`**, or the name of a **`draft API`**. Using just the name is acceptable as long as there is only one draft API with that specific name. However, using the title of an API is not permissible. The same guidelines apply when **`product_name`** is mentioned.

Some commands allow you to download files from the response, which is indicated by a download icon.

Uninstalling API Agent



Uninstall API Agent from Visual Studio Code to remove it from your Extensions list.

About this task

To uninstall API Agent, complete the following steps:

Procedure

1. Open Visual Studio Code, and go to the Extensions panel.
2. In the Search Extensions in Marketplace field, enter `IBM API Agent`.
3. Click IBM API Agent, and select Uninstall.

Searching APIs and tables

Searches across API endpoints and database tables to return detailed metadata, including source location and specifications. Supports filtering by OpenAPI versions and API types, and presents results in clean, markdown-formatted tables for easy readability.

About this task

To search for existing APIs or tables, complete the following steps:

1. Log in to API Agent. For more information, see Getting started.
2. To search for APIs or tables, enter the required prompts and click Send. The Artifacts Searcher tool communicates with the API Agent sources.
   The following table lists sample prompts to search for APIs and tables related to purchase order.

Prompt	Result
`Search for any APIs related to purchase order`	Searches and displays any available APIs.
`Search for table related to purchase order`	Searches and displays the table.

Note: For more information on available prompts and their usage, see Prompts library.

Creating an OpenAPI document from an existing source

You can use the API Agent to quickly generate an OpenAPI document from an existing database table or an IBM connector pack-based application. The generated OpenAPI document is in YAML format and can be used for API development, testing, and publishing.

Procedure

1. Log in to API Agent. For more information, see Getting started.
2. Enter a prompt to create an OpenAPI document from an existing database and click Send.

For example,

- `Create an openapi with the table orders`
- `Create an openapi with the table orders and schema purchase_order`

Note: The schema name is not mandatory, but it becomes necessary if the table name is not unique.
The OAS Creator tool communicates with the API Agent sources and displays the proposed plan.

3. To view the results, click Start. The API Agent generates the OpenAPI document in YAML format.
4. Click download to save the YAML file.
5. To view the downloaded YAML file, open Explorer in the left panel of the Visual Studio Code.

Generating python code from an OpenAPI

API Agent helps you to generate Python code from an OpenAPI specification, deploy the generated code to IBM Code Engine, and update the source OpenAPI document to reflect the Code Engine application URL after deployment.

About this task

Use API Agent to generate Python FastAPI server code based on your OpenAPI Specification 3.0. For more details about how to generate the Python FastAPI server code, see OpenAPI Python Generator tool.

The following steps gives you a single scenario flow example of how to create server code for a database CRUD server.

Procedure

To generate a Python code, complete the following steps:

1. Log in to API Agent. For details, see Getting started.
2. Enter the following prompt, and click Send:

   ```
   Generate some Python FastAPI server with database interaction code based on the following openapi @
   ```

   and select the required file, for example, `order_apispec.yaml`.
   Note: Entering @ after the prompt displays a list of OpenAPI documents available in your workspace.
3. Click Send. The OpenAPI Python Generator tool communicates with the API Agent sources and displays the proposed plan.
4. Click Start to begin code generation. Once complete, you can view a brief summary of the next steps that are required to download the generated code as well as how to run and deploy it.
5. Click the download icon to save the ZIP file containing the code.
6. In Visual Studio Code, open the Terminal and run the following command to extract the downloaded file into a folder, for example, `app-code`.

   ```
   unzip PostgreSQL-order-python.zip
   ```

7. Open the `README.md` file to view the instructions on how to get started with the downloaded code. The `README.md` provides detailed information on how to build, install, customize, and deploy the application.
8. Enter the following prompt to deploy zip up the generated folder (ensure that your credentials are filled in):

   ```
   zip -r code.zip app_code/
   ```

   Note: The file size must be less than 1MB. Remove the `venv/` folder before zipping your code and deploying.
9. The next action suggested:

   ```
   Deploy the application code from code.zip
   ```

   Note: If the next planned action is to deploy the generated Python FastAPI server application to IBM Code Engine using the Code deployment tool, ensure that the source OpenAPI document from which the application was generated is updated after deployment to reflect the Code Engine application URL as the value of `servers[0].url`. This step is crucial if the subsequent planned action is to create a draft API and publish it in API Connect using the API Connect Task tool. For more information, see the Code deployment status section.

Deploying application to IBM Code Engine

About this task

Use API Agent to streamline the deployment of application source code to supported services. For more details about how to deploy code, see Code deployment tool.

Procedure

To deploy application to IBM Code Engine, complete the following steps:

1. Log in to API Agent. For details, see Getting started.
2. Enter the following prompt, and click Send:

   ```
   Deploy the application code from @
   ```

   and select the required file, for example, `app-code.zip`. The file must be a .zip file containing application code, which was produced by the OpenAPI Python Generator tool.
   Note: Entering @ after the prompt displays a list of files available in your workspace.

3. Click Send. The API Agent displays the proposed plan.
4. Click Start. This is an asynchronous operation and takes time to complete. In the next step you can see how to query the deployment status separately to retrieve results.
5. Enter the following prompt to check the deployment status:

   ```
   What is the status of the deployment for the application code of file app-code?
   ```

6. Click Send. API Agent retrieves the status of a deployment based on the .zip file name that is provided by the user. See the deployment status section for the possible deployment status. If all stages display the COMPLETED status, the tool provides with the Application URL and Application name. This Application URL can then be added to the OpenAPI used to generate the application before publishing it to API Connect. To create, publish, and test a draft API, see Creating, publishing, and testing a draft API.
7. Once the application is deployed, enter the following prompt to fetch logs of the application.

   ```
   Provide the application logs of app-code
   ```

8. Click Send. The fetched logs are displayed and are packaged as a .log file and provided for download and debugging.
9. To delete the deployed application, enter the following prompt:

   ```
   Delete the deployed application from the application code file incident
   ```

10. Click Send. The API Agent displays the proposed plan.
11. Click Start. The API Agent deletes the application and its related resources.

Creating, publishing, and testing a draft API

Use the API Agent to create, publish, and test a draft API from an existing OpenAPI document. The tool guides you through selecting a file, publishing to the Sandbox catalog, and running test cases, helping you validate your API before deployment.

Procedure

1. Log in to API Agent. For more information, see Getting started.
2. Enter the following prompt:

   ```
   Create a draft api from @
   ```

   and select the required file.
   Note: Entering @ after the prompt displays a list of OpenAPI documents available in your workspace.
3. Click Send. The API Connect Task tool communicates with the API Agent sources and displays the proposed plan.
4. Click Start to view the following options and take the corresponding actions:
   - Download
   - Validate
   - Publish
5. Select the Publish option, and click Send. The tool displays the proposed plan that shows where the API will be published.
   Note: The Sandbox catalog is a default catalog in the API Agent sources.
6. Click Start. API Agent displays a message indicating that the API is published successfully.
7. To download the published YAML file, click the download icon.
8. To test the draft API, perform the following actions:
   a. Create test case
   b. Run test case

API Agent tools

API Agent uses set of tools to automate and assist with API management tasks. Each tool is designed for a specific purpose, making it easier for users to build, test, govern, and enhance APIs efficiently.

API Agent uses the following tools to perform various actions for use cases:

- **Artifacts Searcher**
  The Artifacts Searcher tool searches and retrieves detailed information about API, application source objects, and table artifacts based on user queries.
- **OAS Creator**
  The OpenAPI Specification (OAS) Creator tool generates OpenAPI specification from backend database or XML schema files. This tool supports a code-first approach for building API services.
- **API Governance**
  The API Governance tool validates the OpenAPI documents against spectral rulesets.
- **API Connect Tester**
  The API Connect Tester tool tests APIs generates test cases, test suites, and more.
- **API Connect Task**
  The API Connect Task tool performs operations on an API Connect instance (on-premises and SaaS) and IBM webMethods Hybrid Integration (iPaas) API Connect instance. Once API Agent is enabled and configured in API Connect instance, you can use the Visual Studio Code plug-in chat interface to connect to a provider organization and input prompts to use the following operations.
- **OpenAPI Python Generator**
  The OpenAPI Python Generator tool creates Python FastAPI server code based on your OpenAPI specification 3.0 specification. This code helps you quickly scaffold API endpoints that are defined in your OpenAPI document so that you can focus on implementing business logic instead of writing boilerplate code.
- **OpenAPI Enhancer**
  The OpenAPI Enhancer tool improves your APIs by generating intelligent recommendations for descriptions and examples. It also helps identify validation errors and potential issues that might affect API correctness.

- **OpenAPI Generator**
  The OpenAPI generator tool generates OpenAPI documents from scratch based on the prompts that you provide.
- **Code deployment**
  The Code deployment tool is used to deploy application source code to IBM® Code Engine, which simplifies the deployment process and reduces manual effort.

Artifacts Searcher

The Artifacts Searcher tool searches and retrieves detailed information about API, application source objects, and table artifacts based on user queries.

The Artifacts Searcher tool supports filtering by source type and provides structured results in markdown format with the following columns:

- Name
- Type
- Location
- Source ID

Use this tool to quickly locate and retrieve relevant technical details across various domains, including:

APIs
: Find API documentation and usage guidelines stored in database tables. This helps developers understand how to integrate and use APIs effectively.

Application objects
: Application objects refer to entities and components within software platforms. Examples include Salesforce and ServiceNow. Use the tool to fetch metadata about these objects, such as their properties and methods.

Database tables
: Database tables are structured storage units that organize and retrieve data efficiently. You can use the tool to:

  - Access API documentation stored in tables for quick reference.
  - Retrieve application object details, including attributes and behaviors.
  - Explore table structures, such as column names and data types, to understand data organization.

Key highlights

- Searches across API endpoints, application source objects, and database tables.
- Displays detailed metadata including source location and specifications.
- Supports filtering by OpenAPI versions and API types.
- Provides formatted markdown tables for easy reading.

The following operations are supported in the Artifacts Searcher tool:

- Search for API artifacts
- Search for table artifacts

Search for API artifacts

When you enter a prompt to search for application source artifacts, the tool searches for APIs matching the specified criteria and displays detailed information about their specifications and locations.

This operation displays a markdown-formatted table containing API metadata.

Table 1. Parameters

Parameter	Required	Description
`text`	Yes	Search query for API names or descriptions.
`source_type`	Yes	Set to `"API"` for this operation.

Example prompts

- `List all APIs that support the OpenAPI 3 specification`
- `Show me all APIs that have paths containing the word 'order'`
- `What are all the APIs supporting user authentication operations?`

Search for table artifacts

When you enter a prompt to search for table artifacts, the tool searches for database tables matching the specified criteria and displays their schema and metadata information.
Note: When you search for an artifact, the tool displays only the top five matches by default, even if more entries exist in the database for your query.
This operation displays a markdown-formatted table containing table metadata.

Table 2. Parameters

Parameter	Required	Description
`text`	Yes	Search query for table names or descriptions.
`source_type`	Yes	Set to `"endpoint_schema"` for this operation.

Example prompts

- `search for available tables with name procurement_order`
- `What are all the tables supporting order-related operations?`

- `List all tables in the sales schema`

OAS Creator

The OpenAPI Specification (OAS) Creator tool generates OpenAPI specification from backend database or XML schema files. This tool supports a code-first approach for building API services.

Generate OpenAPI specifications with create, retrieve, update, and delete operations from database tables or uploaded XML schema files. The tool outputs specifications in YAML or JSON format and includes all required paths, schemas, and operations.

Key highlights

- Retrieves configured table and schema details from backend services.
- Generates API service code by using the OpenAPI specification as input.

The following operations are supported in the OAS Creator tool:

- This operation connects to a data source by using the provided credentials and generates a complete OpenAPI specification with create, retrieve, update, and delete operations for the specified table. For more information, see Generate OpenAPI specification for API Agent sources table.
- This operation processes an uploaded XML schema file and generates a complete OpenAPI specification for the defined entities. For more information, see Generate an OpenAPI specification from schema file.

Generate OpenAPI specification from API Agent sources table

This operation connects to the data source by using the provided credentials, generates an OpenAPI specification with create, retrieve, update, and delete operations for the selected table, and displays the result as a downloadable YAML file.

Table 1. Parameters

Parameter	Required	Description
`Table_name`	Yes	Name of the table for which the OpenAPI spec must be created.
`schema_name`	Yes	Name of the table's schema for which the OpenAPI spec must be created.
`object_name`	Yes	Name of the object that is `"schema_name"+_+"table_name"`
`source_id`	Yes	Unique ID for API Agent sources configured source.

Example prompts

- `Generate an openapi for a customers table with the schema name purchase_order`
- `Create an openapi for a customers table with the schema name purchase_order`

Suggested next action

Enter the following prompt:

```
Generate some Python FastAPI server code based on the following openapi @customers_openapi.yaml
```

Generate an OpenAPI specification from an XML schema file

This operation generates an OpenAPI specification with create, retrieve, update, and delete operations for the uploaded XML schema, and displays the result as a downloadable YAML file.

Table 2. Parameters

Parameter	Required	Description
`Table_name`		Uploaded schema file name as table name.
`schema_file_name`	Yes	Uploaded schema file name for which the OpenAPI specification must be created.

Example prompts

```
Generate an openapi spec from @schema.xml
```

Suggested next action

Enter the following prompt:

```
Generate some Python FastAPI server code based on the following openapi @customers_openapi.yaml
```

API Governance

The API Governance tool validates the OpenAPI documents against spectral rulesets.

This tool is provided so that the API governance capabilities of API Connect can be used from API Agent. For example, validating the OpenAPI documents against spectral rulesets. Also, it can also be used to fix (remediate) spectral validation findings within an OpenAPI 3.0 document.

Tool details and limitations

The following are the API Governance tool details and limitations:

- To use this tool with on-premises installations of API Connect, enable API Governance in the Management CR.
- Currently, the API Governance tool supports working the newest versions of rulesets in the API governance service. For example, you can validate an OpenAPI document with the newest version of a ruleset. However, you cannot specify an older version when you use prompt. This limitation also applies to the remediation operation for fixing validation findings in an OpenAPI document.
- The remediation (with rulesets) operation of this tool uses AI-based remediation and can take some time. This time takes longer for larger, more complex OpenAPI documents. A default timeout of three minutes is applied. If remediation takes more than three minutes for an OpenAPI document, the tool times-out.
- To accommodate the three-minute maximum duration of remediation, make sure that your cluster Ingress controller, Ingress Route, or HAProxy timeout settings does not timeout in less than three minutes.

The following features of API governance are made available in API Agent:

- List Rulesets
- List rules in a Ruleset
- Validate and OpenAPI document using Rulesets
- Fix an OpenAPI document

List Rulesets

You can list the spectral rulesets that are provided to you as part of API Governance within your provider organization.

A table displays the following details about the rulesets:

- Name
- Version
- Description

Example prompt

```
List rulesets
```

Next action suggested

- Validate api {@filename} by using ruleset {ruleset}
- Validate api {draft-api-name}:{draft-api-version} by using ruleset {ruleset}

List rules in a Ruleset

You can list all the individual rules that are part of the spectral rulesets available to you within your provider organization.

- A table shows the following details about each rule within the specified ruleset:
  - Name
  - Description

Table 1. Parameters

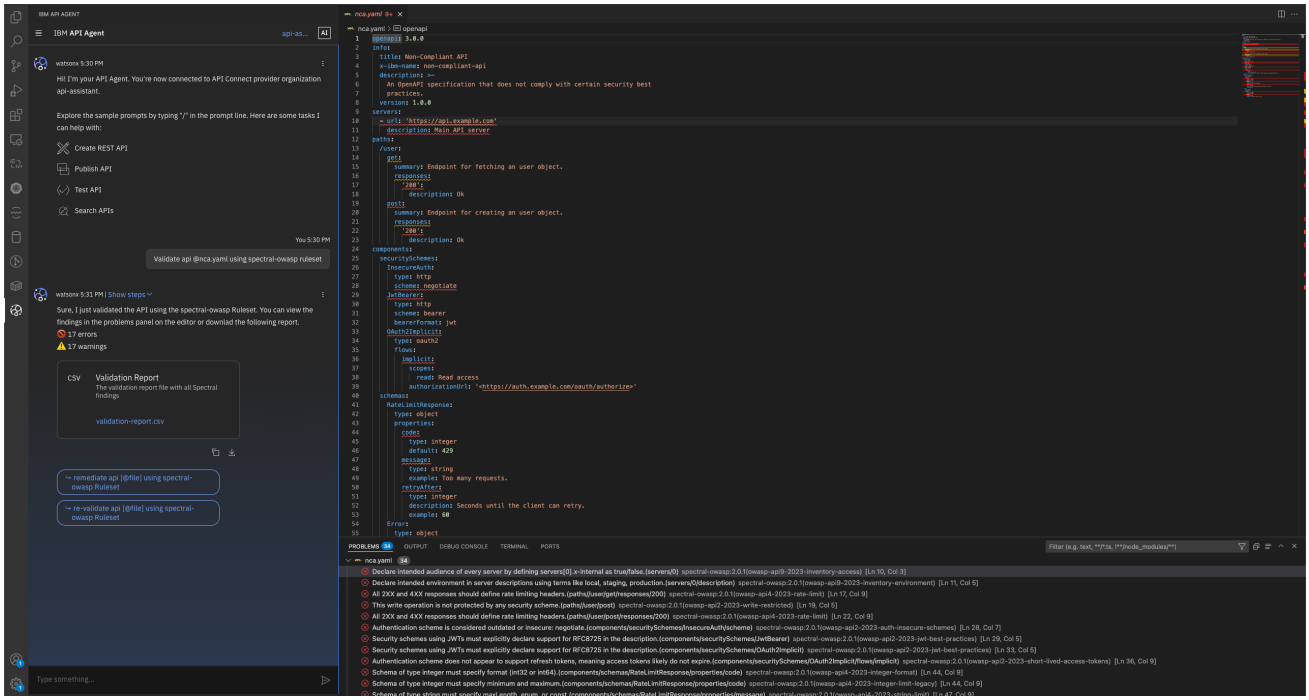
Parameter	Required	Description	Default
`ruleset`	Yes	The ruleset name, which you want to list the rules for.	None

Example prompts

```
List rules in ruleset {ruleset}
```

Next action suggested

- Validate api {@filename} by using ruleset {ruleset}
- Validate api {draft-api-name}:{draft-api-version} by using ruleset {ruleset}



Validate an OpenAPI document by using rulesets

You can validate OpenAPI documents with spectral rulesets in your provider organization with the following options:

- Using a local file attachment upload in the Visual Studio Code plug-in chat window.
- Providing the name and version of an existing draft API within the provider organization of the user on the API Manager.

This operation displays the following details:

- A brief summary of the number of spectral findings and their severity.
- A validation report .CSV file that can be downloaded, containing the complete set of the following findings:
  - Rule and ruleset of the rule
  - A message that describes the validation finding that violates the rule.
  - Line number in the OpenAPI document corresponds to the finding.
  - Location (JSON path) of the finding within the OpenAPI document.
- The findings and their locations also open in the PROBLEMS panel, as shown in following screenshot.

- If the OpenAPI document is a local file, it automatically opens in the Visual Studio Code file editor. All spectral findings are highlighted in the file.

Table 2. Parameters

Parameter	Required	Description	Default
`input_file`	No	The OpenAPI specification in YAML or JSON format to be validated.	None
`api_name`	No	The name (`info.x-ibm-name`) of the draft API to be validated.	None
`api_version`	No	The version (`info.version`) of the draft API to be validated.	None
`ruleset`	Yes	List of rulesets to use in the validation.	None

Example prompts

To validate a local file against a single Ruleset, run the following prompt:

```
validate api {@filename} using {ruleset} ruleset
```

To validate a local file against two or more Rule sets, run the following prompt

```
Validate api {@filename} using rulesets {ruleset-1}, {ruleset-2}
```

To validate a draft API against a single Ruleset, run the following prompt

```
Validate api {api-name}:{api-version} using {ruleset} ruleset
```

To validate a draft API against multiple Rulesets, run the following prompt

```
Validate api {api-name}:{api-version} using Rulesets {ruleset-1}, {ruleset-2}
```

Next action suggested

- Remediate api {@filename} by using ruleset {ruleset}
- Revalidate api {@filename} by using ruleset {ruleset}

Or

- Remediate api {draft-api-name}:{draft-api-version} by using ruleset {ruleset}
- Revalidate api {draft-api-name}:{draft-api-version} by using ruleset {ruleset}

Remediate (fix) an OpenAPI document that uses rulesets

If API Governance validation of an OpenAPI document reveals findings based on spectral rulesets within your provider organization, you can use AI-based remediation to attempt to resolve these findings. Upload a local file in the Visual Studio Code plug-in chat window or specify an existing draft API on the API Manager.

This operation displays the following details:

- An OpenAPI document file that can be downloaded that contains all the applied remediation that the AI-based remediation was able to fix automatically for the chosen rulesets.
- Also, the remediated OpenAPI document file automatically opens in the Visual Studio Code file editor. The applied fixes get highlighted directly in the file.
- The following details of each applied fix are shown in the AI RECOMMENDATIONS panel:
  - Path (JSON Path) to the recommendation
  - Recommendation (a description)
  - Explanation (explains the recommendation)

- Details of the Spectral Rule that the recommendation comes from (Severity, Ruleset name, Rule name, and message).

Note:

- The AI-based remediation is only supported for the spectral-owasp and spectral-oas rulesets from API Governance. If prompted to remediate by using an unsupported ruleset, you receive a warning that the unsupported ruleset was not used in the chat response from the API Agent.
- The tool expects that a valid OpenAPI 3.0 document is used as input. No warning is given if an invalid file is supplied. For example, supplying an AsyncAPI document as input against a ruleset with rules that apply to an OpenAPI document, and vice-versa.
- You can run remediation multiple times on the same OpenAPI document to remediate an issue if it is not found initially.
- Applying fixes through AI can introduce new violations of other spectral rules because the system does not automatically validate its fixes and recommendations against the rulesets after each change.

Table 3. Parameters

Parameter	Required	Description	Default
`input_file`	No	The OpenAPI Specification in YAML or JSON format to be remediated.	None
`api_name`	No	The name (`info.x-ibm-name`) of the draft API to be remediated.	None
`api_version`	No	The version (`info.version`) of the draft API to be remediated.	None
`ruleset`	Yes	List of rulesets to use in the remediation.	None

Example prompts

To remediate a local file against a ruleset, run the following prompt:

```
Remediate api {@filename} using {ruleset} ruleset
```

To remediate a local file against two or more Rulesets, run the following prompt:

```
Remediate api {@filename} using rulesets {ruleset-1}, {ruleset-2}
```

To remediate a draft API against a single Ruleset, run the following prompt:

```
Remediate api {api-name}:{api-version} using {ruleset} ruleset
```

To remediate a draft API against multiple Rulesets, run the following prompt:

```
Remediate api {api-name}:{api-version} using Rulesets {ruleset-1}, {ruleset-2}
```

Next action suggested

- Reremediate api {@filename} by using ruleset {ruleset}
- Validate api {@filename} by using ruleset {ruleset}

Or

- Reremediate api {draft-api-name}:{draft-api-version} by using ruleset {ruleset}
- Validate api {draft-api-name}:{draft-api-version} by using ruleset {ruleset}

API Connect Tester

The API Connect Tester tool tests APIs generates test cases, test suites, and more.

The tool completes operations that are supported by the API Test and Monitor (ATM) tool. It tests APIs to ensure that they are functioning as expected. It focuses on verifying that the API endpoints display the correct responses for various inputs and scenarios, by creating test assertions.

Tool details

- The API Test can be accessed under the API Tests tab in the API Manager.
- This tool uses the `Smart Generation` feature to generate test cases.

The following operations are supported in the API Connect Tester tool:

- Generate test cases
- Run test cases
- Test API
- List test suites
- List test cases
- Delete test suites
- Delete test cases
- Publish test cases
- Get test status for test cases
- Create webhooks
- List webhooks
- Delete webhooks

Generate test cases

The `Generate test case` operation creates a test suite from the provided API or OpenAPI specification file. The API can be either a draft or published in a specific catalog. Each test case in the suite corresponds to a different endpoint. If a test suite exists for the given API or OpenAPI specification file, it is deleted and a new one gets created. You can control the number of test cases that are listed by using the **limit** and **offset** parameters.

This operation displays a list of test cases as links, directing you to the corresponding test cases in the API Manager.
Note:

- If the catalog name is not specified, the test suite is created for a draft API with the given name (if available). To generate test cases against a published API, specify the catalog name.
- If the OpenAPI specification of an API is updated after a test suite has been created, the existing test suite must be deleted. A new test suite must be created based on the updated API specification.

Table 1. Parameters

Parameter	Description	Default value	Required
`api_name`	The name of the API for which test cases must be created.	None	Optional
`api_file`	The name of the open API specification for which the test case must be run.	None	Optional
`catalog`	The catalog name that the user published the API in.	None	Optional
`version`	The specific version of the API that has been published or the version that is specified in the API.	None	Optional
`limit`	Maximum number of test cases, which is in the response. Takes an integer value.	15	Optional
`Offset`	Skip this number of test cases and retrieves the remaining test cases. Takes an integer value.	0	Optional

Example prompts

- `Generate test case for Swagger-Petstore api`
- `Generate test case for Swagger-Petstore api in sandbox`
- `Generate test for Swagger-Petstore:1.0.0 api`
- `Generate test for Swagger-Petstore api with version 1.0.0 in sandbox`
- `Generate test case for Swagger-Petstore api with limit 5 offset 15`
- `Generate test case for @bookshop.yaml`

Suggested next action

`Run test case for the test suite {testsuite_name}`

Run test cases

The run test case runs the test cases in the given test suite or created for an API. During run, API calls are made, and the assertions are validated. The API can be a draft or published in a specific catalog. You can control the number of test cases that are listed by using the **limit** and **offset** parameters. This operation can only be performed after the Generate test case operation.

During this operation, each test case is verified for a valid server URL to make API calls. If the server URL is missing, as in draft APIs, the test case will not run. The user is prompted to update the server URL in the editor through a clickable link to the test case. If the test case has a valid server URL, a link directs you to the Report tab of the test cases in the API Manager, where you can review the test results.

Table 2. Parameters

Parameter	Description	Default value
`api_name`	Name of the API for which test cases must be run.	None
`api_file`	The name of the open API specification for which the test case must be run.	None
`test_name`	Name of the test case, which must be run.	None
`testsuite_name`	Name of the testsuite for which test cases must be run.	None
`catalog`	The catalog name that the user published on the API.	None
`version`	The specific version of the API that has been published or the version that is specified in the API.	None
`limit`	Maximum number of test cases, which is shown in the response. Takes an integer value.	15
`Offset`	Skip this number of test cases and retrieves the remaining test cases. Takes an integer value.	0

Example prompts

- `run test for AA_TEST_SUITE_Swagger_Petstore_1.0.0`
- `run test for Swagger-Petstore api`
- `run test for Swagger-Petstore api in sandbox`
- `run test for Swagger-Petstore:1.0.0 api`
- `run test for Swagger-Petstore api with version 1.0.0 in sandbox`
- `run test for AA_TEST_CASE_get/200 in AA_TEST_SUITE_Swagger_Petstore_1.0.0`
- `run test for AA_TEST_CASE_get/200 in AA_TEST_SUITE_Swagger-Petstore-1.0.0 test suite`
- `run test for Swagger-Petstore api with limit 5 offset 15`

Suggested next action

`Get test status for the {api_name} api`

`Get test status for the test suite {testsuite_name}`

Test API

The Test API operation generates test cases and runs them for the given API or OpenAPI specification file. The API can either be a draft or published in a specific catalog. You can control the number of test cases that are listed by using the **limit** and **offset** parameters.

The operation presents these test cases as clickable links, directing you to the Report tab of the test cases in the API Manager, where you can review the test results.

Table 3. Parameters

Parameter	Description	Default value
`api_name`	Name of the API for which test cases must be created and run.	None
`api_file`	Name of the open api specification for which test case has to be created and run.	None
`catalog`	The catalog name in which the user published the API in.	None
`version`	The specific version of the API that has been published or the version that is specified in the API.	None
`limit`	Maximum number of test cases, which will be shown in the response. Takes an integer value.	15
`offset`	Skip this number of test cases and retrieves the remaining test cases. Takes an integer value.	0

Example prompts

- `test api Swagger-Petstore api`
- `test api Swagger-Petstore api in sandbox`
- `test api Swagger-Petstore:1.0.0 api`
- `test api Swagger-Petstore api with version 1.0.0 in sandbox`
- `test api for Swagger-Petstore api with limit 5 offset 15`
- `test api for @bookshop.yaml`

Suggested next action

```
Get test status for the {api_name} api
 Get test status for the test suite {testsuite_name}
```

List test suites

The list test suite operation provides a list of all test suites present in the Provider organization.

Example prompt:

```
list test suites
```

List test cases

The list test cases operation displays the list of test cases present for the given test suite or API. The API can be either a draft or published in a specific catalog. You can control the number of test cases that are listed by using the limit and offset parameters.

Table 4. Parameters

Parameter	Description	Default value
`api_name`	Name of the API name to list the test cases generated under it.	None
`catalog`	The catalog name in which the user published the API in.	None
`testsuite_ name`	Name of the test suite to list the test cases inside it.	None
`limit`	Maximum number of test cases, which will be shown in the response. Takes an integer value.	15
`offset`	Skip this number of test cases and retrieves the remaining test cases. Takes an integer value.	0

Example prompts

- `list test cases in AA_TEST_SUITE_Swagger_Petstore_1.0.0`
- `list test cases in Swagger-Petstore api`
- `list test cases in Swagger-Petstore api in sandbox`
- `list test cases in Swagger-Petstore api with limit 5 offset 15`

Delete test suite

The `delete test suite` operation deletes a test suite, along with all the test cases created within that test suite.

Table 5. Parameters

Parameter	Description	Required
`testsuite_name`	Name of the test suite which needs to be deleted.	Yes

Example prompt

```
delete test AA_TEST_CASE_get/200 in AA_TEST_SUITE_Swagger_Petstore_1.0.0
```

Delete test case

The `delete test case` operation deletes a specific test case within a test suite.

Table 6. Parameters

Parameter	Description	Required
`test_name`	Name of the test case that should be deleted.	Yes

Parameter	Description	Required
`testsuite_name`	The name of the test suite in which the test case to be deleted is present.	Yes

Example prompt

```
delete test AA_TEST_CASE_get/200 in AA_TEST_SUITE_Swagger_Petstore_1.0.0
```

Publish test cases

After configuring and verifying your test, you can publish it. This operation publishes a specific test case within a test suite if a name is provided, or all test cases in the suite if no test suite name is specified.

Table 7. Parameters

Parameter	Description	Default value	Required
`test_name`	Name of the test case that should be published.	None	Yes
`testsuite_name`	The name of the test suite in which the test case that needs to be published are is presented.	None	Yes

Example prompts

- `publish test in test suite AA_TEST_SUITE_Swagger_Petstore_1.0.0`
- `publish test AA_TEST_CASE_get/200 in test suite AA_TEST_SUITE_Swagger_Petstore_1.0.0`

Get test status for test cases

The Get status operation furnishes the execution status of test cases for the specified API or test suite, whether it's a draft or published in a specific catalog. The number of test cases can be controlled through the limit and offset parameters.

This operation provides a consolidated summary of test status and individual case status. For each executed test case that has run, it displays successful and failed assertion counts, along with a link to the Report tab of the test cases in the API Manager. If a test case has not been run, its status is displayed as `Not run yet` for the particular test case.

Table 8. Parameters

Parameter	Description	Default value
`api_name`	The name of the API for which the status of test cases must be fetched.	None
`test_name`	Name of the test case for which status must be fetched.	None
`catalog`	The catalog name in which the user published the API.	None
`testsuite_ name`	Name of the test suite for which status must be fetched.	None
`limit`	The maximum number of test cases, which will be shown in the response. Takes an integer value.	15
`offset`	Skip this number of test cases and retrieve the remaining test cases. Takes an integer value.	0
`version`	The specific version of the API that has been published or the version that is specified in the API.	None

Example prompts

- `get test status for Swagger-Petstore api`
- `get test status for Swagger-Petstore api in sandbox`
- `get test status for Swagger-Petstore:1.0.0 api`
- `get test status for Swagger-Petstore api with version 1.0.0 in sandbox`
- `get test status for test suite AA_TEST_SUITE_Swagger-Petstore-1.0.0`
- `get test status for AA_TEST_CASE_get/200 in test suite AA_TEST_SUITE_Swagger-Petstore-1.0.0`

Create webhook

The `create webhook` operation enables the creation of a webhook for a specific test suite, allowing creation of multiple webhooks per suite. You can create webhooks by providing a name, description, and the test suite name. The operation shows the URL of the created webhook, along with guidelines on how to generate the key and secret required to access the webhook.

Accessing the hook

To use the API hook, you are required to generate an API key and secret.

To generate an API key and secret, complete the following steps:

1. Go to test suite > Settings.
2. Select API hooks and keys.
3. In the Keys section, click Add.

Table 9. Parameters

Parameter	Description	Default value	Required
`testsuite_name`	Name of the test suite for which the hook must be created.	None	Yes
`name`	Hook must be created with this name.	None	Yes
`des_hooks`	Description for the hook.	""	Yes

Example prompts

- `create hook with name test-hook for test suite AA_TEST_SUITE_Swagger-Petstore-1.0.0`

- `create hook with name test-hook with description 'For testing purpose' for the test suite AA_TEST_SUITE_Swagger-Petstore-1.0.0`

List webhooks

This operation lists all the webhooks that are created for a particular test suite.

Table 10. Parameters

Parameter	Description	Required
`testsuite_name`	The name of the test suite for which the hook must be listed.	Yes

Example prompt

```
list hooks for test suite AA_TEST_SUITE_Swagger_Petstore_1.0.0
```

Delete webhooks

This operation deletes a specific webhook with the given name from the specified test suite.

Table 11. Parameters

Parameter	Description	Required
`name`	Name of the hook that needs to be deleted.	Yes
`testsuite_name`	The name of the test suite in which the hook to be deleted is present.	Yes

Example prompt

```
delete hook test-hook in test suite AA_TEST_SUITE_Swagger-Petstore-1.0.0
```

API Connect Task

The API Connect Task tool performs operations on an API Connect instance (on-premises and SaaS) and IBM webMethods Hybrid Integration (iPaas) API Connect instance. Once API Agent is enabled and configured in API Connect instance, you can use the Visual Studio Code plug-in chat interface to connect to a provider organization and input prompts to use the following operations.

Catalog-dependent operations

For the following operations, the specified catalog must be enabled for API Agent in the API Manager UI. If the catalog is not enabled, the operation fails. For more information about catalog and drafts, see API Connect catalogs and drafts.

- List gateways in catalog
- List consumer organizations
- List applications in catalog
- List published APIs
- List published products
- List consumer app credentials
- Publish API
- Publish product
- Create consumer app
- Create subscription

Draft-dependent operations

To use the following operations, drafts must be enabled for API Agent in the API Manager UI:

- Create draft API
- Download draft API
- Delete draft API
- Update draft API
- List draft APIs
- List draft Products
- Validate draft API (when working with a draft)
- Review security of a draft API
- Add security to a draft API
- Remove security from a draft API

Draft-independent operations

The following operations work regardless of whether drafts are enabled or disabled in the API Agent settings:

- Create API Connect API that uses a URL
- Create API Connect API from file ***`@filename`***
- Validate API in file **`@filename`**
- Review security of API in file ***`@filename`***
- Add security to an API in a file ***`@filename`***
- Remove security from an API in a file ***`@filename`***

Note:

- Any changes that are made to the API Agent settings, such as enabling catalogs or drafts, or database configuration changes, in the API Manager UI take effect only in new chat sessions. The existing sessions do not reflect the updated configurations.
- When writing prompts to use an existing resource, the prompt must include the name (or ID) of the object or resource. Providing the title of the resource as input can cause errors. The resources that require a name or ID as input includes the following details:
  - Catalogs
  - Draft APIs
  - Draft products
  - Published APIs
  - Published products
  - Gateways
  - Consumer organizations
  - Consumer applications
  - Subscriptions
- Spaces feature in API Connect is not supported from API Agent.

The following section describes different operations supported by the API Connect Task tool.

- **API-related operations**
  You can create, update, validate, publish, download, delete, and secure APIs by using simple prompts. Add client credentials, review security, and control where your APIs are published by using guided, confirmation-based commands.
- **Product-related operations**
  Use the `Publish product` operation to publish a draft product to an API Connect instance. This operation enables the availability of product through the specified catalog and gateway services.
- **Consumer application operations**
  Use the `Create consumer app` operation to create a consumer application in a specified catalog for a consumer organization in API Connect.
- **List operations**
  Use the `list` prompt to retrieve a paginated list of catalogs, draft or published APIs or products, gateways, consumer organizations, and apps within a provider organization.
- **Plans with multiple tool operations**

API-related operations

You can create, update, validate, publish, download, delete, and secure APIs by using simple prompts. Add client credentials, review security, and control where your APIs are published by using guided, confirmation-based commands.

Create draft APIs or API Connect APIs

The `Create draft API` prompt creates a draft in the API Connect instance. The `create API Connect API` prompt displays the draft as a file in response, and no draft is created in the API Connect instance. The API definition can be provided as:

- A URL that links to a Swagger (OpenAPI 2.0), OpenAPI (3.x), or API Connect document.
- A file upload that contains the API specification.

Note:

- The user confirmation is required before execution.
- Only REST proxy APIs can be created from the existing Swagger, OpenAPI, or API Connect documents.

Note: Before creating a Draft API from a file, ensure that the `url` value in the file is accurate and points to the server where the application is running. You can also update the `url` in the draft file before publishing it.

- For Swagger 2.x files: Verify the `host` and `basePath` values.
- For OpenAPI 3.x files: Verify the value of `servers > url`.
- For API Connect documents: In addition to the above, check the `target-url` value in the `x-ibm-configuration` section.

Example:

If the API file is generated using the "create openapi spec" and "generate python fastapi server code" prompts:

- If the generated fastapi server code runs on a machine in your network, the `url` will point to that machine's hostname or IP address.
- If the generated fastapi server code is deployed to IBM Code Engine using the "Deploy the application code" prompt, the `url` is the application URL value obtained when you run the "give deployment status for the application code" prompt.

Table 1. Parameters

Parameter	Type	Required	Description	Valid values	Default
`url`	string	Optional	A URL from which a Swagger (OpenAPI 2.0), OpenAPI (3.x), or API Connect document can be downloaded to create the draft API or API Connect API. • If the document is in YAML, explicitly set `document_format: yaml`. • Default format, if unspecified: JSON.	Valid URL that points to a JSON or YAML document. If both `url` and `input_file` are provided, `url` takes priority.	None

Parameter	Type	Required	Description	Valid values	Default
`input_file`	file	Either `url` or `input_file` must be provided. If both `url` and `input_file` are provided, `url` takes priority.	A file that contains the API definition in JSON or YAML format.	Supported document types: • Swagger (OpenAPI 2.0) • OpenAPI (3.x) • API Connect	None
`gateway_type`	String	Optional	The gateway type for which the API definition is created.	• `"datapower-api-gateway"` • `"apigw"` • `"datapower-gateway"` • `"v5gw"` • `"event-gateway"`	`"datapower-api-gateway"`
`document_format`	String	Optional	Specifies the format of the API document when `url` is used.	`"json"`, `"yaml"`	`"json"`

You can use the following prompts to create draft APIs or API Connect APIs.

Table 2. Create a draft API or API Connect APIs

Action	Prompt	Command

Create draft API	`create draft api from URL`
	
	`create draft api from URL and with format yaml`
	
	`create draft api from URL and with format json and gateway type datapower-api-gateway`
	
	`import api URL`
	
	`import api @filename`
	
	`create draft api using @filename`
	
	`create draft api using @filename and gateway type datapower-api-gateway`
		`/create_draft_api url:URL`
		
		`/create_draft_api url:URL document_format:yaml`
		
		`/create_draft_api url:URL document_format:json gateway_type:datapower-api-gateway`
		
		`/create_draft_api input_file:@filename`
		
		`/create_draft_api input_file:@filename gateway_type:datapower-api-gateway`

Create API Connect API	`create apiconnect api from URL`
	
	`create apiconnect api from URL and with format yaml`
	
	`create apiconnect api from URL and with format json and gateway type datapower-api-gateway`
	
	`create apiconnect api using @filename`
	
	`create apiconnect api using @filename and gateway type datapower-api-gateway`
		`/create_apiconnect_api url:URL`
		
		`/create_apiconnect_api url:URL document_format:yaml`
		
		`/create_apiconnect_api url:URL document_format:json gateway_type:datapower-api-gateway`
		
		`/create_apiconnect_api input_file:@filename`
		
		`/create_apiconnect_api input_file:@filename gateway_type:datapower-api-gateway`

Update draft API

The **`update draft API`** prompt updates an existing draft API in the API Connect instance. The operation requires the name and version of the draft API and the updated draft content. User confirmation is required before the update is applied.

Table 3. Parameters

Parameter	Type	Required	Description
`api_name`	string	Yes	Identifier of the draft API to update. The identifier can be in the form of the API name, `api_name:version`, or the ID of the draft API.
`version`	string	No	Version of the draft API.
`input_file`	file	Yes	The file that contains the updated API definition. This file must be an API Connect-specific OpenAPI document, in either JSON or YAML format. This file is used to overwrite the existing draft API content.

You can use the following prompts to update a draft API.

Table 4. Update a draft API

Action	Prompt	Command

Update draft API	`update draft api DRAFT_API using content from @file_name`
	
	The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.
	
	`update draft api with name APINAME and version VERSION and using content from @file_name`
	
	`create draft api using @filename and gateway type datapower-api-gateway`
		`/update_draft_api api_name:DRAFT_API input_file: @file_name`
		
		`/update_draft_api api_name:APINAME version:VERSION input_file: @file_name`

Download a draft API

The **`download draft API`** prompt downloads a draft API from the API Connect instance. This operation requires the draft API name, with or without the version number, or the draft API ID as input.

Table 5. Parameters

Parameter	Type	Required	Description

Parameter	Type	Required	Description
`api_name`	string	Yes	Identifier of the draft API that needs to be downloaded. This identifier can be in the form of the API name, `api_name:version`, or the ID of the draft API.
`version`	string	No	Version of the draft API.
`format`	JSON/YAML	No	The format of the output file. The default is JSON.

You can use the following prompts to download draft APIs.

Table 6. Download a draft API

Action	Prompt	Command

Download draft API	`download draft api DRAFT_API`
	
	`download draft api with name APINAME and version VERSION`
	
	`download draft api DRAFT_API in yaml format`
	
	The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.
		`/download_draft_api api_name:DRAFT_API`
		
		`/download_draft_api api_name:APINAME version:VERSION`
		
		`/download_draft_api api_name:APINAME version:VERSION format:yaml`
		
		The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.

Validate draft API

The `validate draft api` prompt validates an API draft either from an existing draft or from a file upload. The operation runs immediately without user confirmation and returns the validation results.

Table 7. Parameters

Parameter	Type	Required	Description
`api_name`	string	Either `api_name` or `input_file` must be provided. If neither is set, the operation fails. If both are provided, `api_name` takes precedence.	Specifies the name of the draft API to validate. This name can be in the form of the API name, `api_name:version`, or the ID of the draft API.
`version`	string	No	Version of the draft API.
`input_file`	String	required if `api_name` is not provided	A file that contains the draft API definition. The file can be in JSON or YAML format and must contain a Swagger, OpenAPI, or API Connect definition.
`catalog`	String	No	Name or ID of the catalog to validate against.
`gateway_service_names`	String	No	A comma-separated list of gateway service names to use for validation while checking against a catalog or gateway.

You can use the following prompts to validate draft APIs.

Table 8. Validate draft API

Action	Prompt	Command

Validate draft API	`validate api DRAFT_API`
	
	`validate api with name APINAME and version VERSION`
	
	`validate api @file_name`
	
	`validate api DRAFT_API in catalog CATALOG_NAME`
	
	`validate api DRAFT_API in catalog CATALOG_NAME and gateway service GATEWAY_SERVICE_NAMES`
	
	`validate api @file_name in catalog CATALOG_NAME`
	
	`validate api @file_name in catalog CATALOG_NAME and gateway service GATEWAY_SERVICE_NAMES`
	
	Note: The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.
		`/validate_api api_name:DRAFT_API`
		
		`/validate_api api_name:APINAME version:VERSION`
		
		`/validate_api input_file:@file_name`
		
		`/validate_api api_name:DRAFT_API catalog:CATALOG_NAME`
		
		`/validate_api api_name:DRAFT_API catalog:CATALOG_NAME gateway_service_names:GATEWAY_SERVICE_NAMES`
		
		`/validate_api input_file:@file_name catalog:CATALOG_NAME`
		
		`/validate_api input_file:@file_name catalog:catalog_name gateway_service_names:GATEWAY_SERVICE_NAMES`
		
		Note: The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.

Publish APIs

The `publish api` prompt publishes an API to the API Connect instance. You can publish the API by either:

- Providing the name of an existing draft API
- Uploading an OpenAPI specification file that represents the API

Note: User confirmation is required before execution.

Table 9. Parameters

Parameter	Type	Required	Description
`api_name`	string	Required if `api_file` is not provided.	The name of the draft API to publish.
`api_file`	string	Optional	The path to a file that contains the OpenAPI specification. Required if `api_name` is not provided. The file must be in JSON or YAML format and conform to Swagger or OpenAPI standards.
`product_file`	string	Optional	The path to a file that contains the product definition that is associated with the API. If not provided, a wrapper product is autogenerated during publishing.
`gateway_names`	string	Optional	A comma-separated list of gateway service names to which the API is published. If not specified, the API is published to all relevant gateway services that are configured in the target catalog.
`catalog`	string	Optional	The name or ID of the catalog where the API is published. If not specified, `"sandbox"` is used by default.

You can use the following prompts to publish APIs.

Table 10. Publish API

Action	Prompt	Command

Publish API	• Publish an API by name (default catalog: sandbox)
	`publish api sample`
	• Publish an API by name to a specific catalog, for example, test
	`publish api sample to catalog test`
	• Publish an API by name to a specific gateway and specific catalog.
	`publish api sample using gateway gw-service to catalog test`
	• Publish an API from an OpenAPI spec file to a specific catalog
	`publish api @sample-api.yaml to catalog test`
	• Publish an API from an OpenAPI spec file with a product file to a specific catalog
	`publish api @sample-api.yaml with product @product.yaml to catalog test`
		• Publish an API by name (default catalog: sandbox)
		`/publish_api name:sample`
		• Publish an API by name to a specific catalog (for example, test)
		`/publish_api name:sample catalog:test`
		• Publish an API by name to a specific gateway and specific catalog.
		`/publish_api name:sample gateway_names:gw-service catalog:test`
		• Publish an API from an OpenAPI spec file to a specific catalog
		`/publish_api api_file: @sample-api.yaml catalog:test`
		• Publish an API from an OpenAPI spec file with a product file to a specific catalog
		`/publish_api api_file: @sample-api.yaml product_file: @product.yaml catalog:test`

Delete draft API

The **`delete draft api`** prompt deletes a draft API from the API Connect instance. This operation requires the draft API name, with or without the version number, or the draft API ID as an input.

Table 11. Parameters

Parameter	Type	Required	Description
`api_name`	string	Yes	Identifier of the draft API to delete. This identifier can be in the form of the API name, **`api_name:version`** or the ID of the draft API.
`version`	string	No	Version of the draft API.

You can use the following prompts to delete a draft API.

Table 12. Delete draft API

Action	Prompt	Command
Delete draft API	**`delete draft api *DRAFT_API*`** The value of DRAFT_API can be **`apiname`** or **`apiname:version`** or the ID of the draft API. **`delete draft api with name APINAME and version VERSION`**	**`/delete_draft_api api_name:DRAFT_API`** **`/delete_draft_api api_name:APINAME version:VERSION`**

Add security to API

The **`add security to api`** prompt adds a security scheme to a draft API. You can run this operation by using either an existing draft API or a file that represents a draft. The specified security scheme is added to the available security definitions and is configured for the API.

Behavior

- When a client secret security scheme is added, a corresponding client ID security scheme is also automatically added and configured.
- By default, security schemes are configured as header parameters.
  To configure the security schemes as query parameters instead, set the **`use_query_params_for_apikey_security`** property to **`true`** when this operation is started.
- You can configure both header and query parameter styles by running this operation multiple times with the appropriate settings.

Note:

- User confirmation is required before this operation is executed.
- Only the **`apiKey`** security scheme type is supported in this release.
- **`oauth2`** and **`Basic Authentication`** are not supported.

Table 13. Parameters

Parameter	Type	Required	Description
`api_name`	string	Yes	Identifier of the draft API to which the security scheme will be added. This identifier can be in the form of the API name, **`api_name:version`**, or the ID of the draft API. Either **`api_name`** or **`input_file`** must be provided. If both are specified, **`api_name`** takes precedence.
`version`	string	No	Version of the draft API.
`input_file`	string	Required if **`api_name`** is not provided	A file that contains the draft API definition. The file can be in JSON or YAML format and must contain a Swagger, OpenAPI, or API Connect definition.
`security_type`		No	The type of security scheme to configure. Only **`apiKey`** is supported.
`client_id`	Boolean	No	Indicates whether to configure a **`client_id`** security scheme. Set to **`true`** to include it in the configuration.
`client_secret`	Boolean	No	When set to **`true`**, both **`client_id`** and **`client_secret`** schemes are added automatically.

Parameter	Type	Required	Description
`use_query_params_for_apikey_security`	Boolean	No	Determines where the security scheme is applied in the API request. • `false` (default): Security is configured as a header parameter. • `true`: Security is configured as a query parameter.

You can use the following prompts to add security to a draft API.

Table 14. Add security to a draft API

Action	Prompt	Prompt

Add security to a draft API	`add security to api DRAFT_API`
	
	`add security to api with name APINAME and version VERSION`
	
	`add client id security to api DRAFT_API`
	
	`add client id security to api with name APINAME and version VERSION`
	
	`add client secret security to api DRAFT_API`
	
	`add client secret security to api with name APINAME and version VERSION`
	
	`add client id security as a query parameter to api DRAFT_API`
	
	`add client secret security as a query parameter to api DRAFT_API`
	
	`add security to api in file @filename`
	
	`add client id security to api in file @filename`
	
	`add client secret security to api in file @filename`
	
	`add client id security as a query parameter to api in file @filename`
	
	`add client secret security as a query parameter to api in file @filename`
	
	The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.
		`/add_security_to_api api_name:APINAME version:VERSION`
		
		`/add_security_to_api api_name:APINAME version:VERSION client_secret:true`
		
		`/add_security_to_api api_name:APINAME version:VERSION use_query_params_for_apikey_security:true`
		
		`/add_security_to_api api_name:APINAME version:VERSION client_secret:true use_query_params_for_apikey_security:true`
		
		`/add_security_to_api input_file: @filename`
		
		`/add_security_to_api input_file: @filename client_secret:true`
		
		`/add_security_to_api input_file: @filename client_secret:true use_query_params_for_apikey_security:true`

Review security of API

The `review security of api` prompt reviews the security schemes that are defined and configured in a draft API. You can run this operation by using either an existing draft API or a file that represents a draft. This operation runs automatically and returns output without requiring user confirmation.

Table 15. Parameters

Parameter	Type	Required	Description
`api_name`	string	Yes	Identifier of the draft API to review. This identifier can be in the form of the API name, `api_name:version`, or the ID of the draft API. Either `api_name` or `input_file` must be provided. If both are specified, `api_name` takes precedence.
`version`	string	No	Version of the draft API.
`input_file`	string	Required if `api_name` is not provided	A file that contains the draft API definition. The file can be in JSON or YAML format and must contain a Swagger, OpenAPI, or API Connect definition.

You can use the following prompts to review the security of a draft API.

Table 16. Review security of a draft API

Action	Prompt	Command

Review security of a draft API	`review security of api DRAFT_API`
	
	The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.
	
	`review security of api with name APINAME and version VERSION`
	
	`review security of api in file @filename`
		`/review_security_of_api api_name:DRAFT_API`
		
		The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.
		
		`/review_security_of_api api_name:APINAME version:VERSION`
		
		`/review_security_of_api input_file: @file_name`

Remove security from a draft API

The `remove security scheme from draft api` prompt removes one or more security schemes from a draft API. You can do this operation on an existing draft API or by using a file that represents the draft.

The specified security schemes are removed from the following locations, if present:

- The security definitions of the API
- The list of configured security schemes at the API level

- Any path or method-level security configurations

Note: User confirmation is required before execution.

Table 17. Parameters

Parameter	Type	Required	Description
`api_name`	string	Either `api_name` or `input_file` must be provided. If neither is set, the operation fails. If both are provided, `api_name` takes precedence.	The identifier of the draft API from which the security schemes are removed. This identifier can be in the form of the API name, `api_name:version`, or the ID of the draft API.
`version`	string	No	Version of the draft API.
`input_file`	String	Required if `api_name` is not provided	A file that contains the draft API definition. The file can be in JSON or YAML format and must contain a Swagger, OpenAPI, or API Connect definition.
`security_scheme`	String	No	The exact name of the security scheme to remove, which is defined in the draft.
`remove_all_security_schemes`	Boolean	No	Set to `true` to remove all defined and configured security schemes from the draft. When this parameter is set to `true`, the `security_scheme` parameter is ignored.

The following prompts that you can use to remove the security of a draft API:

Table 18. Remove security of a draft API

Action	Prompt	Command

Remove security of a draft API	`remove security scheme SECURITY_SCHEME_NAME from api DRAFT_API`
	
	`remove security scheme SECURITY_SCHEME_NAME from api with name APINAME and version VERSION`
	
	`remove security scheme SECURITY_SCHEME_NAME from file @filename`
	
	`remove all security schemes from api DRAFT_API`
	
	`remove all security schemes from api with name APINAME and version VERSION`
	
	`remove all security schemes from file @filename`
	
	The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.
	
	Note: While removing a security scheme from a draft, the exact scheme name as present in the draft need to be provided in the input.
		`/remove_security_from_api api_name:DRAFT_API security_scheme:SECURITY_SCHEME_NAME`
		
		`/remove_security_from_api api_name:APINAME version:VERSION security_scheme:SECURITY_SCHEME_NAME`
		
		`/remove_security_from_api security_scheme:SECURITY_SCHEME_NAME input_file: @filename`
		
		`/remove_security_from_api api_name:DRAFT_API remove_all_security_schemes: true`
		
		`/remove_security_from_api api_name:APINAME version:VERSION remove_all_security_schemes: true`
		
		`/remove_security_from_api remove_all_security_schemes: true input_file: @filename`
		
		The value of DRAFT_API can be `apiname` or `apiname:version` or the ID of the draft API.

Product-related operations

Use the `Publish product` operation to publish a draft product to an API Connect instance. This operation enables the availability of product through the specified catalog and gateway services.

Publish product

Note: User confirmation is required before publishing.

Table 1. Parameters

Parameter	Type	Required	Description
`product_name`	string	Required	The name of the draft product to publish.
`gateway_names`	string	Optional	A comma-separated list of gateway service names where the product is published. If not specified, the product is published to all relevant gateway services that are configured in the target catalog.
`catalog`	string	Optional	The name of the catalog where the product is published. If not specified, `"sandbox"` is used by default.

You can use the following prompts to publish a product.

Table 2. Publish product

Action	Prompts	Commands

Publish product	• Publish a product by name (default catalog: sandbox)
	
	`publish product sample`
	
	• Publish a product by name to a specific catalog, for example, test
	
	`publish product sample to catalog test`
	
	• Publish a product by name to a specific gateway and specific catalog.
	
	`publish product sample using gateway gw-service to catalog test`
		• Publish a product by name (default catalog: sandbox)
		
		`/publish_product name:sample`
		
		• Publish a product by name to a specific catalog, for example, test
		
		`/publish_product name:sample catalog:test`
		
		• Publish a product by name to a specific gateway and specific catalog
		
		`/publish_product name:sample gateway_names:gw-service catalog:test`

Download draft product

You can download draft product from the API Connect instance.

Table 3. Parameters

Parameter	Type	Required	Description
`product_name`	string	Yes	The name of a draft product.
`file_format`	string	Optional	The format in which the file will be downloaded either in the YAML or JSON format. If not specified, `YAML` is used by default.

You can use following prompts to download draft products:

Table 4. Download product draft

Action	Prompts	Commands

Download draft product	• Download draft product by API name (default YAML file format)
	`download draft product sample-product`
	• Download draft product by name and in the JSON format
	`download draft product sample-product in json format`
		• Download draft product by API name (default YAML file format)
		`/download_draft_product product_name:sample-product`
		• Download draft product by name and in the JSON format
		`/download_draft_product product_name:sample-product file_format:json`

Consumer application operations

Use the **`Create consumer app`** operation to create a consumer application in a specified catalog for a consumer organization in API Connect.

Create consumer application

The **`create consumer app`** creates a consumer application in the specified catalog for a specific consumer organization in the API Connect instance. User confirmation is required before this operation is performed.

Table 1. Parameters

Parameter	Type	Required	Description
`title`	string	Required if `name` is not provided.	The displayed title of the consumer application.
`name`	string	Required if `title` is not provided.	The unique name (identifier) of the consumer application.
`consumer_org`	string	Required	The name of the consumer organization under which the application will be created.
`catalog`	string	Optional	The name of the catalog in which to create the consumer application. If not specified, `"sandbox"` is used by default.

You can use the following prompts to create a consumer application:

Table 2. Create a consumer application

Action	Prompts	Commands

Create a consumer app	• Create a consumer application by title (default catalog: sandbox)
	`create consumer app with the title test app for consumer org test-org`
	• Create a consumer application by name to a specific catalog, for example, test
	`create consumer app with the name test-app for consumer org test-org in catalog test`
	• Create a consumer application by name and title to a specific catalog, for example, test
	`create consumer app with the title test app and the name test-app for consumer org test-org in catalog test`
		• Create a Consumer App by title (default catalog: sandbox)
		`/create_consumer_app title:test app consumer_org:test-org`
		• Create a Consumer App by name to a specific catalog, for example, test
		`/create_consumer_app name:test-app consumer_org:test-org`
		• Create a Consumer App by name and title to a specific catalog, for example, test
		`create_consumer_app title:test app name:test app consumer_org:test-org`

List consumer application credentials

This tool allows to list credentials from the given consumer application and consumer organization in the catalog from API Connect instance.

Table 3. Parameters

Parameter	Type	Required	Description
`consumer_app`	string	Yes	The name of the consumer application.
`consumer_org`	string	Yes	The name of the consumer organization.
`catalog`	string	Optional	The name of the target catalog. If not specified, `Sandbox` is used by default.

You can use the following prompts to create a consumer application credentials:

Table 4. List consumer application credentials

Action	Prompts	Commands

Action	Prompts	Commands

List consumer application credential	• List consumer application credential by title (default catalog: sandbox)
	`list consumer app credentials for consumer app test-app and consumer org test-org`
	• List consumer application credential by name to a specific catalog, for example, test
	`list consumer app credentials for consumer app test-app and consumer org test-org from catalog test`
		List consumer application credential by title (default catalog: sandbox)
		`/list_consumer_app_credentials consumer_name:test-app consumer_org:test-org`
		`/list_consumer_app_credentials consumer_name:test-app consumer_org:test-org catalog:test`

Create subscription

You can create a subscription for a consumer application to a product or API within a consumer organization and catalog in the API Connect instance. User confirmation is required before this operation is performed.

Table 5. Parameters

Parameter	Type	Required	Description
`api_name`	string	Required if `product_name` is not provided.	The name of the API to subscribe to.
`product_name`	string	Required if `api_name` is not provided.	The name of the product to subscribe to.
`consumer_app`	string	Optional	The name of the consumer application. If not specified, and only one consumer application exists in the system, that application is used by default.
`consumer_org`	string	Optional	The name of the consumer organization. If not specified, and only one consumer organization exists in the system, that organization is used by default.
`plan`	string	Optional	The name of the plan to use for the subscription. If not specified, and the product contains only one plan, that plan is used by default.
`catalog`	string	Optional	The name of the target catalog where the subscription is created. If not specified, `"sandbox"` is used by default.

You can use following prompts to create a subscription:

Table 6. Create subscription

Action	Prompts	Commands

Create subscription	• Create a subscription by API name (default catalog: sandbox)
	`create subscription for api sample-api`
	• Create a subscription by API name to a specific catalog, for example, test
	`create subscription for api sample-api to catalog test`
	• Create a subscription by the Product name to a specific catalog, for example, test
	`create subscription for product sample-product to catalog test`
	• Create a subscription by API name by using a specific plan to a specific catalog
	`create subscription for api sample-api using plan default-plan to catalog test`
	• Create a subscription by API name to a specific consumer app and consumer org to a specific catalog
	`create subscription for api sample-api for consumer app test-app and consumer org test-org in catalog test`
		• Create a subscription by API name (default catalog: sandbox)
		`/create_subscription api_name:sample-api`
		• Create a subscription by API name to a specific catalog, for example, test
		`/create_subscription api_name:sample-api catalog:test`
		• Create a subscription by the Product name to a specific catalog, for example, test
		`/create_subscription product_name:sample-product catalog:test`
		• Create a subscription by API name by using a specific plan to a specific catalog
		`/create_subscription api_name:sample-api plan:default-plan catalog:test`
		• Create a subscription by API name to a specific consumer app and consumer org to a specific catalog
		`/create_subscription api_name:sample-api consumer_app:test-app consumer_org:test-org catalog:test`

List subscription

You can list subscriptions of an application from the API Connect instance.

Table 7. Parameters

Parameter	Type	Required	Description
`api_name`	string	Optional	The name of the API.
`product_name`	string	Optional	The name of the product.
`consumer_app`	string	Optional	The name of the consumer application.
`consumer_org`	string	Optional	The name of the target organization. If not specified, `Sandbox` is used by default.

You can use following prompts to list subscriptions:

Table 8. List subscription

Action	Prompts	Commands

Action	Prompts	Commands

List subscription	• List subscriptions by API name (default catalog: sandbox)
	`list subscriptions for api sample-api`
	• List subscriptions by API name from a specific catalog, for example, test
	`list subscriptions for api sample-api from catalog test`
	• List subscriptions by product name from a specific catalog, for example, test
	`list subscriptions for product sample-api from catalog test`
	• List subscriptions by consumer application name and consumer org name from specific catalog
	`list subscriptions for consumer app test-app and consumer org test-org from catalog test`
		• List subscription by API name (default catalog: sandbox)
		`/list_subscriptions api_name:sample-api`
		• List subscription by API name to a specific catalog, for example, test
		`/list_subscriptions api_name:sample-api catalog:test`
		• List subscription by the Product name to a specific catalog, for example, test
		`/list_subscriptions product_name:sample-product catalog:test`
		• List subscription by API name by using a specific plan to a specific catalog
		`/list_subscriptions consumer_app:test-app consumer_org:test-org catalog:test`

List operations

Use the **`list`** prompt to retrieve a paginated list of catalogs, draft or published APIs or products, gateways, consumer organizations, and apps within a provider organization.

List resources

This operation executes immediately without requiring user confirmation and returns the requested data directly in the response. Use the **`limit`** and **`offset`** parameters to control pagination.

Table 1. Parameters

Parameter	Type	Description	Default value
`limit`	integer	Maximum number of catalogs to return in the response. Controls pagination by specifying the page size.	100
`offset`	integer	Number of catalogs to skip before starting to return results. Used for pagination to navigate through large datasets.	0

You can use following prompts to li:

Table 2. List resources

Action	Prompt	Commands

List catalogs	`list catalogs`
	`list catalogs with limit 5`
	`list catalogs with offset 4`
	`list catalogs with limit 5 and offset 5`
		`/list_catalogs`
		`/list_catalogs limit:5`
		`/list_catalogs offset:4`
		`/list_catalogs limit:5 offset:5`

List draft products	`list draft products`
	`list draft products with limit 5`
	`list draft products with offset 4`
	`list draft products with limit 5 and offset 5`
		`list draft products`
		`list draft products with limit 5`
		`list draft products with offset 4`
		`list draft products with limit 5 and offset 5`

List gateways	`list gateways in catalog`
	`list gateways in catalog with limit 5`
	`list gateways in catalog with offset 4`
	`list gateways in catalog with limit 5 and offset 5`
	`list gateways in catalog` ***`CATALOG_NAME`*** `and limit 5`
	`list gateways in catalog` ***`CATALOG_NAME`*** `and limit 5 and offset 3`
		`/list_gateways_in_catalog`
		`/list_gateways_in_catalog catalog:CATALOG_NAME`

List consumer organizations	`list consumer orgs`
	`list consumer orgs with limit 5`
	`list consumer orgs with offset 4`
	`list consumer orgs with limit 5 and offset 5`
	`list consumer orgs in catalog` ***`CATALOG_NAME`*** `with limit 5`
	`list consumer orgs in catalog` ***`CATALOG_NAME`*** `with limit 5 and offset 3`
		`/list_consumer_orgs`
		`/list_consumer_orgs limit:5`
		`/list_consumer_orgs offset:4`
		`/list_consumer_orgs limit:5 offset:5`
		`/list_consumer_orgs limit:5 catalog:CATALOG_NAME`
		`/list_consumer_orgs catalog:CATALOG_NAME limit:5 offset:3`

Action	Prompt	Commands

List published products	`list published products`
	`list published products with limit 5`
	`list published products with offset 4`
	`list published products with limit 5 and offset 5`
	`list published products in catalog CATALOG_NAME with limit 5`
	`list published products in catalog CATALOG_NAME with limit 5 and offset 3`
		`/list_published_products`
		`/list_published_products limit:5`
		`/list_published_products offset:4`
		`/list_published_products limit:5 offset:5`
		`/list_published_products limit:5 catalog:CATALOG_NAME`
		`/list_published_products catalog:CATALOG_NAME limit:5 offset:3`

List draft APIs	`list draft apis`
	`list draft apis with limit 5`
	`list draft apis with offset 4`
	`list draft apis with limit 5 and offset 5`
		`/list_draft_apis`
		`/list_draft_apis limit:5`
		`/list_draft_apis offset:4`
		`/list_draft_apis limit:5 offset:5`

List published APIs	`list published APIs`
	`list published apis with limit 5`
	`list published apis with offset 4`
	`list published apis with limit 5 and offset 5`
	`list published apis in catalog CATALOG_NAME with limit 5`
	`list published apis in catalog CATALOG_NAME with limit 5 and offset 3`
		`/list_published_apis`
		`/list_published_apis limit:5`
		`/list_published_apis offset:4`
		`/list_published_apis limit:5 offset:5`
		`/list_published_apis limit:5 catalog:CATALOG_NAME`
		`/list_published_apis catalog:CATALOG_NAME limit:5 offset:3`

List apps	`list apps in catalog`
	`list apps in catalog with limit 5`
	`list apps in catalog with offset 4`
	`list apps in catalog with limit 5 and offset 5`
	`list apps in catalog CATALOG_NAME with limit 5`
	`list apps in catalog CATALOG_NAME with limit 5 and offset 3`
	`list apps in catalog for consumer org corg1`
	`list apps in catalog CATALOG_NAME with limit 5 and consumer org corg1`
	`list apps in catalog CATALOG_NAME with limit 5 and offset 3 and consumer org corg1`
		`/list_apps_in_catalog`
		`/list_apps_in_catalog limit:5`
		`/list_apps_in_catalog offset:4`
		`/list_apps_in_catalog limit:5 offset:5`
		`/list_apps_in_catalog limit:5 catalog:CATALOG_NAME`
		`/list_apps_in_catalog catalog:CATALOG_NAME limit:5 offset:3`
		`/list_apps_in_catalog consumer_org:CONSUMER_ORG_NAME`
		`/list_apps_in_catalog catalog:CATALOG_NAME limit:5 consumer_org:CONSUMER_ORG_NAME`
		`/list_apps_in_catalog catalog:CATALOG_NAME limit:15 offset:5 consumer_org:CONSUMER_ORG_NAME`

Plans with multiple tool operations

Here are a few example prompts to generate plans using multiple tools:

Example prompts

To list catalogs, enter the following prompts:

```
list catalogs and use the selected catalog to list published apis
```

```
list catalogs and use the selected catalog to list published products
```

```
list catalogs and use the selected catalog to list consumer orgs
```

```
list catalogs and use the selected catalog to list apps
```

To create a draft API and use the API name to validate the API, enter the following prompt:

```
create draft api @file_name.json and validate the api created
```

To create a draft API and download it, enter the following prompt:

```
create draft api @file_name.json and download the draft api created
```

To create a draft API and validate the API and publish it, enter the following prompt:

```
create draft api @file_name.json and validate the api and publish it to catalog with name catalog1
```

To validate and review security of the API, enter the following prompts:

```
validate api API_NAME and add client secret security to that api
```

```
review security of api API_NAME and publish the api to catalog CATALOG_NAME
```

```
validate api with name API_NAME and version VERSION and add client secret security to that api and publish to catalog CATALOG_NAME
```

To list apps in catalog and use the selected app to list subscriptions, enter the following prompt:

```
List apps in catalog with name CATALOG_NAME and use the selected app to list subscriptions
```

To list published products and APIs in a catalog, enter the following prompts:

```
List published products in catalog CATALOG_NAME and list apps in catalog and create subscription for the selected app
```

```
List published apis in catalog CATALOG_NAME and list apps and create subscription for the selected application
```

OpenAPI Python Generator

The OpenAPI Python Generator tool creates Python FastAPI server code based on your OpenAPI specification 3.0 specification. This code helps you quickly scaffold API endpoints that are defined in your OpenAPI document so that you can focus on implementing business logic instead of writing boilerplate code.

Important: Ensure that you have created OpenAPI document beforehand.

Key highlights

- Generates a Python FastAPI backend server based on an input OpenAPI 3.0 specification.
- Supports generation of three different server types:
  - Simple Server for mocking API responses.
  - Database creates, retrieve, update, and delete Server for direct database interactions.
  - Connector Pack Server for interacting with the IBM Connectivity Pack applications.

The following operations are supported in the OpenAPI Python Generator tool:

- Simple server
- Database CRUD server
- Connector Pack Server

Table 1. Parameters

Parameter	Required	Description	Default
`input_file`	Yes	The OpenAPI Specification in YAML or JSON format.	None
`server_type`	No	The server type that you want to generate.	Blank (indicating a simple server type)
`database_type`	No	The database language type that you want to use when generating the database CRUD type server	Postgres

Simple server

A minimalist server that provides the basic setup to start building your service.

Example prompt

```
Generate some Python FastAPI server code based on the following openapi @<filename.yaml>
```

Database CRUD server

An extension of the Simple Server that incorporates database logic to perform create, read, update, and delete (CRUD) operations, directly on your own database. This type is suitable for applications that require persistent data management. You can also specify a database language to use by default Postgres is used to but you can also use DynamoDB and Db2.

Example prompts

```
Generate some Python FastAPI server with database interaction code based on the following openapi @<filename.yaml>
```

```
Generate some Python FastAPI server with postgres database interaction code based on the following openapi
@<filename.yaml>
```

```
Generate some Python FastAPI server with dynamodb database interaction code based on the following openapi
@<filename.yaml>
```

```
Generate some Python FastAPI server with db2 database interaction code based on the following openapi @<filename.yaml>
```

Connector Pack server

The Connector Pack server variant is designed to generate code for integrating with the IBM Connectivity Pack. Start by using `OASCreator Tool` to craft a tailored OpenAPI 3.0 specification for this server type. This code generation allows to provide important information that is required for connector application generation. From that specification, the generator produces both a FastAPI backend and a Client SDK library that handles all communication with the IBM Connectivity Pack endpoint.

The following IBM Connectivity Pack applications are supported:

- Postgres
- DynamoDB
- Db2
- Salesforce
- ServiceNow

Example prompts

```
Generate some Python FastAPI server for a connector based on the following openapi @<filename.yaml>
```

```
Generate some Python FastAPI server for a postgres connector based on the following openapi @<filename.yaml>
```

```
Generate some Python FastAPI server for a dynamodb connector based on the following openapi @<filename.yaml>
```

```
Generate some Python FastAPI server for a db2 connector based on the following openapi @<filename.yaml>
```

```
Generate some Python FastAPI server for a salesforce connector based on the following openapi @<filename.yaml>
```

```
Generate some Python FastAPI server for a servicenow connector based on the following openapi @<filename.yaml>
```

Important:

1. The IBM Connectivity Pack Connector URL must be inserted into the generated `config.json` based on the endpoint for your IBM Connectivity Pack deployment.
2. For the applications supported by the API Agent you must bring your own credentials to make API calls to the IBM Connectivity Pack route provided. These credentials must be inputted into the generated `config.json`. The credentials setup varies between applications.

OpenAPI Enhancer

The OpenAPI Enhancer tool improves your APIs by generating intelligent recommendations for descriptions and examples. It also helps identify validation errors and potential issues that might affect API correctness.

The OpenAPI Enhancer tool communicates with the API Agent. After you enter a prompt and click Send in the API Agent, a proposed plan is displayed. To begin the specification enhancement or auto-correction of the OpenAPI, click Start. After the process is finished, you can download the improved OpenAPI file.

Key highlights

- Enhance your OpenAPI 3.0 documentation by generating recommendations for your descriptions and examples.
- Improves your OpenAPI 3.0 specification through identifying validation errors and generating potential corrections.

The following operations are supported in the OpenAPI Enhancer tool:

- Specification enhancements
- Specification validation errors

Table 1. Parameters

Parameter	Required	Description	Default
`input_file`	No	The OpenAPI specification in YAML or JSON format.	None
`api`	No	The draft API name.	None
`version`	No	The draft API version.	None
`file_format`	No	The format of the generated OpenAPI file that is displayed, either JSON or YAML.	YAML
`oai_feature_type`	Yes	Select the type of GenAI enhancement that you want to apply, either suggest improvements or automatically correct the content.	None

Specification enhancements

Enhance your OpenAPI documentation by analyzing the API definition, and generating recommendations for your descriptions and examples.

Example prompts

```
Augment the following openapi with enhanced descriptions and examples @openapi-sample.yaml
```

Or from a Draft API (with API name: version)

```
Augment the following openapi with enhanced descriptions and examples openapi-sample:1.0.0
```

Note: Select the required file, for example, `openapi-sample.yaml`. Entering @ after the prompt displays a list of OpenAPI documents available in your workspace.

Specification validation errors

Improve your APIs by analyzing your OpenAPI 3.0 specification, and generating potential API corrections for any validation errors.

Example prompts

```
Correct the validation errors in the following openapi file @openapi-sample.yaml
```

Or from a Draft API (with API name: version)

```
Correct the validation errors in the following openapi file openapi-sample:1.0.0
```

Note: By default, the format of the augmented OpenAPI document is YAML. If you need your OpenAPI document to be in JSON format, specify it clearly in the prompt. These API Agent capabilities are also available in the API Manager UI.

OpenAPI Generator

The OpenAPI generator tool generates OpenAPI documents from scratch based on the prompts that you provide.

The OpenAPI generator tool can be used to generate OpenAPI 3.0 documents in JSON or YAML format from scratch based on prompts that are provided by the user that uses Natural Language Processing (NLP). Given a natural language description of an API or application as input that the user would like to generate an OpenAPI document for, the tool uses the Granite 3 model available on IBM watsonx to generate a starter stub of an OpenAPI document that the user can then take and continue to build on. Note: The tool generates an OpenAPI documents from a natural language description, whereas the OAS creator tool generates the OpenAPI documents from an existing database schema that added to the API Agent sources.

Tool details and limitations

The following are the Open API Generator tool details and limitations:

- This tool is provided to assist users with the task of generating an OpenAPI document from scratch based on a natural language description, it should not be confused with the OAS creator tool, also available to the API Agent, which is used for generating an OpenAPI document from an existing database schema added to the API Agent sources.
- This tool relies on the Granite 3 foundation model available IBM watsonx for OpenAPI document generation.
- Given that this tool relies on the output of the foundation model based on the provided input description, like all AI models, the output is subject to errors.
- If the generated OpenAPI document does not match the description that is provided as input, try again and consider rephrasing the description.
- If the generated OpenAPI document that is displayed from the model contains errors, such as OpenAPI specification errors, or semantic errors, the tool automatically passes the document through the fix (auto-correct) operation of the OpenAPI Enhancer tool. If still errors are present after this correction, these will be reported in the chat window.
- If the generated OpenAPI document contains JSON or YAML syntax errors that cannot be fixed (auto-corrected) by the OpenAPI Enhancer tool, the tool does not display the document. In this situation, the system displays the following message: **`please re-phrase and try again`**. Try rewording the input description before trying again, such as using a different ordering or combination of words in the input prompt.
- All OpenAPI documents that are generated by this tool should be reviewed for correctness and accuracy before being used.

Generate an OpenAPI document from a natural language description

You can generate an OpenAPI 3.0 document from scratch in either JSON or YAML format, from a natural language description given in English (one or more sentences) for the API or application that you would like to generate. Simply start your chat prompt with **`Generate an openapi for...`**. The generated OpenAPI document contains component schemas relevant to the API or application that is described, and path items for create, retrieve, update, and delete operations for those schemas. Also, the generated document includes recommended operation-level security and security schemas by default, unless explicitly prompted not to do so.

Note: Break the prompt as multiple meaningful sentences. You can mention the type of API you want to generate in the first sentence and the required specifications in the following sentences.
This operation shows with the following details: The generated OpenAPI 3.0 document in JSON or YAML format (By default, if the YAML format not specified in the input prompt message) that can be downloaded.

Table 1. Parameters

Parameter	Required	Description	Default
`text`	Yes	The natural language description of the OpenAPI 3.0 specification to be generated Note: The entire input prompt message is used as the text parameter value. It does not need to be referenced explicitly.	None
`file_format`	No	The Open API Generator tool supports the output format of the generated OpenAPI document file in JSON and YAML.	YAML

Example prompts

```
Generate an OpenAPI spec for a weather application

Generate an OpenAPI spec for a book library application

Generate an openapi for a blog application in yaml format

Generate an OpenAPI spec for a blog application. Include operations for searching for blogs by most recommended topics.
Searching for blogs should not require any authentication

Generate an OpenAPI spec for a weather application. Include an operation to provide a 7-day forecast for a given location

Genrate an OpenAPI spec for a book library application. Include operations to add and remove books from the library. Also
include an operation to search the books in the library with a title
```

Next action suggested

- Generate fastapi server code for the openapi file {@filename}
- Generate fastapi server code with database integration for the openapi file {@filename}

Code deployment

The Code deployment tool is used to deploy application source code to IBM® Code Engine, which simplifies the deployment process and reduces manual effort.

The Code deployment tool provides a streamlined and automated deployment process. It supports user-managed deployment, and offers features such as retrieving the status of the deployment process, retrieving logs of the deploy application, and deletion of the specified application.

User-managed deployment

Easily deploy application code that uses the Agent interface to a user-specified IBM Code Engine service, which offers flexibility and control. The following key features are included:

User-controlled resources
: You can retain full control over the lifecycle and configuration of deployed resources.

Deployment details
: The tool provides the application URL endpoint and application name upon successful deployment.

Features

Deploying application code
: Deploy a .zip file that contains application code to user-managed Code Engine environment.

- Deploying application code is an asynchronous operation.
- Query the deployment status separately to retrieve results.

Note:

- Only `.zip` files are supported for deployment. Other formats are not accepted.
- The file size must be less than 1 MB.
- For information about basic predeployment validation checks, see Predeployment checks for user-managed Code Engine.
- The tool determines the resource allocation for the deployed application as follows:
  - 0.125 CPU
  - 0.5 GB of memory

Check deployment status
: Retrieve the status of a deployment based on the .zip file name that is provided by the user.

- After the deployment is completed, the tool displays the deployment status and the application name and URL endpoint.
- For more information about the deployment statuses, see Deployment status.

Fetch logs of the application
: Retrieve the logs of the application that is deployed in Code Engine.

- The fetched logs are packaged as a `.log` file and provided for download and debugging.

Delete application
: Delete the application and its related resources.

Predeployment checks for user-managed Code Engine

User-managed code engine does the checks that are performed before deploying the application and its associated resources.

For user-managed environments, the following conditions must be met.

Table 1. Requirements

Check	Requirements
Project limit	The total number of projects must be less than 20. If the limit is reached, the project must exist in the list of projects.
Project state	The project must not be in the creating state.

Note: Deployment proceeds only if all the conditions are met. If any condition is not met, a warning message is displayed that specifies which check failed.

Naming conventions for deployment of resources

To ensure consistency and traceability, the Code deployment tool follows standardized naming patterns when it creates resources.

IBM Code Engine
: Use the following naming conventions when you create deployment resources in the IBM Code Engine services:
The following table shows how resources are created for an application with code file name **`app-code`**, which is deployed by user **`123`** under the provider organization **`abc`**.

Table 2. Naming conventions

Resource type	Format	Naming convention
Project	`aa-<provider_organization>-project` Note: Projects in IBM Code Engine are scoped to the provider organization within API Connect.	`aa-abc-project`
Registry secret	`<project_name>-registry-secret`	`aa-abc-project-registry-secret`
Image build	`<project_name>-<application_code_file_name>-<user_id>-<resource_name>`	`aa-abc-project-app-code-123-image-build`
Image builds run	`<project_name>-<application_code_file_name>-<user_id>-<resource_name>`	`aa-abc-project-app-code-123-image-build-run`
Configmap	`<project_name>-<application_code_file_name>-<user_id>-<resource_name>`	`aa-abc-project-app-code-123-cm`
Secret	`<project_name>-<application_code_file_name>-<user_id>-<resource_name>`	`aa-abc-project-app-code-123-secret`
Application	`<project_name>-<application_code_file_name>-<user_id>-<resource_name>`	`aa-abc-project-app-code-123-app`

Deployment status

When you start the deployment status operation, different status are returned by the Code deployment tool to identify the progress or outcome of the deployment.

IBM Code Engine deployment status
: The following statuses represent the stages of deployment within IBM Code Engine:

Table 3. Statuses

Stage	Description	Statuses
Project creation	Project and secret setup	`PENDING, IN_PROGRESS, COMPLETED, FAILED`
Image building	Image build and push	`PENDING, IN_PROGRESS, COMPLETED, FAILED`
Application deployment	Application, configmap, and secret creation	`PENDING, IN_PROGRESS, COMPLETED, FAILED`

Note:

- All three stages are displayed to indicate which stages are completed, which one is in progress, and which are still pending.
- If any part of the process fails, the failed stage displays the FAILED status and a reason for the failure.
- If all stages display the COMPLETED status, the tool provides the Application URL and Application name.
- Ensure that the source OpenAPI document that the deployed application was generated from is now updated to use the IBM Code Engine Application URL as the value of the `servers[0].url`. This is essential if the next planned action is to create a draft API and publish it in API Connect with the API Connect Task tool.

Prompts library

The API Agent prompts library provides a comprehensive guide on using prompts to complete various tasks.

Guidelines for using prompts

To achieve accurate and efficient results, use the following guidelines when you enter the prompt:

1. Avoid the words or tone that convey sarcasm or humor, as they can be misinterpreted.
2. Use active voice, correct grammar, spelling, and keep your request clear and specific.
3. Provide clear context and relevant keywords, and avoid vague or domain-specific terms. For example, `generate test` or `build API`.
4. If the system is unable to understand your request, it offers suggestions for the requests.

Prerequisites

The API Agent plug-in can be used to complete tasks that are related to API Connect.

- Ensure that you are logged in to API Agent. For login and operation instructions, see Getting started.
- You must have valid permissions to use the API Agent. For more information, see API Agent user roles.
- Ensure that you have the same permissions through the API Connect's API Manager interface. Even if you have permission to use the API Agent plug-in, actions fail if you do not have the necessary permissions to complete the same tasks through the API Manager UI.

Usage of prompts for different cases

The following table explains the prompts and its usage for different actions.

Table 1. Prompts usage

Action	Prompt	Description
Generating test cases	Generate test cases for the API `Generate test cases for <pulbished api name>`	• Check that the API is published before you generate test cases for it. For more information, see Creating and publishing draft API. • API Agent connects to smart generation feature of test module, which creates test cases iteratively for the first 15 endpoints in the available API file. The test cases are stored in a test suite that is suffixed with `AA_Test_Suite` along with `api name (AA_Test_Suite_<api_name>)`. • After generation is completed, API Agent displays the status message that shows the number of test cases that are created and the name of the test suite where they were created. • You can find the generated test cases in the Test module of the API Manager console.
Running test cases	Run test cases for the API `Run test cases for <pulbished api name>` Note: The `<published api name>` must contain the name of the API. Do not combine the version information. For example, `petstore`.	• You can use to run test cases for a published API in Visual Studio Code, including initiating the test, viewing results, and optionally deleting a test case. • The Smart Generation feature of the API Agent test module generates the data for input parameters to run the test. The API Agent displays the status message and the URLs of test results in Visual Studio Code after runs are initiated successfully. Click the hyperlink to view the results of the individual test cases in the API Manager console.
Deleting test cases	`delete test case <test_name> in suite <suite_name>`	
Listing test suites	`List test suites`	You can use to list test suits. Also, you can delete a test suite by entering a prompt with the suite name.
Deleting test suite	`delete test suite <suite_name>`	
Listing test cases	`List test cases for test suite <test suite name>`	• You can use to list test cases corresponding to a test suite. • Ensure that the test suites are available. If not available, follow the steps that are mentioned in the Generating test cases row. • To identify the available test suites, see the Listing test suites row.

Action	Prompt	Description

Creating an OpenAPI	• To create an API specification for orders table
	`create openapi for orders table`
	or
	`generate api spec for orders table`
	Note: The database must not contain another table with the same name in any other schema, as this situation might cause confusion.
	• To create an API specification for orders table
	`create openapi for orders table with schema_name as purchase_order`
	Or
	`create openapi for orders table in purchase_order schema`
	• To create an API specification for orders table by using object name and without schema name
	`create openapi for orders table with object_name as purchase_order_orders`
	• To create an API specification for orders table by using source ID
	`create openapi for orders table with source_id as 6c115670-a7e1-11ef-b576-fa5e88d5392d`
	• To extract the OpenAPI specification for the table name and transforms to code generator-specific format
	`Extract the openapi spec for the given table name and transforms to Code generator specific format`
		The following are the examples of prompts that you can use to create an Open API

Generating code	• To generate code for a simple server type
	`Generate some Python FastAPI server code based on the following openapi @my_file.yaml`
	Or
	`Please build FastAPI backend code using the OpenAPI file @api_spec.yaml`
	Or
	`Can you develop a Python FastAPI server using the openapi specification provided in @service_definition.json`
	• To generate code for a database create, retrieve, update, and delete server type
	`Generate some Python FastAPI server code based on the following openapi @my_file.yaml that handles database operations`
	Or
	`Can you develop a database driven Python FastAPI server using the openapi specification provided in @service_definition.json`
	Note: To know more information about usage of prompts by using OpenAPI Python Generator tool, see OpenAPI Python Generator tool.	

Action	Prompt	Description

	• To view the list of enabled servers
	`List me all the MCP servers that are currently enabled`
	Or
	`List all available MCP servers`
	• To get the details of the MCP server
	`Fetch the details of GitHub™ MCP server`
	• To update the MCP server
	`Update the enabled MCP server gitlab™ with updated deployed url [Add URL]`
	• To disable the MCP server from GitHub
	`Remove the github™ MCP server from the enabled tools`
	• To retrieve detailed information about a specific MCP server
	`Fetch details of the mcp server postman™`
	or
	`Show me the configuration details for the github™ MCP server`
	Or
	`Get information about the weather MCP server`
	• To check whether an MCP server exists or not
	`Check the existence of mcp server Github™`
	Or
	`check availability of mcp server postman™`
	Or
	`check if postman™ mcp server is available`
		Use the following prompts to do the following actions with the MCP server:
		• List of enabled servers
		• Server details
		• Update
		• Disable
		• Details about a specific MCP server
		• Check existence of MCP server

Sequential prompts

You can use API Agent to chain multiple tools together in a single prompt and then run one after another. The following are examples of sequential prompts:

1. To create and run test cases

   `create test cases for the petstore api and run the test cases`

2. To list draft or published APIs or products

   `list draft apis, draft products, published apis and published products`

   Or

   `list published apis`

3. To create a draft API and generate FastAPI server code

   ```
   create draft api from file @openapi.yaml and generate fastapi server code from the same api file
   ```

   Or

   ```
   create draft api using @file_name
   ```

4. To review security of an API

   ```
   review security of api API_NAME:VERSION
   ```

5. To review security and validate an API

   ```
   review security of api API_NAME:VERSION
   ```

   Or

   ```
   validate api API_NAME:VERSION
   ```

Troubleshooting

You can resolve common issues with API Agent in Visual Studio Code, such as authentication errors or missing source IDs.

Unable to use API Agent

Symptoms
: After you are redirected to Visual Studio Code, API Agent displays the following error message: `Error unable to fetch user.`

Causes
: This issue occurs if there is a problem with user authentication or API Agent configuration.

Resolving the problem
: Click the IBM API Agent menu and click New chat.

API Agent extension issues

Symptoms
: API Agent extension window disappears

Cause

Resolving the problem
: To activate the extension window, complete the following steps:

  1. Enter CMD + SHIFT + P to open the Visual Studio Code command palette.
  2. In the command palette, enter **View: Show IBM API Agent**.

Known limitations

During the public preview phase, API Agent has limitations for new chat sessions, chat interface settings, and login behavior.

New chat session

When you use the API Agent in Visual Studio Code, you can start a new chat session at any time. However, when you switch to a new session, you cannot return to or access the previous session.

Chat interface settings

For this public preview, the Settings option in API Agent is disabled. In the Settings section, you can view the URL and the organization that is associated with it.

API Connect login behavior in Visual Studio Code

When you use the API Agent in Visual Studio Code, you might experience multiple UI reloads after you log in to the API Connect UI. The issue typically resolves itself automatically after a few reloads.

Firefox login limitation

Logging in to the webMethods Hybrid Integration environment by using a private browsing window in Firefox is not supported.

Air-gapped installation

For this release, API Agent does not support an air-gapped installation.

API Agent displays an error message on the settings page

- When you add or edit a database type source and expand an application object corresponding to a database table to view its columns, the API Agent Settings page displays the following error message: **`HTTP 503 service unavailable`**.
- A spinner appears indefinitely for that application object, preventing you from viewing the columns of the expanded database table application object.
- You can still select or clear the database application object, and move to the next page.

Authentication issue on Windows with Chrome and Edge

The API Agent currently only works with Firefox on Windows. When using Chrome or Edge, it does not redirect back to Visual Studio Code after login.

To authenticate and redirect successfully using API Agent on Windows, complete the following steps:

1. Set Firefox as the default browser on Windows.
2. After authenticating, confirm and click the pop-up window that appears in Firefox.
3. Manually return to the Visual Studio Code, and click the pop-up that requests permission to open the API Agent. This activates the Visual Studio Code plug-in.

Developing your APIs and applications

You develop APIs by using the IBM® API Connect developer toolkit.

The API Connect developer toolkit provides both the API Designer user interface and a command line interface that you can use to develop APIs and publish them to API Connect.

Security tip: While developing your API, remember to protect sensitive data that might be exposed to consuming applications. For information on configuring security requirements for your APIs, see Enforcing security requirements on an API.
You publish APIs by including them in a "product" and then publishing that product. Define your APIs and products by creating and validating YAML definition files in your local file system, or using the API Connect UI. You can then interact with API Connect using either the UI or the toolkit commands.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The developer toolkit is described in detail in the following subsections:

- **API development checklist**
  A summary, with links, of the key tasks for developing APIs in IBM API Connect.
- **API discovery**
  Use API discovery to discover the APIs in your organization, and copy them into API drafts to enable lifecycle management.
- **Working with the toolkit**
  Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM API Connect and publish APIs that you have defined in your file system.
- **Managing platform REST API keys**
  Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.
- **Searching for items in API Manager**
  Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- **Working with API definitions**
  An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser-based API Manager UI.
- **Working with Products**
  In IBM API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.
- **Creating and validating API and Product definitions by using the CLI**
  The developer toolkit of IBM API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.
- **Working with global policies**
  Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can upload global policies into each of the gateway services in your catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.

- **Reference**
  Reference information for developing your APIs in API Connect, including context variables, and template variables.

API development checklist

A summary, with links, of the key tasks for developing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	For you to be able to connect to a Management server by using either the API Designer or API Manager user interfaces, one or other of the following prerequisites must be satisfied: • Your administrator has created a provider organization, specifying you as the owner; see Creating a provider organization. • You have been added as a member of a provider organization; see Adding provider organization users and assigning roles.
Install the developer toolkit	The developer toolkit provides a command-line environment and an API Designer user interface, both of which enable you to develop and work with your APIs on your local machine; you publish your APIs to the Management server when ready. You can also develop your APIs directly on the Management server by using the API Manager user interface.
Log in to the user interface; see Logging in from API Designer, or Accessing the API Manager user interface, depending on which user interface you want to use.	After you have activated your account, you can log in to your Management server from either user interface. You can also use the API Designer in offline mode, but to be able to test and publish APIs you must be connected to a Management server.
Create your API definitions	You can create API definitions in the following ways: • Create a REST API definition either by composing the API definition, and its operations, from scratch, creating a proxy API that calls an existing endpoint, or importing an OpenAPI definition. • Expose an existing SOAP service as an API. • Create a GraphQL API proxy definition that proxies a backend GraphQL server.
• Secure your APIs (OpenAPI 2.0) • Secure your APIs (OpenAPI 3.0)	You configure security for an API by creating one or more security definitions that you then apply to your API, and to the operations in your API. Security mechanisms include basic authentication through a user registry, and token based authentication with OAuth.
Test your APIs	The user interfaces provide a test tool with which you can test your APIs through the gateway.
Productize and publish your APIs	To make your APIs available to application developers, you include them in a Product that you then publish to the gateway.
Apply visibility controls and rate limiting to your APIs	Visibility settings control which APIs the application developers can subscribe to. Rate limiting controls the usage of your APIs; for example, you can apply a rate limit of 100 calls per minute.
Develop your APIs by using the developer toolkit CLI	You can use the developer toolkit CLI to develop APIs based on OpenAPI definition files in YAML or JSON format.

API discovery

Use API discovery to discover the APIs in your organization, and copy them into API drafts to enable lifecycle management.

IBM® API Connect includes an optional API discovery capability that enables you to quickly discover the APIs in your organization. You can then easily copy the APIs that you want to work with into API drafts, so that they can be fully managed within API Connect. API discovery uses data source collectors that are configured to integrate with gateways and ingresses to give you the visibility of the API traffic in your networks. The logs from this traffic are forwarded to the discovery capability, analyzed, and then API documents are generated and presented for review. These generated API documents can then be copied to draft APIs as required, to enable full lifecycle management.

Note:

- Before you can create API discovery sources, the API discovery capability must be enabled on your provider organization by your system administrator. For more information, see Enabling API discovery on Kubernetes.

The following types of data source collectors are supported:

- GitHub
- DataPower® API Gateway proxy
- OpenTelemetry

Restriction: The following limitations apply to the API discovery capability.

- The API discovery capability is available only in the API Manager UI. It's not available in the API Designer UI.
- The toolkit CLI can be used for operations on the discovered APIs and sources, but not on configuring the collectors.

See the following topics for detailed information about how to configure and run API discovery.

1. Configure one or more data source collectors for discovering APIs:
   - Configuring a GitHub collector for API discovery
   - Configuring a DataPower API Gateway proxy collector for API discovery
   - Configuring an OpenTelemetry collector for API discovery
2. Discover and review the APIs that are collected. See Reviewing your discovered APIs.
3. Manage the lifecycle of your discovered APIs. See The API discovery lifecycle in API Manager.

- **Configuring a GitHub collector for API discovery**
  How to add a GitHub data source collector to your API discovery capability.
- **Configuring a DataPower API Gateway proxy collector for API discovery**
  How to add a DataPower API Gateway proxy data source collector to your API discovery capability.
- **Configuring Noname collector for API discovery**
  Using the Noname collector, you can discover APIs from the Noname environment. This document provides step-by-step instructions to add a Noname data source collector to your API discovery capability.
- **Configuring an OpenTelemetry collector for API discovery**
  How to add an OpenTelemetry collector to your API discovery capability. The collector can be based on an Istio or an NGINX data source.
- **Reviewing your discovered APIs**
  How to review the discovered OpenAPI documents in your API discovery capability.
- **The API discovery lifecycle in API Manager**
  When you manage your discovered APIs in the API Manager UI, you move them through a series of lifecycle states. From initially discovering an OpenAPI document, through to copying that document to API drafts to make it available to your API developers, and to eventual archiving.

Configuring a GitHub collector for API discovery

How to add a GitHub data source collector to your API discovery capability.

Before you begin

Before you can configure an API discovery GitHub collector, the following prerequisites are required:

- You must have a GitHub repository that contains one or more OpenAPI reference documents.

One of the following provider organization roles is required to be able to manage sources:

- Organization Administrator
- Owner
- Custom role with the **`Settings: Manage`** permission.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. Before you can discover any APIs, you must configure one or more data source collectors. These collectors then get automatically added to the Sources tab in the API Manager UI when the collector sends the first OpenAPI documents to your provider organization.

To configure an API discovery GitHub collector, you create a GitHub Actions workflow in your GitHub repository. This workflow enables your OpenAPI reference documents to be automatically sent to, and kept in sync with, API Connect. These OpenAPI documents can then be copied to draft APIs as required, to enable full lifecycle management in API Manager.

Note: When an API with a large payload is sent (for example, a complex API that's more than 1 MB in size), there might be some delay in creating the discovered API. It is recommended that you don't run another workflow simultaneously, until you see that an API has been created in the API discovery service.

Procedure

To configure a GitHub collector, complete the following steps.

1. Create a .github/workflows directory in your repository on GitHub (if that directory doesn't exist).
2. In the .github/workflows directory, create a file for your workflow action, for example discover-api.yml.
3. In the workflow action file, copy the following workflow job.
   The following YAML contains the workflow for the **`run-discovery`** job. On a push commit to the GitHub repository, this job checks to see whether there are any changes to the files or folders that are specified and, if there are, the job sends the git difference of the commits in the files to API Connect. **`API_FILES`** can be changed to **`API_FOLDERS`** when one or more entire folders need to be discovered.

```
name: Sync Discovered API with APIConnect

on: [pull_request, workflow_dispatch, push]

env:
  API_HOST: <host-name>
  PLATFORM_API_PREFIX: <platform-api>
  PROVIDER_ORG: <porg-name>
  API_FILES: <file/files name>

jobs:
  run-discovery:
    runs-on: ubuntu-latest
    steps:
    - uses: actions/checkout@v4
    - name: Difference
      id: difference-output
      run: |
        echo "action_updates=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} |
xargs)" >> $GITHUB_OUTPUT
    - uses: ibm-apiconnect/apic-discovery-action@main
      id: discover-apis
      with:
        api_host: ${{ env.API_HOST }}
        platform_api_prefix: ${{ env.PLATFORM_API_PREFIX }}
        provider_org: ${{ env.PROVIDER_ORG }}
```

```
        api_key: ${{ secrets.apicApikey }}
        if: env.API_FILES
        api_files: ${{ env.API_FILES }}
        else if: env.API_FOLDERS
        api_folders: ${{ env.API_FOLDERS }}
        resync_check: ${{ true }}
        git_diff: ${{ steps.difference-output.outputs.action_updates }}
    - name: Display the action-result
      run: |
        echo "Result of the action: ${{ steps.discover-apis.outputs.action-result }}"
        echo "End"
```

Note that you can optionally also use the following **check_changes_job** workflow file. On a push commit to the GitHub repository, this job checks to see if there are any changes to the files or folders that are specified, or a change to the discover-api.yml file, and if there are, the job sends the files to API Connect. **API_FILES** can be changed to **API_FOLDERS** when one or more entire folders need to be discovered.

```
name: Sync Discovered API with APIConnect

on: [pull_request, workflow_dispatch, push]

env:
  API_HOST: <host-name>
  PLATFORM_API_PREFIX: <platform-api>
  PROVIDER_ORG: <porg-name>
  API_FILES: <file/files name>

jobs:
  check_changes_job:
    runs-on: 'ubuntu-20.04'
    # Declare outputs for next jobs
    outputs:
      action_changed: ${{ steps.check_workflow_changed.outputs.action_updates }}
      changed_filename: ${{ steps.changed_filename.outputs.api_file }}
      apifiles_env: ${{ steps.changed_filename.outputs.apifiles_env }}
      folder_changed: ${{ steps.check_apifolders_changed.outputs.folder_updates }}
    steps:
    - uses: actions/checkout@v4
      with:
        fetch-depth: 2
    - name: Check Workflow changed
      id: check_workflow_changed
      run: |
        echo "action_updates=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} |
grep discover-api.yml | xargs)" >> $GITHUB_OUTPUT
    - name: Changed API File Name
      id: changed_filename
      run: |
        echo "api_file=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} | xargs)"
>> $GITHUB_OUTPUT
        echo "apifiles_env=$(echo $API_FILES)" >> $GITHUB_OUTPUT
    - name: Check API Folders changed
      id: check_apifolders_changed
      run: |
        echo "folder_updates=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} |
grep $API_FOLDERS | xargs)" >> $GITHUB_OUTPUT
  run-discovery:
    runs-on: ubuntu-latest
    needs: [ check_changes_job ]
    if: ${{ (contains(needs.check_changes_job.outputs.apifiles_env,needs.check_changes_job.outputs.changed_filename)) ||
(needs.check_changes_job.outputs.action_changed) || (needs.check_changes_job.outputs.folder_changed) }}
    steps:
    - uses: actions/checkout@v4
    - uses: ibm-apiconnect/apic-discovery-action@main
      id: discover-apis
      with:
        api_host: ${{ env.API_HOST }}
        platform_api_prefix: ${{ env.PLATFORM_API_PREFIX }}
        provider_org: ${{ env.PROVIDER_ORG }}
        api_key: ${{ secrets.apicApikey }}
        if: env.API_FILES
        api_files: ${{ env.API_FILES }}
        else if: env.API_FOLDERS
        api_folders: ${{ env.API_FOLDERS }}
        resync_check: ${{ needs.check_changes_job.outputs.action_changed && true || false }}
    - name: Display the action-result
      run: |
        echo "Result of the action: ${{ steps.discover-apis.outputs.action-result }}"
```

Where:

- **name** is the name of your GitHub Action workflow.
- **API_HOST** is the domain name of the API Connect instance where the discovered APIs will be sent. For example, **dw-rosa-01.owe.p1.openshiftapps.com**.
- **PLATFORM_API_PREFIX** has a default value of **platform-api**. You can change it to match your system configuration, if different.
- **INSECURE_SKIP_TLS_VERIFY** if set to **true**, this action skips the validity check for the server certificate. This action might be required if your API Connect system is using self-signed certificates. Note that setting this action to **true** makes your HTTPS connections insecure.
- **PROVIDER_ORG** is the name of the API Connect provider organization.
- **API_FILES** or **API_FOLDERS** specifies whether you want single or multiple API files or folders to be considered for the workflow action. Separate multiple files or folders by using a comma, for example **mail-api.yaml,my-api.json,APIfolder/pet-exp.json**. The API files can be in json or yaml format.
- **resync_check** indicates whether changes to the action, such as at initial creation, should trigger an api-file synchronization.
- **git_diff** checks the difference between the current and the previous commit. If multiple files have changed in the commit, the workflow only runs if one or more of the files that are supplied in **API_FILES** or **API_FOLDERS** has changed.

- **`api_key`** are the credentials that are required for pushing API files to the API Manager. You can get the API key from the user who has access to the API Manager for posting APIs. For information about how to obtain an API key, see Managing platform REST API keys. You must then store the API key in a GitHub secret, that can then be used by this GitHub Action workflow. In the YAML in this step the **`api_key`** is called **`apicApikey`**, so if you want to reuse this YAML ensure that you create your secret with the same name. For information about how to store API keys as secrets in GitHub Actions, see Using secrets in GitHub Actions in the GitHub Docs.

To understand more about the **`apic-discovery-action`**, and how to use it, see apic-discovery-action and apic-discovery-test on **`github.com`**. These API Connect resources include working examples with a test repository.

4. Commit the workflow file to a branch in your GitHub repository.
   Committing the workflow file triggers a **`push`** event and runs the sync workflow with API Connect.
5. In the API Manager UI, click the Discover icon  , then click the Sources tab to view your GitHub collector.
   Sources can have the following status:
   - Enabled - the source is enabled, and synchronizes with the collector according to its configuration.
   - Disabled - the source is disabled, and API Connect won't accept any files from the collector. This status is set by the discovery service if a discovery operation fails.
   - Unhealthy - the source collector is unavailable.
   - Paused - the source is paused, and API Connect won't accept any files from the collector.
6. Optional: You can click the Options icon ⋮ next to a source to change its status.
   - Pause collector - to pause the source.
   - Delete collector - to delete the source from the API Manager UI. The external source files are not deleted.
   - Resume collector - to restart a paused or disabled source.
7. Optional: You can click the Manage columns icon on the table header to change the order and view of the columns.

Results

Your GitHub data source collector is now ready to synchronize with API Connect. When the collector sends the first OpenAPI documents to your provider organization, the collector becomes listed in the Sources tab in the Discover section of API Manager. A GitHub collector posts updates to API Connect only when a difference is detected due to a commit or PR event in the original data source.

What to do next

You can click the APIs tab in the Discover section of the API Manager UI, and review the API traffic in your GitHub source. For more information, see Reviewing your discovered APIs.

Configuring a DataPower API Gateway proxy collector for API discovery

How to add a DataPower® API Gateway proxy data source collector to your API discovery capability.

Before you begin

Before an API discovery DataPower API Gateway proxy collector can collect data from a provider organization, you must first enable sharing of your provider organization analytics data; see Sharing analytics data for API discovery.

One of the following provider organization roles is required to be able to manage sources:

- Organization Administrator
- Owner
- Custom role with the **`Settings: Manage`** permission.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. Before you can discover any APIs, you must configure one or more data source collectors. These collectors then get automatically added to the Sources tab in the API Manager UI when the collector sends the first OpenAPI documents to your provider organization.

To configure an API discovery DataPower API Gateway proxy collector, you can either create a proxy API definition, or update an existing proxy API, in your provider organization in API Connect. This new or existing proxy API will contain the endpoint of an existing REST service that you want to use to discover OpenAPI documents from. The discovered OpenAPI documents can then be copied to draft APIs as required, to enable full lifecycle management in API Manager. If you're updating an existing proxy API definition, the minimum fields that are required for collection to occur, are the inclusion of the **`invoke`** policy **`log`** segment, and both of the **`set-variable`** segments, that are shown in the example YAML in Step 1.

Procedure

To configure a DataPower API Gateway proxy collector by using the API Manager UI, complete the following steps. You can also use the toolkit CLI to create your proxy API definition. For general information about how to use the toolkit CLI, see Overview of the command-line tool.

1. Create a YAML file for your proxy API definition, like the following example:

```
swagger: '2.0'
info:
  version: version
  title: title
  x-ibm-name: name
  contact:
    name: contact_name
basePath: /
x-ibm-configuration:
  properties:
    target-url:
      value: target_url
      description: url_description
      encoded: false
  cors:
    enabled: true
  gateway: datapower-api-gateway
  type: rest
  phase: realized
  enforced: true
  testable: true
  assembly:
    execute:
      - invoke:
          title: invoke
          version: 2.0.0
          verb: keep
          target-url: $(target-url)$(request.path)$(request.search)
          follow-redirects: false
          timeout: 60
          parameter-control:
            type: allowlist
            values: []
          header-control:
            type: blocklist
            values: []
          inject-proxy-headers: true
          persistent-connection: true
      - log:
          version: 2.1.0
          title: log
          log-level: default
          mode: gather-only
      - set-variable:
          version: 2.0.0
          title: set-variable
          actions:
            - set: log.custom_data.discoveryServiceCollection
              value: 'true'
              type: string
          description: Setting specific collector key

      produces: []
    parameters:
      - name: +pathparam
        in: path
        required: true
        type: string
schemes:
  - https
```

Where:

- ***version*** is the version number of the API.
- ***title*** is the title of the API. For example, **My proxy API**.
- ***name*** is the name of the API. The value of the ***name*** field must be a single string that can be used to identify the API in commands, for example, **my-proxy-api**.
- ***contact_name*** is the name of a contact for the API.
- ***target_url*** is the URL endpoint of the existing REST service that you want to expose. For example, **https://myorg.com/api/**.
- ***url_description*** is a description of the target URL.
- **$(target-url)$(request.path)$(request.search)** is an **invoke** policy that allows wildcard paths and parameters to be passed after the ***target_url*** endpoint of the existing REST service. Suffixing the **$(target-url)** with **$(request.path)$(request.search)**, means that any number (1-n) of request paths and any number (1-n) of path parameters that are invoked by the users of the API, are captured and processed by the discovery collector, regardless of them not being explicitly defined in the proxy OpenAPI schema definition.
- **log** is a **log** policy that enables a custom log to been added.
- **set-variable** are **set-variable** policies that set a specific collector key that is called **discoveryServiceCollection**, and a specific collector target URL called **apiTargetURL**. The collector uses the **discoveryServiceCollection** key to filter analytics data for events that are associated with the proxy API definition, and the **apiTargetURL** to filter the duplicate invokes from different data sources.
- **activity-log** is an **activity-log** policy that decides how complete the discovered OpenAPI reconstruction is. Setting both **success-content** and **error-content** fields to **payload** gives the collector enough data to be able to ensure that the request and response schemas can be created correctly. You can also set these fields to **activity** or **header** data, which in both cases mean that less of the OpenAPI structure is discoverable. Note that the collector does not look at the payload values, and these values are redacted before being sent from the collector to the discovery capability.
- **paths** is set to a wildcard value, for example **{+pathparam}**, to ensure that there is the maximum range of discoverable paths available on the proxy API. The **paths.parameters** section should be defined to the same value. Under the **paths:/{+pathparam}** property, stub methods for **get**, **post**, **patch**, **put**, and **delete** can be added to give maximum reach through the proxy for all of the operations that can be discovered.

2. Log in to your provider organization in the API Manager UI.
3. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
4. In the Import section, select Existing OpenAPI, then click Next.
5. Choose one of the following methods to select your YAML file:
   - Drag the file.
   - Browse for the file.
   - Specify the URL of the file.

   The wizard checks the validity of the YAML, and displays a message indicating successful validation.
6. Click Next to import the selected file.
   A summary of the import confirms that an API definition is created.
7. Click Edit API.
   Your API definition opens in the Design tab.
8. Click the Test tab to start making your API discoveries.
   You use the Request field to find your API traffic by passing the **GET**, **POST**, **PATCH**, **PUT**, and **DELETE** methods through the proxy API. For example:

   ```
   GET https://myorg.com:9443/test/sandbox/users
   ```

   Returns a list of users.
   After API traffic is found, the DataPower API Gateway proxy collector becomes available in the API discovery capability.
9. In the API Manager UI, click the Discover icon  , then click the Sources tab to view your DataPower API Gateway proxy collector.
   Sources can have the following status:
   - Enabled - the source is enabled, and synchronizes with the collector according to its configuration.
   - Disabled - the source is disabled, and API Connect won't accept any files from the collector. This status is set by the discovery service if a discovery operation fails.
   - Unhealthy - the source collector is unavailable.
   - Paused - the source is paused, and API Connect won't accept any files from the collector.
10. Optional: You can click the Options icon ⋮ next to a source to change its status.
    - Pause collector - to pause the source.
    - Delete collector - to delete the source from the API Manager UI. The external source files are not deleted.
    - Resume collector - to restart a paused or disabled source.
11. Optional: You can click the Manage columns icon ⚙ on the table header to change the order and view of the columns.

Results

Your DataPower API Gateway proxy data source collector is now ready for API traffic discovery. The collector posts updates to API Connect when a manual request for testing is made, or when the proxy API is provided to users, in order to interact with the applications that are accessible on the paths that are available behind the

target_url of the proxy. Every time an API definition is discovered and processed, the Last run field of the data source is changed to reflect the activity.

What to do next

You can click the APIs tab in the Discover section of the API Manager UI, and review the API traffic in your data source collector. For more information, see Reviewing your discovered APIs.

Configuring Noname collector for API discovery

Using the Noname collector, you can discover APIs from the Noname environment. This document provides step-by-step instructions to add a Noname data source collector to your API discovery capability.

Before you begin

Important:
The time required to process and collect APIs varies based on the number of APIs in the Noname environment.

Before configuring an API discovery Noname collector, make sure that the following prerequisites are met.

- Download both the helm chart and collector image from https://github.com/ibm-apiconnect/api-discovery-noname-collector/.
- Install the Helm package manager for Kubernetes on your client.
  For more information, refer to the Helm installation guide available at https://helm.sh/docs/intro/install/.

- Make sure that at least one of the following provider organization roles is assigned to the users. The user role helps in managing the sources.
  - Organization administrator
  - Owner
  - Custom role
    You can assign a custom user role by selecting Settings > Manage permission.

About this task

To configure an API discovery Noname collector, deploy it using a Helm chart. Once deployed, the collector retrieves data from the Noname environment and discovers the APIs in the environment. These discovered APIs are then sent to the Discovery service of API Connect by the API discovery Noname collector.

API discovery is an optional add-on to IBM® API Connect that you can use to discover and add APIs to your API development process. Before you can discover any API, you must configure one or more data source collectors. These collectors are automatically added to the Sources tab in the API Manager when the collector sends the first OpenAPI documents to your provider organization.

To enable full lifecycle management in API Manager, you can copy OpenAPI documents to draft APIs as required.

Procedure

1. Create a service account in the Noname environment by completing the following steps:
   a. Log in to the Noname security host.
   b. From the Menu bar, click Settings.
   c. From the side navigation panel, click User Management.
   d. Select the Service Accounts tab and then click Create Service Account.
   Tip: Using the service account, you can retrieve a Client ID and a Client Secret.
2. In the Helm directory, open the values.yaml file.
3. Update the following parameters based on your API Connect provider organization and authentication.

   - noname.host_name
     The hostname of the Noname securities.

   - noname.client_id
     Client ID configuration.

   - noname.client_secret
     Client secret configuration.
     The Client Secret is added to a Kubernetes secret as part of the deployment and then mounted on the collector deployment pod.

   - discovery.datasource_name
     The data source name for all APIs discovered by the Noname collector.
     If data source name is empty, the collected API namespace is used.

   - discovery.platform_api_prefix
     The Platform API prefix has a default value of **platform-api**, the same as the prefix value for API Connect on Cloud. You can change it to match your system setup when it is different from the default.

- discovery.apic_host_domain
  Domain name of the API Connect instance where the discovered APIs are sent. For example, `us-east-a.apiconnect.automation.ibm.com`.
- discovery.provider_org
  The provider organization name of the API Connect manager.
- discovery.api_key
  You can obtain an API key from the API Manager for a user who has permission to post the API.
  You can create an API key logging in to the API Manager and then selecting the My API Keys using the Profile icon.
  The API key is added to the Kubernetes Secret during deployment and then mounted on the collector pod.
- discovery.namespace
  The namespace where the Noname collector is deployed in your cluster.
- logging.log_level
  Default `log_level` is debug.
- images.api_discovery_noname_collector
  Update this property to upgrade the Noname collector deployment.
  Note: Update the collectors periodically to maintain compatibility with the Discovery service.

The following example depicts sample parameters of values.yaml file:

```
host_name: noname_domain
client_id: xxxxxx
client_secret: xxxxxx
discovery:
datasource_name: ibmsec-data-source
platform_api_prefix: platform-api
apic_host_domain: us-east-a.apiconnect.automation.ibm.com
provider_org: myOrgName
api_key: xxxxxx
namespace: default
logging:
log_level: debug
images:
api_discovery_noname_collector: ghcr.io/ibm-apiconnect/api-discovery-noname-collector:7-2025-04-16-18-39-15
```

4. Save the values.yaml file.
5. Run the following command to deploy the collector.

   ```
   helm template . | kubectl apply -f -
   ```

   The output indicates that the required Kubernetes resources are deployed for the Noname collector.

   ```
   secret/noname-client-secret created
   secret/noname-porg-secret created
   service/management-api-discovery-noname-collector created
   deployment.apps/management-api-discovery-noname-collector created
   ```

   After the collector is deployed, any APIs that are discovered are sent to the API Connect Discovery service.

   When the collector sends the first OpenAPI documents to your provider organization, you can view the collector that is listed in the Sources tab in the Discover section in API Manager. You can review the discovered APIs by selecting the APIs tab under the Discover section of API Manager. For more information, see Reviewing your discovered APIs.
   Tip: You can uninstall the collector from Helm by running the following command.

   ```
   helm template . | kubectl delete -f -
   ```

6. To view the collector, and any traffic being received, log in to your provider organization by using API Manager.
7. In the navigation panel, click the Discover icon, then click the Sources tab to view your Noname collector.
   Sources have the following status:

   Enabled
   : The source is enabled, and synchronizes with the collector according to its configuration.

   Disabled
   : The source is disabled, and API Connect won't accept any files from the collector. This status is set by the discovery service if a discovery operation fails.

   Unhealthy
   : The source collector is unavailable.

   Paused
   : The source is paused, and API Connect won't accept any files from the collector.

8. Optional: To change the source status, click the Options icon next to the source.
   - Pause collector - To pause the source.
   - Delete collector - To delete the source from API Manager. The external source files are not deleted.
   - Resume collector - To restart a paused or disabled source.

Results

Your Noname data source collector is now ready to discover APIs from the Noname environment. When the collector sends the first OpenAPI documents to your provider organization, the collector becomes listed in the Sources tab in the Discover section of API Manager.

What to do next

You can review the collected APIs by selecting the APIs tab in the Discover section of API Manager. For more information, see Reviewing your discovered APIs.

Configuring an OpenTelemetry collector for API discovery

How to add an OpenTelemetry collector to your API discovery capability. The collector can be based on an Istio or an NGINX data source.

Before you begin

Before you can configure an API discovery OpenTelemetry collector, the following prerequisites are required:

- You need to download both the helm chart and collector image from https://github.com/ibm-apiconnect/api-discovery-otel-collector/.
- You must have the Helm package manager for Kubernetes installed on your client. For more information, see the Helm installation guide at https://helm.sh/docs/intro/install/.
- If your data source is Istio:
  - You must have Istio installed on your cluster where you want to discover the API traffic from. If you don't have Istio installed, see the Getting Started guide at https://istio.io/latest/docs/setup/getting-started/.
  - You need to deploy both the Istio mesh, and the sample application. For more information, see the Istio Getting Started guide at https://istio.io/latest/docs/setup/getting-started/.
- If your data source is NGINX:
  - You must have NGINX installed on your cluster where you want to discover the API traffic from. If you don't have NGINX installed, see the NGINX installation guide at https://docs.nginx.com/nginx/admin-guide/installing-nginx/.

One of the following provider organization roles is required to be able to manage sources:

- Organization Administrator
- Owner
- Custom role with the **`Settings: Manage`** permission.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. Before you can discover any APIs, you must configure one or more data source collectors. These collectors then get automatically added to the Sources tab in the API Manager UI when the collector sends the first OpenAPI documents to your provider organization.

To configure an API discovery OpenTelemetry collector, you must configure your Istio or NGINX data source, and then deploy the collector by using a Helm chart. After the collector is deployed, any pods that have API traffic running through Envoy then send this data to API Connect. The OpenAPI documents can then be copied to draft APIs as required, to enable full lifecycle management in API Manager.

Procedure

To configure an OpenTelemetry collector, complete the following steps.

1. Configure your Istio or NGINX data source to support the collector.

   Configuring an Istio data source

   Register the collector in your Istio **`MeshConfig`** by running the following command, and adding a discovery provider.

   ```
   kubectl edit configmap istio -n istio-system
   ```

   Where ***`istio-system`*** is the namespace where Istio is deployed on your cluster. The default namespace is **`istio-system`**.
   Update the **`extensionProviders`** section with the following information:

   ```
   extensionProviders:
     - name: "discoveryOtelCollector"
       opentelemetry:
         service: "management-api-discovery-otel-collector.istio-system.svc.cluster.local"
         port: 5555
   ```

   For more information about providers, see the Provider Selection section in the Istio documentation at https://istio.io/latest/docs/tasks/observability/telemetry/#provider-selection.
   If you deployed Istio by using the **`IstioOperator`**, you can configure the information by using the **`MeshConfig`**. For more information, see the Istio documentation at https://istio.io/v1.10/docs/reference/config/istio.mesh.v1alpha1/#MeshConfig.

   Configuring an NGINX data source

   There are multiple ways that you can configure your NGINX data source to support the OpenTelemetry collector, but the following information shows the four main options. For more detailed information about the configuration, see the NGINX readme on **`github.com`**.

   a. NGINX **`otel-webserver-module`**
      To configure the **`webserver`** module to send traces to the OpenTelemetry collector, you can update the NGINX deployment to use the **`OTEL_EXPORTER_OTLP_ENDPOINT`**. For example:

      ```
      env:
      - name: OTEL_EXPORTER_OTLP_ENDPOINT
        value: management-api-discovery-otel-collector.namespace.svc:5555
      ```

      Or, you can update the **`NginxModuleOtelExporterEndpoint`** in the OpenTelemetry configuration on your NGINX server.

   b. NGINX **`instrumentation`** module
      Similarly to the **`webserver`** module, you can update the NGINX deployment to use the **`OTEL_EXPORTER_OTLP_ENDPOINT`**, or you can configure the endpoint in the **`otel-nginx.toml`**.

      This module allows different variables to be used in the **`nginx.conf`** in order to customize the traces that can be sent to the API discovery service.

   c. Ingress-Nginx Controller

The Ingress-Nginx Controller uses the **instrumentation** module, so the same configuration options apply. As a minimum, the Kubernetes Ingress-Nginx Controller **ConfigMap** needs to be configured with the following details to collect the traces from the backend service:

```
enable-opentelemetry: "true"
otlp-collector-host: "management-api-discovery-otel-collector.namespace.svc:5555"
```

d. NGINX OpenTelemetry module
You can configure this module to send traces to the OpenTelemetry collector by setting the **otel_exporter** in the NGINX configuration.

This module allows different variables to be used in the **nginx.conf** in order to customize the traces that can be sent to the API discovery service.

2. In your Helm directory, update the values.yaml file with the following parameter values, as required for your collector configuration.
   - **discovery.datasource_type** - the datasource type (optional). Valid values are **istio**, **nginx**, or left blank. If **istio**, the required Istio Telemetry CR is installed. Otherwise, Helm ignores the telemetry creation.
   - **discovery.datasource_name** - the datasource name for all of the APIs that are discovered by the collector (optional). If the datasource name is empty, the namespace of the collected API is used.
   - **discovery.apic_host_domain** - the domain name of the API Connect instance where the discovered APIs are being sent. For example, **dw-rosa-01.owe.p1.openshiftapps.com**.
   - **discovery.provider_org** - the name of the provider organization in API Manager.
   - **discovery.api_key** - the credentials that are required for pushing API files to the API Manager. You can get the API key from the user who has access to the API Manager for posting APIs. For information about how to obtain an API key, see Managing platform REST API keys. The **api_key** is added to a Kubernetes secret as part of the deployment, and then mounted on the collector deployment pod.
   - **discovery.processors** - the flag to enable or disable the processors. Can be set to **enabled** or **disabled**. If set to **enabled**, the **ConfigMap** enables the existing batch and memory limiter processor, and will not provide any processors in other cases. If you attempt to send a trace with more than 11000 spans at a time, the collector will reject the payload, and you will be required to turn on the batch processor. The available batch and memory limiter processors are configurable according to the base system requirements. The **limit_mib** in the memory limiter processor can be increased if you update the resource limits of the collector deployment. Keeping the **attributes/ibm-apiconnect**, **redaction/ibm-apiconnect**, **filter/ibm-apiconnect**, **transform/ibm-apiconnect**, and **resource/ibm-apiconnect** processors in the **service.pipelines.traces.processors** in the same order when enabling processors is required, as there are built-in processors that enhance the performance of the collector. If you don't include these processors, the quality of the collected traffic is degraded, as well as the performance of the collector. For more information, see an example processor ConfigMap template, information about the OpenTelemetry batch processor, and information about the OpenTelemetry memory limiter processor.
   - **namespace** - the namespace where Istio or NGINX is deployed on your cluster. As required by the Istio telemetry integration, the collector pod will also be deployed here.
   - **images.api_discovery_collector** - enables the upgrade of the collector deployment as new versions are released. Note that collectors will require updates in the future to ensure that they remain compatible with the discovery service. Details of any updates are available in the https://github.com/ibm-apiconnect/api-discovery-otel-collector repository.
   - **logging.log_level** - the log level; the default level is **info**. For debug purposes the level can be increased to **debug** if needed.
   - **logging.debugexporter_verbosity** - the verbosity level of the debug log; the default value is **basic**. For detailed information about the exporter, the verbosity level can be increased to **detailed**. However, it is recommended to keep the verbosity as **basic** for a collector with a large amount of traffic flowing through it.

   The following values are specific to Istio data sources:
   - **telemetry_namespace** - the namespace where the Istio Telemetry CR will be deployed (optional). By default, the values file sets this namespace to **istio-system**, as the root configuration namespace to provide mesh level collection configuration. However, this setting can be customized based on your collection requirements for the deployed applications that you want to be discovered. For more information, see the Telemetry information at https://istio.io/latest/docs/reference/config/telemetry/.

   The following example shows some sample parameter values for an Istio data source:

```
---
discovery:
  # platform_api_prefix is not required to change for API Connect on Cloud
  datasource_type: istio
  # supported values are istio, nginx
  datasource_name: my-data-source
  platform_api_prefix: platform-api
  apic_host_domain: us-east-a.apiconnect.automation.ibm.com
  provider_org: myOrgName
  api_key: xxxxxx
  namespace: istio-system
  telemetry_namespace: istio-system
  # Enable the processor and edit the processor-configmap to choose values for batch and memory_limiter
  # supported values are enabled and disabled
  processors: disabled
logging:
  log_level: info
  # supported values are json and console
  log_encoder: json
  # supported values are basic and detailed
  debugexporter_verbosity: basic

images:
  api_discovery_collector: ghcr.io/ibm-apiconnect/api-discovery-otel-collector:20240612-173911
```

   To understand more about configuring the OpenTelemetry collector, see the OpenTelemetry collector for API discovery readme on **github.com**. These API Connect resources include working examples with a test repository.

3. Run the following command to deploy the collector:

```
helm template . | kubectl apply -f -
```

   The following example shows the response displayed for an Istio data source, confirming that the required Kubernetes resources are deployed:

```
helm template . | kubectl apply -f -
secret/api-discovery-secret created
service/management-api-discovery-otel-collector created
deployment.apps/management-api-discovery-otel-collector created
telemetry.telemetry.istio.io/api-discovery-otel created
```

After the collector is deployed, any data source instrument pods that have traffic running through Envoy will start to be discovered, and the traffic sent to the API Connect discovery capability.

4. The view the collector, and any traffic being received, log in to your provider organization in the API Manager UI.
5. In the navigation pane, click the Discover icon  , then click the Sources tab to view your OpenTelemetry collector.
   Sources can have the following status:
   - Enabled - the source is enabled, and synchronizes with the collector according to its configuration.
   - Disabled - the source is disabled, and API Connect won't accept any files from the collector. This status is set by the discovery service if a discovery operation fails.
   - Unhealthy - the source collector is unavailable.
   - Paused - the source is paused, and API Connect won't accept any files from the collector.
6. Optional: You can click the Options icon ⋮ next to a source to change its status.
   - Pause collector - to pause the source.
   - Delete collector - to delete the source from the API Manager UI. The external source files are not deleted.
   - Resume collector - to restart a paused or disabled source.
7. Optional: You can click the Manage columns icon on the table header to change the order and view of the columns.

Results

Your OpenTelemetry data source collector is now ready to discover API traffic. When the collector sends the first OpenAPI documents to your provider organization, the collector becomes listed in the Sources tab in the Discover section of API Manager.

What to do next

You can click the APIs tab in the Discover section of the API Manager UI, and review the API traffic. For more information, see Reviewing your discovered APIs.

If required, you can uninstall the collector from Helm by running the following command:

```
helm template . | kubectl delete -f -
```

Reviewing your discovered APIs

How to review the discovered OpenAPI documents in your API discovery capability.

Before you begin

One of the following roles is required to be able to edit discovered APIs:

- Organization Administrator
- Owner
- Custom role with any of the following permissions:
  - Settings: Manage
  - Api-Drafts: Edit

A custom role with the Settings: View or Api-Drafts: View permission is able to view discovered APIs.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. After a source collector is added to the API discovery capability, you can manage the discovered OpenAPI documents in API Manager.

Procedure

To manage your discovered OpenAPI documents, complete the following steps.

1. In the API Manager UI, click the Discover icon  , and then ensure that the APIs tab is selected.
2. The list of discovered OpenAPI documents is displayed in the table. The OpenAPI documents in the list are updated according to the configuration settings on their source.
   The OpenAPI documents can have one of the following states:
   - Discovered - the OpenAPI document is discovered by the source.
   - Copied to drafts - the OpenAPI document is copied to the APIs tab in the Develop section of the API Manager UI.
3. To view the metadata of an OpenAPI document, click the Options icon ⋮ next to the document that you want to review, and select View metadata.
   A brief description of the API is displayed. You can then click View API to view the complete OpenAPI document, or click Hide API to hide the API in the list.
4. To view the complete OpenAPI document, click the title of the document in the APIs table.

A read-only version of the complete OpenAPI document is displayed, which you can explore in the UI. You can also download the OpenAPI document as a JSON or YAML file.

5. To copy an OpenAPI document into a draft API, you can use one of the following methods:
   - From the list of available OpenAPI documents in the APIs tab, click the Options icon ⋮ next to the document that you want to copy, and select Copy to draft.
   - From within an OpenAPI document, click Copy to draft.

   You can then click the APIs tab in the Develop section of the API Manager UI, and your copied document is shown in the list of APIs. You can now edit and manage the lifecycle of this API in API Manager; for more information, see API development checklist and Working with API definitions.

6. Optional: You can click the Options icon ⋮ next to an OpenAPI document to further manage the document. The following options are available:
   - Download - to download the API.
   - View metadata - to view a brief description of the API.
   - Copy to draft - to copy the document into a draft API.
   - Hide API - to hide the document from the list of APIs. Hidden APIs can be unhidden by clicking the Filters icon, selecting Hidden APIs under the Show category, and clicking Apply. You can then select the Show API option against the document that you want to display again. To see the API, you must then change the filter to clear the Hidden APIs checkbox.
   - Remove API - to remove the document from the list of APIs. If the API has been copied to drafts, the API is removed only from the list of discovered APIs; it isn't removed from list of draft APIs. A removed API can be discovered again if it still exists in the source. If you want to remove an API document from the list, and not discover it again, you can select the Hide API option.
7. Optional: You can click the Manage columns icon on the table header to change the order and view of the columns.

Results

You reviewed your discovered OpenAPI documents, and copied the required APIs to drafts to enable full API lifecycle management in API Manager.

The API discovery lifecycle in API Manager

When you manage your discovered APIs in the API Manager UI, you move them through a series of lifecycle states. From initially discovering an OpenAPI document, through to copying that document to API drafts to make it available to your API developers, and to eventual archiving.

The following sections describe the various lifecycle states for a discovered OpenAPI document.

Discovered

The OpenAPI document is discovered by the source. The document can be reviewed, and can be Copied to drafts to enable full API lifecycle management. The document can also be downloaded, hidden from view, or removed from the list of APIs.

Copied to drafts

The OpenAPI document is copied to the APIs tab in the Develop section of the API Manager UI. The API is visible to your provider organization, and can be edited and managed through the full API lifecycle. For more information, see the API development checklist and Working with API definitions.

Hidden APIs

The OpenAPI document is hidden from the list of APIs. Hidden APIs can be unhidden by clicking the Filters icon, selecting Hidden APIs under the Show category, and clicking Apply. You can then select the Show API option against the document that you want to display again. To see the API, you must then change the filter to clear the Hidden APIs checkbox.

Removed APIs

The OpenAPI document is removed from the list of APIs. If the API has been copied to drafts, the API is removed only from the list of discovered APIs; it isn't removed from the list of draft APIs. A removed API can be discovered again if it still exists in the source. If you want to remove an API document from the list, and not discover it again, you can use the Hide API option.

Working with the toolkit

Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM® API Connect and publish APIs that you have defined in your file system.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The following subsections describe how to install and use the toolkit:

- **Installing the toolkit**
  You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM API Connect.

- **Logging in from API Designer**
  To log in from the API Designer user interface for IBM API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.
- **Using the developer toolkit command-line tool**
  The IBM API Connect developer toolkit provides a command-line tool, **apic**, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + Designer: provides a command line environment for working with IBM API Connect, including API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Clients tile. The two toolkit options are listed under the Toolkit tab.
     - Click your platform alongside either the CLI option or the CLI + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
     - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 4.
2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:
   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.
3. Run the CLI.
   - For the macOS or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       ```
       chmod +x download_name
       ```

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - If you are using macOS, remove the quarantine attribute by running the following command:

       ```
       sudo xattr -dr com.apple.quarantine apic-slim
       ```

     - Run CLI commands as follows:

       ```
       ./apic command_name_and_parameters
       ```

       or

       ```
       ./apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see the toolkit CLI reference documentation.

- For the Windows platform, complete the following steps:
  - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
  - Run CLI commands as follows:

    ```
    apic command_name_and_parameters
    ```

    or

    ```
    apic-slim command_name_and_parameters
    ```

    For details of the CLI commands, see the toolkit CLI reference documentation.

Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

4. Install the toolkit credentials.

   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   ```
   apic client-creds:set toolkit_credentials_file_path/credentials.json
   ```

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.

   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.

   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   ```
   apic client-creds:clear
   ```

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:

   a. Log in to the management server as an administrator; see Logging in to a management server.

   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

5. Install the API Designer credentials.

   If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **APIC_DESIGNER_CREDENTIALS** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **APIC_DESIGNER_CREDENTIALS** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:

     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:
       - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
       - On the Advanced tab of the System Properties dialog box, click Environment Variables.
       - In the "User variables" section, click New and create an environment variables with the following settings:
         - Variable: **APIC_DESIGNER_CREDENTIALS**
         - Value: *<designer_credentials_file_path>*\designer_credentials.json where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.
       - Click OK to save the new environment variable, and then exit the dialog box.
     - If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
       - Open the Windows command prompt.
       - Run the following command to set the temporary environment variable:

         ```
         set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
         ```

         where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.

         Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
       - Now run the following command to start API Designer:

         ```
         C:\"Program Files\API Designer\API Designer.exe"
         ```

         By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

   - Mac:

     If you are using macOS, create an environment variable using one of the following methods:

     - Run the following command to set the global environment variable:

       ```
       launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
       ```

       where ***<designer_credentials_file_path>*** is the location where you stored the API Designer credentials JSON file.
     - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

       ```
       APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
       <designer_application_file_path>/'API Designer.app'
       ```

where:
- `<designer_credentials_file_path>` is the location to which you downloaded the API Designer credentials JSON file.
- `<designer_application_file_path>` is the location to which you downloaded and uncompressed the API Designer application.

6. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Logging in from API Designer

To log in from the API Designer user interface for IBM® API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.

About this task

API Designer provides a secure login to a management server for staging and publishing APIs and Products. You log in to the same host that was configured for API Manager and use your API Manager user name and password. You will need an account on API Manager and membership in a provider organization to access the API Designer.

You can also use the Explorer tab to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and refine any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note:

- Configuration changes that are made in API Manager are not available in API Designer concurrently. You will need to log out of API Designer and log back in to access any updates.
- Set `SKIP_IBMID_LOGIN=true` as an environment variable to bypass the IBM ID login screen for API Designer. This applies to users who are working on an internal network, without access to external networks.

Procedure

To log in to API Designer, complete the following steps:

1. Download and extract API Designer, as described in Installing the toolkit.
2. Start the API Designer user interface by running the application from the location where you extracted the contents of the toolkit compressed file.
   Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.
3. Optional: If you see the Accept License page, click the URL read the license agreement, then click the button to accept the license. This prompt appears only one time. It does not appear once you have accepted the license on the current system.
4. Optional: If you see the IBM ID login page, enter your IBM customer ID.
   Note: You won't receive the IBM ID page if you are already authorized, or if you have set the `SKIP_IBMID_LOGIN` environment variable to `true`.
5. Open a directory on your local file system to store the API and Product specifications that you create in API Designer. The system defaults to a previously-accessed directory.
   If you want to switch to a different directory after logging in, click Switch directory on the menu bar in the header.

   Note: If you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, don't copy the file into your API Designer directory.
   Such an API will **not** be visible in the API Designer user interface if it doesn't contain the API Connect specific sections that are required by API Designer.

   Instead, copy the OpenAPI definition file to another folder, then import it into API Designer; the import operation adds the necessary API Connect specific sections; see Adding a REST API by importing an OpenAPI definition file.

   For more information on the API Connect specific sections in an OpenAPI definition file, see IBM extensions to the OpenAPI specification.

6. If this is the first time you have logged in, establish a connection to API Connect by completing the following steps:
   - Contact your administrator and request the "management endpoint URL" for connecting to API Connect.
     The management endpoint URL looks similar to the following example: https://*<host.domain>* and indicates the location where the API Manager is running.

     Note: If you are using API Connect as a component of Cloud Pak for Integration, the management endpoint URL follows this format:
     https://*cpd-your-company.domain*/integration/apis/*APIC_namespace*/*APIC_instance*

     Example: https://cpd-company.com/integration/apis/apic/production

     Do not add /manager to the URL. If you include /manager at the end of this URL, the connection with Cloud Pak for Integration will fail with a message stating that the host URL is invalid.

   - In the dialog window, enter the management endpoint URL as the Host URL and click Next.
   - Type the user name and password for your API Manager account.
   - Select a User Registry from the list.

- Click Sign In.

7. For subsequent log ins, select the appropriate cloud where you will be working. You can select from any previous cloud connections.
8. When more than one cloud connection is configured, you can switch clouds when developing APIs and Products. See Switching clouds from API Designer.
   Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.
9. Click Add Another Cloud to add another cloud connection. Enter the URL, user name and password, and user registry to add the cloud connection.
   Note: If you are using an OIDC user registry that supports single sign-on (SSO), and you are already logged in, you cannot add a new cloud connection to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then add the new cloud connection.
10. Delete a cloud connection by selecting the trash can icon.
11. API Designer will launch with the organization set to your provider organization in the selected cloud. If you have accounts for multiple provider organizations, it will default to the first organization in alphabetical order.
12. To choose another provider organization, select it from the drop-down list.

- **Setting the locale for API Designer**
  How to set one of the supported locales when you start the API Designer application.
- **Switching clouds from API Designer**
  You can switch clouds to work in another cloud in API Designer.
- **Working offline with API Designer**
  You can work offline (without a connection to the cloud) with API Designer to create APIs. Some functionality is missing due to the lack of a cloud connection.
- **Gathering support information in API Designer**
  When you report an issue with the API Designer application, enable debug mode and provide as much information as possible.

Setting the locale for API Designer

How to set one of the supported locales when you start the API Designer application.

About this task

If you want to use a different locale than your current operating system (OS) locale, you can set a locale code by using the **`--lang`** argument when you start the API Designer application. This locale is then effective for the duration that the application is open. If no **`--lang`** argument is set, then the current OS locale is used.

Procedure

To change the locale for API Designer, complete the following instructions.

From the command line, run the following command to start the API Designer application with the **`--lang`** argument:

Mac OS X Mac:

```
open "API Designer.app" --args --lang=locale_code
```

Windows Windows:

```
"API Designer".exe --args --lang=locale_code
```

Where ***`locale_code`*** is one of the following supported locale codes:

Table 1. List of supported locale codes and their associated language

Locale code	Language
`cs`	Czech
`de`	German (Standard)
`en-US`	English (United States)
`es`	Spanish
`fr`	French (Standard)
`it`	Italian (Standard)
`ja`	Japanese
`ko`	Korean
`nl`	Dutch (Standard)
`pl`	Polish
`pt-br`	Portuguese (Brazil)
`ru`	Russian
`tr`	Turkish
`zh-cn`	Chinese (PRC)
`zh-tw`	Chinese (Taiwan)

For example, running the following command on a Mac:

```
open "API Designer.app" --args --lang=es
```

sets the API Designer language to Spanish.

Switching clouds from API Designer

You can switch clouds to work in another cloud in API Designer.

About this task

API Designer allows the flexibility to connect to multiple clouds. For example, your organization may have separate clouds for testing, development, and demos. You select the cloud connection when you log in, but you can also switch clouds when you are developing APIs and Products. Multiple clouds must be configured in order to switch clouds. You must have a valid API Manager account to connect to a cloud.

Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.

Procedure

To switch clouds for working in API Designer, complete the following steps:

1. Log in to API Designer and select a cloud, or configure a new cloud connection.
2. From the Develop: APIs and Products screen, you can switch to another cloud by selecting it from the Switch Cloud Connection menu.
3. Delete a cloud connection by selecting the trash can icon.

Working offline with API Designer

You can work offline (without a connection to the cloud) with API Designer to create APIs. Some functionality is missing due to the lack of a cloud connection.

About this task

API Designer provides the capability to work in offline mode without a connection to a management server. You can work on APIs with no management server, but some functions will be changed or missing.

The preferred method for working in API Designer is with a Cloud Connection to the management server when logging into API Designer. Working while connected to a management server provides full functionality, with automatic field completion. When working offline, you will need to remember the values to complete the fields that are backfilled from the management server.

Following are the differences when working in offline mode:

- There is no connection to a management server.
- There is no Provider Organization selection.
- Only the Develop APIs and Products tile may be selected. The Learn more and Connect menu tiles are not available.
- When creating an API, the Gateway Type defaults to V5 Gateway and the default policies are loaded.
- Stage and Publish for APIs and Products functions are not available.
- The Sandbox catalog is not available.
- When configuring a Security Definition, there are no selection lists available for the User Registry for a Basic Auth security definition or for the OAuth Provider for an OAuth 2 security definition. You will need to enter the User Registry and OAuth Provider values correctly as text.
- When adding custom Visibility and custom Subscribability values for a product, there is no selection list for the Organization field. You will need to enter the organization name correctly as text.

Procedure

To work in offline mode in API Designer, complete the following steps:

1. Log in to API Designer and open a directory location.
2. To start offline mode, choose Work Offline from the selector in the upper right corner of the Connect to Cloud screen.
3. The Home page appears with the Develop APIs and Products tile. Select Develop APIs and Products to start working in offline mode.
4. To return to online mode, choose Connect to Cloud in the upper right hand corner and select the management server to log in to.

Gathering support information in API Designer

When you report an issue with the API Designer application, enable debug mode and provide as much information as possible.

To report an issue with API Designer, enable debug mode, collect the recommended information, and submit it with your report. Including the information will help IBM resolve the problem more quickly.

- Enabling debug mode on Mac
- Enabling debug mode on Windows
- Enabling debug mode on Linux
- Information to gather for support

Enabling debug mode on Mac

Start API Designer with debug mode enabled:

1. Start a terminal or command prompt.
2. Navigate to the directory where API Designer is installed.
3. Run the following command to start API Designer in debug mode:

   ```
   DESIGNER_DEBUG=true open API/Designer.app/
   ```

   If you add **DESIGNER_DEBUG=true** to your .bash_profile, then every time you start API Designer it will open in debug mode.

Enabling debug mode on Windows

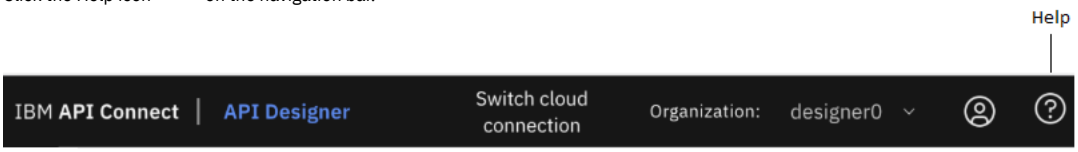
Add a Windows environment variable that enables debug mode for API Designer:

1. Type "Environment" in the Windows search bar (on the task bar) and select Edit environment variables for your account.
2. In the Environment Variables dialog box, click New in the "User variables" section.
3. In the New User Variable dialog box, add the following variable settings and then click OK:
   - Variable name: `DESIGNER_DEBUG`

   - Variable value: `True`

4. Click OK to save your change.

Enabling debug mode on Linux



To start API Designer with debug mode enabled, add the following command to your .bash_profile:

```
EXPORT DESIGNER_DEBUG=true
```

Information to gather for support

Gather the following information about your problem and include it with your report.

- Operating system where you are running API Designer (Mac, Windows, or Linux)
- Product versions for API Designer and the API Manager that is connects to:
  1. Open API Designer.
  2. Click the Help icon on the navigation bar.

  3. On the Help page, click the Product information tile.
  4. On the Product information page, note down the following values for the following labels on the page:
     - Connected to API Manager Product version
     - Package
- HAR file
  The HAR file contains the information about your browser's interaction with the web, and can be helpful in determining why your problem is happening. Complete the following steps to export the HAR file from the browser where you use API Designer:
  1. Open API Designer.
  2. Open the browser's developer console; for example in Google Chrome, click > More tools > Developer tools.
  3. In the developer console, click the Network tab.
  4. Click to download the HAR file.
- Are you using API Designer in Online mode or Offline mode?
  If you're using Online mode, are you connecting to a local test environment, or to an API Manager server?
- When does the problem happen?
  Provide reproducible steps with optional screen captures or video so the support team can recreate the problem.
- Supporting data.
  Provide any related data that would be useful while examining the problem; for example, a copy of the API or Product that you were using.
- How often does the problem happen?

Is the problem intermittent? Does it happen constantly? Does it only happen with certain artifacts (for example, only with a particular API)? If the problem is associated with an artifact, try to include it with your report.

Using the developer toolkit command-line tool

The IBM® API Connect developer toolkit provides a command-line tool, **apic**, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

The command line tool is described in detail in the following subtopics. For summary reference material for each of the available commands for the developer toolkit, see the toolkit CLI reference documentation.

- **Overview of the command-line tool**
  The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- **Logging in to a management server**
  You log in to a management server from the command line by using the `apic login` command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
- **Logging in to a management server with an OIDC registry**
  Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.
- **Cloud administration commands**
  A summary of the cloud administration commands in the IBM API Connect developer toolkit.
- **API development and management commands**
  A summary of the core commands in the IBM API Connect developer toolkit.
- **Creating APIs and applications**
  You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.
- **Publishing APIs and applications**
  To publish APIs and applications by using the developer toolkit of IBM API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.
- **Managing API Products**
  Use the `apic products` and `apic apis` commands to manage Products and APIs published to IBM API Connect Catalogs. Use the `--scope space` option to manage Products and APIs published to Spaces within Catalogs.
- **Working with Drafts**
  Colocate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration. The developer toolkit provides the bridge from the developer's environment to the IBM API Connect runtime services.
- **Reading input from the command line**
  If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.
- **Scripting with the toolkit commands**
  The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- **Working with OpenAPI extensions**
  Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.
- **Using the toolkit CLI to execute API tests**
  The IBM API Connect developer toolkit provides CLI commands for automated API behavior testing.

Overview of the command-line tool

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Command syntax

In general, commands have the following syntax:

```
apic command:sub-command [argument] [options]
```

where

- *command* is the command, usually the thing on which you are acting (for example, product, app, API, Catalogs, and so on).
- *sub-command* is the action to perform.
- *argument* is the argument, where applicable (for example,`catalog`).
- *options* are any number of command-line options, which have the form `--option [value]`. Options also have a short form with a single dash instead of a double dash.

For example, `apic apps:publish --server mgmnthost.com`.
For some commands, either the command or sub-command portion is optional. For example:

- `apic products:publish` is equivalent to `apic publish`.
- `apic products:list` is equivalent to `apic products`.

The `create` command has a slightly different syntax:

```
apic create:type [options]
```

Use the `-h` or `--help` option to view command help.
Note: The language in which the CLI help text, and other command response text, is displayed is determined by the locale setting on your local machine.

Viewing command line tool help

Display general command-line help information by entering the following command: **apic --help** or **apic -h**. Display help information for a specific **apic** command by entering the following command: **apic *command_name* --help** or **apic *command_name* -h**.

Viewing version information

Display the version of the command-line tool by entering the command: **apic --version**.

Setting the mode

The API Connect toolkit CLI runs commands on either the provider organization or on the consumer organization. When you run the command, you use the different mode options to identify the instance on which you want to run the command. The following list provides a summary of the modes that are available:

apim
: This mode applies to the administrative instances of the CLI. When you run commands in this mode, it uses the overall API Manager as its scope. This mode is the default mode.
An example of running a command in the apim mode:

```
apic extensions:list-all --mode apim --scope catalog --server server1 --catalog catalog1 --org myOrg --configured-gateway-service service1
```

portaladmin
: This mode applies to the developer portal instances of the CLI. This mode supports commands that you can use to replicate all or part of your Developer Portal environment.
An example of running a command in the portaladmin mode:

```
apic --mode portaladmin custom-theme:create-export --catalog catalog1 --org myOrg --server server1 --format json
```

consumer
: This mode applies to the consumer instances of the CLI. This command uses the consumer organizations that you have permission to access as its scope. You must specify this mode or set it as the default value for the command to use it.
An example of running a command in the consumer mode:

```
apic catalogs:list --mode consumer --scope catalog --server server1 --catalog catalog1 --org myOrg
```

To avoid having to supply the parameter on every consumer CLI command, you can set the **mode** configuration variable, as described in the next section.

Using configuration variables

You can set the values of commonly-used properties in configuration variables. In general, it's easier and more consistent to set configuration variables instead of specifying them using command-line options.
Note:
The configuration variables for OpenAPI projects are always global. The values of global configuration variables are stored in the *user-home-dir*/.apiconnect/config file, where *user-home-dir* is the user's home directory.

Use the following commands to work with configuration variables:

- **apic config:get *varname*** - Get a configuration variable. Use **apic config** to display the values of all local configuration variables or **apic config -g** to display the values of all global configuration variables.
- **apic config:set *varname*** - Set or update the specified configuration variable.
- **apic config:delete *varname*** - Delete the specified configuration variable.
- **apic config:clear** - Delete all configuration variables.

You set configuration property values by using the **apic config:set** command. By setting configuration properties (for example **catalog** and **app**), you do not need to supply values for these options when you enter a command.

Additionally, you can use **apic properties** commands to work with configuration properties:

- **apic properties:clear** - Clear the configuration properties.
- **apic properties:create** - Augment the configuration properties with additional name/value pairs.
- **apic properties:delete** - Delete the configuration property.
- **apic properties:get** - Get the configuration property.
- **apic properties:list** - List the configuration properties.
- **apic properties:update** - Update the configuration property.

Note:
If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called **SPACE** then, by default, that value will be assumed for the value of the **--space** parameter in the following command, regardless of any **space** configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called **APIC_LOAD_FROM_ENV**, set to the value **false**.

The following table describes the configuration variables:

Table 1. Configuration variables

Variable name	Description	Use instead of (or override with) these flags...
catalog	Default Catalog name for all commands that manage aspects of a Catalog. The Catalog value can be specified as either: • The full Catalog URI that includes server name and organization name: ***mgmt-server*/api/catalogs/*org-name*/*catalog-name***. In this case, you do not need to specify **--catalog**, **--organization**, or **--server** when you make CLI calls, since their values are included in the full Catalog URI. • The Catalog name, for example: **sandbox**. In this case, you still need to specify **--organization** and **--server** when you make CLI calls. Note: The Catalog name **apic-dev** is reserved for local testing.	• If Catalog URI used in variable assignment: **--catalog, --organization, --server** • If Catalog name used in variable assignment: **--catalog**
cloud	Default management server host name for cloud administration commands. Form: ***mgmt-server*/api/**.	**--server**
consumer	Default URI of an API consumer. Form: ***mgmt-server*/api/consumer-orgs/*org-name*/*catalog-name*/*consumer-org-name***, where *mgmt-server* is the management server, *org-name* is the organization name, *catalog-name* is the Catalog name, and *consumer-org-name* is the consumer organization name.	**--server, --organization, --catalog, --consumer**
mode	The default value of the **--mode** parameter for CLI commands. Set the value to **apim** or **consumer** depending on whether you want to run commands on a provider organization or a consumer organization. If you do not set this variable, and do not supply a **--mode** parameter on a command, the value **apim** is assumed.	--mode
org	Default org name for all commands that manage organizations. Form: ***mgmt-server*/api/orgs/*org-name***, where *mgmt-server* is the management server, *org-name* is the organization name. The org value can be specified as either: • The full org URI that includes the server name: ***mgmt-server*/api/orgs/*org-name***. In this case, you do not need to specify **--server** or **--organization** when you make CLI calls, since their values are included in the full org URI. • The org name, for example: **providerorg1**. In this case, you still need to specify **--server** when you make CLI calls.	• If org URI used in variable assignment: **--organization, --server** • If org name used in variable assignment: **--organization**
space	Default Space URI for all commands that manage aspects of a Space. Form: ***mgmt-server*/api/spaces/*org-name*/*catalog-name*/*space-name***, where *mgmt-server* is the management server, *org-name* is the organization name, *catalog-name* is the Catalog name, and *space-name* is the Space name. You can append the port number to the server name if it is not the default value of 443.	**--server, --organization, --catalog, --space**

To set configuration properties, enter the following command:

```
apic config:set name=value
```

where *name* is the name of the configuration property and *value* the value to assign to it.
For example:

```
apic config:set catalog=sandbox
```

Scripting commands

It's often helpful to automate a series of **apic** commands In a shell script. Since the **apic** tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.
To disable collection of usage analytics, enter this command:

```
apic --live-help
```

Setting the language

You can configure the language for the CLI command outputs by using the **--lang** flag. This flag allows the developer toolkit to provide command outputs in the specified language. The following table contains the supported languages:

Table 2. Supported languages

Language value	Language
en-us	English (US)
cs	Czech
de	German
es	Spanish
fr	French
it	Italian
ja	Japanese
ko	Korean
nl	Dutch
pl	Polish
pt-br	Portuguese (Brazil)
ru	Russian
tr	Turkish

Language value	Language
zh-cn	Chinese (Simplified)
zh-tw	Chinese (Traditional)

Use a language values based on your needs. Use French as an example. To set the language to French, run the following command:

```
apic --lang fr
```

After you run the command, the outputs are displayed in French. For example:

```
apic config get invalid
Error: invalid n'est pas une variable de configuration valide
```

When you provide an invalid value that is not a supported language, the system displays the following error:

```
apic --lang invalid
Error: Value invalid is not valid for lang. Valid values are: en-us, cs, de, es, fr, it, ja, ko, nl, pl, pt-br, ru, tr, zh-cn, zh-tw
```

Logging in to a management server

You log in to a management server from the command line by using the **apic login** command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.

Attention: If you want to log in with an OIDC user registry or if you are an IBM Cloud Pak for Integration (CP4I) user, see Logging in to a management server with an OIDC registry.

1. Clear the credentials from any previous login by running the following command:

   ```
   apic client-creds:clear
   ```

   Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

   ```
   apic client-creds:set path_to_credentials/credential.json
   ```

   Where ***path_to_credentials*** is the location of the credential.json file that you want to use. For example:

   ```
   apic client-creds:set /Users/local_user/credential.json
   ```

3. Log in using one of the following methods.
   - To log in using a username and password, run the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm realm
   ```

   - To log in using the apikey, run the following command:

   ```
   apic login --sso --server mgmt_endpoint_url --apiKey apikey --context provider
   ```

The parameters for the **apic login** command are as follows:

mgmt_endpoint_url
: The URL depends on the type of organization that you are logging in with:

  - Cloud admin organization or Provider organization, use one of the following URLs:
    - Platform API endpoint URL (note that if you want to run commands that relate to API governance, you must use the platform API endpoint URL to log in).
    - Management API manager URL.
  - Consumer organizations, use the consumer API endpoint URL.

  These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints, ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

user_id
: The user ID you want to log in with. Depending on the tasks that you want to perform, this user ID might be any of the following:

  - A user ID that is a member of the cloud administration organization. This is an ID that you could also use to log in to the Cloud Manager user interface.
  - A user ID that is a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
  - A user ID that is a member of a consumer organization. This is an ID that you could also use to log in to the Developer Portal.

password
: The password associated with the supplied user ID.

realm
: The *realm* parameter specifies the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
  The format of the *realm* depends on the type of user, as follows:

  - Member of the cloud administration organization:

`admin/identity_provider`

To determine the identity provider, see How to determine the identity provider.

- Member of a provider organization:

  `provider/identity_provider`

  To determine the identity provider, see How to determine the identity provider.

- Member of a consumer organization:

  `consumer:provider_org:catalog/identity_provider`

  where *provider_org* is the name of your provider organization, and *catalog* is the name of the Catalog in that provider organization.
  To determine the identity provider, see How to determine the identity provider.

  Important:
  - If you have installed toolkit credentials, as detailed in Installing the toolkit, then at any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
    To revert to the default pre-supplied toolkit credentials for all login operations from the toolkit CLI, use the following command:

    `apic client-creds:clear`

  - If you log in to the CLI as a member of a consumer organization, you must supply the `--mode=consumer` parameter to the `apic login` command, and to all consumer commands. To avoid having to type the parameter every time, you can set the `mode` configuration variable, by entering the following command:

    `apic config:set mode=consumer`

apikey
: The apikey serves as the code to authenticate the user. For more information about creating apikey, see Managing platform REST API keys

You can also use the command interactively; enter `apic login` and you will be prompted for the values. For example:

```
apic login
Enter your API Connect credentials
Server? platform-api.myserver.com
Realm? provider/default-idp-2
Username? myuser
Password?
Logged into myserver.com successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.

How to determine the identity provider

If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

`apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm`

where *scope* has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`, and the default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
By default, API Connect creates a local user registry for user login for every context. The identity providers associated with these default registries are as follows:

Registry	Identity provider name
Cloud Manager Local User Registry (for login as a member of the cloud administration organization)	default-idp-1
API Manager Local User Registry (for login as a member of a provider organization)	default-idp-2
Sandbox Catalog User Registry (for login as a member of a consumer organization)	sandbox-idp

If you want to log in as a member of a consumer organization, see Logging in as a consumer to the Developer Portal by using the CLI for full details.

Logging out

To log out of a management server, use the following command:

`apic logout --server mgmt_endpoint_url`

Logging in to a management server with an OIDC registry

Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

Attention: Logging in with an OIDC registry is supported for the developer toolkit (used with API Manager) and the Developer Portal admin toolkit, but is not supported for members of consumer organizations. If you are using IBM Cloud Pak for Integration (CP4I), review this topic for login instructions. If you want to log in using a non-OIDC registry, see Logging in to a management server.
To log in, complete the following steps:

1. Clear the credentials from any previous login by running the following command:

   ```
   apic client-creds:clear
   ```

   Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

   ```
   apic client-creds:set path_to_credentials/credential.json
   ```

   where ***path_to_credentials*** is the location of the credential.json file that you want to use. For example:

   ```
   apic client-creds:set /Users/local_user/credential.json
   ```

3. Log in by running the following command:

   ```
   apic login --server mgmt_endpoint_url --sso
   ```

   where***mgmt_endpoint_url*** is the endpoint URL. When you log in with a Cloud admin or Provider organization, specify one of the following URLs:
   - platform API endpoint URL
   - management API manager URL

   These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints, ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

   CP4I: If you are using API Connect as a component of IBM Cloud Pak for Integration (CP4I), your administrator can provide the correct URL.
4. When the toolkit prompts for the context, type `admin` API Connect (administrators) or `provider` (everyone else):

   ```
   Context? provider
   ```

5. The server responds with the following message:
   Note: When users sign in by using the Toolkit login path (a URL that includes `?from=TOOLKIT`), the generated API key has a fixed time-to-live (TTL) of 5 minutes.

   ```
   Please copy and paste the url https://mgmt_endpoint_url/auth/manager/sign-in/?from=TOOLKIT to a browser to start the authentication process.
   Do you want to open the url in default browser? [y/n]: y
   ```

   Take one of the following actions:

   - If you want to use your default browser to log in to API Manager, type `y` and press Enter.
     The API Manager sign-in page opens in a new browser tab.

   - If you don't use to use your default browser, type `n` and press Enter.
     - Copy the URL from the command window.
     - Open a browser, paste the URL, and press Enter.

     The API Manager sign-in page displays.

6. On the API Manager sign-in page, select the OIDC registry and then log in to API Connect.
   CP4I: Select the Common Services User Registry.
   After you log in, API Connect displays the "You are authenticated!" message and provides a temporary token. Copy the token.

   Note: If you create the API key by using the toolkit, it is a single-use key regardless of the settings Multiple use of apikey.
7. Return to the command window. Paste the token at the `API Key?` prompt and press Enter.

When the token is validated and you are successfully logged in to the toolkit, the following message displays:

```
Warning: Using default toolkit credentials.
Logged into mgmt_endpoint_url successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.

Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Cloud administration commands

A summary of the cloud administration commands in the IBM® API Connect developer toolkit.

Authenticating

Use the `apic login` command to authenticate to an API Manager service, and the `apic logout` command to remove your local authentication credentials.

Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. You should therefore set the file permissions in such a way that your credentials are not accessible by others.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Command summary

The following tables summarize **apic** commands for cloud administration.

Table 1. Summary commands for cloud administrators

Command	Description	Sub-commands
apic analytics-services	Analytics Service commands	• **apic analytics-services** - Analytics Service collection operations. • **apic analytics-services:clear** - Clear the Analytics Services. • **apic analytics-services:create** - Create a Analytics Service. • **apic analytics-services:delete** - Delete the Analytics Service by name or ID. • **apic analytics-services:get** - Get the Analytics Service by name or ID. • **apic analytics-services:list** - List the Analytics Services. • **apic analytics-services:update** - Update the Analytics Service by name or ID.
apic associates	Associates commands	• **apic associates** - Associate collection operations. • **apic associates:get** - Get the Associate by name or ID. • **apic associates:list** - List the Associates.
apic availability-zones	Availability Zone commands	• **apic availability-zones** - Availability Zone collection operations. • **apic availability-zones:clear** - Clear the Availability Zones. • **apic availability-zones:create** - Create a Availability Zone. • **apic availability-zones:delete** - Delete the Availability Zone by name or ID. • **apic availability-zones:get** - Get the Availability Zone by name or ID. • **apic availability-zones:list** - List the Availability Zones. • **apic availability-zones:update** - Update the Availability Zone by name or ID.
apic cloud-settings	Cloud settings commands	• **apic cloud-settings:get** - Get the Cloud Setting. • **apic cloud-settings:mail-server-configured** - indicates whether a mail server has been configured. • **apic cloud-settings:topology** - Returns summary details of the configuration of your cloud topology. • **apic cloud-settings:update** - Update the Cloud Setting.
apic configured-gateway-services	Commands for Configured Gateway Services in a Catalog or Space.	• **apic configured-gateway-services** - Configured Gateway Services operations. • **apic configured-gateway-services:clear** - Delete all Configured Gateway Services from a Catalog or Space. • **apic configured-gateway-services:create** - Configure a Gateway Service in a Catalog or Space. • **apic configured-gateway-services:delete** - Delete a Configured Gateway Service from a Catalog or Space. • **apic configured-gateway-services:get** - Obtain the details of a Configured Gateway Service in a Catalog or Space. • **apic configured-gateway-services:list** - List the Configured Gateway Services in a Catalog or Space.
apic credentials	Credential commands	• **apic credentials** - Application Credential collection operations. • **apic credentials:clear** - Clear the Application Credentials. • **apic credentials:create** - Create a Application Credential. • **apic credentials:delete** - Delete the Application Credential by name or ID. • **apic credentials:get** - Get the Application Credential by name or ID. • **apic credentials:list** - List the Application Credentials. • **apic credentials:reset** - Reset the client id and client secret. • **apic credentials:reset-client-secret** - Reset the client secret. • **apic credentials:update** - Update the Application Credential by name or ID. • **apic credentials:verify-client-secret** - Verify the client secret.
apic extensions	Extension commands	• **apic extensions** - Extension collection operations. • **apic extensions:document** - Get the document for an extension by id, or by name and version. • **apic extensions:get** - Get an extension by id, or by name and version. • **apic extensions:list** - List all versions of an extension given the name. • **apic extensions:list-all** - List all versions of all extensions.
apic gateway-services	Gateway service commands	• **apic gateway-services** - Gateway Service collection operations. • **apic gateway-services:clear** - Clear the Gateway Services. • **apic gateway-services:create** - Create a Gateway Service. In order to enable AI Gateway on a DataPower® API Gateway, set the property **ai_gateway_enabled** to **true**, else to **false**. • **apic gateway-services:delete** - Delete the Gateway Service by name or ID. • **apic gateway-services:get** - Get the Gateway Service by name or ID. • **apic gateway-services:list** - List the Gateway Services. • **apic gateway-services:reset-oauth-secret** - Reset the OAuth cryptographic • **apic gateway-services:update** - Update the Gateway Service by name or ID. In order to enable AI Gateway on a DataPower API Gateway, set the property **ai_gateway_enabled** to **true**, else to **false**.

Command	Description	Sub-commands
`apic integrations`	Integrations commands	• `apic integrations` - Integration collection operations. • `apic integrations:clear` - Clear the Integrations. • `apic integrations:clear-all` - Clear all of the Integrations in all of the collections. • `apic integrations:create` - Create a Integration. • `apic integrations:delete` - Delete the Integration by name or ID. • `apic integrations:get` - Get the Integration by name or ID. • `apic integrations:list` - List the Integrations. • `apic integrations:list-all` - List all Integrations in all collections. • `apic integrations:update` - Update the Integration by name or ID.
`apic keystores`	Keystores commands	• `apic keystores` - Keystore collection operations. • `apic keystores:clear` - Clear the Keystores. • `apic keystores:create` - Create a Keystore. • `apic keystores:delete` - Delete the Keystore by name or ID. • `apic keystores:get` - Get the Keystore by name or ID. • `apic keystores:list` - List the Keystores. • `apic keystores:update` - Update the Keystore by name or ID.
`apic mail-servers`	Mail server commands	• `apic mail-servers` - Mail Server collection operations. • `apic mail-servers:clear` - Clear the Mail Servers. • `apic mail-servers:create` - Create a Mail Server. • `apic mail-servers:delete` - Delete the Mail Server by name or ID. • `apic mail-servers:get` - Get the Mail Server by name or ID. • `apic mail-servers:list` - List the Mail Servers. • `apic mail-servers:test-connection` - Test a mail server connection. • `apic mail-servers:update` - Update the Mail Server by name or ID.
`apic notification-templates`	Notification template commands	• `apic notification-templates` - Notification Template collection operations. • `apic notification-templates:get` - Get the Notification Template by name or ID. • `apic notification-templates:list` - List the Notification Templates. • `apic notification-templates:list-all` - List all Notification Templates in all collections. • `apic notification-templates:update` - Update the Notification Template by name or ID.
`apic permissions`	Permissions commands	• `apic permissions` - Permission collection operations. • `apic permissions:get` - Get the Permission by name or ID. • `apic permissions:list` - List the Permissions. • `apic permissions:list-all` - List all Permissions in all collections.
`apic portal-services`	Portal services commands	• `apic portal-services` - Portal Service collection operations. • `apic portal-services:clear` - Clear the Portal Services. • `apic portal-services:create` - Create a Portal Service. • `apic portal-services:delete` - Delete the Portal Service by name or ID. • `apic portal-services:get` - Get the Portal Service by name or ID. • `apic portal-services:list` - List the Portal Services. • `apic portal-services:update` - Update the Portal Service by name or ID.
`apic services`	Services commands	• `apic services` - Service collection operations. • `apic services:clear` - Clear the Services. • `apic services:clear-all` - Clear all Services in all collections. • `apic services:create` - Create a Service. • `apic services:delete` - Delete a Service. • `apic services:get` - Get the Service by name and version. • `apic services:list` - List the Services. • `apic services:list-all` - List all Services in all collections. • `apic services:update` - Update the Service by name and version.
`apic space-settings`	Space settings commands	• `apic space-settings:get` - Get the Space Setting. • `apic space-settings:update` - Update the Space Setting.
`apic spaces`	Space commands	• `apic spaces` - Space collection operations. • `apic spaces:clear` - Clear the Spaces. • `apic spaces:create` - Create a Space. • `apic spaces:delete` - Delete the Space by name or ID. • `apic spaces:get` - Get the Space by name or ID. • `apic spaces:list` - List the Spaces. • `apic spaces:transfer-owner` - Transfer owner to a new member. • `apic spaces:update` - Update the Space by name or ID.
`apic tls-client-profiles`	TLS client profile commands	• `apic tls-client-profiles` - TLS Client Profile collection operations. • `apic tls-client-profiles:clear` - Clear the TLS Client Profiles. • `apic tls-client-profiles:clear-all` - Clear all of the TLS Client Profiles in the collection. • `apic tls-client-profiles:create` - Create a TLS Client Profile. • `apic tls-client-profiles:delete` - Delete the TLS Client Profile by name or ID. • `apic tls-client-profiles:get` - Get the TLS Client Profile by name or ID. • `apic tls-client-profiles:list` - List the TLS Client Profiles. • `apic tls-client-profiles:list-all` - Lists all of the TLS Client Profiles in a collection. • `apic tls-client-profiles:update` - Update the TLS Client Profile by name or ID.

Command	Description	Sub-commands
`apic tls-server-profiles`	TLS server profile commands	• `apic tls-server-profiles` - TLS Server Profile collection operations. • `apic tls-server-profiles:clear` - Clear the TLS Server Profiles. • `apic tls-server-profiles:clear-all` - Clear all of the TLS Server Profiles in the collection. • `apic tls-server-profiles:create` - Create a TLS Server Profile. • `apic tls-server-profiles:delete` - Delete the TLS Server Profile by name or ID. • `apic tls-server-profiles:get` - Get the TLS Server Profile by name or ID. • `apic tls-server-profiles:list` - List the TLS Server Profiles. • `apic tls-server-profiles:list-all` - List all of the TLS Server Profiles in the collection. • `apic tls-server-profiles:update` - Update the TLS Server Profile by name or ID.
`apic truststores`	Truststore commands	• `apic truststores` - Truststore collection operations. • `apic truststores:clear` - Clear the Truststores. • `apic truststores:create` - Create a Truststore. • `apic truststores:delete` - Delete the Truststore by name or ID. • `apic truststores:get` - Get the Truststore by name or ID. • `apic truststores:list` - List the Truststores. • `apic truststores:update` - Update the Truststore by name or ID.
`apic user-registries`	User registry commands	• `apic user-registries` - User Registry collection operations. • `apic user-registries:clear` - Clear the User Registries. • `apic user-registries:create` - Create a User Registry. • `apic user-registries:delete` - Delete the User Registry by name or ID. • `apic user-registries:execute` - Execute a User Registry operation. • `apic user-registries:get` - Get the User Registry by name or ID. • `apic user-registries:list` - List the User Registries. • `apic user-registries:search` - search for users in a user registry. • `apic user-registries:test-connection` - Test a User Registry connection. • `apic user-registries:update` - Update the User Registry by name or ID.
`apic user-registry-settings`	User registry settings commands	• `apic user-registry-settings:get` - Get the User Registry Setting. • `apic user-registry-settings:update` - Update the User Registry Setting.
`apic users`	Users commands	• `apic users` - User collection operations. • `apic users:clear` - Clear the Users. • `apic users:create` - Create a User. • `apic users:delete` - Delete the User by name or ID. • `apic users:get` - Get the User by name or ID. • `apic users:list` - List the Users. • `apic users:request-password-reset` - send a password reset link. • `apic users:search-provider` - Search for provider users from an organization. • `apic users:update` - Update the User by name or ID.
`apic webhooks`	Webhooks commands	• `apic webhooks` - Webhooks collection operations. • `apic webhooks:get` - Get the Webhooks by name or ID. • `apic webhooks:list` - List the Webhooks. • `apic webhooks:update` - Update the Webhooks by name or ID.

API development and management commands

A summary of the core commands in the IBM® API Connect developer toolkit.

Authenticating

Use the **`apic login`** command to authenticate to an API Manager service, and the **`apic logout`** command to remove your local authentication credentials.
Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. Therefore, you should set the file permissions in such a way that your credentials are not accessible by others.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see TLS profiles.

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles that are enabled, follow these steps:

For more information about the NODE_EXTRA_CA_CERTS environment variable, see Node.js documentation.

Creating and managing local files

You create and work with API and Product definition YAML files locally before you stage them to API Manager.

To create a local API definition file, use the **`apic create:api`** command. To create a local Product definition file, use the **`apic create:product`** command.

Use the **`apic apis`** and **`apic products`** commands to list API Manager artifacts of the specified type.

To validate the syntactical correctness of a local API or Product definition file, use the **`apic validate`** command.

To create a draft API in API Manager from a local API or Product definition file, use the **`apic draft-apis:create`** and **`apic draft-products:create`** commands, respectively.

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before an API is validated, created in draft, staged, or published. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Searching API paths with wildcard support

You can perform flexible searches across the full path of APIs published to a catalog using the new **`full_path`** query parameter in the **`apis:list`** and **`apis:list-all`** commands. The **`full_path`** parameter allows you to search using the full API path, which includes both the base path and the path. This enhancement in API path search enables more powerful and flexible searches when you are managing large sets of APIs. Use this feature to quickly locate APIs based on their full published paths, improving efficiency in large environments.

The following wildcards are supported:

- **`*`**: matches zero or more characters.
- **`?`**: matches any single character.

For example,

You can use the following command to search for APIs with the exact path **`/test`**:

```
apic apis:list-all -s <server> --scope catalog -o <org> -c <catalog> --full_path=/test
```

You can use the following command to search for APIs where the full path starts with **`/test`**:

```
apic apis:list-all -s <server> --scope catalog -o <org> -c <catalog> --full_path=/test*
```

Working with Catalogs and Spaces

To create a Catalog, use the **`apic catalog:create`** command. To view information on a Catalog, use the **`apic catalog:get`** command; to list all Catalogs that are contained in organizations that the currently authenticated user is a member of, use the **`apic catalogs`** command.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces within a Catalog are published to the same Developer Portal. For more information about Spaces, see Using syndication in IBM API Connect.

To enable Spaces for a Catalog, use the following command:

```
apic catalogs:set catalog_name --spaces enabled
```

Use the toolkit **`apic spaces`** commands to create and manage Spaces:

- **`apic spaces`** - List Spaces contained in a Catalog.
- **`apic:spaces create`** - Create a Space in a Catalog.
- **`apic:spaces get`** - Get information on a Space in a Catalog.
- **`apic:spaces set`** - Set information on a Space in a Catalog.
- **`apic:spaces delete`** - Delete a Space in a Catalog.

Command summary

The following tables summarize **`apic`** commands for API development and management.

Table 1. Summary of general-purpose commands

Command	Description	Subcommands
`apic config`	List and manage configuration variables. For more information, see Using configuration variables. With no subcommand, lists values of defined configuration variables.	• **`apic config`** - Manage configuration variables • **`apic config:clear`** - Delete all configuration variables • **`apic config:delete`** - Delete a configuration variable • **`apic config:get`** - Get a configuration variable • **`apic config:list`** - List the application and global configuration variables • **`apic config:set`** - Set or update configuration variables
`apic create`	Create a draft API or Product definition YAML file.	• **`create:api`** - Create a draft API OpenAPI definition YAML file • **`create:product`** - Create a Product definition YAML file
`apic extensions`	Manage OpenAPI extensions in a Catalog. With no subcommand, lists the extensions in the production Catalog.	• **`apic extensions`** - Extension collection operations. • **`apic extensions:clear`** - Delete all versions of an extension given the name. • **`apic extensions:clear-all`** - Delete all versions of all extensions. • **`apic extensions:clone`** - Download all versions of all extensions to your local drive. • **`apic extensions:create`** - Create an extension. • **`apic extensions:delete`** - Delete an extension by ID, or by name and version. • **`apic extensions:document`** - Get the document for an extension by ID, or by name and version. • **`apic extensions:get`** - Get an extension by ID, or by name and version. • **`apic extensions:list`** - List all versions of an extension given the name. • **`apic extensions:list-all`** - List all versions of all extensions. • **`apic extensions:update`** - Update an extension by ID, or by name and version.

Command	Description	Subcommands
apic login	Log in to API Manager.	None. Specify server and credentials with the required flags: • **-p, --password** *password* • **-r, --realm** *realm*. Determines the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **-u, --username** *user_name* For full details on how to log in to your management server from the CLI, see Logging in to the management server.
apic logout	Log out from API Manager.	None. Specify server with the required flag: • **-s, --server** *mgmt_service*. You can append the port number to the server name if it is not the default value of 443.
apic validate	Validate API or Product definition YAML file.	None

Table 2. Summary of commands to manage APIs, Products, and Catalogs

Command	Description	Subcommands
apic apis	List and manage APIs that are staged or published to Catalog or Space. Default subcommand is **list-all**.	• **apic apis** - API collection operations • **apic apis:get** - Get the OpenAPI definition YAML file for an API by name and version, or by ID • **apic apis:list** - List an API by name • **apic apis:list-all** - List all APIs in a Catalog or Space • **apic apis:update** - Update an API by name
apic apps	List and manage developer applications that are registered in a consumer organization. Default subcommand is **list**.	• **apic apps** - Application collection operations • **apic apps:clear** - Clear all applications • **apic apps:create** - Create an application • **apic apps:delete** - Delete an application by name or ID • **apic apps:get** - Get an application object by name • **apic apps:list** - List all the applications in a consumer organization • **apic apps:update** - Update an application by name or ID
apic catalogs	List and manage Catalogs in a provider organization. Default subcommand is **list**.	• **apic catalogs:clear** - Clear all Catalogs from provider organization • **apic catalogs:create** - Create a Catalog • **apic catalogs:delete** - Delete a Catalog by name or ID • **apic catalogs:get** - Get a Catalog object by name or ID • **apic catalogs:list** - List all the Catalogs in a provider organization • **apic catalogs:transfer-owner** - Transfer the ownership of a Catalog to another user • **apic catalogs:update** - Update a Catalog by name or ID
apic catalog-settings	Manage the configuration settings for a Catalog	• **apic catalog-settings:get** - Get the Catalog settings. • **apic catalog-settings:update** - Update the Catalog settings.
apic drafts	List and manage the draft API and Product definitions in a provider organization. Default subcommand is **list**.	• **apic drafts** - Draft collection operations • **apic drafts:clear** - Delete all draft APIs and Products in a provider organization • **apic drafts:list** - List the draft APIs and Products in a provider organization
apic draft-apis	List and manage the draft API definitions in a provider organization. Default subcommand is **list-all**.	• **apic draft-apis** - Draft API collection operations • **apic draft-apis:clear** - Delete all versions of a draft API by name • **apic draft-apis:clear-all** - Delete all draft APIs in a provider organization • **apic draft-apis:clone** - Clone all draft APIs in a provider organization • **apic draft-apis:create** - Create a draft API • **apic draft-apis:delete** - Delete a Draft API by name and version • **apic draft-apis:document** - Get the Draft API document by name and version • **apic draft-apis:get** - Get the OpenAPI definition YAML file for an API by name and version • **apic draft-apis:list** - List all versions of a draft API by name • **apic draft-apis:list-all** - List all draft APIs in a provider organization • **apic draft-apis:update** - Update a draft API by name and version, supplying the revised OpenAPI definition file • **apic draft-apis:update-wsdl** - Update a draft SOAP API by name and version, supplying the revised WSDL definition file in a .wsdl or .zip format Note: There must be a match of the service names in the existing WSDL with the revised WSDL. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed. • **apic draft-apis:validate** - Validates a draft API • **apic draft-apis:wsdl** - Get the Draft API WSDL document by name and version

Command	Description	Subcommands
apic draft-products	List and manage the draft Product definitions in a provider organization. Default subcommand is **list-all**.	• **apic draft-products** - Draft Product collection operations • **apic draft-products:clear** - Delete all versions of a draft Product by name • **apic draft-products:clear-all** - Delete all draft Products in a provider organization • **apic draft-products:create** - Create a draft Product • **apic draft-products:delete** - Delete a draft Product by name and version • **apic draft-products:get** - Get the Draft Product by name and version • **apic draft-products:list** - List the Draft Products • **apic draft-products:list-all** - List all draft Products in a provider organization • **apic draft-products:publish-all** - Publishes the Draft Product • **apic draft-products:update** - Update a draft Product by name and version, supplying the revised definition file • **apic draft-products:validate** - Validates a draft Product
apic members	List and manage the members of a provider organization, consumer organization, Catalog, or Space. Default subcommand is **list**.	• **apic members** - Member operations • **apic members:clear** - Delete all members • **apic members:create** - Create a member • **apic members:delete** - Delete a member by name or ID • **apic members:get** - Get a member object by name or ID • **apic members:list** - List all members • **apic members:update** - Update the member by name or ID
apic member-invitations	List and manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space. Default subcommand is **list**.	• **apic member-invitations** - Member invitation collection operations. • **apic member-invitations:clear** - Delete all member invitations. • **apic member-invitations:create** - Create a member invitation. • **apic member-invitations:delete** - Delete a member invitation by name or ID. • **apic member-invitations:get** - Get a member invitation object by name or ID. • **apic member-invitations:list** - List all member invitations. • **apic member-invitations:update** - Update a member invitation by name or ID.
apic orgs	List and manage provider organizations, and the admin organization. Default subcommand is **list**.	• **apic orgs** - Organization collection operations • **apic orgs:clear** - Delete all organizations • **apic orgs:create** - Create an organization • **apic orgs:delete** - Delete an organization by name or ID • **apic orgs:get** - Get an organization object by name or ID • **apic orgs:list** - List all organizations • **apic orgs:transfer-owner** - Transfer ownership of an organization • **apic orgs:update** - Update an organization by name or ID
apic org-settings	Manage settings for provider organizations, and the admin organization.	• **apic org-settings:get** - Get the settings object for an organization • **apic org-settings:update** - Update the settings for an organization
apic policies	List and manage policies in a Catalog. Default subcommand is **list**.	• **apic policies** - Policy collection operations • **apic policies:clear** - Clear the Policies • **apic policies:clear-all** - Clear all Policies in all collections • **apic policies:create** - Create a Policy • **apic policies:delete** - Delete a Policy • **apic policies:get** - Get the Policy by name and version • **apic policies:list** - List the Policies • **apic policies:list-all** - List all Policies in all collections • **apic policies:update** - Update the Policy by name and version
apic products	List and manage Products that are staged or published to Catalog or Space. Default subcommand is **list-all**.	• **apic products** - Product collection operations • **apic products:clear** - Delete all versions of a Product by name • **apic products:clear-all** - Delete all Products • **apic products:delete** - Delete a Product by name and version • **apic products:execute-migration-target** - Products execute migration target operations • **apic products:get** - Get a Product object by name and version • **apic products:list** - List all versions of a Product by name • **apic products:list-all** - List all Products • **apic products:publish** - Publish a Product to a Catalog or Space, supplying the Product definition YAML file • **apic products:replace** - Replace a Product with another Product • **apic products:set-migration-target** - Set the target Product for migrating subscriptions from a Product • **apic products:supersede** - Supersede a Product with another Product • **apic products:update** - Update a Product by name and version, supplying the revised Product definition YAML file
apic identity-providers	View information about identity providers.	• **apic identity-providers** - Identity provider operations • **apic identity-providers:list** - List the identity providers.

Command	Description	Subcommands
`apic spaces`	List and manage Spaces contained in a Catalog. Default subcommand is `list`.	• `apic spaces` - Space collection operations • `apic spaces:clear` - Delete all Spaces from a Catalog • `apic spaces:create` - Create a Space in a Catalog • `apic spaces:delete` - Delete a Space from a Catalog, by name or ID • `apic spaces:get` - Get a Space object by name or ID • `apic spaces:list` - List all the Spaces in a Catalog • `apic spaces:transfer-owner` - Transfer the ownership of a Space to another user • `apic spaces:update` - Update a Space by name or ID
`apic subscriptions`	List and manage subscriptions in a Product or a Catalog. Default subcommand is `list`.	• `apic subscriptions` - Subscription collection operations • `apic subscriptions:clear` - Clear the Subscriptions • `apic subscriptions:create` - Create a Subscription • `apic subscriptions:delete` - Delete the Subscription by name or ID • `apic subscriptions:get` - Get the Subscription by name or ID • `apic subscriptions:list` - List the Subscriptions • `apic subscriptions:update` - Update the Subscription by name or ID

Table 3. Summary of other commands for API developers and managers

Command	Description	Subcommands
`apic consumer-orgs`	Manage consumer organizations	• `apic consumer-orgs` - Consumer Organization collection operations. • `apic consumer-orgs:clear` - Clear the Consumer Organizations. • `apic consumer-orgs:create` - Create a Consumer Organization. • `apic consumer-orgs:delete` - Delete the Consumer Organization by name or ID. • `apic consumer-orgs:get` - Get the Consumer Organization by name or ID. • `apic consumer-orgs:list` - List the Consumer Organizations. • `apic consumer-orgs:transfer-owner` - Transfer owner to a new member. • `apic consumer-orgs:update` - Update the Consumer Organization by name or ID.
`apic consumer-org-settings`	Manage consumer organization settings	• `apic consumer-org-settings:delete` - Delete the Consumer Organization Setting. • `apic consumer-org-settings:get` - Get the Consumer Organization Setting. • `apic consumer-org-settings:update` - Update the Consumer Organization Setting.
`apic groups`	Manage groups	• `apic groups` - Group collection operations. • `apic groups:clear` - Clear the Groups. • `apic groups:create` - Create a Group. • `apic groups:delete` - Delete the Group by name or ID. • `apic groups:get` - Get the Group by name or ID. • `apic groups:list` - List the Groups. • `apic groups:update` - Update the Group by name or ID.
`apic invitations`	Manage invitations. An invitation is created when a user is invited to be the owner of a provider organization, consumer organization, Catalog, or Space.	• `apic invitations` - Invitation collection operations. • `apic invitations:clear` - Delete all invitations. • `apic invitations:create` - Create an invitation. • `apic invitations:delete` - Delete an invitation by name or ID. • `apic invitations:get` - Get the details of an invitation by name or ID. • `apic invitations:list` - List all invitations. • `apic invitations:update` - Update an invitation by name or ID.
`apic member-invitations`	Manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space.	• `apic member-invitations` - Member invitation collection operations. • `apic member-invitations:clear` - Delete all member invitations. • `apic member-invitations:create` - Create a member invitation. • `apic member-invitations:delete` - Delete a member invitation by name or ID. • `apic member-invitations:get` - Get the details of a member invitation by name or ID. • `apic member-invitations:list` - List all member invitations. • `apic member-invitations:update` - Update a member invitation by name or ID.
`apic members`		• `apic members` - Member collection operations. • `apic members:clear` - Clear the Members. • `apic members:create` - Create a Member. • `apic members:delete` - Delete the Member by name or ID. • `apic members:get` - Get the Member by name or ID. • `apic members:list` - List the Members. • `apic members:update` - Update the Member by name or ID.

Command	Description	Subcommands
`apic registrations`		• `apic registrations` - Registration collection operations. • `apic registrations:clear` - Clear the Registrations. • `apic registrations:create` - Create a Registration. • `apic registrations:delete` - Delete the Registration by name or ID. • `apic registrations:get` - Get the Registration by name or ID. • `apic registrations:list` - List the Registrations. • `apic registrations:update` - Update the Registration by name or ID.
`apic role-defaults`		• `apic role-defaults` - Role Default collection operations. • `apic role-defaults:clear` - Clear the Role Defaults. • `apic role-defaults:create` - Create a Role Default. • `apic role-defaults:delete` - Delete the Role Default by name or ID. • `apic role-defaults:get` - Get the Role Default by name or ID. • `apic role-defaults:list` - List the Role Defaults. • `apic role-defaults:list-all` - List all Role Defaults in all collections. • `apic role-defaults:update` - Update the Role Default by name or ID.
`apic roles`		• `apic roles` - Role collection operations. • `apic roles:clear` - Clear the Roles. • `apic roles:create` - Create a Role. • `apic roles:delete` - Delete the Role by name or ID. • `apic roles:get` - Get the Role by name or ID. • `apic roles:list` - List the Roles. • `apic roles:update` - Update the Role by name or ID.
`apic tasks`		• `apic tasks` - Task collection operations. • `apic tasks:clear` - Clear the Tasks. • `apic tasks:create` - Create a Task. • `apic tasks:delete` - Delete the Task by name or ID. • `apic tasks:get` - Get the Task by name or ID. • `apic tasks:list` - List the Tasks. • `apic tasks:update` - Update the Task by name or ID.
`apic user-registries`		• `apic user-registries` - User Registry collection operations. • `apic user-registries:clear` - Clear the User Registries. • `apic user-registries:create` - Create a User Registry. • `apic user-registries:delete` - Delete the User Registry by name or ID. • `apic user-registries:execute` - Execute a User Registry operation. • `apic user-registries:get` - Get the User Registry by name or ID. • `apic user-registries:list` - List the User Registries. • `apic user-registries:search` - search for users in a user registry. • `apic user-registries:test-connection` - Test a User Registry connection. • `apic user-registries:update` - Update the User Registry by name or ID.
`apic user-registry-settings`		• `apic user-registry-settings:delete` - Delete the User Registry Setting. • `apic user-registry-settings:get` - Get the User Registry Setting. • `apic user-registry-settings:update` - Update the User Registry Setting.
`apic users`		• `apic users` - User collection operations. • `apic users:clear` - Clear the Users. • `apic users:create` - Create a User. • `apic users:delete` - Delete the User by name or ID. • `apic users:get` - Get the User by name or ID. • `apic users:list` - List the Users. • `apic users:request-password-reset` - send a password reset link. • `apic users:search-provider` - Search for provider users from an organization. • `apic users:update` - Update the User by name or ID.
`apic test`	Test your APIs	• `apic test {yaml-files}` - Define the tests. • `apic test {yaml-files} --insecureSkipVerify` - Test the APIs with certificate checks disabled. • `apic test {yaml-files} --certPath={location of certs folder}` - Specifies the location of the CA certificate if it is not available in the system keystore. • `api test {yaml-files} --mTLS --certPath={location of certs folder}` - Test the APIs with `mTLS` enabled. • `api test {yaml-files} --config-file={location of config file}` - Define the tests by passing the external configuration.

- **Configure user limit and invitation resend interval for Consumer organization**
  You can use the CLI commands in the toolkit CLI to configure user limit and invitation resend interval.

Configure user limit and invitation resend interval for Consumer organization

You can use the CLI commands in the toolkit CLI to configure user limit and invitation resend interval.

Before you begin

To complete this scenario, you must have a Developer Portal enabled. The tutorial Creating the Portal explains how to enable the portal if you haven't enabled it already.

To view the management commands, see API development and management commands.

About this task

In this task, you use the toolkit CLI to configure user limit and invitation resend interval for Consumer organization.

This task takes you through the following steps:

1. Logging in to a management server
2. Obtain the .yaml file
3. Edit the .yaml file
4. Update the .yaml file

Logging in to a management server

- Log in as Provider org:

  ```
  apic login --server management_server --realm provider/identity_provider --username provider_username --password provider_password
  ```

  You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

  ```
  apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
  ```

  For example,

  ```
  apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
  total_results: 2
  results:
    - title: API Manager User Registry
      realm: provider/default-idp-2
    - title: Corporate LDAP user registry
      realm: provider/corporate-ldap
  ```

  The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
  For full details of the `apic login` command, see Logging in to a management server.

Obtain the .yaml file

- Run the following command to get the `catalog-setting.yaml`:

  ```
  apic catalog-settings:get -s <management server endpoint> -o <org name> -c <catalog name>
  ```

  Where:
  - *<management server endpoint>* is the management server endpoint (required).
  - *<org name>* is the organization name (required).
  - *<catalog name>* is the name of the catalog (required).

Edit the .yaml file

- Run the following command to edit `catalog-setting.yaml`:

  ```
  vi catalog-setting.yaml
  ```

- To edit the invitation interval, edit the following parameter:

  ```
  corg_member_invitation_regenerate_delay: 0
  ```

  Enter the invitation delay in minutes. The default value is 0, and the maximum value is one week (10,080 minutes).
- To edit the user limits, edit the following parameter:

  ```
  max_corg_members: 2147483647
  ```

  Enter the number of members that you want to add to the Consumer organization. The default value for this property is 2,147,483,647.
  Note: When the total of existing members and pending member invitations in a consumer organization reaches the configured limit, any attempt to create a new member invitation results in an error.

Update the .yaml file

- Run the following command to update the edited `catalog-settings.yaml`:

  ```
  apic catalog-settings:update -s <management server endpoint> -o <org name> -c <catalog name> catalog-settings.yaml
  ```

  Where:
  - ***<management server endpoint>*** is the management server endpoint (required).
  - ***<org name>*** is the organization name (required).
  - ***<catalog name>*** is the name of the catalog (required).

Result

You used the toolkit CLI to configure user limit and invitation resend interval for Consumer organization.

Creating APIs and applications

You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.

You can use the developer toolkit to create language-independent APIs by using OpenAPI to proxy to an existing backend implementation or to augment applications that are developed in other languages or frameworks such as Express, Java™, Swift, Go, and others.

Creating development artifact definitions

Use the **`apic create`** command to create development artifacts, by using the following commands:

Command	Description
`apic create:api`	Create an OpenAPI definition.
`apic create:api --wsdl filename`	Create a SOAP API definition from a WSDL definition file, or a .zip file that contains the WSDL definition files for a service. The name and version of the generated API are obtained from the WSDL file. If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.
`apic create:product`	Create an API Product definition.

Note: You can create an API or Product from an OpenAPI template file by using the `--template template-name` option.
You can also create Product and API definitions non-interactively by providing the `--title` option. This option sets several values that you can also customize with additional options; for example:

```
apic create:api --title Routes
apic create:product --title "Climb On"
```

You can also create the API and Product definitions at the same time:

```
apic create:api --title Routes --product "Climb On"
apic create:api --wsdl globalweather.wsdl --product "Weather Forecasting"
```

Alternatively, you can create APIs and then reference them when you create a new Product; for example:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
```

Validating development artifact definitions

After you edit development artifacts or before you publish artifacts, best practice is to validate them; for example:

```
apic validate routes.yaml                    # Validate an API
apic validate climb-on.yaml                  # Validate the Product and its APIs
apic validate climb-on.yaml --product-only   # Validate the Product only (do not validate the referenced APIs)
```

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file,the **`$ref`** field is replaced with the contents of the target file before the draft API is created with the **apic drafts:validate** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Publishing APIs and applications

To publish APIs and applications by using the developer toolkit of IBM® API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.

See the following sections for more information:

- Setting configuration variables
- Logging in to API Connect
- Publishing APIs

Setting configuration variables

The **apic config** command provides global and project-based configuration variables that specify the target Catalog for publishing APIs and applications. The values of these variables are stored in **~/.apiconnect/config** (for global variables) and ***project-dir*/.apiconnect** (for project variables). For a full list of configuration variables, see Overview of the command-line tool.

Set the **catalog** configuration variable to the URI of an API Connect Catalog to define a default Catalog target for all commands managing Catalogs. The **catalog** URI has the form:

https://*mgmt_endpoint_url*/api/catalogs/*org_name*/*catalog_name*

where *mgmt_endpoint_url* is the platform API endpoint URL, *org_name* is the provider organization name, and *catalog_name* is the Catalog name. The *mgmt_endpoint_url* portion sets the default value of the **--server** option, the *org_name* portion sets the default value of the **--org** option, and the *catalog_name* portion sets the default value of the **--catalog** option; you can override any of these values by including the corresponding option in a command.

Set the **space** configuration variable to the URI of an API Connect Space, to define a default Space target for all commands that manage Spaces. The **space** URI has the form:

https://*mgmt_endpoint_url*/api/spaces/*org_name*/*catalog_name*/*space_name*

where *mgmt_endpoint_url* is the platform API endpoint URL, *org_name* is the provider organization name, *catalog_name* is the Catalog name, and *space_name* is the name of the Space. The *mgmt_endpoint_url* portion sets the default value of the **--server** option, the *org_name* portion sets the default value of the **--org** option, the *catalog_name* portion sets the default value of the **--catalog** option, and the *space_name* sets the default value of the **--space** option; you can override any of these values by including the corresponding option in a command.
Although setting these configuration variables is not required, doing so simplifies commands that interact with API Connect clouds by providing default values for frequently used command-line options.

Here is an example of publishing with and without the **catalog** configuration variable set.

Without the configuration variable set:

```
apic products publish climb-on.yaml --server mgmnthost.com --org climbon --catalog sandbox
```

With the configuration variable set:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
catalog: https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic products publish climb-on.yaml
```

You can override default values provided by the **catalog** configuration variable by providing one of the standard options with a different value. For example, use the **--catalog** option with the **apic products publish** command to specify the **qa** Catalog:

```
apic products publish climb-on.yaml --catalog qa
```

Don't forget about global configuration variables. If you use the same Catalog as the default target for multiple projects, set the value globally:

```
apic config:set --global catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
```

Note:
If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called **SPACE** then, by default, that value will be assumed for the value of the **--space** parameter in the following command, regardless of any **space** configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called **APIC_LOAD_FROM_ENV**, set to the value **false**.

Logging in to API Connect

Use the **apic login** and **apic logout** commands to manage your authentication. For details, see rapic_cli_login.html.

Publishing APIs

Publishing APIs to API Catalogs in API Connect clouds enables you to socialize the APIs by using the Developer Portal and secure them by using the Gateway.

An *API Product* (or simply *Product*) is used to compose APIs for publishing. API Product managers can use it to bundle one or more APIs together, control the visibility of the Product in the Developer Portal (for example, only allow partners x, y, and z to view and subscribe to the Product), and define Plans to provide consumption options. The Products that reference the APIs and define the consumption Plans are also the primary unit of lifecycle management for APIs.

Use the **apic products publish** command (equivalent to **apic products:publish**) to publish API Products to an API Connect cloud. The following example demonstrates how to create APIs composed by a Product, and publishing the Product and its APIs to a Catalog:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/default-idp-2
apic products publish climb-on.yaml
```

For full details on how to log in to your management server from the CLI, see Logging in to a management server.

Add the **--stage** option to **apic publish** to stage the Product into a Catalog instead of publishing it. Products in a Catalog can be in the following states: staged, published, deprecated, or retired. For example:

```
apic products publish --stage climb-on.yaml
```

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces within a Catalog are published to the same Developer Portal. For more information about Spaces, see Using syndication in IBM API Connect.

If default configuration values have been set for the Space, Catalog, organization and management server, the following publish command could be used:

```
apic products publish --scope space product.yaml
```

where *product* is the name of the product that you want to publish.
Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the Product that contains the API is staged or published with the **apic publish** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Managing API Products

Use the `apic products` and `apic apis` commands to manage Products and APIs published to IBM® API Connect Catalogs. Use the `--scope space` option to manage Products and APIs published to Spaces within Catalogs.

Product management command summary

The following table summarizes the commands available for managing API Products. Usage examples follow.

Example command	Description
`apic config:set catalog=https://platform-api.myserver.com/api/catalogs/myorg/sandbox`	Set the default Catalog.
`apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/my-identity-provider`	Login into the management server. For full details on how to log in to your management server from the CLI, see Logging in to the management server.
`apic create:api --title Routes --product "ClimbOn"`	Create the Product and API.
`apic products:publish climbon.yaml`	Publish the Product to the default catalog. Add --stage argument to stage the Product.
`apic products:list-all --scope catalog`	List the Products in the default catalog.
`apic products:get climbon:1.0.0 --output -`	Display the Product's properties. Omit the output argument to download to a file.
`apic apis:list-all --scope catalog`	List the APIs in the Catalog.
`apic apis:get routes:1.0.0 --output -`	Get the API properties. Omit the output argument to download to a file.
`apic products:replace climbon:1.0.0 mapfile.txt`	Replace the Product indicated on the command with the staged or published Product that is designated in the mapfile. The replaced Product is retired.
`apic products:supersede climbon:1.0.0 mapfile.txt`	Supersede the Product indicated on the command with the staged or published Product that is designated in the mapfile. The superseded Product is deprecated.
`apic products:delete climbon:1.0.0`	Delete the Product from the Catalog. The Product must be either retired or deprecated.

Using the `products` and `apis` commands through a full lifecycle

This example shows a complex lifecycle where a new version of a Product and API replaces the original version at run time.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the Product that contains the API is staged or published with the **apic publish** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Set the default Catalog and login to the mgmnthost.com API Connect cloud

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm my-identity-provider
```

For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Create and publish an initial version

```
apic create:api --title Routes --version 1.0.0 --filename routes100.yaml
apic create:product --title "Climb On" --version 1.0.0 --apis routes100.yaml --filename climbon100.yaml
apic products:publish climbon100.yaml
```

Create a new version to fix a bug in the API, stage it to the Catalog

```
apic create:api --title Routes --version 1.0.1 --filename routes101.yaml
apic create:product --title "Climb On" --version 1.0.1 --apis routes101.yaml --filename climbon101.yaml
apic products:publish --stage climbon101.yaml
```

Inspect the Catalog

```
apic products:list-all --scope catalog
```

This command lists all Products in the catalog. Copy the ID of the `climbon:1.0.1` Product. The ID resembles the following example.

```
https:/server/api/catalogs/3eca6046-3c27-4ad/ab8772bf-0f65-45/products/8f854623-bda1-4f9
```

Create a mapping file

For example, if you replace a Product, the mapping file specifies the Product to replace and maps the Plans from the source Product to the target Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then `product_url` property specifies the URL of `climbon:1.0.0`.

This file takes the following form:

```
product_url: https:/server/api/catalogs/{id}/products/{id}
plans:
- source: {source_plan_name_1}
  target: {target_plan_name_1}
- source: {source_plan_name_2}
  target: {target_plan_name_2}
            .
            .
            .
```

Note:

- The source and target Plan names can be the same or different.
- Every Plan in the Product you are replacing must be mapped to a Plan in the replacement Product.

"Hot-replace" version 1.0.0 with 1.0.1

```
apic products:replace climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

After it is replaced in this way, a Product that is specified is retired. It is no longer active.
Note:
The Product that is specified on the command is the replacement Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product that is specified on the command is `climbon:1.0.1`.

Supersede version 1.0.0 with 1.0.1

Rather than hot-replacing an existing Product with a new one (usually an updated version), you can supersede the existing Product with a new one. When you replace a Product, all external application subscriptions to that Product are automatically moved to the new Product. When you supersede a Product, the subscriptions are not automatically moved to the new Product, some action must be taken to subscribe external applications to the superseding Product.
The command to supersede a Product uses the same mapping file as the command to replace a Product. The name of the superseding Product is given on the command.

```
apic products:supersede climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

After a Product is superseded, a Product is marked deprecated, meaning that no further subscriptions to the Product are allowed, although it is still active and existing subscriptions still work.
Note: The Product that is specified on the command is the superseding Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product that is specified on the command is `climbon:1.0.1`. The mapping file specifies the URL of the Product that you are superseding.

Set a migration target

It is possible to set a migration target for the existing Product. This helps migration.
Use a command like the following to set the migration target.

```
apic products:set-migration-target climbon:1.0.0 PRODUCT_PLAN_MAPPING_FILE
```

Note: The Product that is specified on the command is the Product from which you want to migrate subscriptions. The mapping file specifies the target Product for the subscriptions.
After a migration target is set, external application developers are able to migrate their application subscriptions through the Developer Portal with ease. It is also possible to run a subscription migration by using the following command.

```
apic products:execute-migration-target climbon:1.0.0
```

Delete a Product

When the replaced or superseded Product is no longer needed, it can be deleted.

```
apic products:delete climbon:1.0.0
```

Extra Product and API operations

In addition to the lifecycle management capabilities, you can download Products and APIs in a catalog or space by using the `clone` subcommand:

Command	Description
apic products:clone	Download all Products and their APIs from the catalog or space.
apic apis:clone	Download all APIs from the catalog or space.

You can also clear all Products and their APIs from a catalog, which is especially useful for a development catalog. To confirm the operation, you must specify the catalog name as the value of the `--confirm` parameter:

```
apic products:clear --confirm catalog_name
```

where *catalog_name* is the name of the Catalog.
You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces within a Catalog are published to the same Developer Portal. For more information about Spaces, see Using syndication in IBM API Connect.

To manage the Products and APIs published to a Space, include the `--scope space` option with the `apic products` and `apic apis` commands. For example, to list the Products that are contained in a Space that is called *flights*, use the following command:

```
apic products --scope space --space flights --catalog production --org climbonorg --server platform-api.myserver.com
```

Changing the lifecycle state of a Product in a Catalog or Space

To directly change the lifecycle state of a Product that has previously been staged or published to a Catalog or Space, complete the following steps:

- Enter the following command (the terminating hyphen character means that the command takes input from the command):

```
apic products:update product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space] -
```

where:
- *product_name* is the name of the Product whose lifecycle state you want to change.
- *version* is the version of that Product.
- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization* is the name of the provider organization in which the Product was previously staged or published.
- *scope* has one of the following values:
  - `catalog` if the Catalog does not have Spaces enabled.
  - `space` if the Catalog has Spaces enabled. If you specify `space` for the `--scope` parameter, you must also supply the `--space` parameter.
- *catalog* is the name of the Catalog in which the Product was previously staged or published.
- (Optional) *space* is the name of the Space. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope space` in the command.

The command returns:

```
Reading PRODUCT_FILE arg from stdin
```

- Enter the following data, followed by a new line:

  ```
  state: new_state
  ```

  where *new_state* is the state that you want to change the Product to, and must have one of the following values.
  - Staged
  - Published
  - Deprecated
  - Retired
  - Archived
- Press `CTRL D` to terminate the input. If the command is successful, the lifecycle state change is confirmed.
  For example:

  ```
  apic products:update finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox -
  Reading PRODUCT_FILE arg from stdin
  state: published
  finance:1.0.0    [state: published]   https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
  ```

Note:
The command fails if the lifecycle state change is not allowed.

For example, the following lifecycle state changes are allowed:

- From staged to published
- From deprecated to retired

The following lifecycle state changes are not allowed:

- From published to staged
- From retired to published

For full details, see The Product lifecycle.

To list all Products in a Catalog or Space, together with their lifecycle states, use the following command:

```
apic products:list-all --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space]
```

For example:

```
apic products:list-all --server https://myserver.com --org development --scope catalog --catalog sandbox
graphql-services:1.0.0    [state: staged]      https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-9e82-427a-abe6-be5b126210f7/products/7652d568-b396-4bfa-bf71-2f18cea63737
finance:1.0.0             [state: published]   https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

To find out the lifecycle state of a specific Product, use the following command:

```
apic products:get product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space] --fields state --output -
```

For example:

```
apic products:get finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox --fields state --output -
state: published
```

Example scripts

A set of example toolkit scripts that demonstrate how to create and manage organizations, users, apps, Products, and APIs are available at https://github.com/ibm-apiconnect/example-toolkit-scripts.

Working with Drafts

Colocate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration. The developer toolkit provides the bridge from the developer's environment to the IBM® API Connect runtime services.

API Connect provides an online development capability called *Drafts* where you can define API and Product definitions. The **apic drafts** commands enable synchronization of Product and API artifacts between local source code control systems and drafts.

You can use **drafts** to clear and list your drafts. For example:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox    # set the default Catalog
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/myldap  # login
into the management server

apic create:api --title routes --product ClimbOn
apic drafts                                                 # list what is in drafts
apic drafts:clear --confirm drafts                          # clear drafts collection
apic drafts:list                                            # list the available drafts
```

For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Reading input from the command line

If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.

Reading input from a file

Many developer toolkit commands that create or update new objects in API Connect take a file as an input parameter. For example:

- Register a new gateway service:

  ```
  apic gateway-services:create [flags] GATEWAY_SERVICE_FILE
  ```

- Update a provider organization:

  ```
  apic orgs:update [flags] ORG_FILE
  ```

- Create a new Catalog:

  ```
  apic catalogs:create [flags] CATALOG_FILE
  ```

- Create a new consumer organization:

  ```
  apic consumer-orgs:create [flags] CONSUMER_ORG_FILE
  ```

- Register a new developer application:

  ```
  apic apps:create [flags] APP_FILE
  ```

- Create a new email server:

  ```
  apic mail-servers:create [flags] MAIL_SERVER_FILE
  ```

- Update the list of applications that subscribe to a Product:

  ```
  apic subscriptions:update [flags] SUBSCRIPTION_FILE
  ```

You can format the input file as a YAML file (the default) or as a JSON file. To use a JSON file as input, include the **--format json** parameter.

Reading input from the command line

As an alternative to supplying an explicit file name to the command, you can supply a hyphen (-) in place of the file name parameter; the command will then read the file content directly from the command line as shown in the following examples.

- Register a new DataPower® Gateway (v5 compatible) gateway service:

  ```
  apic gateway-services:create --server platform-api.myserver.com --org admin --availability-zone availability-zone-default
  -
  Reading GATEWAY_SERVICE_FILE arg from stdin
  name: dpgw-service
  title: DataPower gateway service, compatible with v5
  gateway_service_type: datapower-gateway
  endpoint: 'https://mygwhost.com:3000'
  api_endpoint_base: 'https://mygwhost.com:9443'
  sni:
    - host: '*'
      tls_server_profile_url: https://platform-api.myserver.com/api/orgs/75203636-f038-4287-a732-24af4bf7059d/tls-server-
  profiles/3c0a0e93-6aa4-4288-b09c-eccf4901b104
  visibility:
    type: public
  ```

  Note: You can obtain the **tls_server_profile_url** property value for a TLS server profile by using the following command, which lists the URLs for all TLS server profiles:

  ```
  apic tls-server-profiles --org organization_name --server mgmt_endpoint_url
  ```

- Create a new provider organization:

  ```
  apic orgs:create --server platform-api.myserver.com -
  Reading ORG_FILE arg from stdin
  name: development
  title: Development organization
  ```

```
owner_url: https://platform-api.myserver.com/api/user-registries/1bbbd414-22f1-47cf-8eac-2050530d29a7/c082d755-866e-4394-959f-fbb264c6c3a1/users/2db491c7-2d0f-4f60-a8ae-f38d07481f21
```

Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```

- Create a new Catalog:

```
apic catalogs:create --server platform-api.myserver.com --org myorg -
Reading CATALOG_FILE arg from stdin
name: production
title: Production Catalog
summary: Catalog containing APIs in production use
```

- Create a new consumer organization:

```
apic consumer-orgs:create --server platform-api.myserver.com --catalog sandbox --org myorg -
Reading CONSUMER_ORG_FILE arg from stdin
name: finance-apps
title: Developers of finance applications
owner_url: https://platform-api.myserver.com/api/user-registries/a1fb8159-fda1-410f-93ab-a0ea5fd04535/70ce7ec3-e83f-4c87-9f3c-4662ad108bbc/users/fddd5df5-c178-4a34-ab92-0a48344d5c9b
```

Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```

- Register a new developer application:

```
apic apps:create --server consumer-api.myserver.com --org my-consumer-org --mode consumer -
Reading APP_FILE arg from stdin
name: finance
title: Finance application
summary: Mobile app for personal finance management
```

- Create a new email server:

```
apic mail-servers:create --org admin --server platform-api.myserver.com  -
Reading MAIL_SERVER_FILE arg from stdin
title: My email server
name: my-email-server
host: smtp.myemail.com
port: 20
credentials:
  username: me@myemail.com
  password: password
```

- Create a new subscription to subscribe an application to a Product:

```
apic subscriptions:create --app myapp --catalog sandbox --org myorg --server platform-api.myserver.com --consumer-org my-consumer-org -
Reading SUBSCRIPTION_FILE arg from stdin
product_url: https://platform-api.myserver.com/api/catalogs/960733c1-d7f7-4b90-9bc7-69dbfbe4ce31/ca34537d-adf4-4320-8495-a7feaa62d679/products/638015c6-a8b0-452e-841f-2ac441ab6962
plan: default-plan
```

Note: You can obtain the `product_url` property value for a Product by using the following command, which lists the URLs for all versions of a Product given the Product name:

```
apic products:list product_name --scope catalog --catalog catalog_name --org provider_org_name --server mgmt_endpoint_url
```

Scripting with the toolkit commands

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Scripting commands

It's often helpful to automate a series of `apic` commands In a shell script. Since the `apic` tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.
Toolkit command scripts allow you to automate many of the tasks that are required to set up and maintain your API products. A set of example scripts are available at **https://github.com/ibm-apiconnect/example-toolkit-scripts**.

These scripts demonstrate how to perform the following tasks.

- Create a Provider Organization
- Configure a catalog to use one or more gateways
- Create draft APIs and Products
- Publish Products
- Replace an existing published product with a new version
- Delete a product
- Create a Consumer Organization
- Create a new consumer app
- Subscribe the new app to an existing published product
- Stage a new product version
- Supersede the existing published product with the new one
- Migrate existing subscriptions from the old product to the new product

Working with OpenAPI extensions

Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API, depending on the version of IBM® API Connect you are using. An extension is imported into a Catalog, or as Space ion a Catalog, then added to the API schema.

The commands that are described here are for importing OpenAPI extensions into a Catalog or Space, and viewing and managing them. After you import an OpenAPI extension, you can reference it in your API definitions; for details, see Referring to an extension in an API definition.

Note: If Spaces are enabled in a Catalog, an OpenAPI extension that you import into one Space is imported into all Spaces; you cannot import an OpenAPI extension into an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.

Command name	Action	Syntax

extensions clear	The **extensions:clear** command deletes all versions of an extension given the extension name.
	
	The parameters are as follows:
	
	--scope
	Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:
	
	`catalog`
	The command is to be applied to Catalog
	`space`
	The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to `space` and supply the `--space` parameter.
	
	--catalog or -c <*catalog_name*>
	Specifies a single Catalog with the Catalog name.
	--space
	Specifies the name of a Space in a Catalog. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope space` in the command.
	--configured-gateway-service <*service_name*>
	Specifies the name of the gateway service.
	--confirm <*catalog_name*>
	Confirms the clear of the extension.
	<*extension_name*>
	Specifies the name of the existing extension.
	Note: This is the extension name, not the file name.
	--org or -o <*organization_name*>
	Specifies a single organization with the organization name.
	--server or -s <*management_server_endpoint*>
	Specifies the server endpoint.
		`apic extensions:clear --scope catalog|space --catalog | -c catalog_name extension_name --server | -s management_server_endpoint --configured-gateway-service gw_service_name --confirm catalog_name --org | -o org_name [--space space]`
		
		Example:
		
		`apic extensions:clear --scope catalog --catalog catalog1 extension1 --server endpoint1 --configured-gateway-service gw_service1 --confirm catalog1 --org my_org`
		
		This example deletes all versions of the `extension1` extension that are in `catalog1` of the `my_org` organization, and are paired with `endpoint1`.

Command name	Action	Syntax
extensions clear-all	The **extensions:clear-all** command deletes all of the extensions in the specified Catalog or Space. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --configured-gateway-service <*service_name*> Specifies the name of the gateway service. --confirm <*catalog_name*> Confirms the clear of the extension. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint.	**apic extensions:clear-all** **--scope catalog|space** **--catalog | -c *catalog_name*** **--server | -s *mgt_server_endpoint*** **--configured-gateway-service *gw_service_name*** **--confirm *catalog_name*** **--org | -o *org_name*** **[--space *space*]** Example: **apic extensions:clear-all --scope catalog** **--catalog catalog1 --server endpoint1** **--configured-gateway-service gw_service1** **--confirm catalog1 --org my_org** This example deletes all the extensions that are in **catalog1** of the **my_org** organization, and are paired with **endpoint1**.
extensions clone	The **extensions:clone** command creates a local definition file for each extension. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:clone --scope catalog|space** **--catalog | -c *catalog_name*** **--org | -o *org_name*** **[--space *space*]** **--server | -s *mgt_server_endpoint*** **--configured-gateway-service *gw_service_name*** Example: **apic extensions:clone --scope catalog** **--catalog catalog1 --org my_org --server endpoint1** **--configured-gateway-service gw_service_1** This example clones the extensions that are in **catalog1** of the **my_org** organization, and are paired with **endpoint1**.

Command name	Action	Syntax
extensions create	The **extensions:create** command creates an extension in a Catalog or Space by using an extension definition file. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. <*extension_file*> Specifies the name of the extension file that contains the new information for your extension. Note: This is the OpenAPI file name, not the name of the extension. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:create** --scope catalog|space *extension_file* --server | -s *mgt_server_endpoint* --catalog | -c *catalog_name* [--space *space*] --org | -o *org_name* --configured-gateway-service *gw_service_name* Example: **apic extensions:create --scope catalog filename.yaml --server endpoint1 --catalog catalog1 --org my_org --configured-gateway-service gw_service_1** This example creates an extension in **catalog1** of the **my_org** organization, which is paired with **endpoint1**, using the **filename.yaml** OpenAPI extension definition file.
extensions delete	The **extensions:delete** command deletes a specific version of an extension. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:delete** --scope catalog|space *extension_name*:*version_number* --catalog | -c *catalog_name* --org | -o *org_name* [--space *space*] --server | -s *mgt_server_endpoint* --configured-gateway-service *gw_service_name* Example: **apic extensions:delete --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1** This example deletes **myextension** version **1.0.0** that is in **catalog1** of the **orgmain** organization, and is paired with **endpoint1**.

Command name	Action	Syntax
extensions get	The **extensions:get** command retrieves the definition file for a specific version of an extension. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:get** [**--scope** **catalog|space**] *extension_name*:*version_number* [**--catalog** | **-c** *catalog_name*] [**--org** | **-o** *org_name* [**--space** *space*]] [**--server** | **-s** *mgt_server_endpoint*] **--configured-gateway-service** *gw_service_name* Example: **apic extensions:get --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1** This example gets **myextension** version **1.0.0** that is in **catalog1** of the **orgmain** organization, and is paired with **endpoint1**.
extensions list	The **extensions:list** command lists all versions of an extension given the extension name. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. <*extension_name*> Specifies the name of the existing extension. Note: This is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:list** [**--scope** **catalog|space**] *extension_name* [**--catalog** | **-c** *catalog_name*] [**--org** | **-o** *org_name*] [**--space** *space*] [**--server** | **-s** *mgt_server_endpoint*] **--configured-gateway-service** *gw_service_name* Example: **apic extensions:list --scope catalog my_extension --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service_1** This example lists all versions of the extension **my_extension** that are paired with **endpoint1**, are in **catalog1**, and in the **my_org** organization.

Command name	Action	Syntax
extensions list-all	The **extensions:list-all** command lists all the extensions that are available in a Catalog or Space. It is the default command if you enter only **apic extensions**. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:list-all** [--scope](#) **catalog|space** [--catalog | -c](#) ***catalog_name*** [--org | -o](#) ***org_name*** **[--space *space*]** [--server | -s](#) ***mgt_server_endpoint*** [--configured-gateway-service](#) ***gw_service_name*** Example: **apic extensions:list-all --scope catalog** **--catalog catalog1 --org my_org --server endpoint1** **--configured-gateway-service gw_service1** This example lists the extensions that are paired with **endpoint1**, are in **catalog1**, and in the **my_org** organization.
extensions update	The **extensions:update** command replaces the information of an existing extension version with the information in an external file. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. <*extension_file*> Specifies the name of the extension file that contains the new information for your extension. Note: This is the OpenAPI file name, not the name of the extension.	**apic extensions:update** [--scope](#) **catalog|space** ***extension_name*:*version_number*** ***extension_file*** [--catalog | -c](#) ***catalog_name*** [--org | -o](#) ***org_name*** **[--space *space*]** [--server | -s](#) ***mgt_server_endpoint*** [--configured-gateway-service](#) ***gw_service_name*** Example: **apic extensions:update** **--scope catalog extension1:1.0.0 extension2.yaml** **--catalog catalog1 --org my_org --server endpoint1** **--configured-gateway-service gw_service1** This example updates **extension1** version **1.0.0** that is paired with **endpoint1**, in **catalog1**, and in the **my_org** organization, from the file **extension2.yaml**.

Using the toolkit CLI to execute API tests

The IBM® API Connect developer toolkit provides CLI commands for automated API behavior testing.

About this task

Use CLI commands to execute API tests.
Note: In order to execute an API for testing purpose, you must make it online. To make the API online and auto-publish your API document, set the **Auto-publish** toggle in the Preferences page to **On** position. For more information, see Activating an API.

Procedure

1. Install the toolkit: Setting up the API Connect toolkit.
2. Open Terminal.
3. Create a YAML file to define your tests. For more information, see API development and management commands.
4. Run the CLI with the following syntax to execute the tests:

   ```
   apic test yaml-files
   ```

   Where, ***yaml-files*** specifies the location of the YAML file. For example, `apic test test1.yaml`
   - For executing tests with certificate checks disabled, run the CLI using the `--insecureSkipVerify` flag. For this, use the following syntax:

     ```
     apic test yaml-files
      --insecureSkipVerify
     ```

     Where, ***yaml-files*** is the location of the YAML file. For example, `apic test test1.yaml`.
   - If the CA certificate is not available in the system's keystore, its location can be specified with `--certPath` flag. For this, run the CLI with the following syntax:

     ```
     apic test yaml-files
      --certPath=location of certs folder
     ```

     Where, ***yaml-files*** is the location of the YAML file. For example, `apic test test1.yaml`. ***location of certs folder*** specifies the location of the CA certificate.
   - For executing tests with mTLS enabled, run the CLI using the `--mtls` flag. For this, use the following syntax:

     ```
     api-test test yaml-files
      --mTLS --certPath=location of certs folder
     ```

     Where, ***yaml-files*** is the location of the YAML file. For example, `apic test test1.yaml`.
   - For passing external configuration, run the CLI using the `--config-file` flag. For this, use the following syntax:

     ```
     api-test test yaml-files
       --config-file=location of config file
     ```

     Where, ***yaml-files*** is the location of the YAML file. For example, `apic test test1.yaml`. ***location of config file*** specifies the location of the configuration file.

   Note: Cert files must be named in the following format:
   - `tls.crt` - public key
   - `tls.key`- private key
   - `ca.crt`- CA certificate

   For more information about how the test is defined as a YAML file, see Test definition syntax.
   For more information about the assigning variables on a YAML configuration file, see Variable assignment in YAML configuration.

- **Test definition syntax**
  Information about how the test is defined as a YAML file.
- **Variable assignment in YAML configuration**
  You can define variables within a YAML configuration file by using the CLI tool. These variables are used to configure various aspects of the tool.

Test definition syntax

Information about how the test is defined as a YAML file.

The test is defined as a YAML file with the following sections:

- `configs` - Displays the configuration values for the variables that are specified in the file.
- `steps` - Displays the flow for the test case and runs through the list of steps in order. Each step has a common set of parameters.

The `type` attribute in the test definition YAML file describes the type of `steps`.

```
requirements: {}

info:
  title: "New Configuration YAML File"
  version: 2

configs:
  globalVariables:
    protocol: https://
    domain: sample-api.us-east-a.apiconnect.automation.ibm.com
    basePath: /bank

  inputs:
    - default:
        value: string
        type: array
    - second:
        value: number
        type: string

  steps:
```

```
  - type: request
    method: get
    url: "{{ configs.globalVariables.protocol }}{{ domain }}{{ globalVariables.basePath }}/branches"
    var: branches
    mode: json

  - type: assert-is
    expression: branches
    value: "{{ type }}"

  - type: assert-exists
    expression: branches.[1]
    stoponfail: true

  - type: assert-is
    expression: branches.[0].type
    value: string
    stoponfail: true

  - type: assert-is
    expression: branches.[0].address.city
    value: string
    stoponfail: true

  - type: assert-compares
    expression1: branches.[0].type
    expression2: branches.[7].type

  - type: request
    method: get
    url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/orders/order/AB1234
    var: payload
    mode: json

  - type: assert-equals
    expression: payload_response_statusCode
    value: 200
    ifexists: false
    stoponfail: false

  - type: assert-equals
    expression: payload_response_header_Content-Type
    value: application/json

  - type: assert-in
    expression: payload_response_header_Content-Type
    values:
      - application/json
      - application/swagger+yaml

  - type: assert-contains
    expression: payload_response_header_Content-Type
    value: app

  - type: assert-matches
    expression: payload_response_header_Content-Type
    value: ^[a-z]+/json

  - type: assert-exists
    expression: "payload"
    stoponfail: false

  - type: assert-is
    expression: "payload.tracking_reference"
    value: "string"
    ifexists: "false"
    stoponfail: false

  - type: assert-exists
    expression: payload.shipped_at
    stoponfail: false

  - type: assert-exists
    expression: payload.status
    stoponfail: false

  - type: assert-exists
    expression: payload.created_at
    stoponfail: false
```

The following table summarizes the set of parameters that are supported by the **type** attribute.

Table 1. Summary of the parameters supported by the **type** attribute

Parameters	Description	Subattributes
globalVariables	Global variables are settings that remain consistent across the entire test and typically do not change between runs.	You can define any attributes here based on your requirements. For example: • **https://** - Used in all requests, ensuring secure communication • **domain**: Specifies the primary server address for API requests • **basepath**: Defines the base path for all API endpoints. For example, **/bank**), which is appended to the domain for constructing request URLs

Parameters	Description	Subattributes
inputs	Defines various sets of input parameters that are used across multiple test scenarios.	You can create multiple datasets with any attributes for specific test scenarios. For example, `default` and `second` are two datasets, each with its own attributes tailored for different scenarios. Note: At least one dataset must be present to run the test.

`request`	Make an HTTP request.	• `method` - defines the HTTP method to use.
		• `url` - defines the URL to make the request to.
		• `params` - defines the key value mapping of parameters to send.
		• `headers` - defines the key value mapping of headers to send.
		• `var` - defines the name of the variable to store the response in.
		• `mode` - defines what type of data to expect and how to parse it (`supported: json`).
		
		For example,
		
		`- type: request`
		`method: get`
		`url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches`
		`var: branches`
		`mode: json`

`assert-is`	Assert that the type of variable from the response is `value`.	• `expression` - defines the variable to test.
		• `value` - defines the `type` that is expected in response.
		
		For example,
		
		`- type: assert-is`
		`expression: branches`
		`value: array`

`assert-exists`	Assert that a particular variable specified in `expression` exists.	• `expression` - defines the variable to test.
		• `stoponfail` - If one of the test fails, the `stoponfail` attribute stops the execution of the remaining tests. For this, `stoponfail` must be set to `true`.
		
		For example,
		
		`- type: assert-exists`
		`expression: branches.[1]`
		`stoponfail: true`

`assert-equals`	Assert that a variable is equal to `value`.	• `expression` - defines the variable to test.
		• `value` - defines the `value` to compare against.
		
		For example,
		
		`- type: assert-equals`
		`expression: payload_response_header_Content-Type`
		`value: application/json`

`assert-greater`	Assert that the variable is greater than `value`.	• `expression` - defines the variable to test.
		• `value` - defines the `value` to compare against.
		
		For example,
		
		`- type: assert-greater`
		`expression: payload_temperature`
		`value: application/json`

`assert-less`	Assert that the variable is lesser than `value`.	• `expression` - defines the variable to test.
		• `value` - defines the `value` to compare against.
		
		For example,
		
		`- type: assert-less`
		`expression: payload_temperature`
		`value: application/json`

`assert-in`	Assert that the element that is identified by a given expression matches at least one item from a given list.	• `expression` - defines the variable to test.
		• `value` - defines an array of values to compare against.
		
		For example,
		
		`- type: assert-in`
		`expression: payload_response_status`
		`value: application/json`

`assert-matches`	Assert that the value of the element that is identified by a given expression matches a specified format.	• `expression` - defines the variable to test.
		• `value` - defines the regex value to compare against.
		
		For example,
		
		`- type: assert-matches`
		`expression: payload_response_header_Content-Type`
		`value: ^[a-z]+/json`

`assert-compares`	Assert that the two elements are equivalent in some way.	• `expression1` - defines the path to the first element for comparison.
		• `expression2` - defines the path to the second element for comparison.
		
		For example,
		
		`- type: assert-compares`
		`expression1: branches.[0].type`
		`expression2: branches.[7].type`

Parameters	Description	Subattributes

`assert-contains`	Assert that the value of the element that is identified by a given expression contains a specific substring.	• `expression` - defines the variable to test.
		• `value` - defines the substring to compare against.
		
		For example,
		
		`- type: assert-contains`
		`expression: payload_response_header_Content-Type`
		`value: app`

`each`	Loop over the array that is referenced in the expression carrying out the substeps for each item found.	`expression` - defines the variable to test.
		
		For example,
		
		`- type: each`
		`expression: "analytics.events"`

For more information about assigning variables on a YAML configuration file, see Variable assignment in YAML configuration.

Variable assignment in YAML configuration

You can define variables within a YAML configuration file by using the CLI tool. These variables are used to configure various aspects of the tool.

You can configure a YAML file in three ways:

- Using the same YAML file.
- Using environmental variables
- Using the external configuration YAML files.

Note: Variables must be enclosed in double curly braces. For example, `"{{configs.base_url}}"` or `"{{paths.basePath}}"`. These placeholders, in the format of `"{{...}}"`, are replaced with their corresponding values from the source YAML file, environmental variables, or the external configuration file depending on the precedence hierarchy.
The precedence hierarchy for variable assignment is as follows:

1. External configuration YAML file (highest precedence)
2. Environmental variables
3. Configuration set in the same YAML file (lowest precedence)

If you configure a YAML file by using all the three methods, the variables that are assigned by using the external configuration YAML file is given priority.

1. Configuration set in the same YAML file

You can assign values to variables from within the same YAML file. For this, you must structure your YAML file in the following manner:

```
configs:
   basePath: ...paths:
       - basePath: ...
```

Here, the `configs` key is used to define variables such as `basePath` and `paths`. These variables can be used throughout the YAML file to configure the tool.

2. Environmental variables

You can override the values of variables that are configured in the YAML file by using environmental variables. When an environment variable shares the same name as a variable defined in the YAML file, the value of the YAML variable is replaced by the corresponding environment variable. This provides a way to customize configurations externally.

For example, if a variable named `base_url` is defined in the YAML file as `"{{configs.base_url}}"`, and its value is replaced by an environment variable named `base_url`. The value of `base_url` in the YAML file is overridden by the value of the `base_url` environment variable.

3. External configuration YAML file

The CLI tool supports the highest level of configuration precedence through external configuration files. To use an external configuration file, you must specify its file path by using the `--config-file` or `-c` flag when y the CLI tool. Any variables that are defined in the external configuration file supersede those defined within the main YAML file or through the environmental variables.

For example, consider an external configuration file config.yaml with the following content:

```
external_config:
   base_url: https://example.comapi_key: your-api-key
```

When you run the CLI tool with the `--config-file=config.yaml` flag, variables that are defined in the `config.yaml` file replaces the corresponding variables in the main YAML file or the environmental variables.

For more information about how the test is defined as a YAML file, see Test definition syntax.

Managing platform REST API keys

Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.

About this task

The API Connect platform REST APIs require authentication for use. To call an API interactively, you can log into the toolkit CLI with an option to generate the API key. To call an API programmatically, you can generate an API key and then exchange it for an API Connect access token. This requirement applies only to the APIs that are provided by API Connect. You do not need the API key for calling APIs that you imported or created. The API key is intended for use with the OIDC user registry type. Remember: By default, API keys are configured to be used onlyonce. However, you can customize the configuration and modify the API lifespan by following thesteps provided in the Configuring API key settingstopic.

Procedure

1. Create an API key:
   a. Log in to API Connect.
   b. On the address bar, add `/apikeys` to the end of the URL (after the organization name).
      For example:

      ```
      https://manager.example.com/manager/myorg/apikeys
      ```

   c. On the API Keys page, click Add.
   d. In the "Create API Connect API Key" box, provide a title for the key (unique within your user account) and a description.
   e. To specify a timeout value, select or type an integer value in the API key timeout field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
      Note: The default timeout value is 5 minutes.
   f. Select Enable multiple use to allow applications to exchange the API key for an access token multiple times.
   g. Click Create.
      Note: The Create button is disabled until you provide a description.
2. Manage API Keys:
   a. Log in to API Connect.
   b. On the address bar, add `/apikeys` to the end of the URL.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager. To start searching, type a string into the Search field and press Enter. Whenever you press Enter in the

Search field, the Search page displays the results and other options. If you press Enter in an empty Search field, or click Search in the navigation list, then the Search page displays a list all items. If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose that you searched for "Crafted". The results might look like the following image, with items that don't match the search string exactly, but do include the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the . . . actions menu next to the item's "Modified" date to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view other types. If you select a type from the More menu, it replaces a type in the list.

If you want to refine the search further, click Options. On the Options pane, click Catalogs to Search and select which catalogs to search (the default is all catalogs). You can select up to 5 catalogs for a limited search.

You can also choose whether only exact matches (the complete string) are included in results, or items containing similar strings are also included.

Working with API definitions

An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser-based API Manager UI.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
If you are working with APIs that conform to the OpenAPI Specification API Connect uses the following terms:

OpenAPI Specification
: The OpenAPI Specification defines a standard, language-agnostic interface to RESTful APIs. API Connect supports version 2.0 and version 3.0 of the OpenAPI Specification.

OpenAPI document
: One or more files that describe an API conforming to the OpenAPI Specification.

OpenAPI definition
: The description of an API that conforms to the OpenAPI Specification. In API Connect, you can create the API definition by filling in settings and properties, or by importing an OpenAPI document that contains an API definition that you want to work with.

The following topics provide full details for creating and configuring your APIs.

- **Using the AI Gateway to support APIs for AI applications**
  API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with AI services to forward requests and manage responses.
- **Creating an API definition**
  You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.
- **Editing an OpenAPI 2.0 API definition**
  IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.
- **Editing an OpenAPI 3.0 API definition**
  IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.
- **LDAP authentication**
  The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.
- **Authentication URL user registry**
  You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.
- **Activating an API**
  After you have created an API definition you can activate it to auto-publish your API document and make it available for testing.
- **Testing an API**
  Select a test tool and verify that your API works as you intended.
- **Staging an API**
  The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- **Publishing an API**
  The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- **Creating a new version of an API definition**
  You can create multiple versions of an API definition and edit the versions independently by using IBM API Connect.
- **Updating an API definition from a file**
  You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.
- **Updating a SOAP API**
  You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.
- **Renaming an API definition**
  By renaming an API definition, you change the `name` property that, together with the version, is used to uniquely identify the API definition in API Connect. The `name` property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.
- **Changing an API rate limit**
  When you activate an API to make it available for testing, as described in Activating an API, no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.
- **Adding an OpenAPI extension to an API**
  You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.
- **Downloading an API definition**
  You can download the details of your API definitions so that you can store them for later recovery.
- **Deleting an API definition**
  You can delete an API definition that is no longer required.
- **Using an options file when importing a WSDL service**
  When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.
- **Variable references in API Connect**
  In API Connect you can reference different variables in your API definition.
- **API properties**
  Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.
- **API policies and logic constructs**
  Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.
- **Tags in API Connect**
  There are a number of forms of tagging in IBM API Connect.

Using the AI Gateway to support APIs for AI applications

API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with AI services to forward requests and manage responses.

AI Gateway functions allows you to access AI Gateway policies directly on the DataPower API Gateway. You can create REST proxies that use the AI Gateway to control access to AI models, providing a seamless way to manage AI access within your API infrastructure while ensuring enhanced security and governance of your AI models.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by an AI service.

Note:

- The AI Gateway is not a separate gateway service; it is enabled by default while registering the DataPower® API Gateway. AI Gateway uses API assembly policies provided by the DataPower API Gateway service, and provides a single point of control for organizations to access AI services through APIs.
- The AI Gateway toggle in gateway service is not supported if you already have a custom gateway extension deployed. However, you can manually enable the AI Gateway extension while retaining your existing gateway extension on the gateway service. For details, see Enabling AI Gateway on gateway service extensions . Even after following this procedure to apply AI Gateway extensions, a current limitation is that APIC UI and CLI will still show that **`Enable AI Gateway`** flag is not enabled on this gateway.

Use cases

There are two cases where you should use the AI Gateway:

- As a reverse proxy for an existing API
  In this case, the API contract with the AI service is unchanged.
- As a development tool for new APIs that use an AI service.
  You can create APIs directly in API Connect and define policies in the API workflow to manage access to AI service.

Benefits

With the API Connect AI Gateway, you can centrally manage the use of AI through policy enforcement, data encryption, masking of sensitive data, access control, audit trails and more, in support of your compliance obligations.
Using the AI Gateway to manage your API access to AI service lets you add controls to the API execution through the following features:

- An interface to each supported AI service
  API Connect provides a policy that enables your API to send requests to a specified AI service.
- Response caching
  The response to an API call to an AI service is cached, which improves response time for API calls and provides cost optimization for the API provider. When you create an API in API Connect, you can specify the duration for that API's response caching.
- Rate limiting
  The AI Gateway enforces defined rate limits on APIs and API plans (which manage access to individual APIs). You can configure rate limits based on the number of requests or generated tokens allowed within a particular time interval.
- Tokenization
  Tokens are used as a unit of cost for LLM APIs. With the AI Gateway, rate limits can use the number of tokens generated by a request as a means of limiting usage and thus controlling costs. The token limit determines how many tokens are allowed to pass through the gateway within a specified period of time.
- Predefined policies and logic structures
  The AI Gateway can use all of the existing policies and logic constructs provided by API Connect (for example, invoke, redact and validate) in the API execution flow.
- API analytics
  API Connect provides an analytics service that provides insights into AI Gateway usage. You can use the analytics data on the AI usage dashboard to manage costs and track performance. For more information, see Accessing analytics in the API Manager UI.

The AI Gateway supports the following AI services:

- **Using the AI Gateway to support watsonx.ai APIs**
  The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with watsonx.ai to forward requests and manage responses.
- **Using the AI Gateway to support OpenAI APIs**
  The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with OpenAI to forward requests and manage responses.
- **Using the AI Gateway to support Gemini APIs**
  The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with Gemini to forward requests and manage responses.
- **Using the AI Gateway to support Azure OpenAI APIs**
  The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with Azure OpenAI to forward requests and manage responses.
- **Enabling AI Gateway on gateway service with gateway extensions**
  The API Connect provides a CLI option to manually enable the AI Gateway extension while retaining your existing gateway extension on the gateway service.

Using the AI Gateway to support watsonx.ai APIs

The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with watsonx.ai to forward requests and manage responses.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by watsonx.ai.

API Connect provides a policy that enables your API to send requests to watsonx.ai. The following watsonx.ai specs are supported:

- **`/text-generate`**
- **`/tokenize`**
- **`/deployment-models`**

Prerequisites for using the AI Gateway with watsonx.ai

Before attempting to use the AI Gateway, complete the following prerequisites:

- Obtain an IBM Cloud API key.
  When you register for an IBM Cloud ID, an API key is automatically assigned. You can create extra API keys if needed. An API key is used by the IBM Cloud authentication user-defined policy to generate a bearer token, which is used to authenticate for the desired watsonx.ai service. For information on managing API key, see Understanding API keys in the IBM Cloud documentation.
- Create a catalog property - for example, **`watsonx-ai-apikey`** - and set its value to the actual API key required for accessing watsonx.ai services. The property name can be anything. For more information on creating catalog-specific property values, see Defining Catalog specific property values.

- Create a watsonx.ai project.
  A watsonx.ai project is required for the user that is identified by the API key. The project has a project ID. For information on creating projects, see Creating a project in the watsonx.ai documentation.
- Link the watsonx.ai project to an LLM service by completing the following steps:
  1. In the project, click Services and Integrations in the navigation list.
  2. Create a service; for example, you might call it "Watson Machine Learning".
  3. Associate that service with your project.

  Failure to configure your project correctly will result in a **`400 Bad Request`** response for attempted watsonx.ai operations.

Getting started with the AI Gateway and watsonx.ai

To use the AI Gateway with watsonx.ai, complete the following steps:

1. Set up your environment as explained in Prerequisites for using the AI Gateway with watsonx.ai.
2. Create an API to use as a reverse-proxy.
3. Add the IBM Cloud Authentication and watsonx.ai invoke policies to the API so it can authenticate with IBM Cloud and access watsonx.ai.
4. Review metrics on the API's performance in the AI usage dashboard, which tracks AI token and model usage.

Using the AI Gateway to support OpenAI APIs

The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with OpenAI to forward requests and manage responses.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by OpenAI.

API Connect provides a policy that enables your API to send requests to OpenAI. The following OpenAI operations are supported:

- **`POST /chat/completions`**
- **`POST /embeddings`**
- **`GET /models`**
- **`GET /models/[model-id]`**

Prerequisites for using the AI Gateway with OpenAI

Before attempting to use the AI Gateway with OpenAI, complete the following prerequisites:

- Register with OpenAI.
  Note: When you register your OpenAI id, a default project is created for you. You can use this project or create additional projects. OpenAI projects will allow customers to organize their work within the OpenAI platform. From the AI Gateway perspective, the OpenAI project id is an optional property that will associate an OpenAI request to a specific project.
- Obtain an OpenAI API key.

Getting started with the AI Gateway and OpenAI

To use the AI Gateway, complete the following steps:

1. Set up your environment as explained in Prerequisites for using the AI Gateway with OpenAI.
2. Create an API to use as a reverse-proxy.
3. Add the OpenAI invoke policy to the API so it can access the OpenAI platform.
4. Review metrics on the API's performance in the AI usage dashboard, which tracks AI token and model usage.

Using the AI Gateway to support Gemini APIs

The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with Gemini to forward requests and manage responses.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by Gemini.

API Connect provides a policy that enables your API to send requests to Gemini. The following Gemini operations are supported:

- **`GET /models`**
- **`GET /models/[model]`**
- **`POST /models/[model]:generateContent`**
- **`POST /models/[model]:countTokens`**
- **`POST /models/[model]:embedContent`**
- **`POST /models/[model]:batchEmbedContents`**

Prerequisites for using the AI Gateway with Gemini

Before attempting to use the AI Gateway with Gemini complete the following prerequisites:

- Register with Google Studio.
  Note: When you register with Google Studio, a default project is created for you. You can use this project or create additional projects.
- Navigate to the API Key Management Page to create an API key. You can also manage projects and API keys in Google Cloud by following the links provided on the API Key Management Page.

Getting started with the AI Gateway and Gemini

To use the AI Gateway, complete the following steps:

1. Set up your environment as explained in Prerequisites for using the AI Gateway with Gemini.
2. Create an API to use as a reverse-proxy.
3. Add the Gemini invoke policy to the API so it can access the Gemini platform.
4. Review metrics on the API's performance in the AI usage dashboard, which tracks AI token and model usage.

Using the AI Gateway to support Azure OpenAI APIs

The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with Azure OpenAI to forward requests and manage responses.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by Azure OpenAI.

API Connect provides a policy that enables your API to send requests to Azure OpenAI. The following Azure OpenAI operations are supported:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

Prerequisites for using the AI Gateway with Azure OpenAI

Before attempting to use the AI Gateway with Azure OpenAI, complete the following prerequisites:

- Register with Azure AI Foundry.
- Create a project in Azure AI Foundry. Upon creation, you will receive the following credentials;
  - API key
  - Resource Id.
- Deploy a model depending on your desired operation. For example, `gpt-4o` for chat completions.
  Required user inputs:

Table 1.

Parameter	Description
`api-key`	Sent as a request header
`resource_id`	Serves as part of endpoint of URL that points to your provisioned resources
`deployment_id`	Name of the project/deployment where the model is deployed
`op-version`	Operation version must be in `YYYY-MM-DD` format

Getting started with the AI Gateway and Azure OpenAI

To use the AI Gateway, complete the following steps:

1. Set up your environment as explained in Prerequisites for using the AI Gateway with Azure OpenAI.
2. Create an API to use as a reverse-proxy.
3. Add the Azure OpenAI invoke policy to the API so it can access the Azure OpenAI platform.
4. Review metrics on the API's performance in the AI usage dashboard, which tracks AI token and model usage.

Enabling AI Gateway on gateway service with gateway extensions

The API Connect provides a CLI option to manually enable the AI Gateway extension while retaining your existing gateway extension on the gateway service.

Before you begin

Ensure you have an existing gateway extension deployed to the gateway service. For example, you can create one using the CLI (logged in as the cloud admin user) or through the Cloud Manager (CM) UI:

```
$ apic gateway-extensions:create <path>/your-existing-gateway-extension.zip --scope org --org admin --gateway-service
<datapower-api-gateway> --availability-zone <availability-zone-name>
```

Procedure

Note: These steps use the `apic` CLI. You must log in as the cloud admin user. Similar steps can be performed using the Cloud Manager UI.

1. Log in with the `apic` CLI as the cloud admin user.

```
$ alias apic="apic -s <your APIC platform API endpoint>"
$ apic login -r admin/default-idp-1 -u <user> -p <password>
```

2. Retrieve the currently deployed gateway extension from the gateway service.

```
$ apic gateway-extensions:implementation --server <apic-manamenet-server> --org admin --gateway-service <datapower-api-gateway> --availability-zone <availability-zone-name>
```

3. Copy the AI Gateway extension from the APIC deployment.
   a. Use the following command to list APIM pod names:

```
$ kubectl -n <namespace> get po -l app.kubernetes.io/name=apim -o name
```

   b. Choose an APIM pod name and copy the AI Gateway extension:

```
$ kubectl cp -c apim <apim pod name>:/apim-init/gateway-extension.zip /tmp/ai-gateway-extension.zip
```

4. Combine the current gateway extension with the AI Gateway extension.
   a. Extract your current gateway extension in one folder:

```
$ unzip current_gateway_extension_implementation.zip -d a_dir
```

   b. Extract the AI Gateway extension in another folder:

```
$ unzip /tmp/ai-gateway-extension.zip -d b_dir
```

   c. Create a new directory to merge the extensions:

```
$ mkdir c_dir
```

   d. Merge the contents of `manifest.json` from `b_dir` into the `manifest.json` in `a_dir`, and save the new file in `c_dir`.
   e. Copy the `.zip` and `.yaml` files from `a_dir` and `b_dir` to `c_dir`:

```
$ cp a_dir/*.zip a_dir/*.yaml b_dir/*.zip c_dir
```

   f. Create a new zip file from contents of `c_dir`:

```
$ cd c_dir
$ zip /tmp/combined-gateway-extension.zip *
```

5. Update the gateway service with the combined extension.

```
$ apic gateway-extensions:update /tmp/combined-gateway-extension.zip --scope org --org admin --gateway-service <datapower-api-gateway> --availability-zone <availability-zone-name>
```

   Note: Even after following this procedure to apply AI Gateway extensions, a current limitation is that APIC UI and CLI will still show that `Enable AI Gateway` flag is not enabled on this gateway.

Creating an API definition

You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.

Before you begin

An API is a set of functions that provide some business or technical capability and can be called by applications by using a defined protocol. Applications are typically mobile or web applications, and they use the HTTP protocol. An API definition is composed of paths, and can be one of the following types:

REST API definition
: A REST API is a defined set of interactions that uses the HTTP protocol, typically by using JSON or XML as the data format that is exchanged. For example, a data request might use an HTTP GET method, and a data record might use an HTTP POST method. The choice of data format depends on the type of application that is calling the API. JSON is commonly used for web pages or mobile applications that present a user interface (by using JavaScript or HTML), whereas XML is often used for machine-to-machine scenarios.

  You can expose and secure your existing APIs by using a Proxy or Invoke policy.

  In either case, you can configure your API definition either by using the API Designer, or by writing an OpenAPI definition file and publishing it using either API Designer or the command line interface.

SOAP API
: You can create SOAP API definitions that are based on an existing Web Services Description Language (WSDL) file. You can use this facility to benefit from the capabilities that are provided by API Connect, which include analytics and mapping between variables. You can also expose the API by using the Developer Portal for any existing SOAP services in your organization, including any SOAP services that are part of a service-oriented architecture (SOA) or Enterprise Service Bus (ESB) infrastructure.

  You can create SOAP API definitions through either the command line interface, or through API Designer.

About this task

You can create definitions for REST APIs or SOAP APIs.

- In the API Designer, you can add a REST API definition either by composing the API definition, and its operations, from scratch, or by importing an OpenAPI definition file. You can also use the tooling to quickly create a proxy API that calls an existing endpoint.
- If you have an existing SOAP service that you want to expose more widely, you can add a SOAP API to IBM® API Connect. You can use the Developer Portal to publicize the SOAP service to the developers. If a developer wants to use the SOAP API, you can use API Connect to manage their sign-up and access to the service, and track the usage of that API.

Procedure

1. Quickly create an API definition by using one of the following wizards:
   - Creating a REST proxy API from a target service
   - Creating a REST proxy API from an existing OpenAPI service
   - Creating a new REST OpenAPI definition
   - Creating a REST proxy API from an existing WSDL service
   - Adding a REST API by importing an OpenAPI definition file
   - Creating a SOAP proxy API from an existing WSDL service
2. After you create your API definition, you can define it in more detail by following the instructions in Editing an OpenAPI 2.0 API definition.

- **Creating a REST proxy API from a target service**
  If you have an existing REST service that you want to expose through an IBM API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.
- **Creating a REST proxy API from an existing OpenAPI service**
  If you have an existing OpenAPI described target service that you want to expose through an IBM API Connect API definition, you can create a proxy API and specify the target endpoint.
- **Creating a REST proxy API from an existing WSDL service**
  If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.
- **Creating a SOAP proxy API from an existing WSDL service**
  If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.
- **Creating a new REST OpenAPI definition**
  You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM API Connect.
- **Adding a REST API by importing an OpenAPI definition file**
  You can use an OpenAPI definition file to import a REST API into IBM API Connect.
- **Adding a SOAP API by importing a zip file**
  You can use an OpenAPI definition file to import a SOAP API into IBM API Connect.
- **Creating a GraphQL proxy API**
  GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.
- **Importing an API from the CP4I asset repository**
  If you are using API Connect with IBM Cloud Pak for Integration, you can import an API definition from the CP4I asset repository.
- **Importing an AsyncAPI from Event Endpoint Management**
  Import one or more AsyncAPI specifications from Event Endpoint Management.
- **Creating an AsyncAPI with Event Endpoint Management**
  Create an AsyncAPI using Event Endpoint Management.
- **Creating a REST proxy for watsonx.ai with the AI Gateway**
  Create a REST proxy that uses the AI Gateway to control access to AI models.
- **Creating a REST proxy for OpenAI with the AI Gateway**
  Create a REST proxy that uses the AI Gateway to control access to AI models.
- **Creating a REST proxy for Gemini with the AI Gateway**
  Create a REST proxy that uses the AI Gateway to control access to AI models.
- **Creating a REST proxy for Azure OpenAI with the AI Gateway**
  Create a REST proxy that uses the AI Gateway to control access to AI models.

Related information

- Using the developer toolkit command-line tool

Creating a REST proxy API from a target service

If you have an existing REST service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the `Api-Drafts:Edit`, `Settings:View`, and `App:View` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Create proxy REST APIs in minutes by using the API Designer tool to create an API from target service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from a target service, complete the following steps.

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From target service.
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. Specify the existing REST API endpoint that you want to call in the Target Service URL field.
6. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
7. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a proxy API from an existing target service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Creating a REST proxy API from an existing OpenAPI service

If you have an existing OpenAPI described target service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Create proxy REST APIs in minutes by using the API Designer tool to create an API from existing OpenAPI service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from an existing OpenAPI service, complete the following steps.

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From existing OpenAPI service, and click Next.
4. To upload the service information from an OpenAPI file, you can either drag and drop your file, or browse and select the file that you want to use. Valid file types are YAML, YML, etc.
   - Click Browse and browse for the OpenAPI file.
   - Drag and drop the file into the active area.

   After you upload the file, the OpenAPI specification is evaluated and a message displays whether it is valid.
5. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
6. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
7. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
8. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

9. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a proxy API from an existing OpenAPI service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Creating a REST proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the REST API definition.

If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the REST API definition.

Procedure

To add a REST API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0.
3. On the Add API pane, select From existing WSDL service (REST Proxy). Click Next.
   The Create API from Existing WSDL Service (REST Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use.
   After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid.

   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
7. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
9. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a REST API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the  Manage page of the API Designer UI.

Creating a SOAP proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Note: By default, the SOAP proxy API that is created will have the basepath set to the WSDL service name. You can edit the SOAP proxy API to change this basepath.
You can add a SOAP API to expose an existing SOAP service by supplying the WSDL file that defines that existing service in one of the following ways:

- If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the SOAP API definition.
- You can provide one or more WSDL files in a single .zip file that contains the WSDL files and any necessary schemas.
  If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the SOAP API definition.
- If you are using API Designer with existing APIs that were created from a WSDL or WSDL.zip file in Version 5 API Designer, make sure that the following requirements are met:
  - The WSDL or WSDL.zip file must be stored in the same directory as the API's YAML file.
  - In the API's YAML file, the **`x-ibm-configuration`** --> **`wsdl-definition`** --> **`wsdl`** property must point directly to the WSDL or WSDL.zip file with no path specified (the files are located in the same directory).

The service must support Web Services Basic Profile Version 1.1 - Second Edition.

Procedure

To add a SOAP API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0.
3. Select From existing WSDL service (SOAP Proxy). Click Next.
   The Create API from Existing WSDL Service (SOAP Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use.
   After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid.

   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.

- The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
- The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
- The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
- The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
- The optional Description helps to identify the API.

7. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
9. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a SOAP API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the Manage page of the API Designer UI.

Creating a new REST OpenAPI definition

You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

To create a new REST OpenAPI definition, complete the following steps.

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select New OpenAPI .
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
6. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
7. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You successfully created a REST API definition. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Adding a REST API by importing an OpenAPI definition file

You can use an OpenAPI definition file to import a REST API into IBM® API Connect.

Before you begin

Your file must conform to version 2.0 or version 3.0 of the OpenAPI specification. The format of the file can be JSON or YAML.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Api-Drafts:Edit`, `Settings:View`, and `App:View` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

Procedure

To add a REST API by importing an OpenAPI file, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select Existing OpenAPI, then click Next.
4. Choose one of the following methods for importing the file:
   - Drag and drop a file
     Open another window, select a file. Drag the file to the Select a file box, and release the file.
   - Browse for a file
     Click the Select a file box. Locate the file and select it.
   - Specify the URL of a file
     In the Or specify a file URL field, type or paste a URL for the file. Optionally add a User name and Password if they are required for accessing the file.

   The following file types are supported if they contain a valid OpenAPI definition: .json, .yml, and .yaml.
5. Click Next to import the selected file.
   The wizard checks the validity of the YAML, and displays a message indicating successful validation.

   Notes:
   - If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
   - Any validation error messages are displayed in English only, and are not translated.
6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
7. Click Next. The Import API Summary panel indicates that the YAML file is loaded and valid.
   If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.
8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Adding a SOAP API by importing a zip file

You can use an OpenAPI definition file to import a SOAP API into IBM® API Connect.

Before you begin

The format of the file must be .zip, and the file must contain the WSDL definition and the YAML file that defines the API. The YAML file must conform to version 2.0 of the OpenAPI specification.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Api-Drafts:Edit`, `Settings:View`, and `App:View` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism that is described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

For more information on how to create a .zip file, see Downloading an API definition.

Procedure

To add a SOAP API by importing a .zip file, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0.
3. In the Import section, select Existing OpenAPI, then click Next.
4. To import a file from your local file system, you can either drag and drop the file or click the link to select the file from your local file system.
   The wizard checks the validity of the WSDL and YAML, and displays a message that indicates a successful validation.
   Note:
   - If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
   - Any validation error messages are displayed in English only, and are not translated.
5. Click Next.
6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating

custom roles.

7. Click Next. The Import API Summary panel indicates that the file is loaded and valid.
   If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.

8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

API Gateway only

Creating a GraphQL proxy API

GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM® API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

GraphQL provides the following particular advantages over REST APIs:

- The application client can request only the data that it needs. For example, when retrieving bank account records, request only the account number and current balance for each account, but not the customer name and address details. With a REST API request, either the backend REST service must provide separate endpoints for different data subsets, or the application client must retrieve the complete records and then discard the unwanted data.
- The application client can retrieve multiple related resources in a single request. For example, a customer's bank account record might include an array that references other finance products that the customer holds. If an application client wants to retrieve the bank account details for a specific customer, and details of the other finance products for that customer, then with a REST API the client would first retrieve the bank account details, then make separate requests for each of the other products. A GraphQL API can be designed to allow the client to retrieve all this information in a single request.

However, this flexibility presents rate limiting challenges, because two seemingly very similar requests might return vastly different amounts of data, and what might have required multiple REST API requests, each counting towards the rate limit, might require only a single GraphQL API request. It is important therefore that rate limiting controls are imposed that reflect the amount of data that is retrieved. API Connect extends the GraphQL standard by providing, in a GraphQL API definition, the ability to configure a range of settings that are used to calculate the complexity of a GraphQL request and an associated cost that counts towards the rate limit.

Procedure

To create a GraphQL API proxy definition, complete the following steps:

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0.
3. Select From existing GraphQL service (GraphQL proxy).
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.

5. In the GraphQL Server section, specify the following values:
   - GraphQL server URL: this is the URL that is used for requests to the backend GraphQL API. The GraphQL schema is imported automatically from the specified URL.
   - Schema name: the name that you enter here is used to identify the schema definition that is created from the imported GraphQL schema. The field is pre-populated with host name segment of the value entered in the GraphQL server URL field, but you can change it.
6. Click Next. If there are any warnings indicated relating to the imported schema, you can review them now by clicking View.
   You can deal with these warnings as appropriate after you have created your GraphQL proxy API.
7. In the Operations and Paths section, select the operations and paths that you want to include.
   The operation path of **`/graphql`** is already selected and you cannot change this setting; this is the path for application client requests to API Connect that invoke the GraphQL API.

   For details of the mechanisms supported for sending a request to the **`/graphql/cost`** endpoint, see Request mechanisms supported by GraphQL endpoints.

   You can also select the operation path of graphql/cost; this path enables application clients to obtain details of the cost of a request to the GraphQL API before making the actual request. In a production environment, in particular, you should consider carefully the resource implications of making this path available. For full details regarding the enablement of the cost endpoint, see Enabling the cost endpoint for a GraphQL API.

   To form the full API paths, these path segments are appended to the **`basepath`** that you specified in step 4.

   To allow application clients to send introspection requests for this GraphQL proxy API, select Support default introspection. For full details, see Supporting introspection for a GraphQL API.

   To allow users to test the GraphQL proxy API from a GraphiQL editor, select Enable GraphiQL editor. For full details, see Enabling the GraphiQL editor for a GraphQL API.

   Note: The graphql/cost, Support default introspection, and Enable GraphiQL editor options each automatically generate policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required.
8. Optionally, you can replace the GraphQL schema that was imported from the GraphQL server URL by uploading a schema from your local file system. Click Replace; you can then either drag and drop your file, or click where indicated to select the file from your local file system. Click Upload when done.
   Note:
   - The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see Type language in the GraphQL documentation at https://graphql.org/.
   - If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.
9. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
10. Optional: Select Activate API if you want to immediately use the API for further development and testing.
    Note:
    - When you select the Activate API option, API Connect automatically completes the following actions:
      - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
      - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
    - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
    - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
11. Click Next to create your API definition.
    The Summary panel displays messages as the definition is created, and the selected security options are enforced.

    If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

12. Click Next to create your API definition.
    The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

13. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

What to do next

Use the GraphQL schema editor to review, and deal with, any warnings associated with the schema, and to configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit; for details, see Using the GraphQL schema editor.

- **Using the GraphQL schema editor**
  The GraphQL schema editor allows you to a configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.
- **Supporting introspection for a GraphQL API**
  If you select the Support default introspection option when creating a GraphQL proxy API, client applications can send GraphQL introspection requests to the API.
- **Enabling the GraphiQL editor for a GraphQL API**
  If you select the Enable GraphiQL editor option when creating a GraphQL proxy API, users can test the API by using a GraphiQL editor in a web browser; API Connect responds to the initial GraphiQL editor request with an HTML page that enables testing from the GraphiQL editor.
- **Enabling the cost endpoint for a GraphQL API**
  If you enable the **`/graphql/cost`** endpoint when creating a GraphQL proxy API, a calling application can obtain details of the cost of executing a request on the backend GraphQL server before making the actual backend request.
- **Securing a GraphQL API by using a client ID**
  If you select the Secure using Client ID option when creating a GraphQL proxy API, API Connect automatically adds Rate limit policies to the API assembly.
- **Request mechanisms supported by GraphQL endpoints**
  API Connect supports various mechanisms for sending requests to GraphQL proxy API endpoints.
- **GraphQL custom schema directives and scalar types**
  The API Connect DataPower API Gateway extends the GraphQL specification by providing additional schema directives and custom scalar types.
- **@remove directive**
  The **`@remove`** GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context.
- **GraphQL limitations**
  This page details the limitations in the API Connect GraphQL implementation for the current release.

API Gateway only

Using the GraphQL schema editor

The GraphQL schema editor allows you to a configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.

Introduction

When the GraphQL schema editor opens, all the types defined in the GraphQL schema are listed. You can expand a type to display all the fields that are defined for that type.

For each type, you can specify the following setting:

Type weight
: The weighting factor that you want to apply to the type for use when calculating the type cost for a request to the GraphQL API. In general, the weighting factor for a type will reflect the resource implications for a request that retrieves values of that type; for example:

  - A complex object might be weighted more heavily than a String.
  - Values of one type might be retrieved from a different backend database to values of another type, and accessing one database requires more CPU resource, so types associated with this database are weighted more heavily.

For each field, you can specify the following settings:

Field weight
: The weighting factor that you want to apply to the field for use when calculating the field cost of a request to the GraphQL API.

Assumed size
: The size limit that the backend server imposes on the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. If an assumed size has been defined for this field in the imported GraphQL schema, its value is displayed. You an enter a value, or change the current value, and the schema definition stored in API Connect is updated accordingly. You must ensure that the specified value corresponds with the implementation or configuration on the backend server so that API Connect can apply rate limiting correctly. The assumed size is intended to be configured for fields that return lists of values, to tell the cost analysis how many values to expect.

Slicing arguments
: A comma separated list of the arguments that are used by the backend server to limit the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. These must correspond with the implementation or configuration on the backend server. For example, there might be slicing arguments of **`first`** and **`last`** that are used to specify a range of objects to be returned by an API request.

Sized fields
: In some cases, a field with a configured Assumed size or Slicing arguments setting returns an object, a field of which returns the values whose number is to be sized. This is common in the connections pattern for pagination, where fields with slicing arguments **`first`** or **`last`** return a **`connections`** object, that contains the sized list in an **`edges`** field. The Sized fields option allows the cost analysis to consider these indirect relationships between assumed sizes or slicing arguments and the sized list of values. Supply a comma separated list of field names.

You access the GraphQL schema editor in either of the following ways:

- Immediately after creating a new GraphQL proxy API , by clicking Edit API, then clicking the GraphQL Schema tab. For GraphQL proxy API creation details, see Creating a GraphQL proxy API.
- By modifying the configuration of an existing API; complete the following steps:
  1. In the navigation pane, click  Develop, then select the APIs tab.
  2. Alongside the GraphQL API definition that you want to work with, click the options icon ⋮ and then click Edit API.
  3. Click the GraphQL Schema tab.

Modifying a setting for a single type or field

For a numerical setting, click the setting alongside the required type or field, then enter the required value, or use the stepper control. For a setting that has a textual value, enter the value directly. You might first want to filter the display to show only a relevant subset of types and fields; see Filtering the display.

Modifying settings for multiple types and fields

To modify settings for multiple types and fields in a single operation, complete the following steps:

1. Select the check boxes alongside the types and fields whose settings you want to modify.
2. Click Apply analysis configuration.
3. On the Type tab, specify the settings that you want to apply to the selected types.
4. On the Field tab, specify the settings that you want to apply to the selected fields.
5. Click Apply to apply the settings to the selected types and fields.
6. When you have made all the required modifications to the selected types and fields, click Done; this actions clears all check box settings.

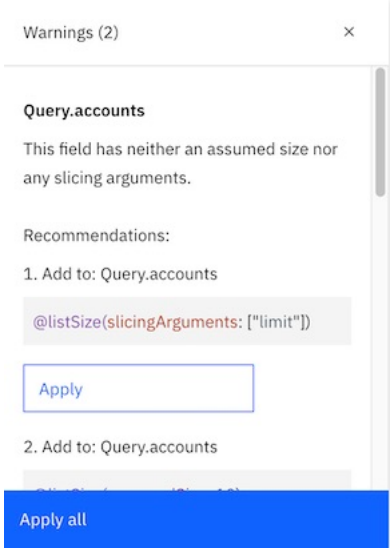
To to restore any type or field settings to the initial default settings after having applied an analysis configuration, select the check boxes alongside the required types and fields, then click Remove analysis configuration.

You might first want to filter the display to show only a relevant subset of types and fields; see Filtering the display.

Filtering the display

To display only those type and fields that contain a specified string, enter the required filter string in the Search schema field, then press Enter.

If a type matches the filter, the type and all its fields are displayed. If a field matches the filter but not its parent type, the parent type is displayed together with all matching fields. You can enter multiple filter strings; the items displayed are those that contain all strings.



You can now use the operations described in Modifying a setting for a single type or field and Modifying settings for multiple types and fields to update the settings for the displayed types and fields.

To remove a specific filter string from the search, click the Close icon for that filter string. To restore the full type and field display by removing all filter strings, click the Clear icon at the end of the search field.

GraphQL schema warnings

Where applicable, API Connect will recommend updates to the analysis configuration to protect the backend server from excessive resource utilization, and to ensure correct cost estimation for requests. These recommendations are displayed as warnings in the GraphQL schema editor.

If a type contains one or more fields with warnings, this is indicated by a warning count icon 2 alongside the type. You can click the warning count icon to see the warnings for that type; the Warnings window opens at the relevant warnings, for example:

To see the fields that have warnings, expand the type; a warning icon is displayed alongside fields with warnings. To see the details of a warning for a field, click the warning icon alongside the field

If you click Accept under any warning in the Warnings window, the recommended update is applied to the schema automatically.

To apply the suggested updates for all warnings in a single operation, click Apply all in the Warnings window, then click Apply to confirm.

You can filter the display to include only items with warnings; click the Menu icon, then select Show warnings only.

Applying @remove directives to types and fields in the GraphQL schema

The **`@remove`** GraphQL schema directive specifies conditions for removing items from validation or introspection for each transaction based on values in the API context. For example, you can prevent specific Plans from using certain types or fields.

For more details on the **`@remove`** directive, including examples, see rapic_graphql_extensions.html#reference_wrt_bk1_5mb__at_remove.

To apply an **`@remove`** directive to an item in your GraphQL schema, complete the following steps:

1. Click the settings icon in the Show/hide column alongside the required item. The Show/hide settings window opens.
2. To remove the item depending on a boolean condition, enter the boolean expression in the Custom expression field; the following directive will be added to the item in the schema:

   ```
   @remove(if: [expression])
   ```

   To remove the item unconditionally, change the Show in schema slider control to Hide in schema; the following directive will be added to the item in the schema:

   ```
   @remove(if: ["true"])
   ```

3. Click Next. A summary window opens. If the removal is permitted, any related items that will also have the `@remove` directive applied are listed; for example, if you apply an `@remove` directive to a type, and that type is referenced as the data type of a field on another type, the `@remove` directive is also applied to that field. If the removal is not permitted, an explanation is displayed.
4. If the removal is permitted, click Done to apply the `@remove` directive. If the removal is not permitted, either click Cancel to close the window or click Back and amend your settings.
5. To see the updates to the GraphQL JSON schema, click View source.

You can use the settings icon to modify or delete previously applied `@remove` directives. To remove a conditional `@remove` directive, delete the expression from the Custom expression field. To remove an unconditional `@remove` directive, change the Hide in schema slider control to Show in schema.

Viewing the GraphQL schema

To view the GraphQL JSON schema that was previously uploaded, click View source. Note that the schema includes `directive` statements and attribute values, added by API Connect, that reflect the configuration settings.

Replacing the GraphQL schema

To replace the GraphQL schema, complete the following steps:

1. Click Replace.
2. Specify the replacement schema:
   - To replace the schema by introspecting a URL, complete the following steps:
     - Select Introspect from URL.
     - Enter the URL in the GraphQL server URL field, then click Introspect.

     Note: If you replace the schema from a URL that is different to the one specified as the backend GraphQL server, in the GraphQL server URL field, when the GraphQL proxy API was created, the schema itself is replaced but the backend URL remains unchanged. You must correspondingly modify the URL setting on the `invoke` policy in the API assembly of your GraphQL proxy API.
   - To replace the schema by uploading a file, complete the following steps:
     - Select Upload schema definition language (SDL) file.
     - Either drag and drop the file or click the link to select the file from your local file system.

     Note:
     - The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see Type language in the GraphQL documentation at https://graphql.org/.
     - If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.

   All the changes between the replacement schema and the current schema are listed.
3. Update the schema as required:
   - To have all new types and fields shown by default, select New schema for the Update schema defaults giving preference to setting. You can then choose to hide specific items by selecting Hide in the Action column alongside an item. Hiding an item causes an `@remove` directive to be added to the item in the schema source, as detailed in Applying @remove directives to types and fields in the GraphQL schema.
   - To have all new types and fields hidden by default, select Old schema for the Update schema defaults giving preference to setting. You can then choose to show specific items by selecting Show in the Action column alongside an item.

   Note: If the current schema contains items that are not in the replacement schema, these items are deleted. Such deletions are shown in the change listing with the Accept setting displayed in the Action column; you cannot change this setting.
4. Click Next. A change summary page is displayed. If any removals are not permitted, an explanation is displayed, and you cannot complete the schema replacement; either click Cancel to close the window or click Back and amend your settings..
5. Click Submit to complete the schema replacement.

Downloading the GraphQL schema

To download the GraphQL schema to a local file, click the Download. Note that the downloaded schema includes all additional settings that reflect your configuration updates.

API Gateway only

Supporting introspection for a GraphQL API

If you select the Support default introspection option when creating a GraphQL proxy API, client applications can send GraphQL introspection requests to the API.

Introspection allows client applications to request details of all the types and fields that are defined in a GraphQL schema. When you create a GraphQL proxy API, introspection requests sent to that API from client applications are handled by the gateway. The response reflects any modifications you have made to the schema by using the GraphQL schema editor.

When you select the Support default introspection option, API Connect creates the introspection endpoint. A GraphiQL editor always attempts to introspect a GraphQL endpoint, so disabling this option significantly reduces the test capability for GraphiQL editor users. This option also automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the API assembly policies for introspection support section for details. Disabling this option also limits the capability of the Developer Portal to test the GraphQL proxy API.

On the other hand, providing introspection support can have resource implications, and you might choose to communicate the schema information in another way. However, note that the GraphiQL editor does not allow custom introspection queries to populate the document explorer. For more information on introspection, see Introspection in the GraphQL documentation at https://graphql.org/.

API assembly policies for introspection support

This section details the API assembly policy configuration that is generated automatically if the Support default introspection option is selected when a GraphQL proxy API is created. If the option is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

A `case` is added to a `switch` policy with the following condition:

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:

Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

GraphQL introspect

Property	Value
Input	message
Output	No value, defaults to input

The automatically generated configuration, as it appears in the assembly UI, is as follows:

Enabling the GraphiQL editor for a GraphQL API

If you select the Enable GraphiQL editor option when creating a GraphQL proxy API, users can test the API by using a GraphiQL editor in a web browser; API Connect responds to the initial GraphiQL editor request with an HTML page that enables testing from the GraphiQL editor.

Disabling the Enable GraphiQL editor option reduces gateway traffic and latency and, furthermore, the Developer Portal provides equivalent test capability regardless of whether or not you enable the option.

This option automatically adds the following property setting to the OpenAPI source for the GraphQL proxy API:

```
html-page: 'store:///graphiql.html'
```

If you disable the Enable GraphiQL editor during API creation and later decide that it is required, you can either manually add this property setting, or you can select Enable GraphiQL editor on the API Setup page of the Design tab of the API..
Note:

- The `html-page` property should be used **only** with a GraphQL proxy API.
- `store:///graphiql.html` is the only value allowed for the `html-page` property.
- If you add the `html-page` property but the Support standard introspection property was not enabled during API creation, the GraphiQL HTML page will not show any documentation regarding the GraphQL backend server, perform query validation, or perform smart lookup. For details on how to manually create the required assembly policy configuration, see Supporting introspection for a GraphQL API.

API Gateway only

Enabling the cost endpoint for a GraphQL API

If you enable the `/graphql/cost` endpoint when creating a GraphQL proxy API, a calling application can obtain details of the cost of executing a request on the backend GraphQL server before making the actual backend request.

The "cost" does not relate purely to monetary cost but can take into account factors such as computational time, memory consumption, and other such factors, in addition to the actual financial costs associated with, say, using third-party systems to retrieve data.

In a production environment, in particular, you should consider carefully the resource implications of making this path available. Note, however, that enabling the `/graphql/cost` endpoint automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the API assembly policies for the cost endpoint section for details.

API assembly policies for the cost endpoint

This section details the API assembly policy configuration that is generated automatically if the **`/graphql/cost`** operation path is selected when a GraphQL proxy API is created. If the path is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

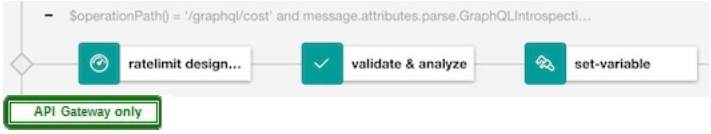
A **`case`** is added to a **`switch`** policy with the following condition:

```
($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:

Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume



Validate

Property	Value
Input	message
Output	No value, defaults to input
Validate against	GraphQL

Set Variable

Property	Value
Action	Set
Set	message.body
Type	any
Value	$(message.attributes.graphql)

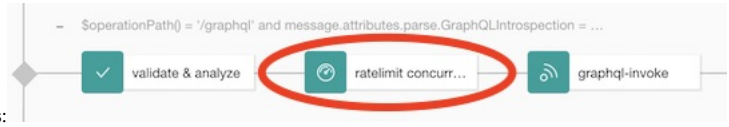
The automatically generated configuration, as it appears in the assembly UI, is as follows:

Securing a GraphQL API by using a client ID

If you select the Secure using Client ID option when creating a GraphQL proxy API, API Connect automatically adds Rate limit policies to the API assembly.

This section details the Rate limit policy configuration that is generated automatically. If the Secure using Client ID option is not selected at creation time, and you later decide that you want to enable it, you must add the appropriate Rate limit policies manually to the API assembly.

The automatically generated Rate limit policies are added to the **`switch`** cases in the assembly as follows:



- **`switch`** case:

  ```
  ($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and
  message.attributes.graphql.operationType = 'subscription')
  ```

  A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Count Limit Name	graphql-subscription-type-cost
Operation	Increment
Count Limit Name	graphql-subscription-field-cost
Operation	Increment

  The policy as it appears in the assembly UI is as follows:

  This Rate limit policy limits the number of HTML web browser requests for a GraphiQL editor sent to the **`/graphql`** endpoint.

- **`switch`** case:

  ```
  ($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and
  message.attributes.graphql.operationType != 'subscription')
  ```

  Two Rate limit policies with the following property settings:

  - Policy 1:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Consume
Rate Limit Name	graphql-field-cost
Operation	Consume

Property	Value
Rate Limit Name	graphql-input-type-cost
Operation	Consume

This Rate limit policy limits calls to the GraphQL proxy API by calculating the expected cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The expected cost is calculating by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see Using the GraphQL schema editor.

The expected cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see Validate.

The details of the cost calculations to which the referenced rate limits are applied are as follows:

- **`graphql-field-cost`**: The weighted sum of fields being selected in a query. Fields that return values of scalar or enum types have a weight of 0.0 and therefore don't affect field cost.
  For example, consider the following query, where it is assumed that the value **`max`** in the **`filter`** argument of field **`Query.offices`** constrains the number of **`Office`** objects being returned:

  ```
  query {
    offices (filter: {location: "NY", max: 3}) {
      address {
        street
      }
    }
  }
  ```

  The **`Address.street`** field is of type **`String`** and therefore has a weight of 0.0. Non scalar and non enum field weights that are not changed in the GraphQL schema editor assume a default value of 1.0. If the **`Office.address`** field weight has been set to 3.0, the total field cost is 10.0, calculated as follows:

Field	Weight	Field cost
`Query.offices`	1.0	1 x 1.0 = 1.0
`Office.address`	2.0	3 x 3.0 = 9.0
`Address.street`	0.0	0.0
	Total cost:	1.0 + 9.0 + 0.0 = 10.0

- **`graphql-type-cost`**:
  The weighted sum of types being returned by a query. Scalar or enum types have a weight of 0.0 and therefore don't affect type cost.

  Considering the previous example, and assuming that all types have a default weight of 1.0, the total type cost is 7 (1 x **`Query`** type + 3 x **`Office`** types + 3 x **`Address`** types.

- **`graphql-input-type-cost`**:
  The weighted sum of input types being sent in a query. Scalar or enum input types have a weight of 0.0 and therefore don't affect input type cost.

  Considering the previous example, the input type cost is 1.0, because one **`FilterInput`** type is sent in the **`filter`** argument. **`FilterInput.location`** is a **`String`** type and **`FilterInput.max`** is an **`Int`** type, so they are not included as they are scalars.

- Policy 2:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Replenish
Rate Limit Name	graphql-field-cost
Operation	Replenish

This Rate limit policy limits calls to the GraphQL proxy API by calculating the actual cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The actual cost is calculating by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see Using the GraphQL schema editor.

Note that if the actual cost is less than the expected cost, this Rate limit policy will appropriately restore some of the available cost balance that had been removed by Policy 1, thereby overriding the original actual cost limitation. The actual cost might be less than the expected cost if, for example, the query requested more data than was available in a backend database. You can delete one or other of these Rate limit policies from the assembly if desired.
Note: Such unused cost is **not** restored if there are GraphQL response errors. The purpose of this restriction is to prevent malicious requests that cause large amounts of erroneous backend processing while only using a small amount of cost.
The actual cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see Validate.

The policies as they appear in the assembly UI are as follows:

- **`switch`** case:

  `($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')`

  A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request

Property	Value
Operation	Consume

The policy as it appears in the assembly UI is as follows:

This Rate limit policy limits the requests sent to the **`/graphql/cost`** endpoint for retrieving the cost of a GraphQL query.

- **`switch`** case:

  `($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')`

  A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

The policy as it appears in the assembly UI is as follows:

This Rate limit policy limits standard introspection requests sent to the **`/graphql`** endpoint.

The rate limits that are referred to by the Rate Limit Name settings in these policies are predefined in Plans that are created in Products that contain one or more GraphQL proxy APIs. You can configure the actual rate limiting values there; for more information, see Editing a draft Product.

For more information on the Rate Limit policy, see Rate Limit.

API Gateway only

Request mechanisms supported by GraphQL endpoints

API Connect supports various mechanisms for sending requests to GraphQL proxy API endpoints.

You can use any of the following mechanisms for sending requests to the **`/graphql`** and **`/graphql/cost`** endpoints on a GraphQL proxy API:

- **`GET`**: the GraphQL query must be specified in a URL query parameter called **`query`**.
  For example:

  `https://hostname/basepath/graphql?query={accounts(limit:100){name{first,last}}}`

  The following example includes the **`variables`** and **`operationName`** properties, with URL encoding:

  ```
  https://hostname/basepath/graphql?
  query=query%20fetchAccounts%20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}}&variables=
  {"limit":100}&operationName=fetchAccounts
  ```

- **`POST`** with a JSON-encoded body: the **`Content-Type`** header must be set to **`application/json`**, and the GraphQL query must be sent in the **`query`** key of the JSON object.
  For example:

  ```
  {
    "query": "query fetchAccounts ($limit: Int) {accounts(limit: $limit) {name{first,last}}}",
    "variables": {"limit": 100},
    "operationName": "fetchAccounts"
  }
  ```

  The **`variables`** and **`operationName`** are optional. For more information, see POST request in the GraphQL documentation at https://graphql.org/..

- **`POST`** with graphql content: the **`Content-Type`** header must be set to **`application/graphql`**; the entire body of the **`POST`** is treated as the GraphQL query

Note: For a request sent to the **`/graphql`** endpoint, the GraphQL proxy API always sends the request to the backend GraphQL server as a **`POST`** with a JSON-encoded body, so the backend GraphQL server must support this mechanism otherwise the call fails.

GraphQL custom schema directives and scalar types

The API Connect DataPower® API Gateway extends the GraphQL specification by providing additional schema directives and custom scalar types.

Custom schema directives

`@cost`

The **`@cost`** directive associates weight values with types or fields. Types are used to calculate type cost of a request to the GraphQL API. Fields are used to calculate field cost of a request to the GraphQL API. For more information, see The Cost Directive.

`@listSize`
The **`@listSize`** directive applies slicing arguments to fields. For more information, see The List Size directive.

`@remove`
The **`@remove`** GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context. For more information, see @remove directive

`@scalarParam`
The **`@scalarParam`** directive allows further customization of custom scalar types. For more information, see @scalarParam directive.

Custom scalar types

`Date`
The **`Date`** custom scalar type is used to define custom scalars that specify dates. For more information, see Date Custom Scalar.

`DateTime`
The **`DateTime`** custom scalar type is used to define custom scalars that specify date and time. For more information, see DateTime Custom Scalar.

`JSON`
The **`JSON`** custom scalar type is used to specify JSON payloads. For more information, see JSON Custom Scalar.

`Long`
The **`Long`** custom scalar type enables the use of integers larger than those allowed by **`Int`**. For more information, see Long Custom Scalar.

Related reference

- Using the GraphQL schema editor

`@remove` directive

The **`@remove`** GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context.

For example, you can prevent specific Plans from using certain types or fields. For more information on the API context, see API Connect context variables.

Note: The **`@remove`** directive dynamically modifies the schema so that queries that do not conform to the schema, after any **`@remove`** directives have been evaluated, would be rejected by a **`validate`** policy.

Syntax

```
@remove(if: [String]) on SCALAR | OBJECT | FIELD_DEFINITION | ARGUMENT_DEFINITION | INTERFACE | UNION | ENUM | ENUM_VALUE | IN
```

Arguments

Argument name	Type	Description
`if`	List of strings	JSONata condition that specifies the criteria for removal of a type or field from validation or introspection.

Limitations and propagation rules
For limitations and propagation rules, see Limitations and propagation rules for the GraphQL **`@remove`** directive.

Example 1
Remove the **`creditCard`** type if the current API plan is **`bronze`**.

```
type creditCard @remove(if: ["plan.name in [\"bronze\"]"])
```

Example 2
Remove the **`creditCard`** type if the current API plan is not **`gold`**, and remove the field **`card1`** if the API plan is **`bronze`**.

```
type creditCard @remove(if: ["$not(plan.name = \"gold\")"]){
   field1: String
}
type User {
  card1: creditCard @remove(if: ["plan.name = 'bronze'", "$not(plan.name = \gold\")"])
}
```

API Gateway only

GraphQL limitations

This page details the limitations in the API Connect GraphQL implementation for the current release.

- Specialized handling of custom scalars is not supported, except for validation of the **`Long`** custom scalar type. Input values provided for all other custom scalar types are passed through.
- The following actions and functions cannot read or write to parsed GraphQL queries. Some of these policies might read and write a serialized form of the GraphQL query.
  - Assembly GatewayScript policy
  - Assembly Map policy
  - Assembly Redaction policy
  - Assembly Set Variable policy
  - Assembly XSLT policy
  - **`setVar()`** function
- When reading parsed GraphQL queries, the Assembly Switch policy cannot use wildcards or read arguments.
- GraphQL schemas cannot be serialized.
- GraphQL messages received with **`Content-Type: application/graphql`** or **`Content-Type: application/json`** will send that same content type to the backend. This behavior cannot be overridden.

- All GraphQL schemas are checked for unbounded lists, including those that are not referenced in the assembly. This behavior can cause validation errors that prevent the GraphQL API from being published.
- The GraphQL schema editor generates warnings for fields that contain unbound lists of values if either of the following conditions is true.
  - The values in the list are of composite type. However, the warning is not valid if the composite type in the list has a defined type weight of 0.0 and all its sub-fields also have weights of 0.0 (both the fields and the types of the values they return).
  - The values in the list are of scalar type, for which a weight other than 0.0 was defined.
- Extending schemas is not supported.
- GraphQL APIs can be tested from the Developer Portal user interface. However, not all authentication methods are supported. You must use one of the following authentication methods:
  - Unsecured
  - Client ID, passed in the header
  - Client ID and secret, passed in the header

  Also, `cost` metrics are not supported, and rate limits specific to GraphQL are not listed in Product plans.

Importing an API from the CP4I asset repository

If you are using API Connect with IBM® Cloud Pak for Integration, you can import an API definition from the CP4I asset repository.

About this task

To complete this task you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select From asset repository, then click Next.
4. Click Launch the asset repository.
5. From the asset repository listing, click the name of the API that you want to import.
   An API explorer window opens, enabling you to examine the details of the API.
6. Click Create from asset.
   The validity of the API definition is checked, and a message is displayed indicating successful validation.
7. Click Next.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
9. Click Next.
   The Summary panel displays messages as the API definition is created.
10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Importing an AsyncAPI from Event Endpoint Management

Import one or more AsyncAPI specifications from Event Endpoint Management.

Before you begin

In this scenario, Event Endpoint Management can be viewed as the authoring tool for your AsyncAPI, as well as the gateway service (and enforcement point provider). API Connect is the place where the API is surfaced, and where events are found and managed. After you import the AsyncAPI, you can use API Connect to package it and offer it to consumers.

Complete the following tasks to prepare your API Connect and the AsyncAPI definition file:

1. Ask your cloud administrator to Register an event gateway service.
2. Add the event gateway to the catalog where you will store the API.

3. To import an individual AsyncAPI to API Connect, first export the YAML file from Event Endpoint Management. To export the YAML file from Event Endpoint Management complete the following steps:
    a. In the Event Endpoint Management UI, navigate to the Topics page, and select the topic you want to export.
    b. Click the Options tab, and then click Export.
    c. Select For IBM API Connect (contains credentials) as the export format, and then click Export.

    For more information, see Exporting an AsyncAPI document for use in API Connect in the Event Endpoint Management documentation.

About this task

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The Developer role has this permission by default; if you are assigned a custom role that it must have this permission. For more information, see Creating custom roles.

Note: API Designer does not support importing an Async API, you must import the API using API Manager.

Procedure

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select the AsyncAPI tab to indicate the type of API that you want to work with.
3. You can import AsyncAPI definitions into API Connect either individually or in bulk.
4. To import AsyncAPI in bulk, complete the following steps:
    a. In the Create section, select AsyncAPI from Event Endpoint Management, then click Next.
    b. Select the APIs you want to import.
    c. Click Next to import the selected files.
    d. Click Done on the summary page that opens.
5. To import an individual AsyncAPI, complete the following steps:
    a. In the Import section, select Existing AsyncAPI, then click Next.
    b. On the Import from file page, choose one of the following methods for importing the file:
        - Drag and drop a file:
          Open another window and select a file. Drag the file to the Select a file box, and release the file.
        - Browse for a file:
          Click the Select a file box. In the File Upload window, locate the file and select it, and then click Open.
        - Specify the URL of a file
          In the Or specify a file URL field, type or paste a URL for the file. Provide a username and password if they are required for accessing the file.

    c. Click Next to import the selected file.
       The import wizard checks the validity of the YAML, and displays a message indicating successful validation: **`YAML has been successfully validated.`**
    d. Select the Gateway tab and then click Gateway and portal settings > Properties.
    e. Locate the **`bootstrapServerAddress`** property and verify that the Value field is not empty.
       If the field is empty, enter: **`${bootstrapServerAddress}`** before proceeding.
    f. Click Next to create the API.
       The Summary confirms that the new API definition is created.

       The new API is created, published to the sandbox catalog, and made available online (activated) for use. If you want to publish the API to a different catalog, add the Event Gateway Service to the catalog and then publish the API directly to that catalog.

       The summary displays the API's endpoint, and the sandbox catalog's client ID and client secret, which you can use for testing the API.

Results

Using one of the two methods discussed in the topic, you imported the AsyncAPI into API Connect.

Creating an AsyncAPI with Event Endpoint Management

Create an AsyncAPI using Event Endpoint Management.

Before you begin

In this scenario, Event Endpoint Management can be viewed as the authoring tool for your AsyncAPI and the gateway service (and enforcement point provider). API Connect is the place where the API is surfaced, and where events are found and managed. After you create an AsyncAPI, you can package it with API Connect to offer it to consumers.

Complete the following tasks to prepare your IBM® API Connect and Event Endpoint Management:

1. Ask your cloud administrator to Register an event gateway service.
2. Add the event gateway to the catalog where you store the API.
3. In Event Endpoint Management, create a topic and add an option to it. Then, publish the option. This option can be created as an AsyncAPI in API Connect.

About this task

To complete this task, you need a role with the **`Api-Drafts:Edit`**. The Developer role includes this permission by default. If you have a custom role, make sure that it includes this permission. For more information, see Creating custom roles.

Notes:

- AsyncAPI published in Event Endpoint Management is read only i API Connect.
- API Designer does not support creating an AsyncAPI, you must create the API by using API Manager.

Procedure

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select the AsyncAPI tab to indicate the type of API that you want to work with.
3. In the Import section, select Event Endpoint Management, then click Next.
4. The Add API page opens. Select the API from the instance. Then click Next.
5. The Summary page displays messages as the AsyncAPI is generated.
6. Click Done.

Creating a REST proxy for watsonx.ai with the AI Gateway

Create a REST proxy that uses the AI Gateway to control access to AI models.

Before you begin

Complete the tasks in Prerequisites for using the AI Gateway to ensure that you can authenticate with IBM Cloud and access watsonx.ai.

About this task

The AI Gateway is only supported by OpenAPI 3.0 APIs.

Procedure

1. In the navigation pane, click  .
2. On the Develop page, click Add > API.
3. On the Select API type page, click the OpenAPI 3.0 tab.
4. In the Create section, select AI gateway, then click Next.
5. On the Create API from AI gateway page, use the Platform field to select watsonx as the AI service that the new API uses.
6. Use the "Info" section to provide basic information about the API, and then click Next:
   - The OpenAPI version is based on the step 3 selection where you clicked OpenAPI 3.0.
   - Title: The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is filled in for you based on the title. The value is a single string that is used to identify the API in developer toolkit CLI commands.
   - Version: Accept the default value or modify it as needed. The version corresponds to the value of the **`info.version`** property of the OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example, `1.0.0`.
   - Base path: Accept the default value or modify it as needed. The API's "base path" is the server URL, which is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the catalog in which the API is published. For an API that is enforced by the DataPower® API Gateway, you only need to provide the base path value. In addition:
     - Do not include the hostname or any additional segments for paths or operations
     - Do not include special characters
     - Begin the URL with a forward slash (/) even if it is otherwise empty
   - Description: The optional description helps to identify the API.
7. Provide information about how the API accesses watsonx.ai to submit requests:
   - Project ID: Provide either the ID of the watsonx.ai project that is used for resolving API requests, or a $(name of a catalog property) whose value is the ID of the watsonx.ai project.
   - Exposed paths: Accept the default list of exposed paths, or select only the paths that you want your API to access. The exposed paths define which watsonx.ai operations are included in the generated API.
   - Enable response caching: Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. If you use response caching, you can specify the duration of the cache in the Cache TTL in seconds field.
     When response caching is enabled, then when a request is sent to the watsonx.ai service, the response cache is inspected to determine whether the request payload has an associated cached response. If so, that response and its associated HTTP response headers are placed into the DataPower API Gateway context message (which by default is named **`message`**). The Output Message property in the policy UI can be modified after the API has been generated if a different message is needed.

     If there is no cached response, the request is passed to the watsonx.ai service, and the response is cached for subsequent operations using the time-to-live specified in the Cache TTL in seconds property.

Cache TTL in seconds: If you enable response caching, configure the duration of the cache by accepting the default value or selecting (or typing) a new value. The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.

8. Provide information for authenticating with watsonx.ai, and then click Next:
   - API key: Provide either the API key of the watsonx.ai server used for resolving API requests, or a $(catalog property name) whose value is the API key of the watsonx.ai server.
     The API key allows the API to authenticate with IBM Cloud Authentication, and is required for access to the watsonx.ai service.
   - Region: Select the IBM Cloud region where watsonx.ai requests are sent.
   - Operation version: Accept the default value or provide the appropriate Active Version Date of the watsonx.ai API, using the format **`yyyy-mm-dd`**.
     To see the available version dates, refer to Active Version Dates in the watsonx.ai API documentation. For information on API versioning in watsonx.ai, see Versioning in the same documentation.
9. In the Rate Limiting section, optionally configure rate limiting, and then click Next:
   a. Select Create product if you want to generate an API Connect product that controls rate limiting for the API.
      In API Connect, a product serves as a container for an API and its associated usage plans, which define rate limits. Setting the product rate limits here creates a plan that contains the required **`watson-ai-default`** and **`watson-ai-infer-text`** assembly rate limits and specifies the limits that you defined.

      If you choose not to generate a product automatically, you must create one as explained in Creating a custom product for a watsonx.ai API.

      Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. Either create the product now, or create a custom product before you publish the API.
   b. Configure the types of rate limiting to enforce on API calls:
      Note: If you choose not to specify the values of a rate limit, then default values for that rate limit will be assigned.
      - Set rate limit : (Time based) Accept the default rate limit or configure a new limit based on the number of API requests that are sent within a specified period. This type of rate limit does not use tokens.
      - Set AI token limit : (Token based) Accept the default rate limit or configure a new limit based on the number of cost-based tokens that are used within a specified period. Token-based rate limiting uses the **`/text-generate`** operation to track token usage.
        The AI token limit applies rate limiting based on the token usage. The rate limit determines how many tokens are allowed to pass through the gateway within a specified period of time.
10. Review the Summary page to verify that the API has no issues, and then click Done.
11. Edit the new API and add policies and logic constructs that control the API's workflow.
    The created API contains the watsonx.ai invoke policies for the exposed paths that were requested. Their properties can be edited as needed.

- **Creating a custom product for a watsonx.ai API**
  Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Creating a custom product for a watsonx.ai API

Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. If you did not select Create product to generate a product while creating the watsonx.ai API, you must create a custom product before you can publish the new API.
Create the product as explained in Creating a draft Product. In the product definition, add a plan with the **`watson-ai-default`** and **`watson-ai-infer-text`** assembly rate limits, as shown in the following example:

```
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/1hour
    assembly-rate-limits:
      watson-ai-default:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: '1'
      watson-ai-infer-text:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: aiGeneratedTokenCount
```

The watsonx.ai assembly rate limits are required
The product must include a plan with the **`watson-ai-default`** and **`watson-ai-infer-text`** assembly rate limits, even if you add other plans to the product. You can configure the rate limits as needed for your own requirements.

Token-based rate limiting requires a token count

The **`weight: aiGeneratedTokenCount`** property is required in the **`watson-ai-infer-text`** assembly rate limit. This variable indicates the number of tokens that will be added to the counter with each API call, and then compared with the rate limit threshold.

Rate limiting can apply to the catalog or to individual client IDs.

Rate limiting is configured for the catalog that contains the API. By default, each client ID that subscribes to the plan within a particular catalog is assigned its own rate limit threshold. To configure a single threshold for the entire catalog, set **`use-client-id: false`** for that rate limit.

Creating a REST proxy for OpenAI with the AI Gateway

Create a REST proxy that uses the AI Gateway to control access to AI models.

Before you begin

Complete the tasks in Prerequisites for using the AI Gateway to ensure that you can access OpenAI.

About this task

The AI Gateway is only supported with OpenAPI 3.0 APIs.

Procedure

1. In the navigation pane, click  .
2. On the Develop page, click Add > API.
3. On the Select API type page, click the OpenAPI 3.0 tab.
4. In the Create section, select AI gateway, then click Next.
5. On the Create API from AI gateway page, use the Platform field to select openai as the AI service that the new API will use.
6. Use the "Info" section to provide basic information about the API, and then click Next:
   - The OpenAPI version is based upon the step 3 selection where you clicked on OpenAPI 3.0
   - Title: The title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The name is filled in for you based on the title. The value is a single string that is used to identify the API in developer toolkit CLI commands.
   - Version: Accept the default value or modify it as needed. The version corresponds to the value of the **`info.version`** property of the OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example, `1.0.0`.
   - Base path: Accept the default value or modify it as needed. The API's "base path" is the server URL, which is used to determine the full URL endpoint for the calling the API, considering any vanity endpoint configuration in the catalog in which the API is published. For an API that is enforced by the DataPower® API Gateway, you only need to provide the base path value. In addition:
     - Do not include the hostname or any additional segments for paths or operations
     - Do not include special characters
     - Begin the URL with a forward slash (/) even if it is otherwise empty
   - Description: The optional description helps to identify the API.
7. Provide information about how the API accesses OpenAI to submit requests, and then click Create:
   - Project ID: Provide either the ID of the OpenAI project used for resolving API requests, or a $(name of a catalog property) whose value is the ID of the OpenAI project.
   - API key: Provide either the API key value, or the $(name of a catalog property) variable whose value is the API key.
     The API key allows the API to authenticate with OpenAI server, and is required for access to the OpenAI service.
   - Exposed paths: Accept the default list of exposed paths, or select only the paths that you want your API to access. The exposed paths define which OpenAI operations are included in the generated API.
   - Enable response caching: Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. If you use response caching, you can specify the duration of the cache in the Cache TTL in seconds field.
     When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that response and its associated HTTP response headers are placed into the DataPower API Gateway context message (which by default is named **`message`**). The Output Message property in the policy UI can be modified after the API has been generated if a different message is needed.

     If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the Cache TTL in seconds property.

     Cache TTL in seconds: If you enable response caching, configure the duration of the cache by accepting the default value or selecting (or typing) a new value. The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.
   - In the **Rate Limiting** section, select **Create product** if you want to generate an API Connect product that controls rate limiting for the API.
     In API Connect, a product serves as a container for an API and its associated usage plans, which define rate limits. Setting the product rate limits here creates a plan that contains the required **`openai-default`** and **`openai-token-weighted`** assembly rate limits and specifies the limits that you defined.

     If you choose not to generate a product automatically, you must create one as explained in Creating a custom product for an OpenAI API.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. Either create the product now, or create a custom product before you publish the API.
Configure the types of rate limiting to enforce on API calls:

Note: If you choose not to specify the values of a rate limit, then default values for that rate limit will be assigned.

- Set rate limit : (Time based) Accept the default rate limit or configure a new limit based on the number of API requests sent within a specified period of time. This type of rate limit does not use tokens.
- Set AI token limit : (Token based) Accept the default rate limit or configure a new limit based on the number of cost-based tokens used within a specified period of time. Token-based rate limiting uses the **`/chat/completions`** operation to track token usage.
  The AI token limit applies rate limiting based on the token usage. The rate limit determines how many tokens are allowed to pass through the gateway within a specified period of time.

8. Review the Summary page to verify that the API has no issues.
9. Edit the new API and add policies and logic constructs that control the API's workflow.
   The created API contains the OpenAI invoke policies for the exposed paths that were requested. Their properties can be edited as needed.

- **Creating a custom product for an OpenAI API**
  Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Creating a custom product for an OpenAI API

Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. If you did not select Create product to generate a product while creating the OpenAI API, you must create a custom product before you can publish the new API.
Create the product as explained in Creating a draft Product. In the product definition, add a plan with the **`openai-default`** and **`openai-token-weighted`** assembly rate limits, as shown in the following example:

```
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/1minute
    assembly-rate-limits:
      openai-default:
        - value: 100/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: '1'
      openai-token-weighted:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: aiGeneratedTokenCount
```

The OpenAI assembly rate limits are required
: The product must include a plan with the **`openai-default`** and **`openai-token-weighted`** assembly rate limits, even if you add other plans to the product. You can configure the rate limits as needed for your own requirements.

Token-based rate limiting requires a token count
: The **`weight: aiGeneratedTokenCount`** property is required in the **`openai-token-weighted`** assembly rate limit. This variable indicates the number of tokens that will be added to the counter with each API call, and then compared with the rate limit threshold.

Rate limiting can apply to the catalog or to individual client IDs.
: Rate limiting is configured for the catalog that contains the API. By default, each client ID that subscribes to the plan within a particular catalog is assigned its own rate limit threshold. To configure a single threshold for the entire catalog, set **`use-client-id: false`** for that rate limit.

Creating a REST proxy for Gemini with the AI Gateway

Create a REST proxy that uses the AI Gateway to control access to AI models.

Before you begin

Complete the tasks in Prerequisites for using the AI Gateway to ensure that you can access Gemini.

About this task

The AI Gateway is only supported with OpenAPI 3.0 APIs.

Procedure

1. In the navigation pane, click  .
2. On the Develop page, click Add > API.
3. On the Select API type page, click the OpenAPI 3.0 tab.
4. In the Create section, select AI gateway, then click Next.
5. On the Create API from AI gateway page, use the Platform field to select Google Gemini as the AI service that the new API uses.
6. Use the "Info" section to provide basic information about the API, and then click Next:
   - The OpenAPI version is based on the step 3 selection where you clicked on OpenAPI 3.0
   - Title: The title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The name is filled in for you based on the title. The value is a single string that is used to identify the API in developer toolkit CLI commands.
   - Version: Accept the default value or modify it as needed. The version corresponds to the value of the **`info.version`** property of the OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example, `1.0.0`.
   - Base path: Accept the default value or modify it as needed. The API's "base path" is the server URL, which is used to determine the full URL endpoint for the calling the API, considering any vanity endpoint configuration in the catalog in which the API is published. For an API that is enforced by the DataPower® API Gateway, you only need to provide the base path value. In addition:
     - Do not include the hostname or any additional segments for paths or operations
     - Do not include special characters
     - Begin the URL with a forward slash (/) even if it is otherwise empty
   - Description: The optional description helps to identify the API.
7. Provide either the API key value, or the $(name of a catalog property) variable whose value is the API key and then click Next. The API key allows the API to authenticate with Google Studio, and is required for access to the Gemini service.
8. Provide information about how the API accesses Gemini to submit requests, and then click Create:
   - Exposed paths: Accept the default list of exposed paths, or select only the paths that you want your API to access. The exposed paths define which Gemini operations are included in the generated API.
   - Enable Response Caching: Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. If you use response caching, you can specify the duration of the cache in the Response Cache Expiration property in the policy UI.
     When response caching is enabled, then when a request is sent to the Gemini service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that response and its associated HTTP response headers are placed into the DataPower API Gateway context message (which by default is named **`message`**). The Output Message property in the policy UI can be modified after the API has been generated if a different message is needed.

     If there is no cached response, the request is passed to the Gemini service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.

     If you enable response caching, configure the duration of the cache in the Response Cache Expiration field in the policy UI by accepting the default value or selecting (or typing) a new value. The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -\- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.
   - In the **Rate Limiting** section, select **Create product** if you want to generate an API Connect product that controls rate limiting for the API.
     In API Connect, a product serves as a container for an API and its associated usage plans, which define rate limits. Setting the product rate limits here creates a plan that contains the required **`gemini-default`** and **`gemini-token-weighted`** assembly rate limits and specifies the limits that you defined.

     If you choose not to generate a product automatically, you must create one as explained in Creating a REST proxy for Gemini with the AI Gateway.

     Attention: A product that is created later with the autopublish feature (when publishing your API) does not include the required plan for using the AI service. Either create the product now, or create a custom product before you publish the API.
     Configure the types of rate limiting to enforce on API calls:

     Note: If you choose not to specify the values of a rate limit, then default values for that rate limit will be assigned.
     - Set rate limit : (Time based) Accept the default rate limit or configure a new limit based on the number of API requests sent within a specified period of time. This type of rate limit does not use tokens.
     - Set AI token limit : (Token based) Accept the default rate limit or configure a new limit based on the number of cost-based tokens used within a specified period of time. Token-based rate limiting uses the **`/chat/completions`** operation to track token usage.
       The AI token limit applies rate limiting based on the token usage. The rate limit determines how many tokens are allowed to pass through the gateway within a specified period of time.
9. Review the Summary page to verify that the API has no issues.
10. Edit the new API and add policies and logic constructs that control the API's workflow.
    The created API contains the Gemini invoke policies for the exposed paths that were requested. Their properties can be edited as needed.

- **Creating a custom product for a Gemini API**
  Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Creating a custom product for a Gemini API

Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. If you did not select Create product to generate a product while creating the OpenAI API, you must create a custom product before you can publish the new API.
Create the product as explained in Creating a draft Product. In the product definition, add a plan with the **gemini-default** and **gemini-token-weighted** assembly rate limits, as shown in the following example:

```
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/1minute
    assembly-rate-limits:
      gemini-default:
        - value: 100/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: '1'
      gemini-token-weighted:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: aiGeneratedTokenCount
```

The Gemini assembly rate limits are required
: The product must include a plan with the **gemini-default** and **gemini-token-weighted** assembly rate limits, even if you add other plans to the product. You can configure the rate limits as needed for your own requirements.

Token-based rate limiting requires a token count
: The **weight: aiGeneratedTokenCount** property is required in the **gemini-token-weighted** assembly rate limit. This variable indicates the number of tokens that will be added to the counter with each API call, and then compared with the rate limit threshold.

Rate limiting can apply to the catalog or to individual client IDs.
: Rate limiting is configured for the catalog that contains the API. By default, each client ID that subscribes to the plan within a particular catalog is assigned its own rate limit threshold. To configure a single threshold for the entire catalog, set **use-client-id: false** for that rate limit.

Creating a REST proxy for Azure OpenAI with the AI Gateway

Create a REST proxy that uses the AI Gateway to control access to AI models.

Before you begin

Complete the tasks in Prerequisites for using the AI Gateway to ensure that you can access Azure OpenAI.

About this task

The AI Gateway is only supported with OpenAPI 3.0 APIs.

Procedure

1. In the navigation pane, click  .
2. On the Develop page, click Add > API.
3. On the Select API type page, click the OpenAPI 3.0 tab.
4. In the Create section, select AI gateway, then click Next.
5. On the Create API from AI gateway page, use the Platform field to select Azure openai as the AI service that the new API will use.
6. Use the "Info" section to provide basic information about the API, and then click Next:
   - The OpenAPI version is based upon the step 3 selection where you clicked on OpenAPI 3.0
   - Title: The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is filled in for you based on the title. The value is a single string that is used to identify the API in developer toolkit CLI commands.
   - Version: Accept the default value or modify it as needed. The version corresponds to the value of the **info.version** property of the OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example `1.0.0`.
   - Base path: Accept the default value or modify it as needed. The API's "base path" is the server URL, which is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the catalog in which the API is published. For an API that is enforced by the DataPower® API Gateway, you only need to provide the base path value. In addition:
     - Do not include the host name or any additional segments for paths or operations

- Do not include special characters
- Begin the URL with a forward slash (/) even if it is otherwise empty

- Description: The optional description helps to identify the API.

7. Provide information about how the API accesses Azure OpenAI to submit requests, and then click Create:
   - API key: Provide either the API key value, or the $(name of a catalog property) variable whose value is the API key.
     The API key allows the API to authenticate with Azure OpenAI server, and is required for access to the Azure OpenAI service.
   - Exposed paths: Accept the default list of exposed paths, or select only the paths that you want your API to access. The exposed paths define which Azure OpenAI operations are included in the generated API.
   - Enable response caching: Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. If you use response caching, you can specify the duration of the cache in the Cache TTL in seconds field.
     When response caching is enabled, then when a request is sent to the Azure OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that response and its associated HTTP response headers are placed into the DataPower API Gateway context message (which by default is named **`message`**). The Output Message property in the policy UI can be modified after the API has been generated if a different message is needed.

     If there is no cached response, the request is passed to the Azure OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the Cache TTL in seconds property.

     Cache TTL in seconds: If you enable response caching, configure the duration of the cache by accepting the default value or selecting (or typing) a new value. The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.
   - In the **Rate Limiting** section, select **Create product** if you want to generate an API Connect product that controls rate limiting for the API.
     In API Connect, a product serves as a container for an API and its associated usage plans, which define rate limits. Setting the product rate limits here creates a plan that contains the required **`azure-openai-default`** and **`azure-openai-token-weighted`** assembly rate limits and specifies the limits that you defined.

     If you choose not to generate a product automatically, you must create one as explained in Creating a custom product for an Azure OpenAI API.

     Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. Either create the product now, or create a custom product before you publish the API.
     Configure the types of rate limiting to enforce on API calls:

     Note: If you choose not to specify the values of a rate limit, then default values for that rate limit will be assigned.
     - Set rate limit : (Time based) Accept the default rate limit or configure a new limit based on the number of API requests sent within a specified period of time. This type of rate limit does not use tokens.
     - Set AI token limit : (Token based) Accept the default rate limit or configure a new limit based on the number of cost-based tokens used within a specified period of time. Token-based rate limiting uses the **`/chat/completions`** operation to track token usage.
       The AI token limit applies rate limiting based on the token usage. The rate limit determines how many tokens are allowed to pass thru the gateway within a specified period of time.

8. Review the Summary page to verify that the API has no issues.
9. Edit the new API and add policies and logic constructs that control the API's workflow.
   The created API will contain the Azure OpenAI invoke policies for the exposed paths that were requested. Their properties can be edited as needed.

- **Creating a custom product for an Azure OpenAI API**
  Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Creating a custom product for an Azure OpenAI API

Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. If you did not select Create product to generate a product while creating the OpenAI API, you must create a custom product before you can publish the new API.
Create the product as explained in Creating a draft Product. In the product definition, add a plan with the **`openai-default`** and **`openai-token-weighted`** assembly rate limits, as shown in the following example:

```
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/1minute
    assembly-rate-limits:
      openai-default:
        - value: 100/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: '1'
      openai-token-weighted:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
```

```
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: aiGeneratedTokenCount
```

The Azure OpenAI assembly rate limits are required
: The product must include a plan with the `openai-default` and `openai-token-weighted` assembly rate limits, even if you add other plans to the product. You can configure the rate limits as needed for your own requirements.

Token-based rate limiting requires a token count
: The `weight: aiGeneratedTokenCount` property is required in the `openai-token-weighted` assembly rate limit. This variable indicates the number of tokens that will be added to the counter with each API call, and then compared with the rate limit threshold.

Rate limiting can apply to the catalog or to individual client IDs.
: Rate limiting is configured for the catalog that contains the API. By default, each client ID that subscribes to the plan within a particular catalog is assigned its own rate limit threshold. To configure a single threshold for the entire catalog, set `use-client-id: false` for that rate limit.

Editing an OpenAPI 2.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
  1. In the navigation pane, click  Develop, then select the APIs tab.
  2. Click the title of the API version that you want to work with.

- **Specifying API metadata**
  API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- **Specifying the host for an API**
  You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.
- **Specifying the basepath for an API**
  The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all operations in the API.
- **Specifying the schemes for an API**
  Schemes define which transfer protocols you want your API to use.
- **Specifying the MIME types that an API consumes**
  You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- **Specifying the MIME types that an API produces**
  You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.
- **Enforcing security requirements on an API**
  To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.
- **Specifying external documentation for an API**
  You can reference an external resource for extended documentation for an API.
- **Adding tags to an API**
  You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Defining Paths for an API**
  A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.
- **Defining schema definitions for an API**
  Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- **Defining parameters for an API**
  Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.
- **Defining responses for an API**
  Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.
- **Specifying gateway and portal settings**
  Define general configuration settings for your API.
- **Defining target services for an API**
  A target service defines a web service that you want to use in your API definition.
- **Setting API properties**
  In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.
- **Configuring application authentication for an API**
  Using this topic, you can configure application authentication for an API.
- **Configuring activity logging**
  You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

- **Configuring v5 compatibility options**
  You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower API Gateway.
- **Including elements in your API assembly**
  An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- **Specifying the gateway type for an API definition**
  An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.
- **Converting an API definition for deployment to the DataPower API Gateway**
  IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.
- **Modifying a GraphQL schema**
  For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.
- **Validating the OpenAPI YAML source**
  How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.
- **Validating an API or product document by using the governance service**
  How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Info.
3. Provide the following information:
   - Title (required): The title of the API.
   - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see Creating a new version of an API definition.
   - Description: An optional description of the API. You can use CommonMark syntax for rich text representation.
   - Terms of Service: A URL to the Terms of Service for the API.
   - Contact Name: The identifying name of the contact person/organization.
   - Contact Url: A URL pointing to the contact information.
   - Contact Email: The email address of the contact person/organization.
   - License Name: The license name used for the API.
   - License Url: A URL to the license used for the API.
4. Click Save when done.

Specifying the host for an API

You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Host.
3. Enter the required host name.
   Note: To enable this capability, you must additionally configure API vanity endpoints in the Catalog Settings for the Catalog to which the API is published. For information on configuring vanity endpoints, see Creating and configuring Catalogs
4. Click Save when done.

Specifying the basepath for an API

The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all operations in the API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Base Path.
3. Enter the required base path, preceded by a forward slash character (/).
4. Click Save when done.

Specifying the schemes for an API

Schemes define which transfer protocols you want your API to use.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more schemes defined, expand Schemes List.
3. To specify a new scheme, click the add icon ⊕ alongside Schemes List. To modify an existing scheme, click the scheme entry in the navigation pane.
4. Select the required scheme from the list provided, then click Create.
5. Click Save when done.

Specifying the MIME types that an API consumes

You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more consumes MIME types defined, expand Consumes.
3. To specify a new MIME type, click the add icon ⊕ alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example, **`application/json`** or **`application/xml`**. Then click Create.
5. Click Save when done.

Specifying the MIME types that an API produces

You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more produces MIME types defined, expand Produces.
3. To specify a new MIME type, click the add icon ⊕ alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example `application/json` or `application/xml`. Then click Create.
5. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme definitions, see Defining security schemes.

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security schemes whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
   a. Click the add icon ⊕ alongside Security in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined; see Defining security schemes.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see Defining OAuth2 security schemes.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
4. To modify an existing security requirement, complete the following steps:
   a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
   e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

- **Defining security schemes**
  A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

- **Enabling CORS support for an API**
  You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Defining security schemes

A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.

- **Defining basic authentication security schemes**
  A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.
- **Defining API key security schemes**
  An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- **Defining OAuth2 security schemes**
  An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Defining basic authentication security schemes

A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see Working with user registries.

To create a user registry with Cloud Manager, see User registries overview.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM® API Connect expects an authentication URL to return an HTTP `200 OK` response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see LDAP authentication.

For information about using an Authentication URL, see Authentication URL user registry.

To make use of a basic authentication security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.

3. To create a basic authentication security scheme, click the add icon alongside Security Schemes, then select basic for the Security Definition Type. To edit an existing basic authentication security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Name field.
5. Select the user registry from the Authenticate using User Registry list.
   The user registries in the list are those that have been enabled in the Sandbox Catalog; for details, see Creating and configuring Catalogs.
6. Optionally, provide a Description for the security scheme. You can use CommonMark syntax for rich text representation.
7. If you are creating a new basic authentication security scheme, click Create.
   The security scheme details are displayed for further editing.
8. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

For more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

Defining API key security schemes

An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security schemes, one for each type of credentials.

To make use of an API key security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an API key security scheme, click the add icon alongside Security Schemes, then select apiKey for the Security Definition Type. To edit an API key existing security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Specify the parameter name in the Name field.
   If your API is not enforced by the API Connect gateway, enter the parameter name required by your gateway.

   If your API is enforced by the IBM® API Connect gateway, the required value depends on the gateway type setting for the API, as follows:
   - DataPower® API Gateway: For a key of type client secret, you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
   - DataPower Gateway (v5 compatible): the value must be as specified in the following table, depending on where the client credentials are located, and the type of credentials.

   Table 1. Client ID and Client secret parameter name values for the DataPower Gateway (v5 compatible)

Location of credentials	Type of credentials	Parameter name
Header	Client ID	X-IBM-Client-Id
Header	Client secret	X-IBM-Client-Secret
Query	Client ID	client_id
Query	Client secret	client_secret

   When you first create an API, a default API key security definition, of type client ID, is provided.

   For information about including API key parameters in an API call, see Calling an API.
   Note:
   - You cannot apply more than two API key security definitions to an API.
   - If you apply an API key security definition for client secret, you must also apply an API key security definition for client ID.
   - If you require the application developer to supply both client ID and client secret, you must apply two separate API key security definitions.
   - You can have at most one API key definition of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
   - You can have at most one API key definition of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
   - The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a `set-variable` policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:
     - In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

Table 2.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	$(request.headers.X-IBM-Client-Secret)

For more information on configuring a Set Variable policy, see Set Variable.

- In the Source tab, add a `set-variable` policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-IBM-Client-Id
            value: $(request.headers.X-IBM-Client-Id)
            type: string
          - set: message.headers.X-IBM-Client-Secret
            value: $(request.headers.X-IBM-Client-Secret)
            type: string
```

For more information on defining a `set-variable` policy in your OpenAPI source, see set-variable.

You should position the `set-variable` before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.

6. Select the Key Type: client_id or client_secret.
   Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.
   If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

   If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

7. Specify whether the credentials are sent in the request header, or as query parameters, by selecting one of the following Located In options:

   header
   : The credentials are sent in the request header. This is the default setting.

   query
   : The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

   The selected option is enforced, and API calls fail if the credentials are included in the wrong location by the caller.

   Note:
   - You must specify the same location for the client ID and client secret, either header or query.
   - If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see Client ID behavior in API key security definitions.

8. Optionally, provide a Description for the security scheme. You can use CommonMark syntax for rich text representation.
9. If you are creating a new API key security scheme, click Create.
   The security scheme details are displayed for further editing.
10. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

- **Client ID behavior in API key security definitions**
  How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.
Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.

Use case	Description of security requirement	V5 behavior	V10 behavior
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	• When Return V5 Responses compatibility option is off: 401 client ID is missing. • When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. For information about setting compatibility options, see Configuring v5 compatibility options.

Defining OAuth2 security schemes

An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme, you must:

1. Create an OAuth provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the OAuth instructions step in Creating and configuring Catalogs.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an OAuth2 security scheme, click the add icon ⊕ alongside Security Schemes, then select oauth2. To edit an existing OAuth2 security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Provide the following information:
   - Security Scheme Name: An identifying name of your choice.
   - OAuth Provider: Select the OAuth provider to be used.
   - Flow: Select one of the following options:
     - Implicit
     - Resource Owner - Password
     - Application
     - Access Code

     Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
     If you selected Resource owner - JWT as the supported grant type when you created the OAuth provider, you must select Resource owner - Password as the Flow for this security scheme.
   - Description: An optional description of the OAuth2 security scheme. You can use CommonMark syntax for rich text representation.
   - The URL endpoints (the applicable endpoints depend on the flow type):
     - Authorization Url
     - Token Url

     Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.

- Scopes (available if you are editing an existing OAuth2 security scheme):
  - To add a new scope, click Add. To edit an existing scope, click the options icon ⋮ alongside the required scope, then click Edit.
  - Provide the following information:
    - Scope: The scope identifier.
    - Description: An optional description of the scope. You can use CommonMark syntax for rich text representation.
    - If you are creating a new scope, click Create.

6. If you are creating a new OAuth2 security scheme, click Create.
   The security scheme details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
  - The **`cors`** preflow policy configures the appropriate response headers.
  - The response headers are set.
- When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
- For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
   The CORS page opens.
3. Select Enabled.
4. Optional: Configure a CORS policy.
   Should you create a CORS policy? Review the following considerations:
   - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
     If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.
   - If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
     If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.
   - To configure a new CORS policy, complete the following steps:
     - Alongside Policy, click Add.
     - To include the header **`Access-Control-Allow-Credentials: true`** in a response. select Allow Credentials. The **`Access-Control-Allow-Credentials`** response header tells browsers whether to expose the response to front-end JavaScript code when the request's credentials mode (**`Request.credentials`**) is set to **`include`**.
     - To append one or more of the following values to the **`Access-Control-Expose-Headers`** response header, select Expose headers, and select from the following options:
       - Predefined - The predefined value of the Gateway. This option is selected by default.
       - Backend - The value of **`Access-Control-Expose-Headers`** from the backend response.
       - Custom - A custom string.
     - Click Create.
     - Alongside Allowed Origins click Add.
     - Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.
   - To modify an existing CORS policy, click its entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

Example

The following example has three rules:

- Accept an Origin header of `https://example.com`, and return `Access-Control-Allow-Credentials: true` in the CORS response.
- Accept an Origin header of `http://domain.com`. No `Access-Control-Allow-Credentials` header will be returned in the response.
- Accept any of the following Origin headers:
  - `http://example2.com`
  - `http://example3.com`
  - `http://example4.com`

  No `Access-Control-Allow-Credentials` header will be returned in the response.

```
cors:
  enabled: true
  policy:
    -
      allow-origin:
        - 'https://example.com'
      allow-credentials: true
    -
      allow-origin:
        - 'http://domain.com'
    -
      allow-origin:
        - 'http://example2.com'
        - 'http://example3.com'
        - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
   a. Add the following headers to your HTTP responses:

   ```
   Access-Control-Allow-Origin: https://<portalhostname>
   Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
   ```

   Where `<portalhostname>` is your Developer Portal host name.

   b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

Important:

- If you implement your own CORS solution, you **must** disable the CORS option described in step 3
- CORS preflight requests are sent by using the HTTP `OPTIONS` method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the `OPTIONS` method for all APIs that will handle preflight requests; see Defining Paths for a REST API.
- `OPTIONS` requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see Defining rate limits for an API operation.

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click External Documentation.
3. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon ⊕ alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
   - Name (required): The name of the tag.
   - Description: An optional description of the tag. You can use CommonMark syntax for rich text representation.
   - External Documentation > URL (available when editing an existing tag): The URL for target documentation that describes this tag.
   - External Documentation > Description (available when editing an existing tag): An optional description of the target documentation.
5. If you are creating a new tag, click Create.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon ⊕ alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
   - Path: A relative path to an individual endpoint.
     The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

     If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

     - * to indicate 0 or more occurrences
     - + to indicate 1 or more occurrences

     The + and * qualifiers can only be used at the end of the path.

     For example, the path:

     ```
     /petstore/{type}/{*category}
     ```

     matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

     ```
     /petstore/cats
     /petstore/cats/supplies
     /petstore/cats/supplies/health
     /petstore/cats/supplies/health/medicines
     /petstore/cats/supplies/health/medicines/a/b/c
     ```

   - $ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.
     The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

     ```
     #/paths/~1mypath
     ```

     The `~1` characters are used to escape the `/` character, which is being used literally in the path name rather than as a special character.
     A reference to a path in an external file called path_fragments.yaml would have the following format:

     ```
     file://path_fragments.yaml/paths/~1mypath
     ```

5. If you are creating a new Path, click Create.
   The Path details are displayed for further editing as described in step 4.
6. Click Save when done.

- **Defining parameters for a path**
  Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.
- **Defining operations for a path**
  Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining parameters for a path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Path Parameters.
4. You can either create a new parameter, or edit any existing parameter.
   - To create a parameter, click the add icon ⊕ alongside Path Parameters, then refer to Creating a parameter.
   - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining operations for a path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required path.
3. Click the add icon ⊕ alongside Operations under the Path in the navigation pane.
4. Provide the following information:
   - Verb: Select the operation type from the following options:
     - get
     - post
     - put
     - delete
     - options
     - head
     - patch
     - trace
   - Summary: A summary of what the operation does.
   - Description: A description of the operation behavior.
   - Operation: Unique string used to identify the operation. The id must be unique among all operations described in the API.
   - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
5. Click Create.
6. Click Save when done.

- **Adding tags to an operation**
  You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Specifying external documentation for an operation**
  You can referencing an external resource for extended documentation for an API operation.
- **Specifying the MIME types that an API operation produces**
  You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.
- **Specifying the MIME types that an API operation consumes**
  You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- **Defining parameters for an operation**
  Responses define the HTTP status code and data returned in a response body and headers.
- **Defining responses for an operation**
  Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can returned by executing the operation.
- **Specifying schemes for an operation**
  The schemes settings define which transfer protocols you want your API operation to use.

- **Enforcing security requirements on an operation**
  To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To add a new operation tag, click the add icon ⊕ alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
5. Provide the following information:
   - Name (required): The name of the tag.
6. If you are creating a new operation tag, click Create.
7. Click Save when done.

Specifying external documentation for an operation

You can referencing an external resource for extended documentation for an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
5. Click Save when done.

Specifying the MIME types that an API operation produces

You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon ⊕ alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.

5. Enter the required value in the Mime Type field; for example **application/json** or **application/xml**. Then click Create.
6. Click Save when done.

Specifying the MIME types that an API operation consumes

You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon ⊕ alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
5. Enter the required value in the Mime Type field; for example, **application/json** or **application/xml**. Then click Create.
6. Click Save when done.

Defining parameters for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter.
   - To create an operation parameter, click the add icon ⊕ alongside Path Parameters, then refer to Creating a parameter.
   - To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can returned by executing the operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.
4. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

Specifying schemes for an operation

The schemes settings define which transfer protocols you want your API operation to use.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing schemes, expand Schemes List.
4. You can either add a new scheme, or edit any existing scheme.
   - To add a scheme, click the add icon ⊕ alongside Schemes List, select the required transfer protocol, then click Create.
   - To edit an existing scheme, click the scheme in the navigation pane, then change the transfer protocol as required.
5. Click Save when done.

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security schemes, see Defining security schemes.

A security requirement specifies one or more security scheme definitions whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see Enforcing security requirements on an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
   a. Click the add icon ⊕ alongside the Security entry for the operation in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have previously been defined; see Defining security schemes.
      If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see Defining OAuth2 security schemes.

      If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

      Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Save when done.
5. To modify an existing security requirement, complete the following steps:
   a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
   e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.

Note: These settings completely override any security requirements defined on the parent API; see Enforcing security requirements on an API.

Defining schema definitions for an API

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
An API created in OpenAPI 2.0 includes a section where API payload definitions are defined. The payload definitions describe the structure of data transmitted in API requests and responses, utilizing a specialized JSON schema variant specific to OpenAPI. Each payload definition corresponds to a schema, which lists the expected data fields. These data fields are represented as properties within the schema and include a set of attributes that describe their type, permissible values, mandatory status, and other characteristics. Although numerous attributes are available, the majority of them are infrequently utilized.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more schemas defined, expand Definitions.
3. You can create a new schema, or edit any existing schema.
   - To create a schema, click the add icon ⊕ alongside Definitions, then refer to Creating schema definitions.
   - To edit an existing schema, click the schema component name in the navigation pane, then refer to Editing schema definitions.

- **Creating schema definitions**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
- **Editing schema definitions**
  Schemas provide developers with information about the request that they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating schema definitions

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
For details of the areas in your API definition from where you can create a schema, see the following topics:

- Defining schema definitions for an API
- Editing a response

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. To create a schema definition, click the add icon ⊕ alongside Definitions.
   The Add object wizard for a schema is displayed.
2. Provide the following information:
   - Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/definitions/Name`

   - Title: The schema title.
   - Type: The schema data type; select one of the following:
     - array
     - boolean

- integer
- number
- object
- string

3. Click Create.
   The schema definitions details are displayed for further editing; see Editing schema definitions.

Editing schema definitions

Schemas provide developers with information about the request that they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
For details of the areas in your API definition from where you can edit a schema, see the following topics:

- Defining schema definitions for an API
- Editing a response

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The table view presents the properties within a schema alongside their essential attributes, such as name, type, description, and required status. The secondary pop-up enables access for viewing and editing the more detailed and less commonly used attributes that are associated with each data field.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

You can configure the following schema definition settings:

- Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/definitions/Name`

  To change the name, click the Source icon, change the value in the field, then click Save.
- Optional: Title: The schema title.
- Type: The schema data type; select one of the following:
  -
    - array
    - boolean
    - integer
    - number
    - object
    - string

  Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon </> .
- Properties: The schema property. To add a property to the schema, click Add alongside the Properties section heading, complete the details and click Save.
- Additional schema settings dependent on the selected Type of property. To view and edit these schema settings, click the Options menu next to the property you want to view and select Details.
  - boolean: no type specific settings.
  - integer:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of an integer instance by this value must result in an integer.
    - Maximum: An integer instance must be less than or equal to this value.
    - Exclusive Maximum: An integer instance must be strictly less than this value.
    - Minimum: An integer instance must be greater than or equal to this value.
    - Exclusive Minimum: An integer instance must be strictly greater than this value.
  - number:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of a number instance by this value must result in an integer.
    - Maximum: A number instance must be less than or equal to this value.
    - Exclusive Maximum: A number instance must be strictly less than this value.
    - Minimum: A number instance must be greater than or equal to this value.
    - Exclusive Minimum: A number instance must be strictly greater than this value.
  - object:
    - Max Properties: The number of properties in an object instance must be less than or equal to this value.
    - Min Properties: The number of properties in an object instance must be greater than or equal to this value.

        - Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
    - string:
        - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
        - Pattern: A regular expression; a string instance must successfully match the expression.
        - Max Length: The maximum allowed number of characters in a string instance.
        - Min Length: The minimum allowed number of characters in a string instance.
        - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- General settings; select the required options:
    - Required: A property associated with this schema is required.
    - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
    - URL (required): The URL for the target documentation.
    - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
    - Name: Replaces the name of the element or attribute that is used for the described schema property.
    - Namespace: The URL of the namespace definition.
    - Prefix: The prefix to be used for the Name.
    - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
    - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/><book/></books>`) or unwrapped (`<book/> <book/>`).
- Click Save when done.

Example

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameters for an API

Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there already one or more parameters defined, expand Parameter Definitions.
3. You can either create a new parameter, or edit any existing parameter.
    - To create a parameter, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
    - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

- **Creating a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
- **Editing a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- Defining parameters for a path
- Defining parameters for an operation
- Defining parameters for an API

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Parameter Name: The name of the parameter.
     Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
   - Located In: The location of the parameter. Select one of the following options:
     - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
     - header: Custom headers that are expected as part of the request.
     - path: The parameter value is part of the operation's URL, enclosed in {}.
     - body: Parameters that describe the body of POST, PUT and PATCH requests.
   - Description: A description of the parameter.
   - Type: The data type of the parameter.
   - Format: Select the data format; the available options depend on the selected Type.
   - Select the following option as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Create.
   The parameter details are displayed for further editing; see Editing a parameter.

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- Defining parameters for a path
- Defining parameters for an operation
- Defining parameters for an API

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
   - Type: The data type of the parameter.
   - Format: Select the data format; the available options depend on the selected Type.
   - Select the following options as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining responses for an API

Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there already one or more responses defined, expand Response Definitions.
3. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon alongside Response Definitions, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

- **Creating a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
- **Editing a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- Defining responses for an API
- Defining responses for an operation

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The HTTP status code.
   - Description (required): A description of the response.
2. Click Create.
   The response details are displayed for further editing; see Editing a response.

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- Defining responses for an API
- Defining responses for an operation

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The HTTP status code.
   - Description (required): A description of the response.
   - Schema: The schema defines the response structure.
     To define a schema for the response, click Create, then refer to Creating schema definitions.

     If the response already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing schema definitions.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
   - Target Services: Define web services that you want to use in your API definition. For details, see Defining target services for an API.
   - Enforced: Select this option to enforce the API by using the DataPower® API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
   - Phase: The phase of the lifecycle that your API is in; select one of the following options:
     - Realized (default) - The API is in the implementation phase.
     - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
     - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
   - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
     Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
   - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see Enabling CORS support for an API.
   - Properties: Add properties that can be referenced in your API definition. For details, see Setting API properties.
   - Catalog Properties: Define property values that are specific to a particular Catalog. For details, see Defining Catalog specific property values.
   - Gateway: For details, see Specifying the gateway type for an API definition.
   - Application Authentication: Enable application authentication to protect your API with a certificate. For details, see Configuring application authentication for an API.

- Application Authentication Source: If application authentication is enabled, specify how the client certificate is sent to the gateway. For details, see Configuring application authentication for an API.
- Activity Log: Configure your logging preferences for the API activity that is stored in analytics. For details, see Configuring activity logging.
- Compatibility: For details, see Configuring v5 compatibility options.
- Html Page: For a GraphQL API, the HTML page with which the API responds to an initial GraphiQL editor request. Currently, the only option is `store:///graphiql.html`. For more information, see Enabling the GraphiQL editor for a GraphQL API.
- Graphql Schema: For a GraphQL API, the name of the schema definition that references the imported GraphQL schema. For information on uploading a schema during GraphQL API creation, see Creating a GraphQL proxy API. For information on replacing the schema for an existing GraphQL API, see Using the GraphQL schema editor.
- Exxtensions: Extensions added to the API to extend the OpenAPI specification. For details, see Adding an OpenAPI extension to an API.

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
   a. Click the add icon ⊕ alongside Target Services in the navigation pane.
   b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

   The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.
4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see API properties.
Note: Once defined, an API property is read only.
For information on how to reference a property in an API definition, see Variable references in API Connect.

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see Creating and configuring Catalogs. Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
   - To define a new API property, complete the following steps:
     - Click the add icon alongside Properties in the navigation pane.
     - Provide the following information:
       - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
       - Property Value: A default value for the property. Leave blank if the property is to have a null vale by default.
       - Description: An optional description of the property. You can use CommonMark syntax for rich text representation.
       - Select Property Value is Base64 Encoded if you want to hide the property values, or protect user passwords from casual observance.
         Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
     - Click Create.
   - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
4. Click Save to save your changes.

- **Defining Catalog specific property values**
  For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see Setting API properties.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
   - To define a new Catalog specific property value, complete the following steps:
     - Click the add icon alongside Catalog Properties in the navigation pane.
     - Type the Catalog Name exactly as it displays in the **`name`** field for the selected Catalog.
       Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
     - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
     - Alongside Property Overrides, click Add.
     - Provide the following information:
       - Property Name to Override: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see Setting API properties.
       - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
     - Click Create.
   - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring application authentication for an API

Using this topic, you can configure application authentication for an API.

About this task

Remember: Sending the client certificate in an HTTP header does not enable cryptographic verification that the caller possesses corresponding to the private key. The only validation performed is a string comparison of the base64-encoded PEM file with the public certificate that you can configure following the steps below.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Enable application authentication, as follows:
   Note: To identify the application, you must enable a security requirement of type **clientID**.
   a. On the API Design page, select the Gateway tab and expand Gateway and portal settings.
   b. In the navigation pane, click Application Authentication.
3. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header. Specify how the client certificate is sent to the gateway, as follows:
   You can choose to send the client certificate as a TLS client certificate, or to include it in the API's HTTP header.

   a. In the navigation pane, click Application Authentication.
      Any existing application authentication source definitions are listed.
   b. On the Application Authentication page, select Certificate.
   c. In the Application pane, click Application authentication source.
   d. On the Application authentication source page, click Add.
   e. In the Add shema dialog box, select the required option .
      - tls-cert - When the API is called, the TLS client certificate is sent to the Gateway service and is used to verify that the API caller holds the corresponding private key.
      - header - When the API is called, an X509 client certificate must be supplied in the specified HTTP header. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see Registering an application. If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

      Attention: Sending the client certificate in an HTTP header does not allow for cryptographic verification that the caller holds the corresponding private key. The only validation performed is a string comparison of the base64-encoded PEM file against the client certificate.
   f. If you select the tls-cert option, enable mTLS at the Gateway level.
      Enable mTLS by setting "Mutual authentication: Required" (or "Requested" if not all APIs use mTLS) in the TLS Server Profile that is specified for the API invocation endpoint in your gateway service configuration. The gateway service is configured in the Cloud Manager UI (requires cloud administrator permissions). For more information, see Registering a gateway service and TLS profiles overview.

      You can create a truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

      The following example cURL command uses a client-cert during SSL:

      ```
      **curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id: 1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
      ```

      Note: This feature is intended for the scenario where different applications are registered with different end certificates in the Developer Portal, which have the same intermediate or root CA issuer. The certificate passes Gateway-level mTLS if it matches the issuer available in the truststore, but allows access only to the API that matches the correct end certificate.
4. Click Add.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the **log** context variable, which populates the API event record on completion of the API execution; for more information, see API activity logging context variables.

Note:
Activity logging that calls for logging of analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description

Field label	Description
Success Content	Defines the type of content to be logged when the operation is successful. • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is activity.
Error Content	Indicates what content to log when an error occurs. • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is payload.
Preserved request header	Click Add to specify customized request headers to preserve for logging to analytics.
Preserved response header	Click Add to specify customized response headers to preserve for logging to analytics.

4. Click Save to save your changes.

Configuring v5 compatibility options

You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower API Gateway.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Compatibility.
3. Select from the following options as required:
   - Return V5 Responses: Return v5-compatible responses, such as OAuth and client security error responses.
   - Copy Id Headers to Message: Copy security headers to the message context for retrieval by the invoke back-end service.
   - Enforce Required Params: Check the request for required parameters during API routing. When enabled, a request that does not provide a required parameter is rejected.
   - Allow Chunked Uploads: Allow the assembly `invoke` policy to send documents to the server with `Transfer-Encoding: chunked`. This setting applies only to the `invoke` 1.5.0 wrapper policy deployed from API Connect using the migration utility. It does not apply to the native API Gateway assembly `invoke` policy.
4. Use the YAML source to set the following options as required:

Option	Valid values	Description
`allow-trailing-slash`	`true / false`	Specify whether to allow the request URL to end with a / character. The default value is `false`.
`get-raw-body-value`	`true / false`	Specify whether the GatewayScript `apim.getvariable()` API returns the raw body instead of parsing. This setting applies only when the context is other than `message`. The default value is `false`.
`request-headers`	`true / false`	Specify whether to populate v5-compatible headers such as `X-Client-IP` and `X-Global-Transaction-ID` in the `request.headers` context variable. The default value is `false`.

5. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
In the Policies view of IBM® API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
  The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

- **Adding elements to your assembly**
  Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.
- **Handling errors in the assembly**
  Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes the following options:

- Palette - lists the available elements in the assembly flow.
- Canvas - used to arrange and visualize the elements in the assembly.
- Property sheet - used to configure the elements in the assembly.

The palette

The palette is a list of different elements that you can include in your assembly. To view the palette, click the plus icon ⊕ on the canvas. You can use the Rotate icon ⟳ to rotate the palette as you prefer. To maximize and minimize the palette view, click the Maximize and Minimize icons.

You can release the palette by clicking the Close icon ✕.

The canvas

You can use the canvas to create a graphical representation of the assembly flow. To add an element to the assembly flow from the palette, click the plus icon ⊕ at the appropriate location on the canvas and select the required element from the available list. To delete an element from the canvas, hover over the element and click the Delete icon 🗑.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.
API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon ⛶.

The property sheet

When you select an element in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element that you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon ✕.

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can be branched, thrown, and caught according to the policies available. The message context flows through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting
: Before the assembly is executed, security and then rate limits are enforced.
First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence
: The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when **`if`** and **`operation-switch`** logic constructs are used, or for the remaining assembly to be ignored when a **`throw`** policy is executed.
The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and at the end of the API call, the message is used as the response.

The request context contains the information that is sent by the API caller and varies with the type of operation called as well as the configuration of that operation. For example, a GET operation can never have a populated **`request.body`**, and you can configure an operation to have **`request.parameters`** (query parameters).
The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts
: Because the message can be overwritten, it is useful to create and reference new contexts where possible so that they are saved and reused during the API call.

- Use the **`map`** policy to overwrite the message context when you need to execute a policy that only acts on the message.
- Use the request context when you want to use the original request made to the API.
- Use the **`map`**, **`invoke`**, and **`proxy`** policies to create new contexts when you want to save your message.

Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

For example, **invoke** is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a **validate** policy, and a **map** policy then saves the message as a new context, ready for a second **invoke** policy to overwrite the message without losing the first **invoke** policy's output.

You can also access contexts outside of the message or your custom contexts, but these contexts cannot be written to. For a list of contexts, see API Connect context variables.

Branches and catches

Using logic constructs, such as **operation-switch** or **if**, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.

When a catch is triggered, either by an error occurring during the execution of a policy or because a **throw** policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

- API Connect context variables

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see execute OpenAPI extension for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see The assembly editor.

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.
   Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version present on the gateway.
   a. Select the Gateway tab, then click Policies in the navigation pane.
   b. Click the plus icon ⊕ at the appropriate location on the canvas to view the palette that lists the available elements.
   c. Select the element that you want to add from the palette to the canvas by clicking it.
      Note:
      - Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
      - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
   d. Add and edit the element properties by clicking the element and using the property sheet.
      For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see API policies and logic constructs. For information about the properties of logic constructs, see Logic Constructs.
   e. Specify a version for the policy.
      To add a version, click the Source icon </>, and complete the **version** section of the policy YAML. For example:

```
execute:
  - invoke:
      version: 2.2.0
      title: invoke
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see execute OpenAPI extension.

4. Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a **throw** element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon if one is displayed.
   The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
   Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, use the Select errors field and select the appropriate error.
9. Optional: To remove an error case from a catch, clear the corresponding checkbox from the Select errors drop-down. To clear all the error cases from a catch, click the cross corresponding to the total number of error cases in the Select errors field.
10. Optional: To change the precedence of your catches, use the Move up or Move down icons.
    If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch from the palette, click the plus icon at the appropriate location in the assembly flow. Select an element that you want to apply to the catch by clicking it.
12. Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the **Invoke** policy in your assembly. Otherwise, if the error occurs during the execution of the **Invoke** policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an **Invoke** policy, see Invoke.

For details of all the errors that can be returned by the assembly and are available to the catch function, see Error cases supported by assembly catches.

Specifying the gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.
DataPower Gateway (v5 compatible) has been available with IBM® API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you create a new API definition, or import an API definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new API definition

Gateway Service enablement in Sandbox Catalog	Default gateway type for new API definition
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import an API definition that already has a gateway type configured, that gateway type is retained.
Note that when you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see execute.

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see invoke.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Click the title of the API you want to update.
3. Select the Gateway tab, then click Gateway and portal settings.
4. Select the type:
   - datapower-gateway for the DataPower Gateway (v5 compatible)
   - datapower-api-gateway for the DataPower API Gateway.

   Note: The Gateway Type selection is not applicable if the Enforced option is disabled, because an unenforced API is not managed on an API Connect gateway.
5. Click Save to retain the changes.
6. In the navigation pane, select Policies to ensure that your API uses policies that are supported by the gateway type you selected.

   Policies in an existing API that are not supported by the new gateway type are grayed out and flagged with a red exclamation point: .

   Some policies are supported by only one gateway type. Some policies are supported by both gateway types, but require a different version of the policy for each gateway type.

Related tasks

- Converting an API definition for deployment to the DataPower API Gateway

Converting an API definition for deployment to the DataPower API Gateway

IBM® API Connect provides two gateway types, DataPower® Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.
DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

To convert an API for deployment to the DataPower API Gateway, you must, as a minimum, change the gateway type setting on the API definition, and ensure that each policy and policy version in the API are supported by the DataPower API Gateway; DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

In addition, depending on the specific policies in your API assembly, some policies might require modification to adapt them for use with the DataPower API Gateway.

The following procedure provides instructions for converting your API definition:

Procedure

1. Set the gateway type for the API to DataPower API Gateway, and ensure policy type and version compatibility. For details, see Specifying the gateway type for an API definition.
2. Refer to the DataPower API Gateway porting notes for detailed instructions on how to convert your API definition.

Modifying a GraphQL schema

For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To open the GraphQL schema editor for a GraphQL API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the GraphQL Schema tab.

What to do next

For full details on how to use the editor, see Using the GraphQL schema editor.

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.

About this task

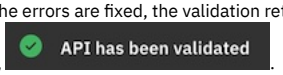
When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate > With specifications. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.
Note:

- OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see Staging an API or Publishing an API.
- You can also validate your API document by using governance rulesets. For more information, see Validating an API or product document by using the governance service.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.



1. Open the required API for editing, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
2. Click Validate > With specifications from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

   For example, 

   .
4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form  view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

   For example, 

   .

Validating an API or product document by using the governance service

How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. For more information, see Enabling governance on Kubernetes for more information. If governance is enabled in your deployment, the Governance icon is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

The governance service is available to all user roles.

The governance service has the following limitations:

- It does not support de-referencing, which means it does not automatically introspect referenced definitions within an API. However, you can explicitly validate referenced objects using custom rules as needed to ensure compliance with your API standards.
- The following OpenAPI Specification (OAS) rules are not enabled in governance service to prevent false positive errors:
  - oas2-unused-definition
  - oas3-unused-component

Tip: Before using the governance service to validate any API documents, you should first run Validate > With specifications to validate the OpenAPI YAML source. For more information, see Validating the OpenAPI YAML source.

About this task

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API and product development process. The service contains the following types of rulesets:

API
: Rulesets to validate your API documents.

  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
  - Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product
: Rulesets to validate your product documents. Note that the validation scan of products looks only at the product yaml; it does not include the scanning of any API documents that the product refers to.

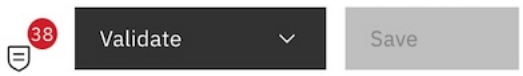
  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
  - Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

You can create your own provider organization rulesets to validate your Swagger, OpenAPI, AsyncAPI, and product documents against, or use the global rulesets that are provided for your organization. For more information about configuring rulesets, see Configuring governance in the API Manager.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

You can complete the instructions that are in this task by using the API Manager UI, or by using API Designer when the UI is online, and is connected to a cloud instance that has the governance microservice enabled on it. You can also use the toolkit CLI; for details see Validating an API or product document by using the toolkit CLI.

The following validation scan methods are available:



- Validate an API document from within an API
- Validate a product document from within a product
- Validate one or more API or product documents from within the Governance section
- Validate one or more published API or product documents from within a catalog or space

Procedure

- To validate an API document from within the API, complete the following steps.
  1. Open the required API for validating, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
  2. Click Validate > With rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your API document against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The API can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The API Design page is displayed.
     If validation errors were found during the scan, the ruleset status icon in the header menu bar displays the number of errors found, for example:

You can click on the ruleset status icon to see a detailed list of the errors, and their location in the YAML. You can also then click on an individual error to navigate directly to the relevant section in the API.

- To validate a product document from within the product, complete the following steps.
  1. Open the required product for validating, by clicking on the title of the product in the Products tab of the Develop page.
  2. Click Validate with rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your product document against, and click Next.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The product can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The product Design page is displayed.
- To validate one or more draft API or product documents from within the Governance section, complete the following steps.
  1. In the side menu bar, click  Governance.
     The Governance page is displayed.
  2. Click the Rulesets tab.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.
- To validate one or more published API or product documents from within a catalog or space, complete the following steps.
  1. Select the catalog or space that you want to run the validation in, and then select Governance from the menu bar.
  2. Select Rulesets.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.

Results

Your API or product document is validated against one or more rulesets.

What to do next

You can use the results of the validation to help you improve your API or product document. You can also use the results to help you edit the rulesets, and create new rulesets; see Configuring governance in the API Manager for more information.
You can also run validation scans on a catalog or space, to check one or more of the API documents that it contains. For more information, see Scanning your catalogs and spaces.

- **Validating an API or product document by using the toolkit CLI**
  How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

Related information

- The governance ruleset lifecycle

Validating an API or product document by using the toolkit CLI

How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

About

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your API or product documents. You can also

validate an API or product document by using the API Manager and the API Designer UIs. For more information about validation scanning, see Validating an API or product document by using the governance service.

The following validation scan methods are available by using the toolkit CLI:

- Validate a single API or product document that is stored locally
- Validate one or more API or product documents that are stored on the management server

Validate a single API or product document that is stored locally

To run a validation scan on a single API or product document against one or more rulesets, complete the following steps. The document must be stored locally.

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server platform_api_host_name --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Run the **compliance:validate** toolkit command in `governance` mode.

   ```
   apic --mode governance compliance:validate --org <target_org> --server <platform_api_host_name> --rulesets
   <ruleset_name_1>,<ruleset_name_2> API_OR_PRODUCT_FILE
   ```

   where:
   - `<target_org>` is the name of the provider organization that owns the APIs to be validated.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `<ruleset_name_1>,<ruleset_name_2>` is a comma-delimited list specifying the names of the rulesets to be applied to the API or product. (Specify each ruleset name; do not use the ruleset IDs.)
   - `API_OR_PRODUCT_FILE` is the path and file name of the document to be validated.

Validate one or more APIs or products that are stored on the management server

This operation runs a validation scan on all of the draft APIs, or all of the products, that are listed in the `COMPLIANCE_REQUEST_FILE`. You can scan only APIs, or only products, at any one time. The APIs must be stored as draft APIs in your provider organization.

1. Create a JSON `COMPLIANCE_REQUEST_FILE` that specifies the rulesets to use during validation, and the location of either the draft APIs or the products that you want to scan. The file can contain URLs only for APIs, or only for products; you cannot list both API and product URLs in the same file.
   The following example shows a configuration file that specifies two draft APIs, and two rulesets. In the `spectral-oas` ruleset, the `info-contact` rule is disabled and will be ignored during validation.

   ```
   {
     "apiUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/a08898fe-b422-41d3-
   b058-c3280d632e93","https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/26692eab-f43b-
   4af3-985c-2deaa401eb7f"],
     "config" : {
       "rulesets": [
         {
           "rulesetName": "spectral-oas",
           "disabled": ["info-contact"]
         },
         {
           "rulesetName": "spectral-owasp",
           "disabled": []
         }
         ]
    }
   }
   ```

   The following example shows a configuration file that specifies one product document.

   ```
   {
     "productUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-product/a07968fe-b422-
   41d3-b058-c3280d632e93"],
     "config" : {
       "rulesets": [
         {
   ```

```
        "rulesetName": "product-info",
        "disabled": ["subscribe"]
      },
      {
        "rulesetName": "product-rate",
        "disabled": []
      }
      ]
 }
}
```

Where:

- **apiUrls** is a comma-delimited list of API URLs. Each URL specifies the location of the draft APIs in a particular provider organization.
- **productUrls** is a comma-delimited list of product URLs. Each URL specifies the location of the product document in a particular provider organization.
- **rulesetName** is a list of rulesets to be applied to the APIs or products during validation.
  For each ruleset in the list, you can optionally add the **disabled** property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization. See Step 1 for details.
3. Run the **compliance:validate_all** toolkit command in **governance** mode.

```
apic --mode governance compliance:validate_all --org <target_org> --server <platform_api_host_name>
COMPLIANCE_REQUEST_FILE
```

where:

- ***<target_org>*** is the name of the provider organization that owns catalog containing the APIs to be validated.
- ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
- ***COMPLIANCE_REQUEST_FILE*** is the path and file name of the configuration file that lists the API or product documents, and the rulesets to be used during the validation (for example, validate-apis.json).

Editing an OpenAPI 3.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
  1. In the navigation pane, click  Develop, then select the APIs tab.
  2. Click the title of the API version that you want to work with.

- **OpenAPI 3.0 support in IBM API Connect**
  IBM API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.
- **Specifying API metadata**
  API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- **Defining servers for an API**
  Server definitions in an API provide information for connecting to target servers.
- **Enforcing security requirements on an API**
  To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.
- **Specifying external documentation for an API**
  You can reference an external resource for extended documentation for an API.
- **Adding tags to an API**
  You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Defining Paths for an API**
  A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.
- **Defining components for an API**
  Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.
- **Specifying gateway and portal settings**
  Define general configuration settings for your API.
- **Defining target services for an API**
  A target service defines a web service that you want to use in your API definition.

- **Setting API properties**
  In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.
- **Configuring application authentication for an API**
  Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.
- **Configuring activity logging**
  You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.
- **Including elements in your API assembly**
  An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- **Validating the OpenAPI YAML source**
  How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.
- **Validating an API or product document by using the governance service**
  How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

OpenAPI 3.0 support in IBM API Connect

IBM® API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.

Overview

A Product can contain any combination of OpenAPI 2.0 and OpenAPI 3.0 APIs. When you publish a Product that contains an OpenAPI 3.0 API, that API is validated to ensure that it is syntactically correct, and that references to configuration resources and policies resolve correctly, in the same way that OpenAPI 2.0 APIs are validated.

You can also validate OpenAPI 3.0 APIs in your local file system by using the **`apic validate`** command provided by the developer toolkit CLI; for details, see Validating the YAML or JSON definition of an API or Product.

If you retrieve an API object by using the developer toolkit CLI or the API Connect REST APIs, there is an **`oai_version`** property that defines which OpenAPI version the API represents.

There is no OpenAPI 3.0 API support with the DataPower® Gateway (v5 compatible); OpenAPI 3.0 API support is provided by the DataPower API Gateway **only**.

Limitations

The limitations to the OpenAPI 3.0 support in API Connect are as follows:

User interface limitations

- Some aspects of the OpenAPI 3.0 specification are not currently supported by the user interface. In such circumstances, use the OpenAPI source directly.
- Validation errors that are identified locally are reflected in the API editor header almost immediately. However, some validation errors can be identified only by the API Manager backend and are not reflected until the API is saved; this means that, on saving an API, some validation errors might appear or disappear.
- The user interface does not currently support referencing a request body component from the request body of an operation. If you want to reference a request body component, add the reference to the request body of the operation directly in the OpenAPI source:

  ```
  requestBody:
    $ref: '#/components/requestBodies/request_body_component_name'
  ```

  The reference **is** confirmed on the details page for the request body in the user interface however.
- If, in the API Designer user interface, you create and activate an API of the same name and version as one that has already been activated from the API Manager user interface, the Edit Rate Limit operation fails.

Limitations for APIs that are enforced by the DataPower API Gateway

To suppress the error message for the following limitations and publish the API, set the **`x-ibm-configuration.compatibility.suppress-limitation-errors`** property to **`true`** as shown in the following example:

```
compatibility:
  suppress-limitation-errors: true
```

Attention: Enabling **`suppress-limitation-errors`** merely disables the error messages so that the API can be published.

- General limitations.
  - The **`servers`** array cannot contain more than one server.
  - The **`url`** entry in the **`servers`** array cannot contain **`variables`**.
  - The **`path`** objects cannot contain server object overrides.
  - There is no support for converting a WSDL defined SOAP service into an OpenAPI 3.0 API.
  - There is no support for callbacks or links, and APIs containing them will not be published.
  - The following constructs of Open API 3.0 are less commonly used, and are not supported:
    - **`allowEmptyValue`**
    - **`allowReserved`**
- Assembly policies.
  - All policies are supported.
  - JSON schema support is limited to Draft 4 and earlier. Therefore, the following policies are limited to those drafts:
    - **`gatewayscript`**
    - **`set-variable`**
    - **`switch`**
    - **`json-to-xml`**

        - `xml-to-json`
        - `parse`
        - `xslt`
        - `map`
        - `validate`

      For detailed information about the Draft 4 and earlier specifications, see https://json-schema.org/specification-links.html#draft-4.
    - Security.
        - The OpenID Connect (OIDC) security scheme is not supported.
        - The use of cookies in an API key is not supported.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General section, then click Info.
3. Provide the following information:
    - Title (required): The title of the API.
    - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
    - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see Creating a new version of an API definition.
    - Description: An optional description of the API. You can use CommonMark syntax for rich text representation.
    - Terms of Service: A URL to the Terms of Service for the API.
    - Contact Name: The identifying name of the contact person/organization.
    - Contact URL: A URL pointing to the contact information.
    - Contact Email: The email address of the contact person/organization.
    - License Name: The license name used for the API.
    - License URL: A URL to the license used for the API.
4. Click Save when done.

Defining servers for an API

Server definitions in an API provide information for connecting to target servers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand General then, if there are already one or more servers defined, expand Servers.
3. To create a new server definition, click the add icon ⊕ alongside Servers in the navigation pane. To edit an existing server definition, click the server URL in the navigation pane.
4. Provide the following information:

- Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

  `/my_basepath`

  For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
- Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
- Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
  - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
  - Provide the following information:
    - Server Variable Name (required).
    - Default value (required).
    - An optional rich text description. You can use CommonMark syntax for rich text representation.
    - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
  - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
  - If required, use the breadcrumb trail to return to your server definition for further editing.

5. If you are creating a new server definition, click Create.
   The server definition details are displayed for further editing as described in step 4.
6. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see Defining security scheme components.

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
   a. Click the add icon ⊕ alongside Security in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see Defining security scheme components.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see Defining OAuth2 security scheme components.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
4. To modify an existing security requirement, complete the following steps:

a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
c. Click Submit when done, then click Save.
d. To delete a security requirement, click the appropriate delete icon, click Delete to confirm, then click Save.
e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

What to do next

Fore more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

- **Enabling CORS support for an API**
  You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
  - The **`cors`** preflow policy configures the appropriate response headers.
  - The response headers are set.
- When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
- For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon.

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
   The CORS page opens.
3. Select Enable CORS.
4. Optional: Configure a CORS policy.
   Should you create a CORS policy? Review the following considerations:
   - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
     If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.
   - If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
     If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.
   - To configure a new CORS policy, complete the following steps:
     - Alongside CORS Policy, click Add.
     - To include the header **`Access-Control-Allow-Credentials: true`** in a response. select Allow Credentials. The **`Access-Control-Allow-Credentials`** response header tells browsers whether to expose the response to frontend JavaScript code when the request's credentials mode (**`Request.credentials`**) is set to **`include`**.
     - To append one or more of the following values to the **`Access-Control-Expose-Headers`** response header, select Expose headers, and select from the following options:
       - Predefined - The predefined value of the Gateway. This option is selected by default.
       - Backend - The value of **`Access-Control-Expose-Headers`** from the backend response.
       - Custom - A custom string.
     - Click Create.
     - Alongside Allowed Origins click Add.
     - Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.
   - To modify an existing CORS policy, click its Allowed Origins entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

   Example

The following example has three rules:

- Accept an Origin header of `https://example.com`, and return `Access-Control-Allow-Credentials: true` in the CORS response.
- Accept an Origin header of `http://domain.com`. No `Access-Control-Allow-Credentials` header will be returned in the response.
- Accept any of the following Origin headers:
  - `http://example2.com`
  - `http://example3.com`
  - `http://example4.com`

  No `Access-Control-Allow-Credentials` header will be returned in the response.

```
cors:
  enabled: true
  policy:
    -
      allow-origin:
        - 'https://example.com'
      allow-credentials: true
    -
      allow-origin:
        - 'http://domain.com'
    -
      allow-origin:
        - 'http://example2.com'
        - 'http://example3.com'
        - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
   a. Add the following headers to your HTTP responses:

   ```
   Access-Control-Allow-Origin: https://<portalhostname>
   Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
   ```

   Where `<portalhostname>` is your Developer Portal host name.
   b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

Important:

- If you implement your own CORS solution, you **must** disable the CORS option described in step 3
- CORS preflight requests are sent by using the HTTP `OPTIONS` method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the `OPTIONS` method for all APIs that will handle preflight requests; see Defining Paths for a REST API.
- `OPTIONS` requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see Defining rate limits for an API operation.

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General section, then click External Documentation.
3. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.

- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon ⊕ alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
   - Name (required): The name of the tag.
   - Description: An optional description of the tag. You can use CommonMark syntax for rich text representation.
   - External Documentation > URL (available when editing an existing tag): The URL for target documentation that describes this tag.
   - External Documentation > Description (available when editing an existing tag): An optional description of the target documentation.
5. If you are creating a new tag, click Create.
   The tag details are displayed for further editing as described in step 4.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The Path is appended to the server URL to form the full URL. For details on configuring servers, see Defining servers for an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon ⊕ alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
   - Path: A relative path to an individual endpoint.
     The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

     If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

     - * to indicate 0 or more occurrences
     - + to indicate 1 or more occurrences

     The + and * qualifiers can only be used at the end of the path.

     For example, the path:

     ```
     /petstore/{type}/{*category}
     ```

     matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

     ```
     /petstore/cats
     /petstore/cats/supplies
     /petstore/cats/supplies/health
     /petstore/cats/supplies/health/medicines
     /petstore/cats/supplies/health/medicines/a/b/c
     ```

   - Ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.
     The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

     ```
     #/paths/~1mypath
     ```

     The `~1` characters are used to escape the `/` character, which is being used literally in the path name rather than as a special character.
     A reference to a path in an external file called path_fragments.yaml would have the following format:

```
file://path_fragments.yaml/paths/~1mypath
```

- Summary: An optional summary, intended to apply to all operations in this path.
- Description: An optional description, intended to apply to all operations in this path. You can use CommonMark syntax for rich text representation.

5. If you are creating a new Path, click Create.
   The Path details are displayed for further editing as described in step 4.
6. Click Save when done.

- **Defining servers for a Path**
  Server definitions for a Path provide alternative target servers when calling the API at that Path.
- **Defining parameters for a Path**
  Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.
- **Defining operations for a Path**
  Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining servers for a Path

Server definitions for a Path provide alternative target servers when calling the API at that Path.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: It is unlikely that you will need to define servers for a Path because it applies only if the API operations are distributed across different gateway endpoints, and such a configuration is possible only if you are hosting your API operations on your own runtime endpoints outside of API Connect. For an API that is published to the DataPower API Gateway, all API operations are invoked on the same gateway service.
A server defined for a Path overrides any server defined for the parent API. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more servers defined for the Path, expand Servers.
4. To create a new server definition for the Path, click the add icon ⊕ alongside Servers under the Path in the navigation pane. To edit an existing server definition, click the server URL under the Path in the navigation pane.
5. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     ```
     /my_basepath
     ```

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
   - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
     - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
     - Provide the following information:
       - Server Variable Name (required).
       - Default value (required).
       - An optional rich text description. You can use CommonMark syntax for rich text representation.
       - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
     - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
     - If required, use the breadcrumb trail to return to your server definition for further editing.
6. If you are creating a new server definition, click Create.
   The path details are displayed for further editing as described in 5.
7. Click Save when done.

Defining parameters for a Path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Parameters.
4. You can either create a new parameter, or edit any existing parameter.
   - To create a parameter, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining operations for a Path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there are one or more operations, expand Operations.
4. To create an operation, click the add icon ⊕ alongside Operations under the Path in the navigation pane. To edit an existing operation, click the operation name under the Path in the navigation pane.
5. Provide the following information:
   - Verb: Select the operation type from the following options:
     - get
     - post
     - put
     - delete
     - options
     - head
     - patch
     - trace
   - Summary: A summary of what the operation does.
   - Description: A description of the operation behavior. You can use CommonMark syntax for rich text representation.
   - Operation ID: Unique string used to identify the operation. The id must be unique among all operations described in the API.
   - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
6. If you are creating a Path operation, click Create.
7. Click Save when done.

- **Adding tags to an operation**
  You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Specifying external documentation for an operation**
  You can referencing an external resource for extended documentation for an API operation.

- **Defining parameters for an operation**
  Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.
- **Defining the request body for an operation**
  A request body defines the structure of the body of an API request.
- **Defining responses for an operation**
  Responses define the HTTP status code and data returned in a response body and headers.
- **Enforcing security requirements on an operation**
  To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.
- **Defining servers for an operation**
  Server definitions for an API operation provide alternative target servers when calling that operation.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To add a new operation tag, click the add icon ⊕ alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
5. Provide the following information:
   - Name (required): The name of the tag.
6. If you are creating a new operation tag, click Create.
   The tag details are displayed for further editing as described in step 5.
7. Click Save when done.

Specifying external documentation for an operation

You can referencing an external resource for extended documentation for an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
5. Click Save when done.

Defining parameters for an operation

Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An operation parameter overrides a parameter of the same name defined on the parent Path; see Defining parameters for a Path.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter.
   - To create an operation parameter, click the add icon ⊕ alongside Parameter, then refer to Creating a parameter.
   - To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining the request body for an operation

A request body defines the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Note: The user interface doesn't currently support referencing a request body component from an operation. However, you can add the reference directly to the OpenAPI YAML source for your API definition, for example:

```
paths:
  /mypath:
    get:
          .
          .
          .
      requestBody:
        $ref: '#/components/requestBodies/my_requestbody_component'
          .
          .
          .
```

For information on request body components, see Defining request body components.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click requestBody.
4. Provide the following information:

- Description: An optional description of the request body. This could contain examples of use. You can use CommonMark syntax for rich text representation.
- Content: A content definition describes the content of the request body.
  To define a new content definition for the request body, click Add, then refer to Creating a content definition.

  To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

- Required: Determines if the request body is required in the request.

5. Click Save when done.

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.
4. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see Defining security scheme components.

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see Enforcing security requirements on an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
   a. Click the add icon ⊕ alongside the Security Requirements entry for the operation in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see Defining security scheme components.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see Defining OAuth2 security scheme components.

If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.

c. Click Create. The security scheme selections are shown; you can change them again before saving.
d. Click Submit when done.

5. To modify an existing security requirement, complete the following steps:
   a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon, click Delete to confirm, then click Save.
   e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.

Note: These settings completely override any security requirements defined on the parent API; see Enforcing security requirements on an API.

Defining servers for an operation

Server definitions for an API operation provide alternative target servers when calling that operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A server defined for an operation overrides any server defined for the parent API or Path. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there already one or more servers defined for the operation, expand Servers.
4. To create a new server definition for the operation, click the add icon alongside Servers under the operation in the navigation pane. To edit an existing server definition, click the server URL under the operation in the navigation pane.
5. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     `/my_basepath`

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
   - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
     - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
     - Provide the following information:
       - Server Variable Name (required).
       - Default value (required).
       - An optional rich text description. You can use CommonMark syntax for rich text representation.
       - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
     - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
     - If required, use the breadcrumb trail to return to your server definition for further editing.
6. If you are creating a new server definition, click Create.
   The path details are displayed for further editing as described in 5.
7. Click Save when done.

Defining components for an API

Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The following subtopics detail the various types of API component:

- **Defining schema components**
  Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- **Defining response components**
  Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.
- **Defining parameter components**
  Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.
- **Defining example components**
  An example component is a reusable example that you can add to an API to make the specification of your API clearer.
- **Defining request body components**
  A request body component is a reusable definition of the structure of the body of an API request.
- **Defining header components**
  A header component defines a reusable custom header that can be sent in an API request or returned in an API response.
- **Defining security scheme components**
  A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.
- **Defining link components**
  A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

Defining schema components

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

An API created in OpenAPI 3.0 includes a section where API payload definitions are defined. The payload definitions describe the structure of data transmitted in API requests and responses, utilizing a specialized JSON schema variant specific to OpenAPI. Each payload definition corresponds to a schema, which lists the expected data fields. These data fields are represented as properties within the schema and include a set of attributes that describe their type, permissible values, mandatory status, and other characteristics. Although numerous attributes are available, the majority of them are infrequently utilized.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a schema component, you reference it from elsewhere in your API definition. You can reference a schema from the following locations:

- An API Path parameter; see Defining parameters for a Path.
- An API operation parameter; see Defining parameters for an operation.
- The request body of an API operation; see Defining the request body for an operation.
- An API operation response; see Defining responses for an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more schemas components defined, expand Schemas.
3. You can create a new schema component, or edit any existing schema component.
   - To create a schema component, click the add icon ⊕ alongside Schemas, then refer to Creating a schema component.
   - To edit an existing schema component, click the schema component name in the navigation pane, then refer to Editing a schema component.

- **Creating a schema component**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
- **Editing a schema component**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating a schema component

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
Launch the schema creation window. For details of the areas in your API definition from where you can create a schema, see the following topics:

- Editing a content definition
- Editing a header
- Editing a parameter
- Defining schema components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. To create a schema definition, open the Componentselement and click the add icon ⊕ alongside Schema.
   The Add object wizard for a schema is displayed.
2. Provide the following information:
   -
     - Schema Name: If you are creating a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/schemas/Name`

     - Title: The schema title.
     - Type: The schema data type; select one of the following:
       - array
       - boolean
       - integer
       - number
       - object
       - string
3. Click Create.
   The schema details are displayed for further editing; see Editing a schema component.

Editing a schema component

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
Open the details form for a schema. For details of the areas in your API definition from where you can edit a schema, see the following topics:

- Editing a content definition
- Editing a header
- Editing a parameter
- Defining schema components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The table view presents the properties within a schema alongside their essential attributes, such as name, type, description, and required status. The secondary pop-up enables access for viewing and editing the more detailed and less commonly used attributes that are associated with each data field.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

You can configure the following schema settings:

- Schema Name: Available if you are editing a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/components/schemas/Name`

  To change the name, click the Source icon, change the value in the field, then click Save
- Optional: Title: The schema title.
- Optional: Type: The schema data type; select one of the following:
  -
    - array
    - boolean
    - integer
    - number
    - object
    - string

  Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon </> .
- Properties: The schema property. To add a property to the schema, click Add alongside the Properties section heading, complete the details and click Save.
- Additional schema settings dependent on the selected Type of property. To view and edit these schema settings, click the Options menu next to the property you want to view and select Details.
  - boolean: no type specific settings.
  - integer:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of an integer instance by this value must result in an integer.
    - Maximum: An integer instance must be less than or equal to this value.
    - Exclusive Maximum: An integer instance must be strictly less than this value.
    - Minimum: An integer instance must be greater than or equal to this value.
    - Exclusive Minimum: An integer instance must be strictly greater than this value.
  - number:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of a number instance by this value must result in an integer.
    - Maximum: A number instance must be less than or equal to this value.
    - Exclusive Maximum: A number instance must be strictly less than this value.
    - Minimum: A number instance must be greater than or equal to this value.
    - Exclusive Minimum: A number instance must be strictly greater than this value.
  - object:
    - Max Properties: The number of properties in an object instance must be less than or equal to this value.
    - Min Properties: The number of properties in an object instance must be greater than or equal to this value.
    - Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
  - string:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Pattern: A regular expression; a string instance must successfully match the expression.
    - Max Length: The maximum allowed number of characters in a string instance.
    - Min Length: The minimum allowed number of characters in a string instance.
    - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- General settings; select the required options:
  - Required: A property associated with this schema is required.
  - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
  - URL (required): The URL for the target documentation.
  - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
  - Name: Replaces the name of the element or attribute used for the described schema property.
  - Namespace: The URL of the namespace definition.
  - Prefix: The prefix to be used for the Name.
  - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
  - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/><book/></books>`) or unwrapped (`<book/> <book/>`).
- Click Save when done.

Example

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining response components

Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a response component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more response components defined, expand Responses.
3. You can create a new response component, or edit any existing response component.
   - To create a response component, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response component, click the response component name in the navigation pane, then refer to Editing a response.

- **Creating a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
- **Editing a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.
- **Creating a content definition**
  A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.
- **Editing a content definition**
  A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.
- **Creating an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information.
- **Editing an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the response; you can either create a response from scratch, or you can reference a response that is defined in a response component.
   - To create the response from scratch, provide the following information on the Definition tab:
     - Response name: A name for the response.
       If you are creating an operation response, this name is the HTTP status code.

       If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/responses/Name`

     - Description (required): A description of the response. You can use CommonMark syntax for rich text representation.
   - To reference a response that is defined in a response component, provide the following information on the Reference tab:
     - Response name: A name for the response.
       If you are creating an operation response, this name is the HTTP status code.

       If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/responses/Name`

     - Reference from: Select a reference to a response component.
2. Click Create.
   The response details are displayed for further editing; see Editing a response.

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Response name: A name for the response.
     If you are editing an operation response, this name is the HTTP status code.

     If you are editing a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/responses/Name`

     To change the name, click Update, then click Save when done.

   - Description: A description of the response. You can use CommonMark syntax for rich text representation.

- Headers: Headers define information that can be returned in the response.
  To define a new header for the response, click Add, then refer to Creating a header.

  To edit an existing header, click the header name, then refer to Editing a header.

- Content: A content definition describes the content of the response.
  To define a new content definition for the response, click Add, then refer to Creating a content definition.

  To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

- Links: Links describe how various values returned by one operation can be used as input for other operations.
  To define a new link for the response, click Add, then refer to Creating a link.

  To edit an existing link, click the link name, then refer to Editing a link.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating a content definition

A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.

Before you begin

Launch the content definition creation window. For details of the areas in your API definition from where you can create a content definition, see the following topics:

- Editing a header
- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
2. Click Create.
   The content definition details are displayed for further editing; see Editing a content definition.

Editing a content definition

A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.

Before you begin

Open the details form for a content definition. For details of the areas in your API definition from where you can edit a content definition, see the following topics:

- Editing a header
- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
   - Schema:
     To define a schema for the content definition, click Create, then refer to Creating a schema component.

     If the content definition already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
   - Examples:
     To add an example of the content, click Add, then refer to Creating an example.

     To edit an existing example, click the example name, then refer to Editing an example.

   - Encoding: An encoding definition describes how a specific schema property is encoded.
     To add an encoding definition, click Add, then refer to Creating an encoding definition.

     To edit an existing encoding definition, click the name, then refer to Editing an encoding definition.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information.

Before you begin

Launch the encoding definition creation window when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property.
   - Content Type: The Content-Type for encoding the property; for example, `application/xml; charset=utf-8`, `image/png, image/jpeg`.
   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type `array` or `object` generate separate properties for each value of the array or key-value pair of the map.

- Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.

2. Click Create.
   The encoding definition details are displayed for further editing; see Editing an encoding definition.

Editing an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information

Before you begin

Open the details form for an encoding definition when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property. To change the name, click Update, then click Save when done.
   - Content Type: The Content-Type for encoding the property; for example:
     - **`application/xml; charset=utf-8`**
     - **`image/png, image/jpeg`**.
   - Headers: A map allowing additional information to be provided as headers.
     To add a new header, click Add, then refer to Creating a header.

     To edit an existing header, click the header name, then refer to Editing a header.

   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type **`array`** or **`object`** generate separate properties for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameter components

Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a parameter component, you must reference it from elsewhere in your API definition.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.

- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more parameter components defined, expand Parameters.
3. You can create a new parameter component, or edit any existing parameter component.
   - To create a parameter component, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter component, click the parameter component name in the navigation pane, then refer to Editing a parameter.

- **Creating a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
- **Editing a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- Defining parameters for a Path
- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the parameter; you can either create a parameter from scratch, or you can reference a parameter that is defined in a parameter component.
   - To create the parameter from scratch, provide the following information on the Definition tab:
     - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/parameters/`*`Name`*

       Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
     - Parameter name (required): The name of the parameter.
     - Located In (required): The location of the parameter. Select one of the following options:
       - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
       - header: Custom headers that are expected as part of the request.
       - path: The parameter value is part of the operation's URL, enclosed in {}.
       - cookie: Used to pass a specific cookie value to the API.
     - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
     - Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
       - matrix: Path-style parameters defined by RFC 6570.
       - label: Label style parameters defined by RFC 6570.
       - simple: Simple style parameters defined by RFC 6570.

- form: Form style parameters defined by RFC 6570.
- spaceDelimited: Space separated array values.
- pipeDelimited: Pipe separated array values.
- deepObject: Provides a simple way of rendering nested objects using form parameters.

- Select the following options as required:
  - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
  - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
  - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
  - Explode: When selected, parameter values of type **`array`** or **`object`** generate separate parameters for each value of the array or key-value pair of the map.
  - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC 3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding. This property applies only if the Located In property is set to query.

- To reference a parameter that is defined in a parameter component, provide the following information on the Reference tab:
  - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

    `#/components/parameters/`*`Name`*

    Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
  - Parameter name (required, available if you are creating a path or operation parameter): The name of the parameter.
  - Reference from: Select a reference to a parameter component.

2. Click Create.
   The parameter details are displayed for further editing; see Editing a parameter.

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- Defining parameters for a Path
- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: Available if you are editing a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/parameters/`*`Name`*

     To change the name, click Update, then click Save when done.
   - Parameter name (required): The name of the parameter.
   - Located In (required): The location of the parameter. Select one of the following options:
     - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
       - DataPower checks the existence of a required query parameter and rejects requests that omit it.
       - DataPower checks the value of a query parameter, but if the parameter is omitted, it does not reject the request and instead generates an error log.
     - header: Custom headers that are expected as part of the request.
       - DataPower checks the existence of a required header parameter and rejects requests that omit it.
     - path: The parameter value is part of the operation's URL, enclosed in {}.
     - cookie: Used to pass a specific cookie value to the API.

        - DataPower does not support the cookie parameter.
    - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
    - Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
        - matrix: Path-style parameters defined by RFC6570.
        - label: Label style parameters defined by RFC6570.
        - simple: Simple style parameters defined by RFC6570.
        - form: Form style parameters defined by RFC6570.
        - spaceDelimited: Space separated array values.
        - pipeDelimited: Pipe separated array values.
        - deepObject: Provides a simple way of rendering nested objects using form parameters.
    - Select the following options as required:
        - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
        - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
        - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
        - Explode: When selected, parameter values of type **`array`** or **`object`** generate separate parameters for each value of the array or key-value pair of the map.
        - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding. This property applies only if the Located In property is set to query.
    - Schema:
      To define a schema for the parameter, click Create, then refer to Creating a schema component.

      If the parameter already has a schema defined, click View to edit the schema.

      For full details on editing a schema, see Editing a schema component.
      Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
    - Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining example components

An example component is a reusable example that you can add to an API to make the specification of your API clearer.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an example component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more example components defined, expand Examples.
3. You can create a new example component, or edit any existing example component.
    - To create an example component, click the add icon ⊕ alongside Examples, then refer to Creating an example.
    - To edit an existing example component, click the example component name in the navigation pane, then refer to Editing an example.

- **Creating an example**
  You add examples to an API to make the specification of your API clearer.
- **Editing an example**
  You add examples to an API to make the specification of your API clearer.

Creating an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Launch the example creation window. For details of the areas in your API definition from where you can create an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the example; you can either create an example from scratch, or you can reference an example that is defined in an example component.
   - To create the example from scratch, provide the following information on the Definition tab:
     - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.
   - To reference an example that is defined in an example component, provide the following information on the Reference tab:
     - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

     - Reference from: Select a reference to an example component.
2. Click Create.
   The example details are displayed for further editing; see Editing an example.

Editing an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Open the details form for an example. For details of the areas in your API definition from where you can edit an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   -
     - Example Name: If you are editing an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

       To change the name, click Update, then click Save when done.
     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - Example Value: A literal example.

- External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining request body components

A request body component is a reusable definition of the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more request body components defined, expand Request Bodies.
3. You can create a new request body component, or edit any existing request body component.
   - To create a request body component, click the add icon ⊕ alongside Request Bodies, then refer to Creating a request body.
   - To edit an existing request body component, click the request body component name in the navigation pane, then refer to Editing a request body.

- **Creating a request body**
  A request body defines the structure of the body of an API request.
- **Editing a request body**
  A request body defines the structure of the body of an API request.

Creating a request body

A request body defines the structure of the body of an API request.

Before you begin

Launch the request body creation window; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the request body; you can either create a request body from scratch, or you can reference a request body that is defined in a request body component.
   - To create the request body from scratch, provide the following information on the Definition tab:
     - Name: A name for the request body.
       If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/requestBodies/Name`

     - Description: A description of the request body. You can use CommonMark syntax for rich text representation.
     - Required: Determines if the request body is required in the request.
   - To reference a request body that is defined in a request body component, provide the following information on the Reference tab:

- Name: A name for the request body.
  If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/components/requestBodies/Name`

- Reference from: Select a reference to a request body component.

2. Click Create.
   The request body details are displayed for further editing; see Editing a request body.

Editing a request body

A request body defines the structure of the body of an API request.

Before you begin

Open the details form for a request body; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: A name for the request body.
     Available if you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/requestBodies/Name`

   - Description: A description of the request body. You can use CommonMark syntax for rich text representation.
   - Content: A content definition describes the content of the request body.
     To define a new content definition for the request body, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

   - Required: Determines if the request body is required in the request.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining header components

A header component defines a reusable custom header that can be sent in an API request or returned in an API response.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a header component, you must reference it from elsewhere in your API definition.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to `header`.
- A parameter can have various format styles, the style of a header is always `simple`.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more header components defined, expand Headers.
3. You can create a new header component, or edit any existing header component.
   - To create a header component, click the add icon ⊕ alongside Headers, then refer to Creating a header.
   - To edit an existing header component, click the header component name in the navigation pane, then refer to Editing a header.

- **Creating a header**
  A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.
- **Editing a header**
  A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Creating a header

A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.

Before you begin

Launch the header creation window. For details of the areas in your API definition from where you can create a header, see the following topics:

- Editing a response
- Editing an encoding definition
- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the header; you can either create a header from scratch, or you can reference a header that is defined in a header component.
   - To create the header from scratch, provide the following information on the Definition tab:
     - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/headers/`*`Name`*

     - Description: A description of the header. You can use CommonMark syntax for rich text representation.
     - Required: Determines whether this header is mandatory.
     - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
     - Allow Empty Value: The header can be sent with an empty value.
     - Explode: When selected, header values of type **`array`** or **`object`** generate separate headers for each value of the array or key-value pair of the map.
     - Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding.
   - To reference a header that is defined in a header component, provide the following information on the Reference tab:.
     - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/headers/`*`Name`*

     - Reference from: Select a reference to a header component.
2. Click Create.
   The header details are displayed for further editing; see Editing a header.

Editing a header

A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Before you begin

Open the details form for a header. For details of the areas in your API definition from where you can edit a header, see the following topics:

- Editing a response
- Editing an encoding definition
- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Header name: If you are editing a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/headers/`*`Name`*

     To change the name, click Update, then click Save when done.
   - Description: A description of the header. You can use CommonMark syntax for rich text representation.
   - Required: Determines whether this header is mandatory.
   - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
   - Allow Empty Value: The header can be sent with an empty value.
   - Explode: When selected, header values of type **`array`** or **`object`** generate separate headers for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
   - Schema:
     To define a schema for the header, click Create, then refer to Creating a schema component.

     If the header already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Content: A content definition describes the content of the header.
     To define a new content definition for the header, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining security scheme components

A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.
HTTP Bearer	Use an HTTP Bearer definition to specify how to validate the Bearer token that is required to call an API.

- **Defining basic authentication security scheme components**
  A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.
- **Defining API key security scheme components**
  An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- **Defining OAuth2 security scheme components**
  An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.
- **Defining OIDC security scheme components**
  An OIDC (OpenID Connect) security scheme defines settings for using your OIDC provider to control access to the API.
- **Defining an HTTP bearer security scheme**
  An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

Defining basic authentication security scheme components

A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see Working with user registries.

To create a user registry with Cloud Manager, see User registries overview.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM API Connect expects an authentication URL to return an HTTP `200 OK` response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see LDAP authentication.

For information about using an Authentication URL, see Authentication URL user registry.

To make use of a basic authentication security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create a basic authentication security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an existing basic authentication security scheme component, click the component name in the navigation pane.
4. If you are creating a new basic authentication security scheme component, you can either create it from scratch or you can reference another basic authentication security scheme component.
   To create a basic authentication security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Scheme Type (required): Select http.
   - Scheme (required): The name of the HTTP Authorization scheme to be used in the Authorization header as defined in RFC7235.
   - Authenticate using User Registry: The name of the user registry to be used for authentication. This is the value of the **name** field that was auto-generated when the user registry was created.
   - Bearer format: A hint to the client to identify how the bearer token is formatted. Bearer tokens are usually generated by an authorization server, so this information is primarily for documentation purposes.
   - Description: An optional description of the basic authentication security scheme. You can use CommonMark syntax for rich text representation.

   To reference another basic authentication security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another basic authentication security scheme component.
5. If you are creating a new basic authentication security scheme component, click Create.
   The security scheme component details are displayed for further editing.
6. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Fore more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

Defining API key security scheme components

An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme component to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security scheme components, one for each type of credentials.

To make use of an API key security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an API key security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an API key existing security scheme component, click the component name in the navigation pane.
4. If you are creating a new API key security scheme component, you can either create it from scratch or you can reference another API key security scheme component.
   To create an API key security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Scheme Type: Select apiKey.
   - Name: The name of the header, query or cookie parameter to be used. For a key of type client secret you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.

Note: The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a `set-variable` policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:

- In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

Table 1.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	$(request.headers.X-IBM-Client-Secret)

For more information on configuring a Set Variable policy, see Set Variable.

- In the Source tab, add a `set-variable` policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-IBM-Client-Id
            value: $(request.headers.X-IBM-Client-Id)
            type: string
          - set: message.headers.X-IBM-Client-Secret
            value: $(request.headers.X-IBM-Client-Secret)
            type: string
```

For more information on defining a `set-variable` policy in your OpenAPI source, see set-variable.

You should position the `set-variable` before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.

- Key Type: Select client_id or client_secret.
  Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.
  If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

  If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

- Located In: Select one of the following options, to specify how the credentials are sent:
  - header: The credentials are sent in the request header.
  - query: The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

  Note: If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see Client ID behavior in API key security definitions.
- Description: An optional description of the API key security scheme. You can use CommonMark syntax for rich text representation.

5. To reference another API key security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/`***`Security_Scheme_Name`***

   - Reference from: Select a reference to another API key security scheme component.
6. If you are creating a new API key security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

- **Client ID behavior in API key security definitions**
  How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.
Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.

Use case	Description of security requirement	V5 behavior	V10 behavior
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	• When Return V5 Responses compatibility option is off: 401 client ID is missing. • When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. For information about setting compatibility options, see Configuring v5 compatibility options.

Defining OAuth2 security scheme components

An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme component, you must:

1. Create an OAuth provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the OAuth instructions step in Creating and configuring Catalogs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an OAuth2 security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an existing OAuth2 security scheme component, click the component name in the navigation pane.
4. If you are creating a new OAuth2 security scheme component, you can either create it from scratch or you can reference another OAuth2 security scheme component.
   To create an OAuth2 security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/`***`Security_Scheme_Name`***

   - Security Definition Type: Select oauth2.
   - Flow: Select one or more of the following options:

- Implicit
- Resource Owner - Password
- Application
- Access Code

Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
If you selected Resource owner - JWT as the supported grant type when you created the OAuth provider, you must select Resource owner - Password as the Flow for this security scheme.

- OAuth Provider: The name of the OAuth provider to be used. This is the value of the **`name`** field that was auto-generated when the OAuth provider was created.
- Description: An optional description of the OAuth2 security scheme. You can use CommonMark syntax for rich text representation.

To reference another OAuth2 security scheme component, provide the following information on the Reference tab:

- Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/components/securitySchemes/`*`Security_Scheme_Name`*

- Reference from: Select a reference to another OAuth2 security scheme component.

5. If you are editing an existing OAuth2 security scheme component, provide the following information:
   - The URL endpoints (the applicable endpoints depend on the flow type):
     - Authorization URL
     - Refresh URL
     - Token URL

     Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.
   - Scopes:
     - To add a new scope, click Add. To edit an existing scope, click the options icon ⋮ alongside the required scope, then click Edit.
     - Provide the following information:
       - Scope: The scope identifier.
       - Description: An optional description of the scope. You can use CommonMark syntax for rich text representation.
6. If you are creating a new OAuth2 security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Defining OIDC security scheme components

An OIDC (OpenID Connect) security scheme defines settings for using your OIDC provider to control access to the API.

Before you begin

Before you can create an OIDC security scheme component, you must create a native OAuth provider and configure the OIDC settings for it.

1. Create an OIDC provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Configure the OIDC parameters for your native OAuth provider.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components > Security Schemes and then click ⊕ to add a new security scheme.
3. In the Add schema dialog box, provide the following settings before clicking Add:
   - Security Scheme Name (Key): provide a name for the new scheme.
   - Security Scheme Type: select openIdConnect
   - OpenID Connect URL: type the authorization endpoint URL for the OIDC provider.
4. On the OpenId Connect Security Scheme page, add information about the OIDC provider:
   - Type: select your OIDC provider from the list.
     The list only displays the native OAuth providers that are configured for OIDC with a discovery URL provided in the OpenIDConnect Discovery path field, and are enabled for the catalog that the API is configured to use.
   - OpenID Connect URL: When you select your provider, the URL is filled in for you with the discovery URL that was configured for the native OAuth provider.
5. Click Save.

Defining an HTTP bearer security scheme

An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

About this task

For information on the use of bearer tokens with OpenAPI 3 APIs, see Bearer Authentication in the OpenAPI 3 specification.

If an HTTP bearer token is found in the request, its value is stored within the context as **`api->security->bearer_token`**. If an external URL validation is invoked, any response with a status code of 200 is stored within the context as **`api->security->bearer_validation_response`**.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components > Security Schemes.
3. Click Add.
4. In the Add Object dialog box, provide the following information:
   - Security Scheme Name (Key) - Provide a descriptive name for the new scheme.
   - Security Scheme Type - Select http.
   - Scheme - Select Bearer.
   - Bearer Format - Select JWT.
   - Validation Method - Select a method. If you select external-url, provide the following additional information:
     - Validation Endpoint - Provide the URL of the server used for validation. To ensure a secure connect, the URL should use the **`https`** protocol.
     - TLS Profile name - If the validation endpoint uses the **`https`** protocol, select the name of the TLS client profile to use for a secure connection.
   - Description - Provide a description of the JWT scheme.
5. Click Create to create the new scheme.
6. Click Save in the page header.

Defining link components

A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a link component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more link components defined, expand Links.
3. You can create a new link component, or edit any existing link component.
   - To create a link component, click the add icon ⊕ alongside Links, then refer to Creating a link.
   - To edit an existing link component, click the link component name in the navigation pane, then refer to Editing a link.

- **Creating a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.
- **Editing a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Creating a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Launch the link creation window. For details of the areas in your API definition from where you can create a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the link; you can either create a link from scratch, or you can reference a link that is defined in a link component.
   - To create the link from scratch, provide the following information on the Definition tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/links/Name`

     - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
     - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
     - Description: A description of the link. You can use CommonMark syntax for rich text representation.
   - To reference a link that is defined in a link component, provide the following information on the Reference tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/links/Name`

     - Reference from: Select a reference to a link component.
2. Click Create.
   The link details are displayed for further editing; see Editing a link.

Editing a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Open the details form for a link. For details of the areas in your API definition from where you can edit a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: If you are editing a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/links/Name`

To change the name, click Update, then click Save when done.
- Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
- Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
- Parameters: A map representing parameters to pass to an operation as specified with Operation ID or identified via Operation Ref. The key is the parameter name to be used, whereas the value can be a constant or an expression to be evaluated and passed to the linked operation.
- Request Body: The request body to use when calling the target operation.
- Description: A description of the link. You can use CommonMark syntax for rich text representation.
- Server: A server to be used by the target operation. Provide the following information:
  - Server URL The specified URL is used to determine the full URL endpoint for the calling the API, according to any vanity endpoint configuration in the Catalog in which the API is published. For full details, see Configuring vanity endpoints for a Catalog.
  - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
  - Server Variables A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
    - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
    - Provide the following information:
      - Server Variable Name (required).
      - Default value (required).
      - An optional rich text description. You can use CommonMark syntax for rich text representation.
      - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
    - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
   - Phase: The phase of the lifecycle that your API is in; select one of the following options:
     - Realized (default) - The API is in the implementation phase.
     - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
     - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
   - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
     Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
   - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see Enabling CORS support for an API.
   - Target Services: Define web services that you want to use in your API definition. For details, see Defining target services for an API.
   - Enforced: Select this option to enforce the API by using the DataPower API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
   - Properties: Add properties that can be referenced in your API definition. For details, see Setting API properties.
   - Catalog Properties: Define property values that are specific to a particular Catalog. For details, see Defining Catalog specific property values.
   - Activity Log: Configure your logging preferences for the API activity that is stored in analytics. For details, see Configuring activity logging.
   - Exxtensions: Extensions added to the API to extend the OpenAPI specification. For details, see Adding an OpenAPI extension to an API.

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
   a. Click the add icon ⊕ alongside Target Services in the navigation pane.
   b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.
4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see API properties.
Note: Once defined, an API property is read only.
For information on how to reference a property in an API definition, see Variable references in API Connect.

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see Creating and configuring Catalogs. Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
   - To define a new API property, complete the following steps:
     - Click the add icon ⊕ alongside Properties in the navigation pane.
     - Provide the following information:
       - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the Name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
       - Value: A default value for the property. Leave blank if the property is to have a null vale by default.
       - Description: An optional description of the property. You can use CommonMark syntax for rich text representation.
       - Select Encoded if you want to hide the property values, or protect user passwords from casual observance.

Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.

- Click Create.

- To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.

4. Click Save to save your changes.

What to do next

Optionally, define a value for the property that is specific to a particular Catalog; see Defining Catalog specific property values.

- **Defining Catalog specific property values**
  For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see Setting API properties.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
   - To define a new Catalog specific property value, complete the following steps:
     - Click the add icon ⊕ alongside Catalog Properties in the navigation pane.
     - Type the Catalog Name exactly as it displays in the **name** field for the selected Catalog.
       Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
     - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
     - Alongside Property Overrides, click Add.
     - Provide the following information:
       - Property Name: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see Setting API properties.
       - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
     - Click Create.
   - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring application authentication for an API

Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.

About this task

Note: This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Enable application authentication, as follows:
   Note: To identify the application, you must enable a security requirement of type **clientID**.
   a. Select the Gateway tab, expand Gateway and portal settings, then click Application Authentication.
   b. Select Certificate.
3. Specify how the client certificate is sent to the gateway, as follows:
   a. In the navigation pane, click Application Authentication Source.
      Any existing application authentication source definitions are listed.
   b. Alongside Application Authentication Source, click Add.
   c. Select the required option, header or tls-cert.
      You can separately add one or both of the options.
      When the API is called, an X509 client certificate must be supplied, either in the specified HTTP header, or as a TLS client certificate from TLS mutual authentication. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see Registering an application.

      The Gateway service to which the API is published can be configured to use TLS mutual authentication to secure API calls made to that Gateway service; for details, see Configuring the initial Gateway service. If you select this option, continue to sub-step d.

      If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

   d. If you select the tls-cert option, enable mTLS at the Gateway level.
      Enable mTLS by setting "Mutual authentication: Required" (or "Requested" if not all APIs use mTLS) in the TLS Server Profile that is specified for the API invocation endpoint in your gateway service configuration. The gateway service is configured in the Cloud Manager UI (requires cloud administrator permissions). For more information, see Registering a gateway service and TLS profiles overview.

      You can create a truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

      The following example cURL command uses a client-cert during SSL:

      ```
      **curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id:
      1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
      ```

      Note: This feature is intended for the scenario where different applications are registered with different end certificates in the Developer Portal, which have the same intermediate or root CA issuer. The certificate passes Gateway-level mTLS if it matches the issuer available in the truststore, but allows access only to the API that matches the correct end certificate.
4. Click Create.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the **log** context variable, which populates the API event record on completion of the API execution; for more information, see API activity logging context variables.

Note:
Activity logging that calls for logging of analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description

Field label	Description
Success Content	Defines the type of content to be logged when the operation is successful. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is activity.
Error Content	Indicates what content to log when an error occurs. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is payload.

4. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

In the Policies view of IBM API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
  The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.
- **Adding elements to your assembly**
  Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.
- **Handling errors in the assembly**
  Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM API Connect.

You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes the following options:

- Palette - lists the available elements in the assembly flow.
- Canvas - used to arrange and visualize the elements in the assembly.
- Property sheet - used to configure the elements in the assembly.

The palette

The palette is a list of different elements that you can include in your assembly. To view the palette, click the plus icon ⊕ on the canvas. You can use the Rotate icon ⟲ to rotate the palette as you prefer. To maximize and minimize the palette view, click the Maximize and Minimize icons.

You can release the palette by clicking the Close icon ✕.

The canvas

You can use the canvas to create a graphical representation of the assembly flow. To add an element to the assembly flow from the palette, click the plus icon ⊕ at the appropriate location on the canvas and select the required element from the available list. To delete an element from the canvas, hover over the element and click the Delete icon 🗑.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.

API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon  .

The property sheet

When you select an element that is in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon ×.

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can be branched, thrown, and caught according to the policies available. The message context flows through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting
: Before the assembly is executed, security and then rate limits are enforced.
First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

  If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence
: The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when **`if`** and **`operation-switch`** logic constructs are used, or for the remaining assembly to be ignored when a **`throw`** policy is executed.
The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and, at the end of the API call, the message is used as the response.

  The request context contains the information that is sent by the API caller and varies with the type of operation called and the configuration of that operation. For example, a GET operation can never have a populated **`request.body`**, and you can configure an operation to have **`request.parameters`** (query parameters).
The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts
: Because the message can be overwritten, it is useful to create and reference new contexts where possible so that they are saved and reused during the API call.

  - Use the **`map`** policy to overwrite the message context when you need to execute a policy that only acts on the message.
  - Use the request context when you want to use the original request made to the API.
  - Use the **`map`**, **`invoke`**, and **`proxy`** policies to create new contexts when you want to save your message.
    Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

  For example, **`invoke`** is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a **`validate`** policy, and a **`map`** policy then saves the message as a new context, ready for a second **`invoke`** policy to overwrite the message without losing the first **`invoke`** policy's output.

  You can also access contexts outside of the message or your custom contexts, but these contexts cannot be written to. For a list of contexts, see API Connect context variables.

Branches and catches
: Using logic constructs, such as **`operation-switch`** or **`if`**, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.
When a catch is triggered, either by an error occurring during the execution of a policy, or because a **`throw`** policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

- API Connect context variables

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see execute OpenAPI extension for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see The assembly editor.

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.
   Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version that is present on the gateway.
   a. Select the Gateway tab, then click Policies in the navigation pane.
   b. Click the plus icon ⊕ at the appropriate location on the canvas to view the palette that lists the available elements.
   c. Select the element that you want to add from the palette to the canvas by clicking it.
      Note:
      - Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
      - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
   d. Add and edit properties of the element by clicking the element and using the property sheet.
      For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see API policies and logic constructs. For information about the properties of logic constructs, see Logic Constructs.
   e. Specify a version for the policy.
      To add a version, click the Source icon </>, and complete the **version** section of the policy YAML. For example:

      ```
      execute:
        - invoke:
            version: 2.2.0
            title: invoke
      ...
      ```

      You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see execute OpenAPI extension.
4. Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a **throw** element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and

each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon if one is displayed.
   The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
   Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, use the Select errors field to select the appropriate error.
9. Optional: To remove an error case from a catch, clear the corresponding checkbox from the Select errors drop-down. To clear all the error cases from a catch, click the cross corresponding to the total number of error cases in the Select errors field.
10. Optional: To change the precedence of your catches, use the Move up or Move down icons.
    If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch from the palette, click the plus icon at the appropriate location in the assembly flow. Select an element that you want to apply to the catch by clicking it.
12. Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the **`Invoke`** policy in your assembly. Otherwise, if the error occurs during the execution of the **`Invoke`** policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an **`Invoke`** policy, see Invoke.

For details of all the errors that can be returned by the assembly and are available to the catch function, see Error cases supported by assembly catches.

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.

About this task

When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate > With specifications. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.
Note:

- OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see Staging an API or Publishing an API.
- You can also validate your API document by using governance rulesets. For more information, see Validating an API or product document by using the governance service.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.

1. Open the required API for editing, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
2. Click Validate > With specifications from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

   For example, 

   .
4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

   For example, 

   .

Validating an API or product document by using the governance service

How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. For more information, see Enabling governance on Kubernetes for more information. If governance is enabled in your deployment, the Governance icon  is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

The governance service is available to all user roles.

The governance service has the following limitations:

- It does not support de-referencing, which means it does not automatically introspect referenced definitions within an API. However, you can explicitly validate referenced objects using custom rules as needed to ensure compliance with your API standards.
- The following OpenAPI Specification (OAS) rules are not enabled in governance service to prevent false positive errors:
  - oas2-unused-definition
  - oas3-unused-component

Tip: Before using the governance service to validate any API documents, you should first run Validate > With specifications to validate the OpenAPI YAML source. For more information, see Validating the OpenAPI YAML source.

About this task

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API and product development process. The service contains the following types of rulesets:

API
: Rulesets to validate your API documents.

  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
  - Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product
: Rulesets to validate your product documents. Note that the validation scan of products looks only at the product yaml; it does not include the scanning of any API documents that the product refers to.

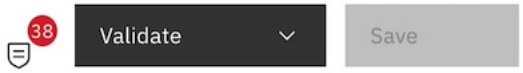
  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
  - Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

You can create your own provider organization rulesets to validate your Swagger, OpenAPI, AsyncAPI, and product documents against, or use the global rulesets that are provided for your organization. For more information about configuring rulesets, see Configuring governance in the API Manager.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

You can complete the instructions that are in this task by using the API Manager UI, or by using API Designer when the UI is online, and is connected to a cloud instance that has the governance microservice enabled on it. You can also use the toolkit CLI; for details see Validating an API or product document by using the toolkit CLI.

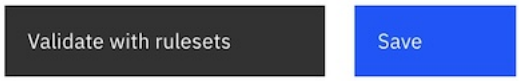
The following validation scan methods are available:



- Validate an API document from within an API
- Validate a product document from within a product
- Validate one or more API or product documents from within the Governance section
- Validate one or more published API or product documents from within a catalog or space

Procedure

- To validate an API document from within the API, complete the following steps.
  1. Open the required API for validating, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
  2. Click Validate > With rulesets from the menu bar in the header.



3. Select the rulesets that you want to validate your API document against, and click Next.
   If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
5. Click Validate.
   If any validation errors are found, a scorecard is displayed showing the results of the validation. The API can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
6. Optional: You can click Download to download the results of the validation into a .csv file.
7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
8. Click Done when finished.
   The API Design page is displayed.
   If validation errors were found during the scan, the ruleset status icon in the header menu bar displays the number of errors found, for example:

   You can click on the ruleset status icon to see a detailed list of the errors, and their location in the YAML. You can also then click on an individual error to navigate directly to the relevant section in the API.

- To validate a product document from within the product, complete the following steps.
  1. Open the required product for validating, by clicking on the title of the product in the Products tab of the Develop page.
  2. Click Validate with rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your product document against, and click Next.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The product can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The product Design page is displayed.
- To validate one or more draft API or product documents from within the Governance section, complete the following steps.
  1. In the side menu bar, click  Governance.
     The Governance page is displayed.
  2. Click the Rulesets tab.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.
- To validate one or more published API or product documents from within a catalog or space, complete the following steps.
  1. Select the catalog or space that you want to run the validation in, and then select Governance from the menu bar.
  2. Select Rulesets.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.

Results

Your API or product document is validated against one or more rulesets.

What to do next

You can use the results of the validation to help you improve your API or product document. You can also use the results to help you edit the rulesets, and create new rulesets; see Configuring governance in the API Manager for more information.
You can also run validation scans on a catalog or space, to check one or more of the API documents that it contains. For more information, see Scanning your catalogs and spaces.

  How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

Related information

- The governance ruleset lifecycle

Validating an API or product document by using the toolkit CLI

How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

About

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your API or product documents. You can also validate an API or product document by using the API Manager and the API Designer UIs. For more information about validation scanning, see Validating an API or product document by using the governance service.

The following validation scan methods are available by using the toolkit CLI:

- Validate a single API or product document that is stored locally
- Validate one or more API or product documents that are stored on the management server

Validate a single API or product document that is stored locally

To run a validation scan on a single API or product document against one or more rulesets, complete the following steps. The document must be stored locally.

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server platform_api_host_name --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Run the **compliance:validate** toolkit command in `governance` mode.

   ```
   apic --mode governance compliance:validate --org <target_org> --server <platform_api_host_name> --rulesets
   <ruleset_name_1>,<ruleset_name_2> API_OR_PRODUCT_FILE
   ```

   where:
   - *`<target_org>`* is the name of the provider organization that owns the APIs to be validated.
   - *`<platform_api_host_name>`* is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - *`<ruleset_name_1>,<ruleset_name_2>`* is a comma-delimited list specifying the names of the rulesets to be applied to the API or product. (Specify each ruleset name; do not use the ruleset IDs.)
   - `API_OR_PRODUCT_FILE` is the path and file name of the document to be validated.

Validate one or more APIs or products that are stored on the management server

This operation runs a validation scan on all of the draft APIs, or all of the products, that are listed in the `COMPLIANCE_REQUEST_FILE`. You can scan only APIs, or only products, at any one time. The APIs must be stored as draft APIs in your provider organization.

1. Create a JSON `COMPLIANCE_REQUEST_FILE` that specifies the rulesets to use during validation, and the location of either the draft APIs or the products that you want to scan. The file can contain URLs only for APIs, or only for products; you cannot list both API and product URLs in the same file.
   The following example shows a configuration file that specifies two draft APIs, and two rulesets. In the `spectral-oas` ruleset, the `info-contact` rule is disabled and will be ignored during validation.

   ```
   {
     "apiUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/a08898fe-b422-41d3-
   b058-c3280d632e93","https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/26692eab-f43b-
   ```

```
4af3-985c-2deaa401eb7f"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "spectral-oas",
        "disabled": ["info-contact"]
      },
      {
        "rulesetName": "spectral-owasp",
        "disabled": []
      }
      ]
 }
}
```

The following example shows a configuration file that specifies one product document.

```
{
  "productUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-product/a07968fe-b422-
41d3-b058-c3280d632e93"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "product-info",
        "disabled": ["subscribe"]
      },
      {
        "rulesetName": "product-rate",
        "disabled": []
      }
      ]
 }
}
```

Where:

- `apiUrls` is a comma-delimited list of API URLs. Each URL specifies the location of the draft APIs in a particular provider organization.
- `productUrls` is a comma-delimited list of product URLs. Each URL specifies the location of the product document in a particular provider organization.
- `rulesetName` is a list of rulesets to be applied to the APIs or products during validation.
  For each ruleset in the list, you can optionally add the `disabled` property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization. See Step 1 for details.
3. Run the **compliance:validate_all** toolkit command in `governance` mode.

```
apic --mode governance compliance:validate_all --org <target_org> --server <platform_api_host_name>
COMPLIANCE_REQUEST_FILE
```

where:

- *`<target_org>`* is the name of the provider organization that owns catalog containing the APIs to be validated.
- *`<platform_api_host_name>`* is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
- *`COMPLIANCE_REQUEST_FILE`* is the path and file name of the configuration file that lists the API or product documents, and the rulesets to be used during the validation (for example, validate-apis.json).

LDAP authentication

The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.

Programming guidelines

When authenticating with LDAP, observe the following guidelines:

- Use only a LDAP interface -- Users can only be authenticated via a connection to an LDAP server.
- Active Directory -- Use of an Active Directory interface is prohibited, however, LDAP authentication with Active Directory is supported.
- Administrator properties -- The LDAP administrator must have access to all user's LDAP properties.

LDAP attributes read by IBM® API Connect are as follows:

Attribute	Definition
`mail`	User's SMTP email address.
`cn`	Used internally to determine user's common name.
`sn`	Used internally to determine user's last name or surname.
`givenname`	Used internally to determine user's first name.
Prefix from `Search dn`	Used as username.

Using an LDAP Server for User Authentication

Every entry in an LDAP directory server has a distinguished name (DN). The DN is the name that uniquely identifies an entry in the directory. A DN is made up of `attribute=value` pairs, separated by commas. For example:

```
cn=Ben Gray,ou=editing,o=New York Times,c=US
cn=Lucille White,ou=editing,o=New York Times,c=US
cn=Tom Brown,ou=reporting,o=New York Times,c=US
```

Any of the attributes defined in the directory schema can be used to make up a DN. The order of the component attribute value pairs is important. The DN contains one component for each level of the directory hierarchy from the root down to the level where the entry resides. LDAP DNs begin with the most specific attribute (usually some sort of name) and continue with progressively broader attributes, often ending with a country attribute. The first component of the DN is referred to as the Relative Distinguished Name (RDN). It identifies an entry distinctly from any other entries that have the same parent. In the previous examples, the RDN "cn=Ben Gray" separates the first entry from the second entry, (with RDN "cn=Lucille White"). These two example DNs are otherwise equivalent. The attribute=value pair making up the RDN for an entry must also be present in the entry. (This is not true of the other components of the DN.)

Examples

In the following examples, a user search is performed from Base DN. The search is done anonymously, or if authenticated bind is used, an authenticated user is used. Search DN appends the prefix, the given user name, and the suffix. If the prefix used is (**uid=** and the suffix used is "**)**", **uid** becomes the user name attribute. The default search filter used is: **(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}))** and attributes used for prefix are also added to the search filter. In this case, where '(**uid=**' is the prefix, when searching for users, the search filter becomes:

```
(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*)(uid={filter}*))
```

where **{filter}** is replaced by actual text.
The authenticated bind DN is a user on the external LDAP server permitted to get base DNs and search the LDAP directory within the defined search base. It should also be able to read other user properties and be used if anonymous access to LDAP to get base DNs and to search and get access to user attributes is not allowed. When a search is performed for *Steve*, the LDAP query filter shown in the following example is used and search is done from base DN specified in UI. When the user's DN is returned, the DN and password are used to authenticate the user:

```
(|(cn=Steve*)(sn=Steve*)(mail=Steve*)(givenName=Steve*)(uid=Steve*)).
```

For bind during login calls, the search string used is the prefix. For example, if the prefix is '(**uid=**', the search string used to search for a user during log in becomes: (**uid=Steve**).

Using the mail attribute as the user name

When you want to use an email address as the user name, (for example *steve@company.com*), you typically use the mail attribute as the prefix '(**mail=**'. In this case, use the following search string to perform the search internally (assuming '(**mail=**' as prefix):

```
(|(cn=steve@company.com*)(sn=steve@company.com*)(mail=steve@company.com*)
(givenName=steve@company.com*)(mail=steve@company.com*))
```

In the previous example, if DN is found, the password is used with the DN to perform a bind. The first result is taken, so be sure to use a unique attribute for username. Next, the LDAP properties for the user are read (**cn**, **sn**, **mail**, **givenName**). If LDAP properties cannot be read using the logged-in user, they are read from the user's DN using authenticated bind credentials. If the user name attribute differs, it is also queried for. For example, if the prefix is '(**uid=**', the **uid** attribute is also read from the user's DN object:

```
(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*))
```

Note: The prefix and suffix cannot be used to get a user's DN directly. For example, the following attempt to directly get a user's DN fails:

```
Prefix: "uid="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_con_ldap_requirements_,
Suffix: ",ou=users,dc=company,dc=com"
```

LDAP referrals

LDAP referrals allow a directory tree to be partitioned and distributed between multiple LDAP servers. An LDAP referral is a domain controller's way of indicating to a client application that it does not have a copy of a requested object, while giving the client a location that is more likely to hold the object. The client then uses the object as the basis for a DNS search for a domain controller.

API Connect support for LDAP referral includes:

- Searching for users that are part of multiple Active Directory trees and forests.
- Authenticating users in the Cloud Manager, API Manager and the Developer Portal.

Note: API Connect LDAP referral support is dependent on the following conditions:

- A single LDAP host/port is configured with administrator credentials and all users are referred to from the tree/server's base DN.
- As part of the user search following the LDAP referral , the same administrator credentials are used in the downstream trees/forests.
- LDAP API authentication does not support external LDAP referral. Internal LDAP referral is supported.

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs in with username: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **cn=spoon,o=eatery**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **access_token**.
- Overriding the **scope** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the authentication URL endpoint can replace the **scope** value that the application receives. For example, you can provide a specific resource owner an account number within the **scope** header response for use in future processing steps.

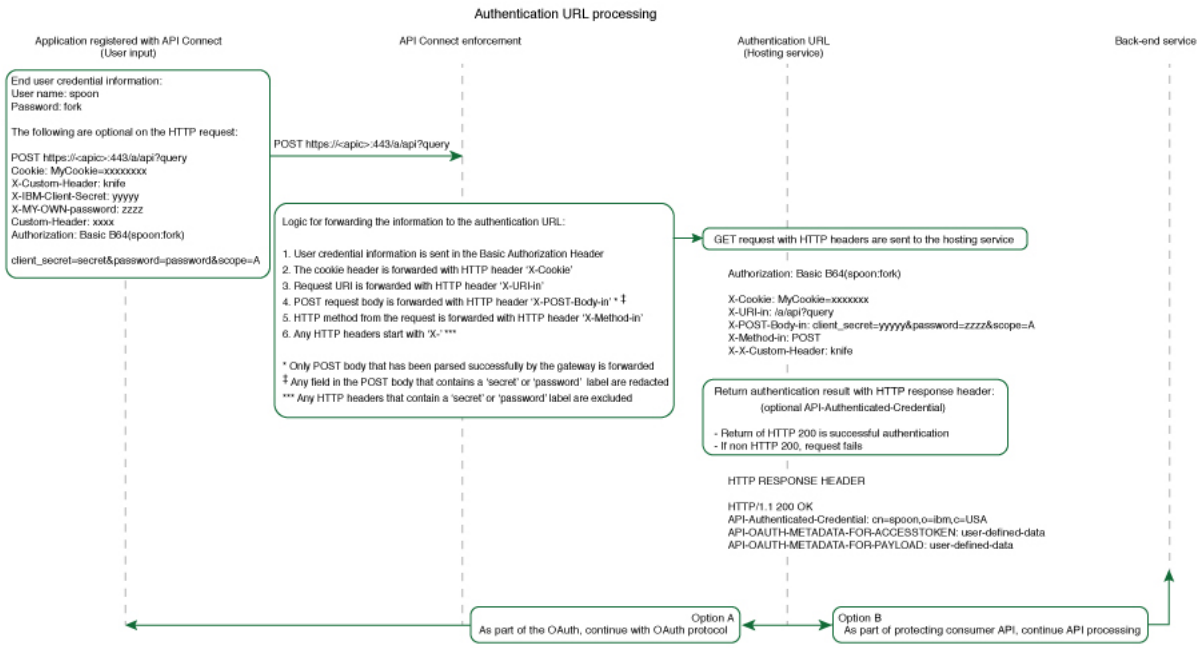
When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect uses `cn=spoon,o=eatery` as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.



API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested `scope` from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Activating an API

After you have created an API definition you can activate it to auto-publish your API document and make it available for testing.

About this task

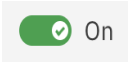
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you activate an API, API Connect automatically completes the following actions:

- Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. Note that if you later want to delete the draft Product, you cannot delete it directly; instead, delete the API and the draft Product is deleted together with the API; see Deleting an API definition. If you want to remove the Product from any Catalogs to which it is published, you must do this separately; see Removing a Product from a Catalog
- Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.

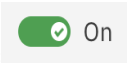
To activate an API, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Note:



- The API activation will not complete successfully if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to activate an API they must be disabled; for information on lifecycle approval settings, see Creating and configuring Catalogs.

- To activate an API from the API Designer user interface, you must be connected to a Management server; API activation is not available with API Designer in offline mode. For more information, see Logging in from API Designer.
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:



```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,
col: 0)
400
```

Procedure

To activate an API and auto-publish your API document, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Under Testtab, click Target Configuration. The Preferences page opens.
4. Set the Auto-publish toggle to the On position: 

Results

On successful completion, the API is shown as On: 

You can stop the API by moving the activation slider control to the Off position: 

If you stop an API, the application subscription is deleted, and the auto Product is removed from the Sandbox Catalog.
Note: You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting **Use the default built-in Sandbox Catalog**. For more information, see Specifying the testing preferences for an API.
If you make a change to the API, it is republished automatically, You can also republish a running API manually by stopping it and then re-activating it.

The error indicator shows whether there are validation errors in the OpenAPI source for the API definition. If there are errors, click the icon for more details:

You can also activate an API during the creation process, and on the API test page; see Creating an API definition and Testing an API.

Note: If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.

Testing an API

Select a test tool and verify that your API works as you intended.

Before you publish an API where customers can access it, you need to test it and ensure that it is defined and implemented correctly. API Connect offers tools for running both simple and complex tests, in different environments. Use the following list of options to choose the test tool that best meets your needs:

- Run and debug the API in the Test tab
  On the Test tab, you can quickly call your API from the API Connect UI with minimal preparation. The Test tab offers full control over the API call through a simple set of fields where you can define your request. The response includes both a visual flow diagram and a code trace that shows how the API's process flow is executed. Note: the Test tab tool is only available to APIs that use the DataPower API Gateway.

- Call the API externally from the Automated API behavior testing application as explained in Testing an API with Automated API behavior testing
  Automated API behavior testing provides a simple set of fields where you can quickly invoke your API. You can automate tests and define schedules for running them. You can even set up API monitoring and receive alerts on your API health before issues occur.

- Call the API from a local test environment
  The Local Test Environment is a lightweight API Manager, running on your computer, that allows you to rapidly test APIs without connecting to an API Connect management server.

- Run a simple test in the Policies editor
  Note: The Test panel is deprecated and might be removed without warning.
- Use the Try it tool in the Explorer tab to run simple tests
  You can use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal . You can check the descriptions of the different artifacts, and review any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note: Due to CORS, when a test call is made with a browser-based API test tool, an HTTP OPTIONS call is made to the API first. The OPTIONS call:

- Does not use any credentials, so is not attributed to any consumer organization.
- Is logged as an API event in the analytics data. Because the OPTIONS call does not use credentials, the API events are only visible in analytics data in the Cloud Manager and API Manager UIs. The OPTIONS events are not visible in the Developer Portal analytics view, which includes only analytics data for a single consumer

organization.
- Is not included in consumer rate limits.
- Is included in consumption-based licensing (if used).

- **Locating API information on the Endpoints tab**
  The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).
- **Using the Test tab to debug your API**
  Use the Test tab to execute calls and trace the API's actions in API Connect.
- **Testing an API with Automated API behavior testing**
  Use the IBM Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it runs properly.
- **Testing an API with the policies editor**
  IBM API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.
- **Testing an API with the Local Test Environment**
  Use the Local Test Environment (LTE) to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.
- **Testing an API with the Explorer tab**
  Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal . You can also use the Try it tool to test the behavior of the API.

Locating API information on the Endpoints tab

The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).

Use the Endpoints tab to retrieve information that you can use when you call the API from an application.

Note: The fields in the Sandbox Sample Application Credentials section apply to the assembly tool's built-in client application and not to any application that you created. The credentials that display here are the default credentials that display in the assembly tool Test panel's "Identification" section.

To copy information from the Endpoints tab, click  next to a field.

The following values for the API are displayed in the Endpoints tab so that you can copy them and paste them into calls:

Base API Endpoint
: The URL representing the endpoint of the API that you are editing and testing. To invoke the API, append one of its supported queries (path and parameters) to this URL.

Client ID and Client Secret
: The values of the built-in test application's client ID and client secret. You can invoke APIs externally by providing the application's credentials in the request header.

OAuth Token URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can obtain an access token for calling the API.

OAuth Auth URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can submit an access token and receive an authorization token in exchange. You then use the authorization token when calling the API.

Rate Limit
: If you specified a rate limit on the Security panel when you created the API, the limit is displayed here for reference. If you did not specify a rate limit, the default rate limit displays.

Using the Test tab to debug your API

Use the Test tab to execute calls and trace the API's actions in API Connect.

The Test tab not only lets you quickly call an API with any needed headers and parameters, but lets you view the content of the response in both parsed and raw format. Additionally, you can view a trace of the actions execute as the API's process flow operates to complete the call. Viewing the trace can help you debug problems with the API's execution.

Note: The Test tab tool is only available to APIs that use the DataPower API Gateway.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Complete the following tasks to prepare your API for testing, execute requests, and debug responses.

1. Preparing an API for debugging with the Test tab
   Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.
2. Specifying the testing preferences for an API
   By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.
3. Sending the API request
   Fill in fields to set up the request for an API that you want to debug on the Test tab.
4. Reviewing the API response and trace
   Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.
5. Testing a GraphQL API with the Test tab
   For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

Preparing an API for debugging with the Test tab

Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To call your API in the Test tab, the following requirements must be satisfied:

The DataPower API Gateway is configured to support the API probe
: To enable the Test tab's trace feature, the DataPower API Gateway must be configured to support gateway peering and the gateway probe. In a gateway service running in Kubernetes, the API probe is automatically enabled. In a gateway service running external to Kubernetes, the DataPower configuration must be added to the application domain supporting API Connect. Check with your administrator to confirm that gateway peering and the gateway probe are enabled as explained in Configuring DataPower API Gateway.

The API uses the DataPower API Gateway
: A gateway exposes APIs to calling applications, and provides processing actions that enable the APIs to integrate with various endpoints. API Connect supports two versions of the DataPower Gateway, but you can only debug APIs that use the DataPower API Gateway. The v5-compatible gateway is not supported. If your API definition has CORS enabled but you cannot see the Test tab, the API is probably configured to use the wrong version of the gateway.
You can determine which gateway your API uses by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop, then select the APIs tab.
3. Click the title of the API that you want to test.
4. On the API's Design page, locate the Gateway field and note which option is selected.

You can change the gateway selection for an API on the Design page, but you must ensure that the policies used in the API's process flow are compatible with the new selection. For information on changing the gateway for an API, see Specifying the gateway type for an API definition.

CORS is enabled in the API definition
: Cross-Origin Resource Sharing support ensures that the API can be accessed from another domain. CORS support must be enabled for your API to be properly invoked and traced. If your API uses the API Gateway but you cannot open the Test tab, it's possible that CORS was not enabled in the API definition.
You can enable CORS for your API by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop.
3. On the Develop page, click the name of the API you want to test. The API's Design page appears.
4. Under the Gateway tab, locate the CORS field and select it to enable support.
5. Click Save in the page header.

The API is published in the sandbox catalog with the default product or plan, or a specified catalog and product or plan
: By default, when you test an API with the Test tab, a default Product/Plan is generated for the API and published to the built-in Sandbox Catalog. However, you can optionally specify a range of API testing preferences including an alternative product or plan, and target Catalog; for more information, see Specifying the testing preferences for an API. When you publish (activate) an API, the API is enabled online and becomes available for use. You cannot execute an offline API, even for testing purposes. You can set an API online by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop.
3. On the Develop page, click the name of the API you want to test.
4. In the Design page header, click the settings icon. The Preferences page appears.
5. Set the Auto-publish toggle to On position.

Next topic: Specifying the testing preferences for an API

Specifying the testing preferences for an API

By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: This feature is not available if you are using the Local Test Environment.

Procedure

1. Open the required API for editing, in either of the following ways:
   - During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
   - To open an existing API for editing, complete the following steps:
     - In the navigation pane, click Develop, then select the APIs tab.
     - Click the title of the API version that you want to work with.
2. Under the Test tab, click Target Configuration.
   The Preferences page opens.

3. Use the Edit links to configure the following testing preferences, as required:

   Auto-publish
   : In order to execute an API for testing purposes, you must make it online. To make the API online and auto-publish your API document, set the Auto-publish toggle to the On position.

   Target catalog
   : The Catalog to which you want to publish the Product that contains the API. The selected Catalog is used as the scope for the other preference settings. You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting Use the default built-in Sandbox Catalog.

   Target Gateway service
   : The gateway service to which you want to publish the Product that contains the API.

   Target product
   : The Product that will contain the API; you can select any of the Products from the selected Target catalog, or you can opt to use an automatically generated Product by selecting Generate Product on Save. The auto-generated Product has the title *api_title* auto product.

   Target product rate limit
   : If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the Target product rate limit option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied.

   Target Plan
   : The Plan in the selected Product that you want the test application to subscribe to. If you opted to use an automatically generated Product, the Target Plan option is not available; instead, the application is subscribed to the Default Plan in the automatically generated Product.

   Test application
   : The application that you want to subscribe to the selected Plan. You can select an application of your choice or, if you opted to use the Sandbox Catalog, you can instead use the pre-supplied test application by selecting Use the built-in Test Application.

   Test Consumer Org
   : The consumer organization that you want to subscribe to the selected Plan. If you selected your own application, the consumer organization is preset to that which contains the application, and cannot be changed. If you opted to use the pre-supplied test application you can, if required, select a consumer organization of your choice.
   Click Reset to reset preferences to the default values.

4. Click Save Preferences when done.
   The Test page header displays the following details:
   - The target catalog.
   - The target gateway services.
   - The target product associated with the current API.
   - If the current status of API is Online or Offline. You can configure this in the API's Design page header.

Results

The next time you bring the API online, the API is published as specified by the preference settings, ready for testing.
Note: These settings are stored in your browser's local storage and will be used for your API testing in subsequent sessions. The following settings are specific to each individual API:

- Target product
- Target product rate limit
- Target Plan

The remaining settings will be applied to all your APIs.
Previous topic: Preparing an API for debugging with the Test tab
Next topic: Sending the API request

Sending the API request

Fill in fields to set up the request for an API that you want to debug on the Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Open the Test tab

1. Log in to API Manager or API Designer.
2. In the navigation list, click  Develop, then select the APIs tab.
3. Click the title of the API that you want to test.
4. On the API Design page, click the Test tab in the page header.

Fill in the Request section

Use the Request section of the page to set up the request URL, the authentication mechanism, and the request parameters. Complete the following steps to fill in the fields that are needed for configuring the request.

Note: The Test tab does not support vanity endpoints; you must specify the gateway endpoint at which the API is invoked. The **Request** field uses the gateway endpoint by default.

1. To fill the Security scheme, complete the following steps:
   a. Click Authorizations and select the security definition that you want. The available security definitions depend on the security schemes that are already configured in the API. To know how to configure security schemes, see Defining security schemes. The available security definitions are:
      - API key
      - Basic
      - OAuth

b. If your API definition uses API key authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:

Name
: The variable name that is auto-populated from security scheme.

Located In
: Location is auto-populated from the security scheme.

Value
: The user can enter the value based on the auto-populated name. For example, if the name is *X-IBM-Client-Id*, the user can enter the same name in the value field.

For more information on API key security schemes, see Defining API key security schemes.

c. If your API definition uses Basic authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:

Username and Password
: Enter the username and Password that is needed for authenticating with the user registry.

For more information on basic security schemes, see Defining basic authentication security schemes.

d. If your API definition uses OAuth authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:
Note:
- The OAuth authorization supports only the native OAuth provider. For more information on native OAuth provider, see Configuring a native OAuth provider
- The available flow options for OAuth authorization are:
  - Implicit
  - Access Code
  - Resource Owner - Password
  - Application

  The fields on the Authorize page are based on the configured flow. For example, in password flow, the Authorization URL field is not available.

Authorization URL
: This URL is used to redirect users for authentication and authorization. The URL is auto-populated from the OAuth Provider that you created in the Resources page.

Name
: The name of the OAuth provider is auto-populated.

Client ID
: This ID is used to authenticate and authorize the client's access to the resources. It is auto-populated based on the application that you selected under Target configuration. For more information, see Specifying the testing preferences for an API.

Client secret
: Enter the secret key corresponding to the Client ID. The client secret is displayed only once when you create the application. Note down the secret key for OAuth authorization.

Flow
: Flow in API authorization refers to the OAuth flow types that determine the process of obtaining authorization. It depends on the flow type that you select when you create the security scheme for the authorization. This field is auto-populated by default.

Scopes
: Select the check boxes of scopes that you want to add. The scopes are included in the access tokens that are generated from the OAuth provider. When an OAuth protected API is invoked, the gateway checks the scopes that are carried in the access tokens. Then it compares them against the list of allowed scopes in the security definition to determine whether to grant access.

Token URL
: This URL is used for obtaining OAuth tokens during the authentication process. The Token URL is auto-populated based on the URL that you add when creating the corresponding OAuth provider on the Resources page.

Redirect URIs
: Select the redirect URIs from the list.

Username and Password
: Enter the username and password of the user registry that is selected under the corresponding OAuth providers on the Resources page.

Click Get Token to create the access token.

The system automatically updates the access token in the Parameter tab when you apply authorization.

For more information on OAuth security schemes, see Defining OAuth2 security schemes.

e. Click Apply.
When you invoke the API, API Connect populates a header using the provided information.

2. Select an operation and request a URL from the list provided.
3. On the Parameters tab, define header, query, and path parameters.
An empty row is provided for you to define parameters, enter the parameter name in the Key field, select query, header, or path in the Located in field as appropriate, and supply a string value in the Value field. As you begin to define a new parameter, a further empty row is added automatically.

Default header parameters and values are provided. For example, if the API has client ID or client secret definitions applied, the corresponding keys are added as header parameters, with the values preset; for details on configuring client ID and client security definitions, see Creating an API key security definition.

The following table lists some common header definitions that are used in a request:

Table 1. Common request headers

Key	Value	Comments
Accepts	*media_type/sub type*	Specify the type of content that the response headers should use. The default is `application/json`.
X-IBM-Client-Id	*client_ID_val*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client ID of your application.
X-IBM-Client-Secret	*client_secret_val ue*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client secret of your application..

Key	Value	Comments
Authorization	Bearer *access_token*	Encode the token in base64. API Connect cannot encode the token for you.
Content-Type	*media_type/sub type*	Specify the type of content that the response body should use; for example, `application/json` or `image/png`.

If the API has path or query parameters that are defined, these are added to the parameters list, ready for you to supply values; for details on configuring path and query parameters, see Defining Paths for a REST API and Configuring an operation.

4. If the operation is POST or PUT, set up the request body.
   a. Click the Body tab.
   b. Type the information for the body of the request.

Send the request

When your API request is configured, click Send to execute the call.

If a message displays indicating "No Response", the API call cannot be completed. Possible causes of this problem are as follows:

- CORS is not enabled in the API's definition
  Edit the API's definition and enable CORS. Then, save the change and publish the API. If you are using your own client app, remember to subscribe it to the API again after publishing.
- The gateway service URL has an invalid certificate
  Follow the instructions to accept the certificate and continue testing.
- The browser cannot connect to the gateway service

Previous topic: Specifying the testing preferences for an API
Next topic: Reviewing the API response and trace

Reviewing the API response and trace

Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When the API request is invoked, the response displays in the "Response" section of the Test tab. The response always includes the HTTP status code the amount of time that it took to receive a response. If the call completes (even if it returns an error), the response also includes headers and a body.

Click the Body tab to see the body of the response. When you review the body of the response, click the Parsed tab to view the response using the format that you specified in the "Accepts" request header. Click the Raw tab to view the unformatted response body.

Click the Headers tab to see the content of request headers and response headers.
Attention: If the assembly or back-end API returns a Cache-Control header, add the `Cache-Control: no-store` request header to prevent the browser from caching the request. Depending on your server, you might want to use the `Cache-Control: no-cache` header instead.
Click the Trace tab to display a record of the API execution so you can see what actions were triggered and the code that we executed for each action.

Examine the trace

Use the Trace tab to see exactly how the API call was executed. This is helpful when the call returned an error and you don't know why. You can debug the API by reviewing the trace to see each step of the API's execution.

Note: The Trace works only with the default Gateway's URL. You cannot select a different Gateway for the trace.
The Trace tab contains the following components to help you debug the API:

Process flow diagram
: In the diagram, the policies (actions) that were executed during the call are highlighted while the rest of the process flow is dimmed. The highlights make it easy to see where the executed actions occurred in the overall flow while clarifying the actual flow of execution for the call. For example, if the process flow includes a switch with three options, only the option that was selected during the call is highlighted.

Policies list
: A list of the highlighted policies lets you select a policy to examine its trace.

Advanced toggle
: The Advanced toggle that lets you control the level of detail in the trace. A basic trace shows the code for the input and output of the selected policy. An advanced trace shows the full code for the policy's execution.

Code box
: The selected level of code for the current policy displays in the code box, where you can review it in detail to see exactly how that policy was executed. By default, a minimal version of the response displays (the endpoint, the request, and the response, and the status message), with sections collapsed. You can expand individual sections by clicking the expand icon next to each. To see the complete response, click the Advanced toggle.

Previous topic: Sending the API request
Next topic: Testing a GraphQL API with the Test tab

Testing a GraphQL API with the Test tab

For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

You can test a GraphQL query in either of the following ways:

- Use a `POST` operation, in which case the query is sent in the body of the operation request.
- Use a `GET` operation, in which case the query is sent as a query parameter.

For each operation type, you can test the query against either the GraphQL API endpoint itself, or against the cost endpoint that returns details of the cost of a request to the GraphQL API endpoint.

Whichever method and endpoint you use, you can either supply the query directly, or you can use the GraphiQL editor to help construct the query; the editor provides type ahead assistance based on the schema that is defined for the API, and highlights errors along with correction suggestions. The schema was initially uploaded when the GraphQL API definition was created, but might have been modified later. For details on creating a GraphQL API definition, see Creating a GraphQL proxy API. For details on modifying the schema, see Using the GraphQL schema editor.

Before you begin

See Preparing an API for debugging with the Test tab for the requirements that your API definition must meet for you to test it with the Test tab.

Procedure

1. In the Request section, select the required operation type and endpoint; for example:
   - `POST https://myserver.com/myorg/sandbox/mybasepath/graphql`
   - `GET https://myserver.com/myorg/sandbox/mybasepath/graphql/cost`
2. On the GraphiQL tab, in the left pane of the editor, supply the query; for example:

```
{
  accounts(limit: 100) {
    name {
      first
      last
    }
  }
}
```

3. If required, you can supply more request headers on the Parameters tab.
4. If your query includes variables, you can supply values for the variables in the Query Variables pane. For example, if the query is as follows:

```
query MyQuery($Query__accounts__limit: Int)
{
  accounts(limit: $Query__accounts__limit) {
    name {
      first
      last
    }
  }
}
```

   you can set a value for the `Query__accounts__limit` by entering the following in the Query Variables pane:

```
{
  "Query__accounts__limit": variable_value
}
```

   where *variable_value* is the required value.
5. Click either Send, or the Execute Query icon ▶ in the editor. The response is displayed in the GraphiQL editor, and the Trace section shows you how the API call was executed. For details on the trace information, see Examine the trace.

Previous topic: Reviewing the API response and trace

Testing an API with Automated API behavior testing

Use the IBM® Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it runs properly.

Automated API behavior testing provides a simple set of fields where you can quickly invoke your API through automation.

Automated API behavior testing is an optional add-on to API Connect, and must be deployed by your administrator. If Automated API behavior testing is available in your deployment, a Test API displays on the Home page in API Manager.

If you want to use Automated API behavior testing for validating an API, complete the following steps to get started.

1. Log in to API Manager.
2. Activate your API to make sure that it's available online.
3. Create a client application and copy its client ID and client secret.
4. Subscribe the client app to the API.
5. Click API Manager in the banner to return to the Home page, and then click the Test API tile.

Getting started

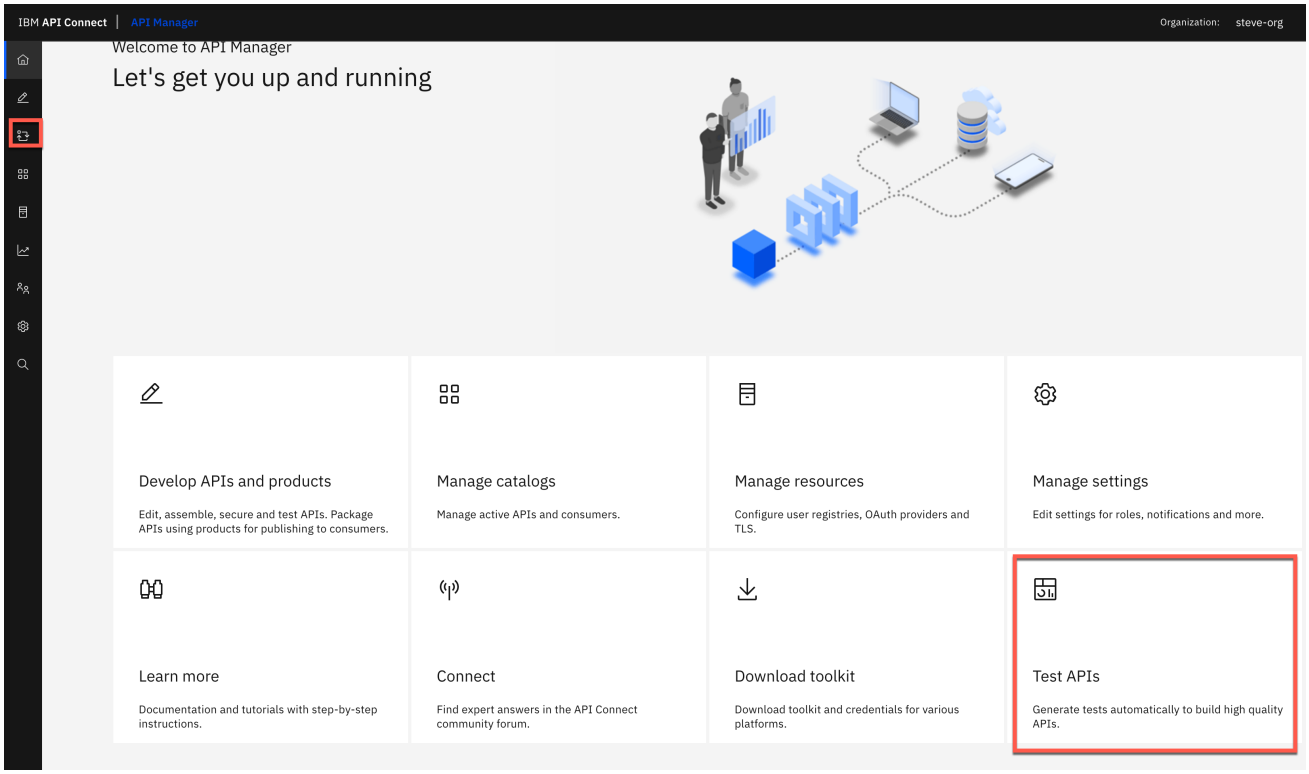
The Automated API behavior testing interface provides collaborative and powerful API testing capabilities.

- **Create automated and simple to use API tests quickly and easily.**
  - Produce high quality APIs consistently, with automated and simple to use API testing that you can rely on.
- **Intelligent validation of API payload accuracy.**
  - Add more intelligence to your tests to verify the accuracy of the payload. You can easily make logical assertions to create flexible and powerful conditions for validation, with no code necessary.
- **Collaborative testing.**
  - Accelerate your API development and testing, by sharing your tests and results.
- **Easily integrate into your CI/CD pipeline to execute tests as part of your deployment.**
  - Create API Hooks to allow your tests to be run via the command line and become part of your automated build processes.
- **No code necessary.**

How to get started

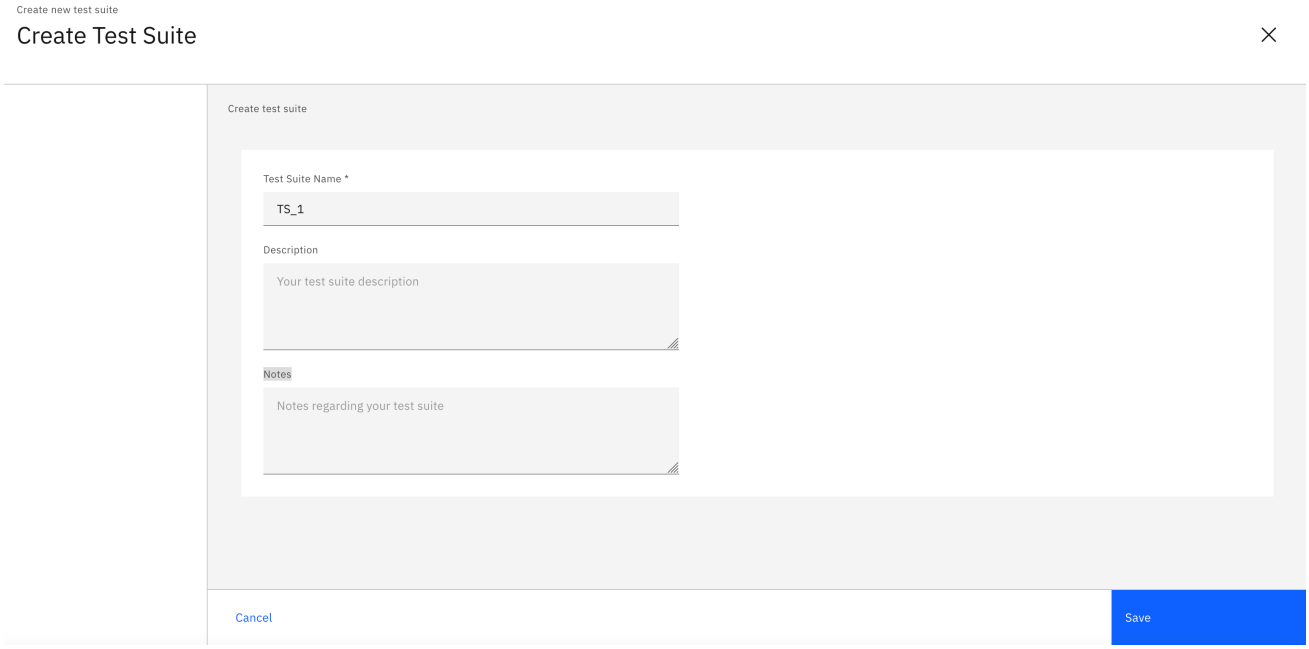
Creating a test involves the following steps:

1. Creating a test suite
2. Creating test cases in a test suite
3. Defining variables
4. Running the test
5. Publishing the test



Explore the following tasks for detailed instructions:

- Creating a test suite
- Modifying a test suite
- Deleting a test suite
- Creating a test case
- Modifying a test case
- Defining variables
- Deleting a test case
- Running a test case
- Viewing the test report
- Publishing a test



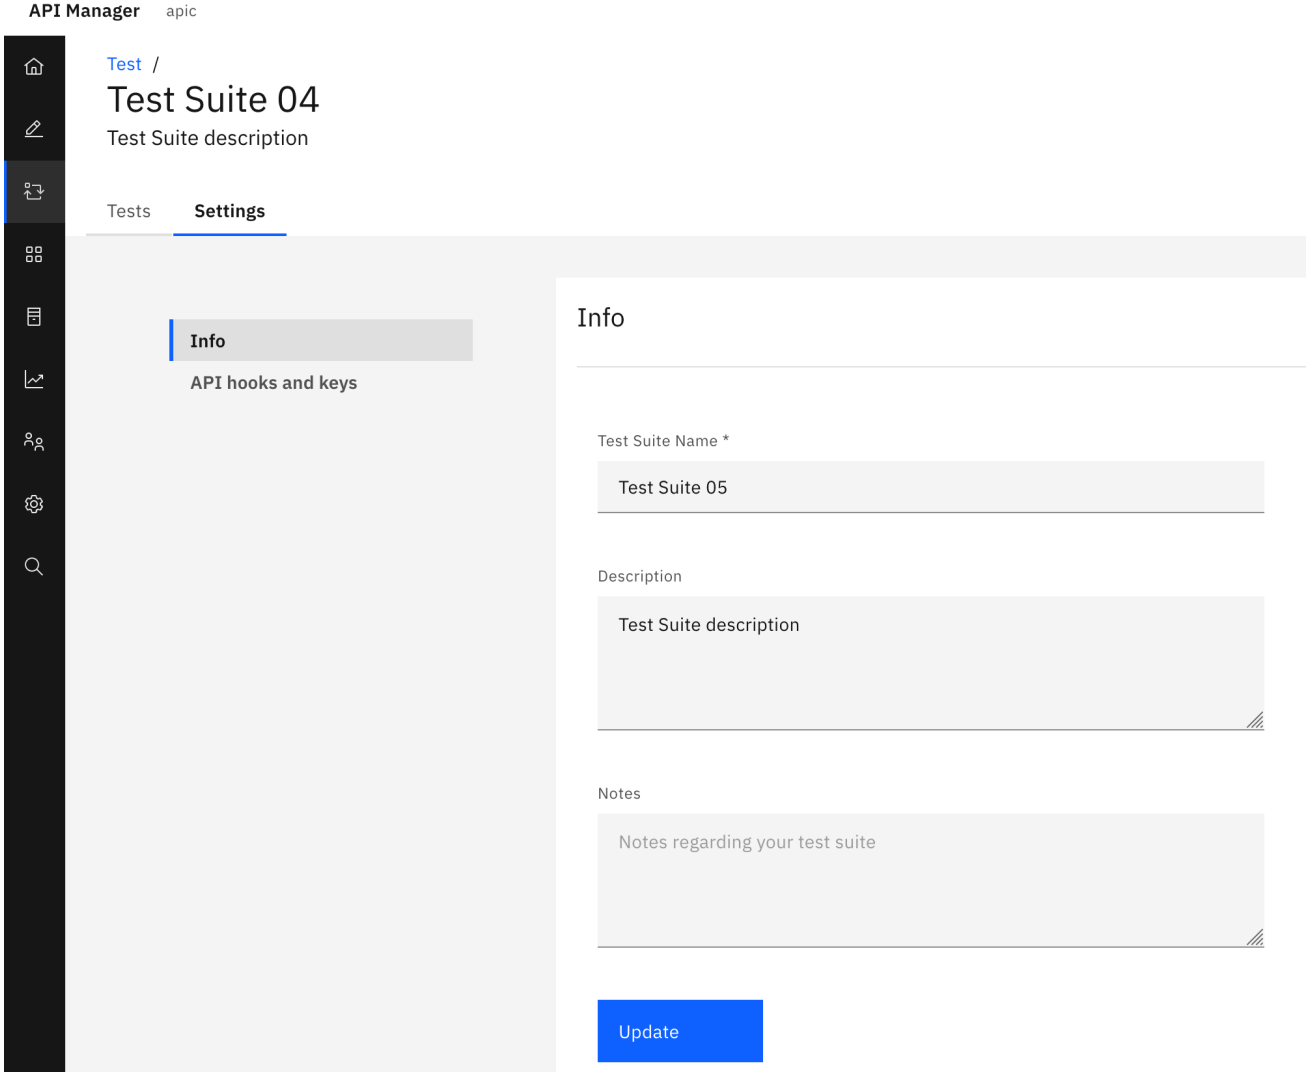
Creating a test suite

The following instructions show you how to create a test suite using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.

3. On the Test page, click **Add test suite**.

4. In the Create Test Suite page, enter a test suite name, description, and any relevant notes for the test suite.
5. Click **Save**. Once the test suite is created, you can add multiple test cases.



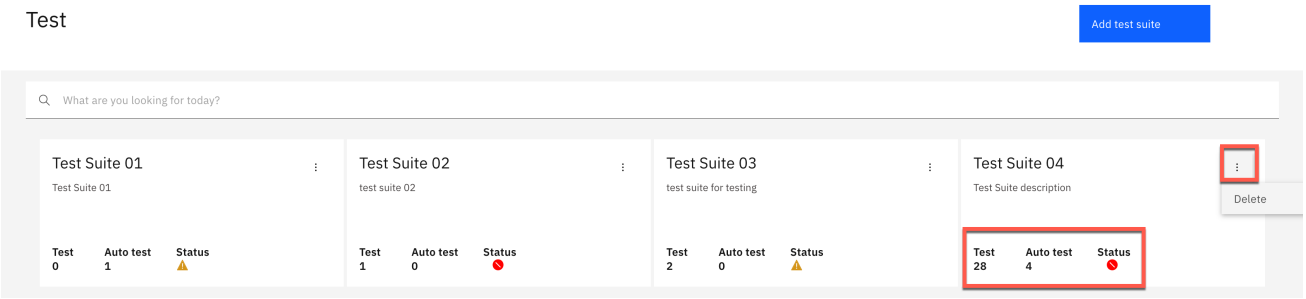
What to do next

- Next topic: Creating a test case

Modifying a test suite

The following instructions show you how to modify a test suite using the **API Manager**.

1. Log in to the API Manager.
2. Click the Test APIs tile.
3. Select a test suite to modify.
4. Go to the **Settings** tab.



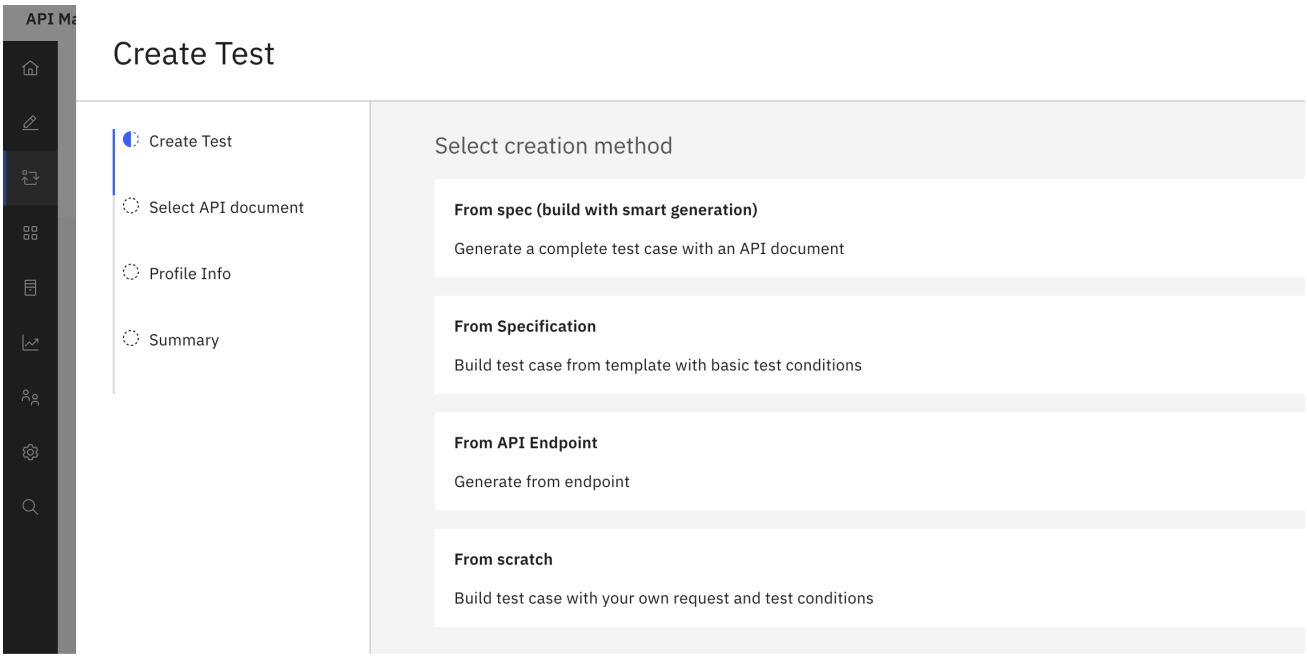
5. In the **Info** tab, update the following:
   - Test Suite Name
   - Description
   - Notes
6. Click **Update**.

- Next topic: Modify a test case

Deleting a test suite

To delete a test suite, complete the following steps:

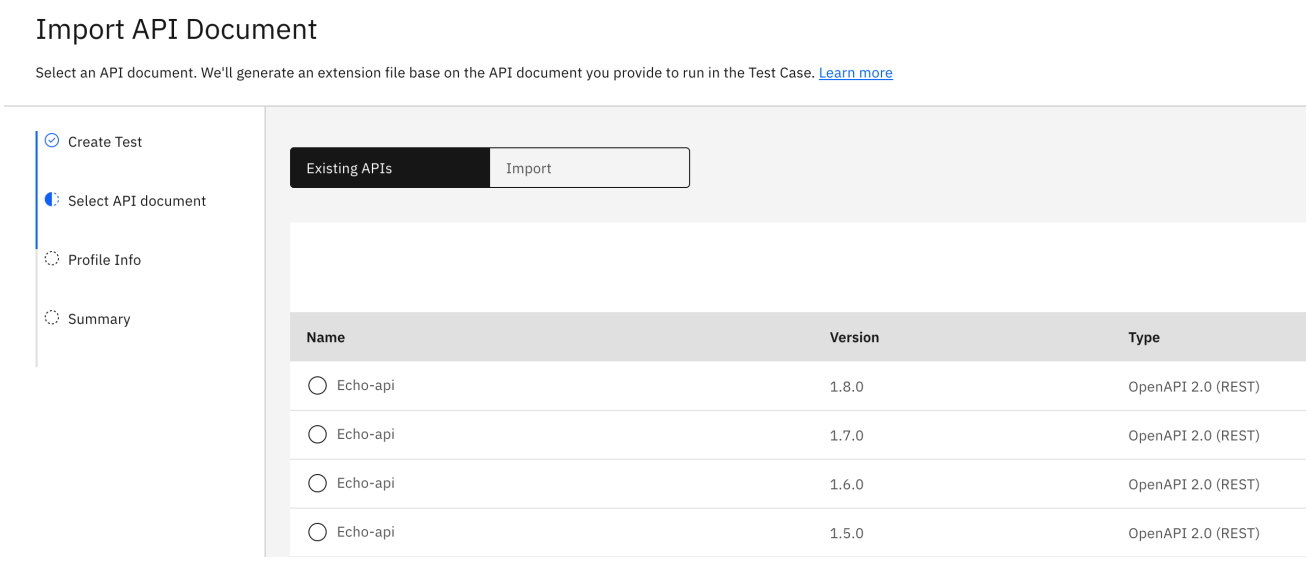
1. Login to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, locate the test suite you want to delete and determine whether it contains any tests by observing the displayed **Test** count.



Note: You can't delete a test suite that contains tests, so if your test suite does contain any tests you must delete them first; see Deleting a test.

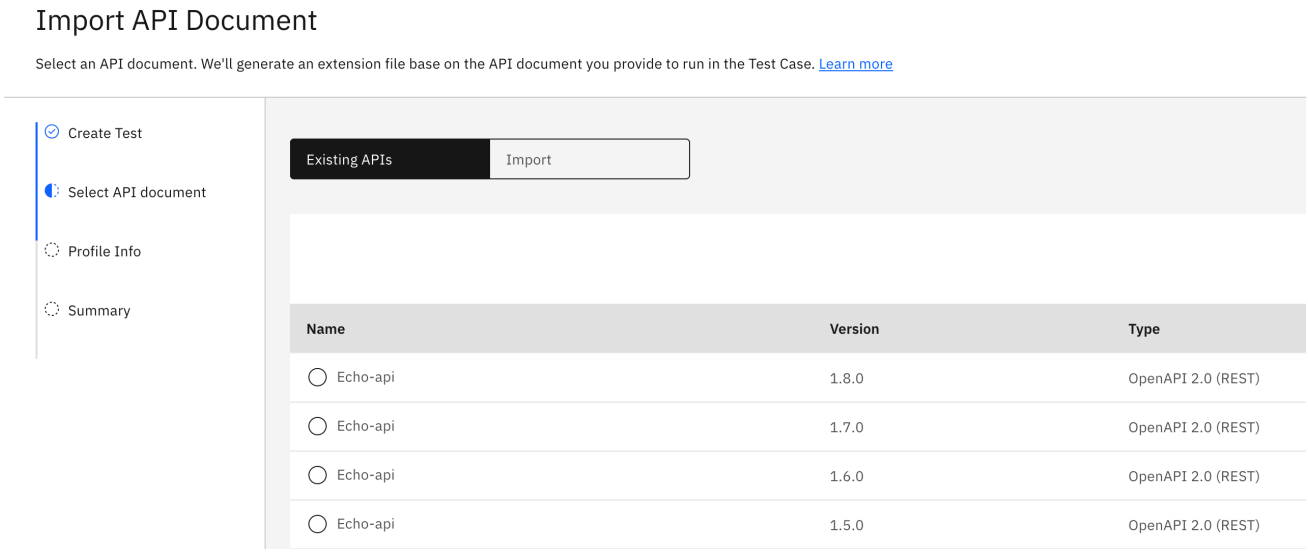
4. To delete the test suite, click its **Options** icon, then click **Delete**.

Creating a test case



The following instructions show you how to create a test case using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. In the Create Test page, go to the **Tests > Test Cases** tab, and click **Add**.
5. Select a test case creation method:

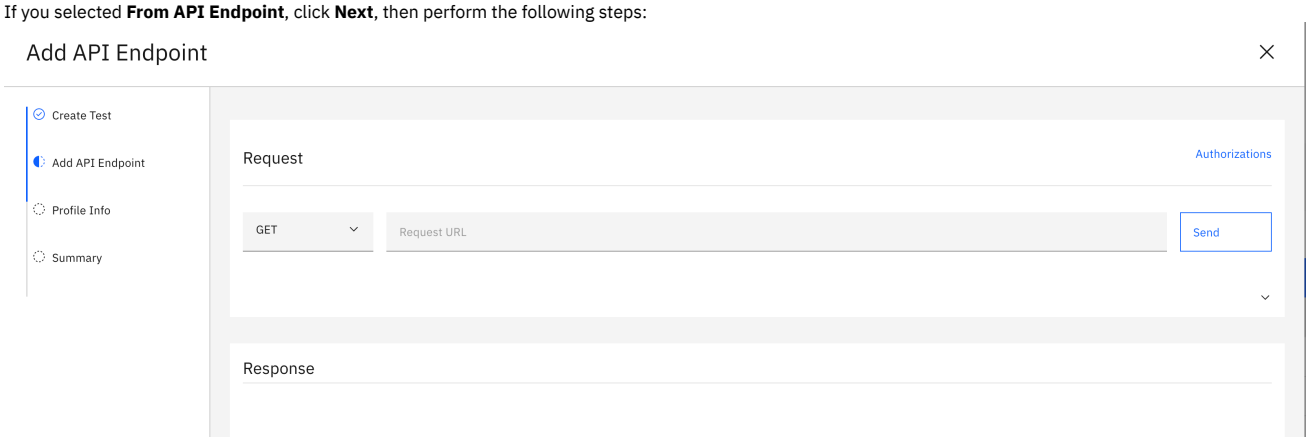


- From spec (build with smart generation): Generates a complete test case that leverages NLP to help developers and QAs test their APIs effectively in an efficient way
- From Specification: Builds test case from OpenAPI specification
- From API Endpoint: Generates test case from a specified endpoint
- From scratch: Creates a test case with your own request and test conditions

6. If you selected **From spec (build with smart generation)**, click **Next**, then perform one of the following steps:

1. Go to the **Existing APIs** tab:
    1. Select a predefined API.
    2. Click **Next**.
    3. Select a path.
    4. Enter the API name.
    5. Provide a brief description.
    6. Add tags.
    7. Click **Next**. You will see the message that the test case has been generated.
    8. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
    9. Click **Save**.
    10. Click **Run Test**.
2. Go to the **Import** tab, do one of the following:
    - Drag and drop a JSON or YAML file that has the API test case definition OR
    - Enter an URL for the API test case. Provide username, and password if required, for authentication.
    1. Click **Next**.
    2. Select a path.
    3. Enter the API name.
    4. Provide a brief description.
    5. Add tags.
    6. Click **Next**. You will see the message that the test case has been generated.
    7. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
    8. Click **Save**.
    9. Click **Run Test**.

7. If you selected **From specification**, click **Next**, then perform one of the following steps:



1. Go to the **Existing APIs** tab:
    1. Select a predefined API.
    2. Click **Next**.
    3. Select a path.

4. Enter the API name.
5. Provide a brief description.
6. Add tags.
7. Click **Next**. You will see the message that the test case has been generated.
8. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
9. Click **Save**.
10. Click **Run Test**.

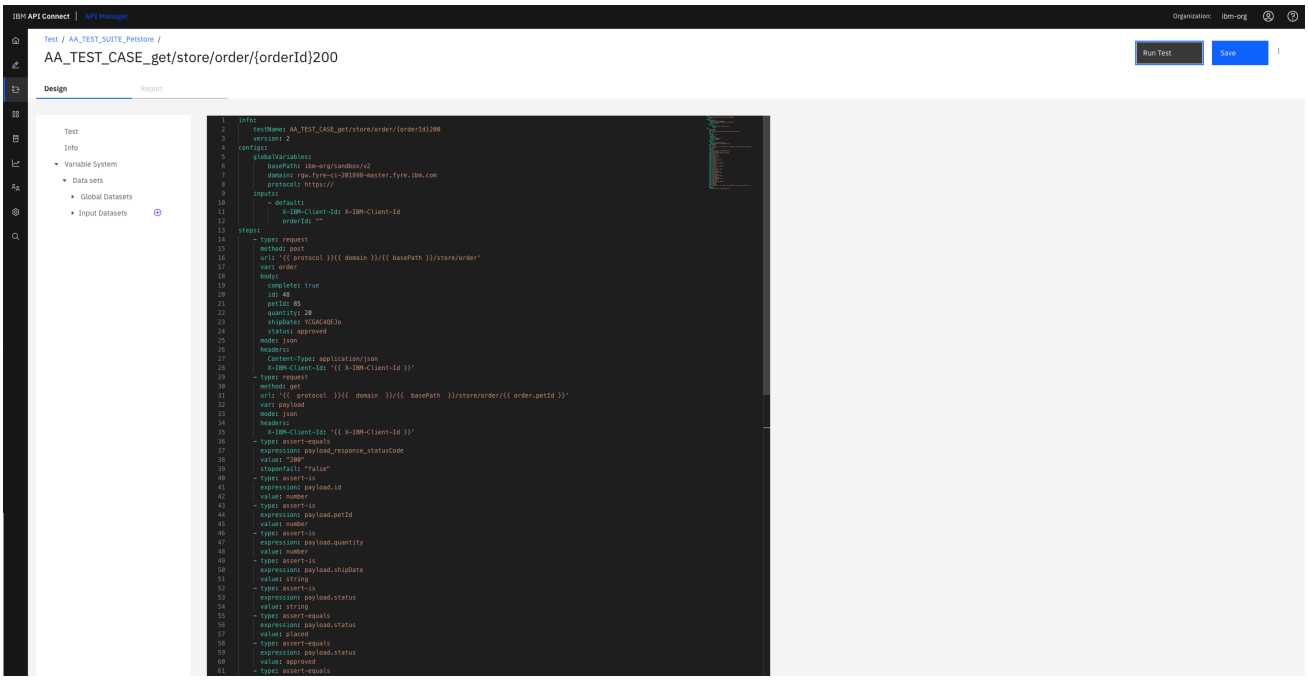
2. Go to the **Import** tab, do one of the following:
   - Drag and drop a JSON or YAML file that has the API test case definition OR
   - Enter an URL for the API test case. Provide username, and password if required, for authentication.
   1. Click **Next**.
   2. Select a path.
   3. Enter the API name.
   4. Provide a brief description.
   5. Add tags.
   6. Click **Next**. You will see the message that the test case has been generated.
   7. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
   8. Click **Save**.
   9. Click **Run Test**.

8. If you selected **From API Endpoint**, click **Next**, then perform the following steps:

   1. In the Request section, select a method, enter the API endpoint that was generated when you published the API, set the authorization if required, and click **Send**. You will see the response in the **Response** section.
   2. Click **Next**.
   3. Enter the test name, description, and tags, then click **Next**. You will see the message that the test case has been generated.
   4. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
   5. Click **Save**.
   6. Click **Run Test**.

9. If you selected **From scratch**, click **Next**, then perform the following steps:

   1. Enter the test name.
   2. Provide a brief description.
   3. Add tags.
   4. Click **Next**. You will see the message that the test case has been generated.
   5. Click **Edit**.
   6. Enter the API definition. Refer to the Test Defintion Syntax for a sample.
   7. Click **Save**.
   8. Click **Run Test**.



What to do next

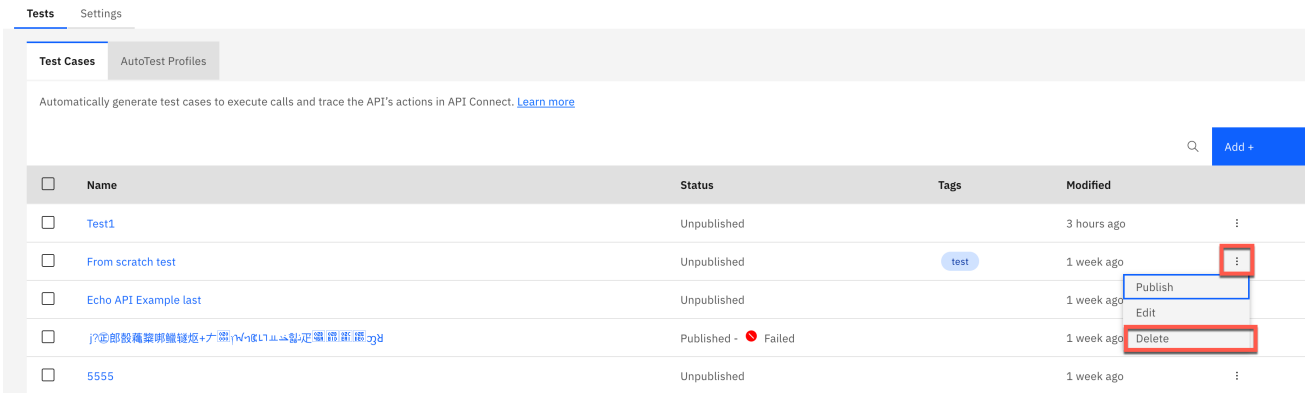
- Next topic: Modifying a test case

Modifying a test case

The following instructions show you how to modify a test case using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, click a test suite tile.
4. Select a test case you wish to edit.
5. Go to the **Design** > **Test** tab, modify the API definition as needed, and click **Save**.

6. To run the test case, click **Run Test**.
7. To update the test case name, description, and tags, go to the **Info** tab, then click **Save**.
8. To update the global or input datasets and modify the request payload, go to the **Variable System** > **Data Sets** > **Global Datasets** or **Input Datasets** tab. Then run the test case for each input dataset.



What to do next

- Next topic: Running a test case

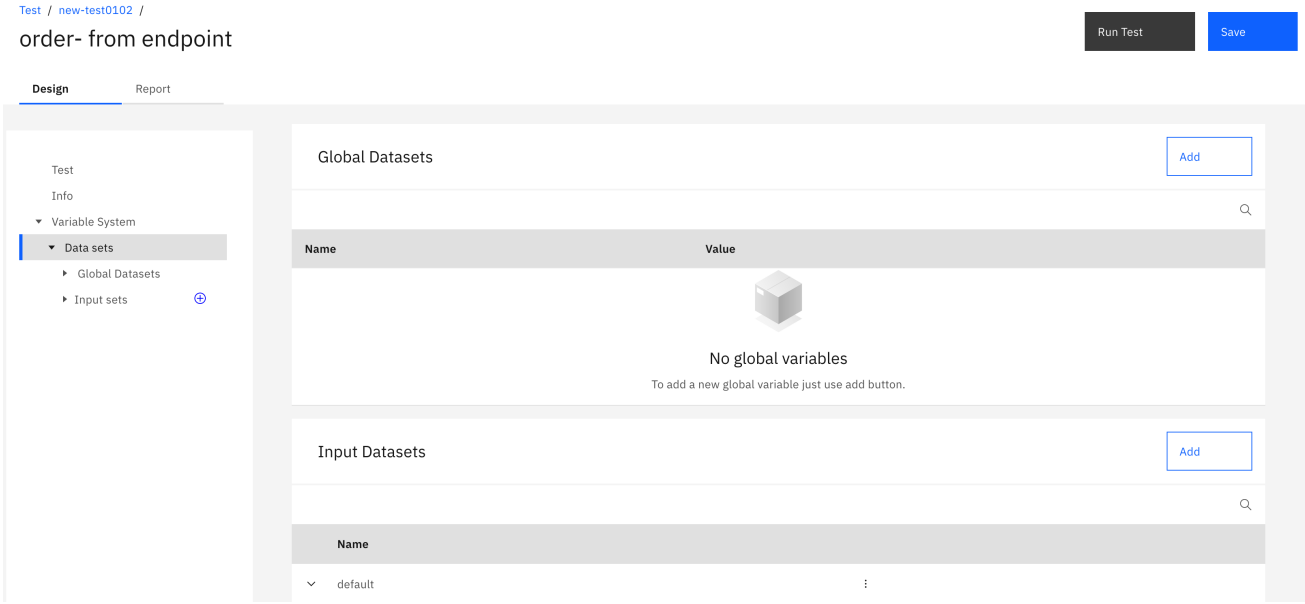
Deleting a test case

To delete a test case, complete the following steps:

1. Login to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. On the **Tests > Test Cases** tab, locate the test case you want to delete and click the **Options** icon > **Delete** option.

5. Click **Yes** for confirmation.

Defining variables

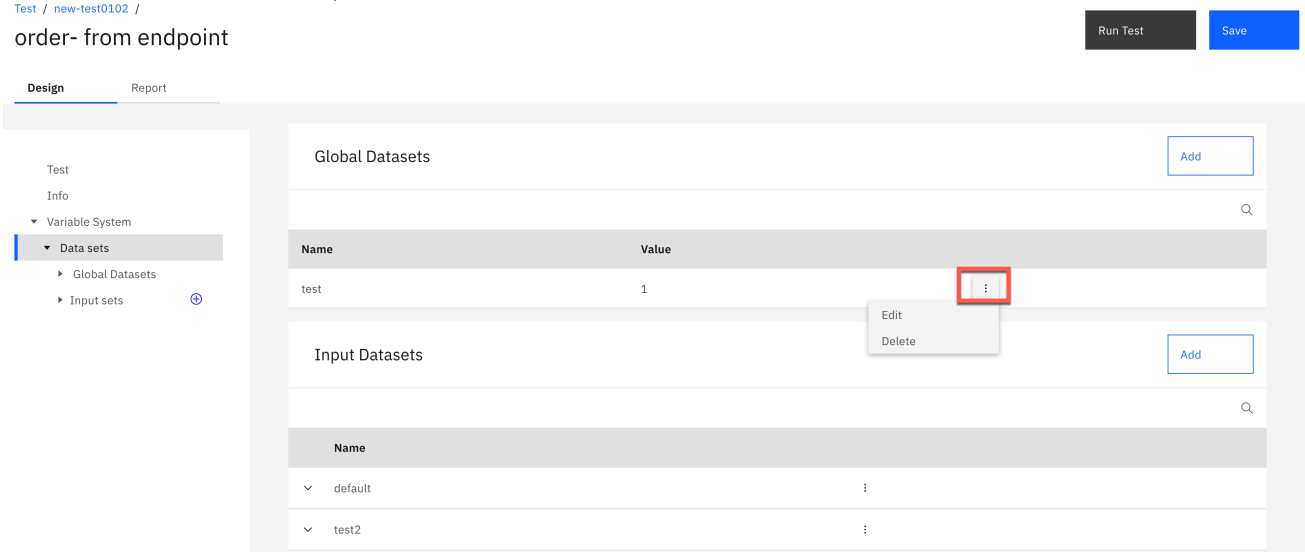


Within API Testing there are multiple ways to define variables to address different requirements.

Global Datasets

Global Datasets are ones that are common across the whole test and typically does not change between runs based on Input Datasets

Adding a global variable

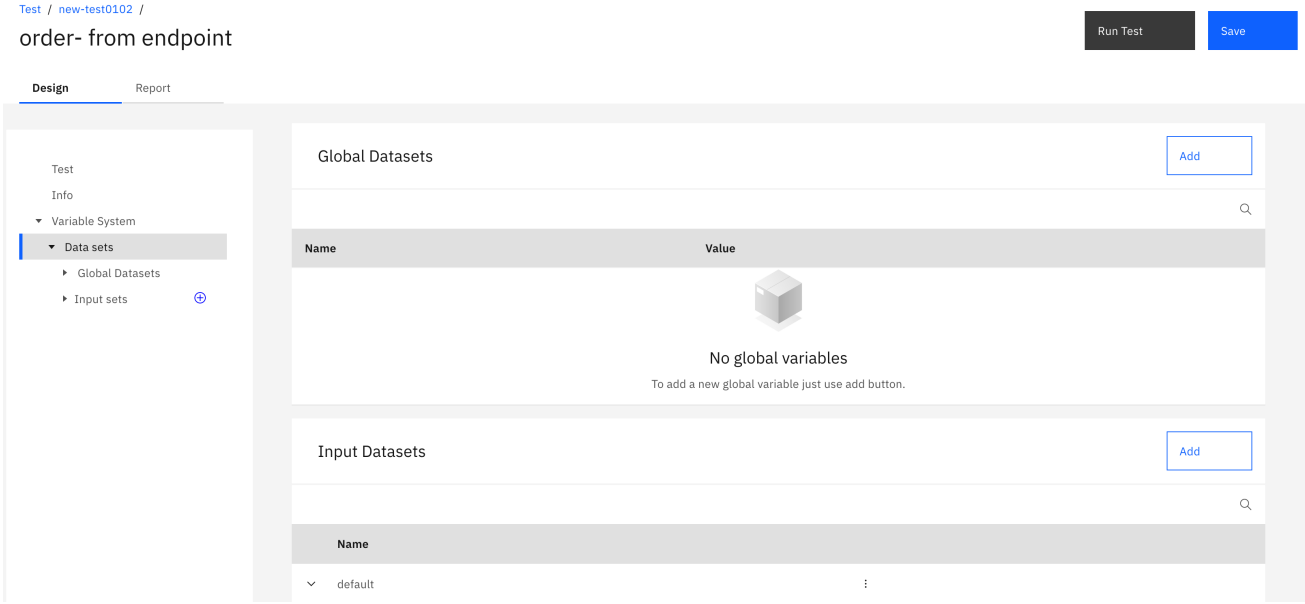


1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. Select a test case.
5. Go to the **Design** > **Variable System** > **Data sets** tab.

6. In the Global Datasets section, click **Add**.
7. Enter the variable name and value.
8. Click **Add**.

Editing or deleting a global variable

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. Select a test case.
5. Go to the **Design** > **Variable System** > **Data sets** tab.
6. In the Global Datasets section, click the options menu and select **Edit**.



7. Update the name and value as needed.
8. Click **Add**.
9. To delete a variable, click the options menu and select **Delete**.

Input Datasets

The input datasets, is a group of input variables representing a scenario (e.g product id). Where the number of input datasets determines how many times the test will be executed using those values. If 3 input datasets are defined, the test will run 3 times using the inputs defined within each of those sets on each run.

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. Select a test case.
5. Go to the **Design** > **Variable System** > **Data sets** tab.

6. In the Input Datasets section, click **Add**.
7. Enter a dataset name.
8. Click **Add**.

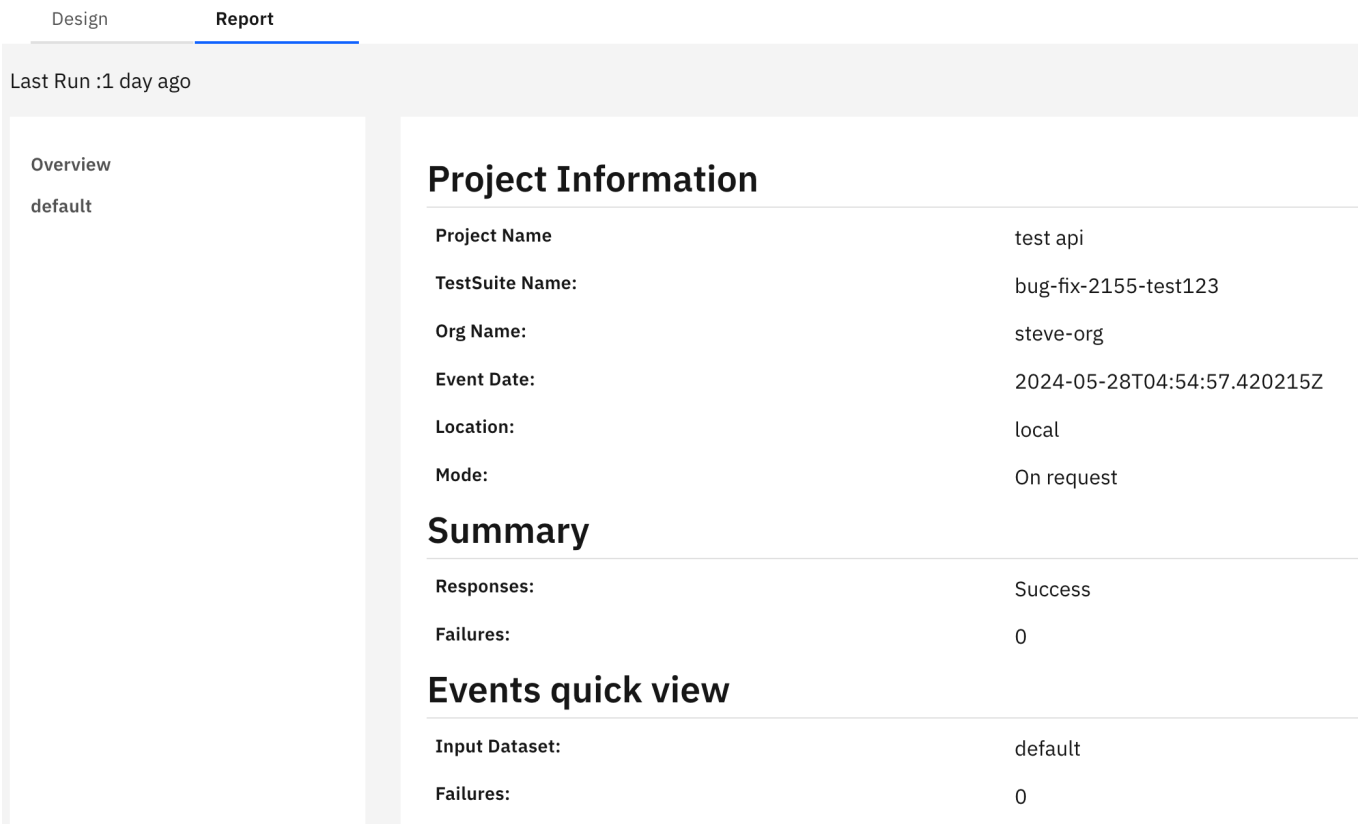
What to do next

- Next topic: Running a test case

Running published test cases

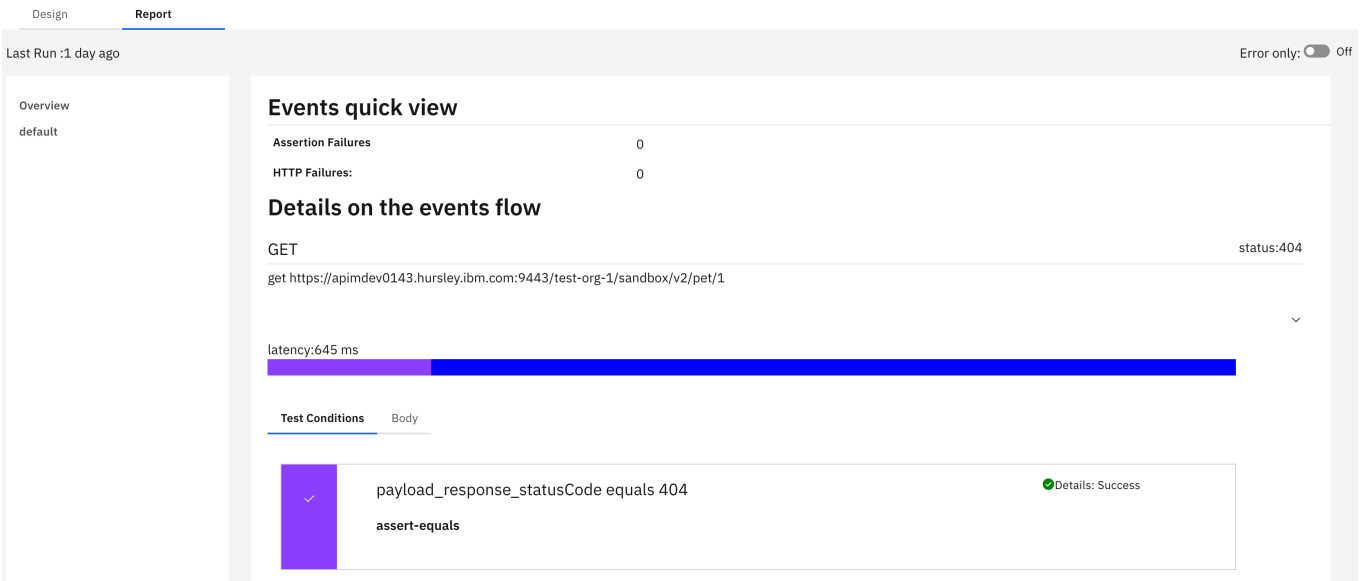
The following instructions show you how to run mutliple test cases that are published using the **API Manager**. To run a single test case, perform the steps as shown in Modifying a test case.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. To run multiple test cases, in the **Tests** > **Test cases** tab, select test cases with the status as **Published**, and click **Run**.



What to do next

- Next topic: Viewing a test report



Viewing a test report

Once a test run has completed (either stopped manually or the configured time to run threshold has been reached) you will be presented with the **Report** section, where you will be able to view the results of the run.

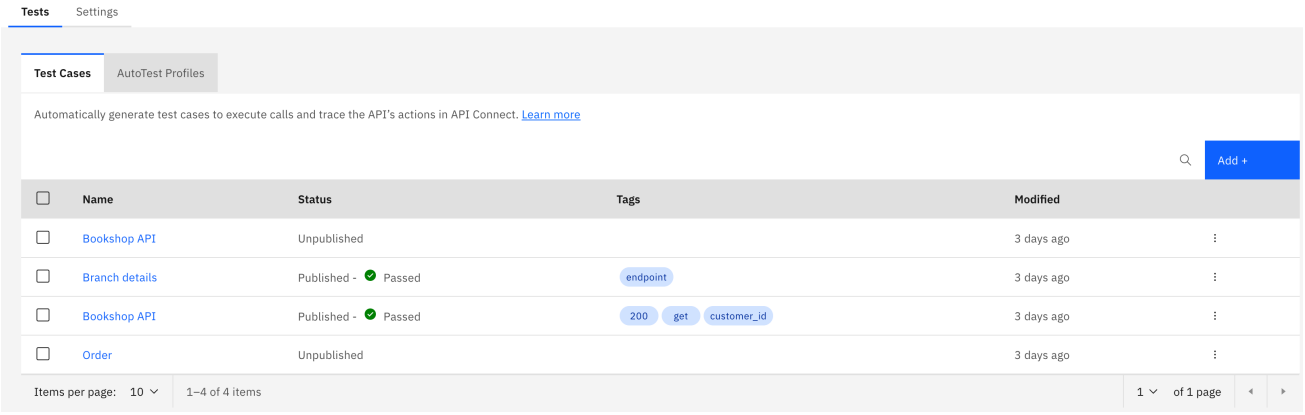
First up is the **Overview** tab, which contains information about the test case. The project Information section details the test case, while the Summary section gives the overall test run status, indicating success or failure and the number of failures, if any. The Events quick view section offers insights into the failures associated with each input dataset

The second tab presents detailed results for each input dataset offering a comprehensive view of the test outcomes for each specific input. The table contains the list of the calls and their respective response statuses.

*Both views allow you to apply **Errors Only** filter using the toggle button. This filter displays only the failed test conditions.*

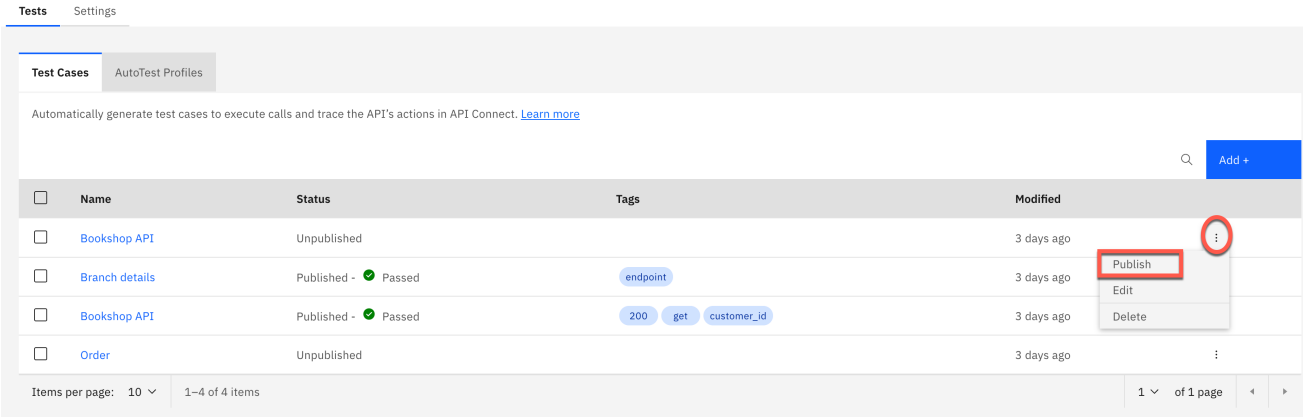
To download the report, click the options menu and select **Download Report**.

What to do next



- Next topic: Publishing a test

Publishing a test case



Once you have completed the configuration of your test, and run it manually to confirm that it works correctly, you can publish the test. After publishing, you have the option to select the published test case from the table, make changes using the editor, and publish it again.

To publish a test, complete the following steps:

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite. A list of tests are displayed. If your test has not been published before, the status shows as **Unpublished**.

4. Select a test that you want to publish by clicking the **Options** icon and selecting **Publish**.

What to do next

- Next topic: Tagging a test

Tagging a test

Adding tags to your tests is an easy way to keep them organized in your Test Suite. Furthermore, tags can be used as a way to selectively execute certain tests in your test suite when running them via an API Hook (see Run Published Tests by Tag for more information).

Note: You can tag a test, while creating a test or after creating a test.

Adding a tag to a test

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile that contains the test that you want to tag.
4. Click the test case you want to edit.
5. To add tags to your test, go to the **Design > Info** tab and start typing the tag name in the Tags box. You can assign multiple tags to a test. To remove a tag, click the **x** button next to the tag.

6. Click **Save**. Tags can be viewed any time in the **Tests > Test Cases** tab.

What to do next

- Next topic: API Hooks

API Hooks

In addition to viewing and executing tests within the IBM API Connect Test interface, you may also perform these actions via an API. This allows tests to be executed via the command line, through third-party applications, or as part of a CI/CD pipeline. API hooks form the basis of this API, providing a base URL on which subsequent API operations can be performed. To start using an API Hook, see:

- Creating An API Hook.

API Hooks require authentication to use in the form of an API Key and Secret. Once you have created your API Hook, view the following page to learn how to create an API Key and Secret for your Test Organization:

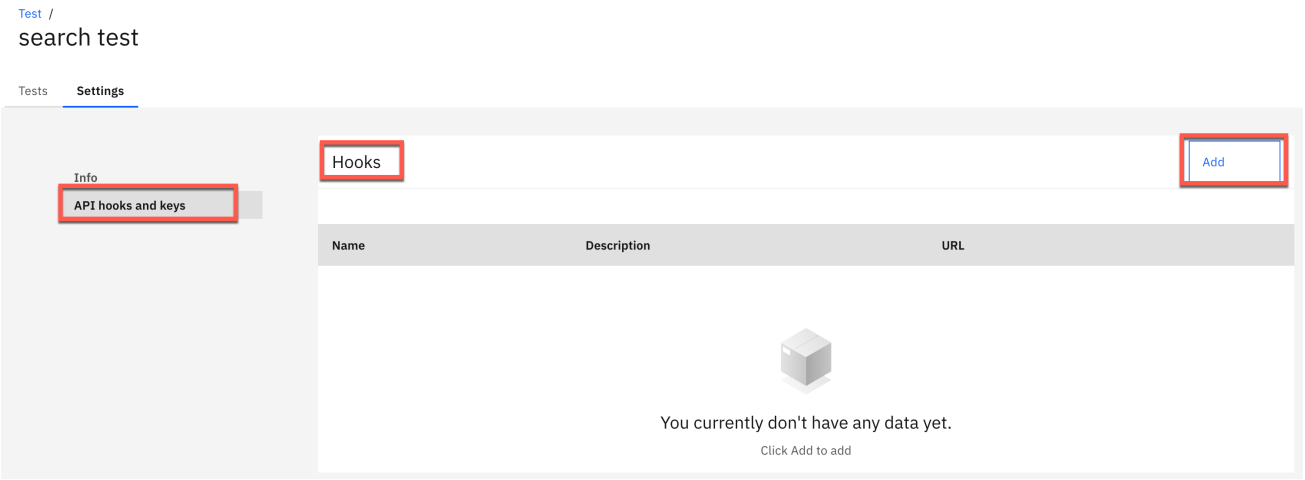
- Creating API Keys and Secrets

Once you've set up your API Hook, Key and Secret, see:

- Using API Hooks

Creating an API Hook

You can generate an API hook for each of the Test Suites within your Test Organization. API hooks are scoped to only one test suite and thus will only have access to operate on the data within that test suite; that is, if an API Hook is generated for **`Test Suite 1`**, it may only access the tests and test results associated with **`Test Suite 1`**. If you wish to interact with tests in multiple test suites, you will need to generate an API hook for each Test Suite.



API Hooks are protected and require an API Key and Secret to be used. You can find out how to create a API Key and Secret here.

If there are no Test Suites here, you can create one by clicking the **Create Test Suite** button after the Test Status chart.

How to create an API Hook

1. Log in to the API Manager.
2. Click the Test APIs tile.
3. Select a test suite.

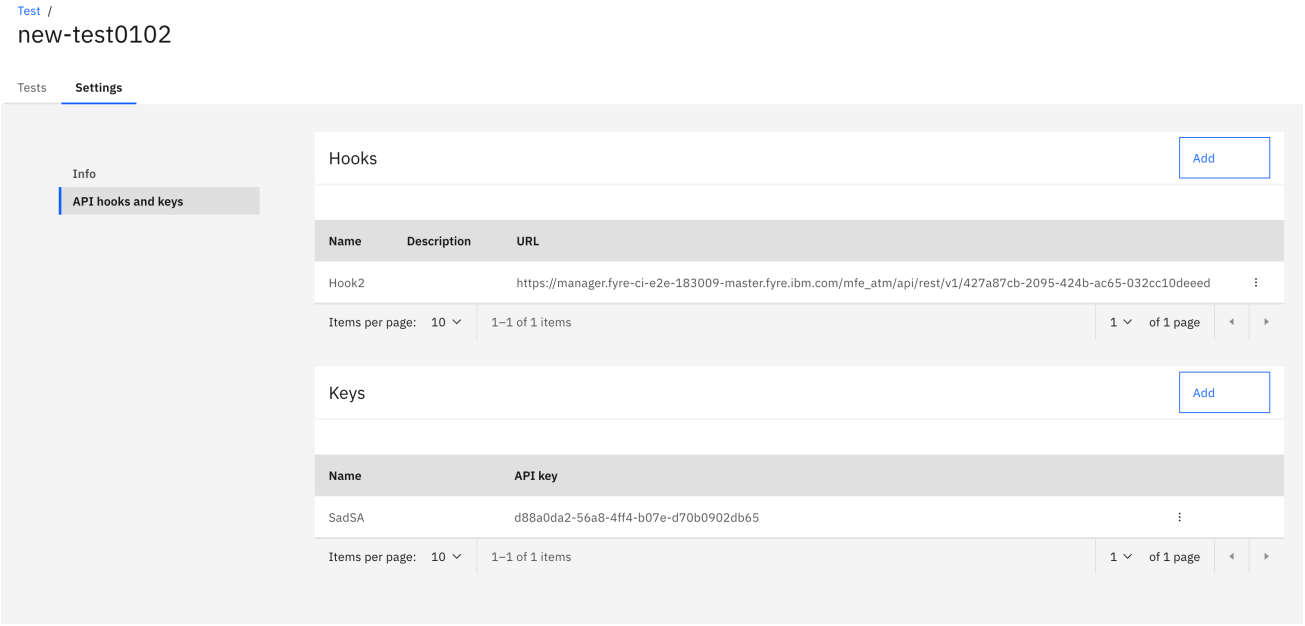
4. Select the **Settings** > **API hooks and keys** tab.

- Go to the Hooks section, and click **Add**.
- Enter name.
- Enter description.
- Click **Save**. You've now created the API Hook URL for your Test Suite. Make a note of this URL as this will form the base path of all future API requests you make to to this test suite. Close the Hook URL dialog box. You can see that your new API Hook is now in the list of API Hooks. You can click on this at anytime to view the URL again in the future should you need. Note that this URL will remain active until it is deleted. To delete the API Hook, simply click on the **Delete** icon next to the API Hook you want to remove.

What to do next

- Next Topic: Creating API Keys and Secrets

Creating API Keys and Secrets



API Keys and Secrets are the credentials required to use an API Hook. For a request to an API Hook to be authorised, both the **`X-API-Key`** and **`X-API-Secret`** headers must be provided. The values of the API Key and Secret represent the values of these headers respectively.

Unlike API Hooks which are scoped to a single Test Suite, API Keys and Secrets are scoped to a Test Organization. Therefore, any API Key and Secret pair which is generated within a Test Organization will have permission to authorise requests to all API Hooks within the same organization, regardless of the Test Suite the API Hook is associated with.

How to create an API Key and Secret

1. Log in to the API Manager.
2. Click the Test APIs tile.
3. Select a test suite.
4. Go to the **Settings** > **API hooks and keys** tab.

5. To use your new API Hook, you need to ensure you have an API Key and Secret.

   - Go to the Keys section and click **Add**.
   - Enter the key name.
   - Click **Save**. The system will display the key and the secret. Copy it for future reference. if your Key and Secret is set up, see Using API Hooks for more information on how to use the API Hook.

Your new API Key is now active and will now appear in the list of API Keys in the navigation menu. Clicking on the key will show you the API Key's value should you need to reference this again in the future. If you want to remove the API Key at any point, simply click on the **Delete** icon next to the API Key you want to remove. This will invalidate all future requests to API Hooks using this Key and Secret combination.

What to do next

- Next Topic: Using API Hooks

Using API Hooks

API Hooks provide a mechanism to interact with tests within a Test Suite via an API. Whilst the API Hook itself defines the basepath of this API, it also exposes a series of endpoints which, when appended onto this basepath, allow you to list and execute published tests within the API Hook's scope. The following pages detail these endpoints and subsequent parameters you can provide to either list, execute all, or execute only specific tests within a test suite.

Endpoints

- List All Tests
  Lists all of the published tests within an API Hook's scope.
- Run All Published Tests
  Runs all of the published tests within an API Hook's scope.
- Run Published Tests By Tag
  Runs the published tests within an API Hook's scope that match the tags specified in the request body.
- Run Published Test By ID
  Run a specified test within an API Hook's scope.

List All Tests

Description

The List All Tests endpoint lists all of the published tests within an API Hook's scope.

HTTP Request

```
GET <API-Hook-URL>/tests
```

Sample Method Invocation

```
curl -X GET \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
<API-Hook-URL>/tests
```

Parameters	**Header Parameters** API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.

Response Content	**MIME type: application/json**
	
	`[ { testId: string, testName: string, testDescription: string, lastModified: string, authorName: string, tags: array[string] } ]`
	
	Response Description
	• `testId`
	  ◦ ID of the test.
	• `testName`
	  ◦ Name of the test.
	• `testDescription`
	  ◦ Description of the test.
	• `lastModified`
	  ◦ Date and time the test was last modified.
	• `authorName`
	  ◦ User who composed the test.
	• `tags`
	  ◦ Array of tags associated with the test.

Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Run All Published Tests

Description

The Run All Tests endpoint executes all of the published tests within an API Hook's scope.

HTTP Request

```
POST <API-Hook-URL>/tests/run
```

Sample Method Invocation

```
curl -X POST \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
```

```
    -H Content-Type:application/json \
    -d '
        {
          "options": {
              "allAssertions": boolean,
              "JUnitFormat": boolean
          },
          "variables": {
              string: string,
          }
        }
      ' \
    <API-Hook-URL>/tests/run
```

Parameters	Header Parameters API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.

Request Body	**MIME type: application/json**
	
	`{ options: { allAssertions: boolean, JUnitFormat: boolean }, variables: { string: string, } }`
	
	Body Parameters
	
	• `options` (Only required if providing a child element)
	  ◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted.
	  ◦ Child Elements:
	  ▪ `allAssertions` (Optional)
	  ▪ When `false`, only the results of failing assertions in the test are returned. When `true`, all assertions in the test are returned. `allAssertions` is `false` by default.
	  ▪ `JUnitFormat` (Optional)
	  ▪ When `false`, `application/json` format is returned for the test results. When `true`, `text/xml` JUnit format is used for the test results (see `text/xml` response). `JUnitFormat` is `false` by default.
	• `variables` (Optional)
	  ◦ The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.

Response Content	**MIME type: application/json** `application/json` is the default response from the endpoint. `[{ testRunId: string, testId: string, testName: string, location: string, initiated: string, duration: integer, status: enum['passed' or 'failed'], reportUrl: string, results: { warningsCount: integer, failureCount: integer, httpFailures: array[object], criticalFailures: array[object], assertions: array[object] } }]` **Response Description**

- `testRunID`
  - ID of the test run.
- `testId`
  - ID of the test which was executed.
- `testName`
  - Name of the test.
- `location`
  - Location of the agent which excuted the test.
- `initiated`
  - Date and time when the test was initiated.
- `duration`
  - Total duration of the test run in seconds.
- `status`
  - Overall result of the test.
- `reportUrl`
  - URL to the test run report.
- `results`
  - A wrapper object containing the results of the test run.
  - Child Elements:
    - `warningsCount`
      - Count of the HTTP warnings returned by the test assertions.
    - `failureCount`
      - Count of the HTTP status code responses that are greater than 400.
    - `httpFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 400.
    - `criticalFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 500.
    - `assertions`
      - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receieve a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test reults with a build pipline such as Jenkins, via the JUnit plugin.

```
<?xml version="1.0" encoding="UTF-8"?>
<testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
<testcase name="" classname="" time="">
  <failure message="" type="" />
</testcase>
</testSuite>
```

Response Description

- `<testSuite>`
  - Child Elements: `<testCase>`
  - Attributes:
    - `name`
      - Test Suite name.
    - `tests`
      - Number of published tests ran.
    - `disabled`
      - Number of disabled tests.
    - `errors`
      - Number of errors.
    - `failures`
      - Number of tests within the test suite that failed.
    - `timestamp`
      - Date and time the tests were ran.
    - `time`
      - Total duration of all test runs in seconds.
- `<testCase>`
  - Child Elements: `<failure>`
  - Attributes:
    - `name`
      - Test name.
    - `classname`
      - ID of the test which was executed.
    - `time`
      - Total duration of the test run in seconds.
- `<failure>`
  - Attributes:
    - `message`

	▪ Failure message containing the expected and actual response. ▪ `type` ▪ Type of failure.
Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Run Published Tests By Tag

Description

The Run Published Test By Tag endpoint executes all of the published tests within an API Hook's scope that match the tags specified in the request body. See Tagging a Test for more information on how to tag a test.

HTTP Request

```
POST <API-Hook-URL>/tests/run/tag
```

Sample Method Invocation

```
curl -X POST \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
-H Content-Type:application/json \
-d '
    {
      "options": {
          "allAssertions": boolean,
          "JUnitFormat": boolean
      },
      "variables": {
          string: string,
      },
      "tags": {
        "tagList": array[string],
        "operator": enum['not' or 'and' or 'or']
      }
    }
  ' \
<API-Hook-URL>/tests/run/tag
```

Parameters	**Header Parameters** API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.

Request Body	**MIME type: application/json**
	
	`{`
	`options: {`
	`allAssertions: boolean,`
	`JUnitFormat: boolean`
	`},`
	`variables: {`
	`string: string,`
	`},`
	`tags: {`
	`tagList: array[string],`
	`operator: enum['not' or 'and' or 'or']`
	`}`
	`}`
	
	Body Parameters
	
	• `options` (Only required if providing a child element)
	◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted.

- Child Elements:
  - **allAssertions** (Optional)
    - When **false**, only the results of failing assertions in the test are returned. When **true**, all assertions in the test are returned. **allAssertions** is **false** by default.
  - **JUnitFormat** (Optional)
    - When **false**, **application/json** format is returned for the test results. When **true**, **text/xml** JUnit format is used for the test results (see **text/xml** response). **JUnitFormat** is **false** by default.
- **variables** (Optional)
  - The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.
- **tags** (Required)
  - A wrapper object containing both the list of tags and the operator to use on them.
  - Child Elements:
    - **tagList** (Required)
      - The list of tags which correspond to the tests you want to execute or ignore (see **operator** element).
    - **operator** (Required)
      - The operator indicates how to treat the list of tags and can be either one of three values: **not**, **and**, **or**.
        - The **not** operator will omit executing any test within the API Hook's scope that has been tagged with a tag listed in the **tagList**.
        - The **and** operator will include any test within the API Hook's scope that has been tagged with all the tags provided in the **tagList**.
        - The **or** operator will include any test within the API Hook's scope that has been tagged with at least one of the tags provided in the **tagList**.

Response Content

MIME type: application/json

application/json is the default response from the endpoint.

```
[
{
  testRunId: string,
  testId: string,
  testName: string,
  location: string,
  initiated: string,
  duration: integer,
  status: enum['passed' or 'failed'],
  reportUrl: string,
  results: {
    warningsCount: integer,
    failureCount: integer,
    httpFailures: array[object],
    criticalFailures: array[object],
    assertions: array[object]
  }
}
]
```

Response Description

- **testRunID**
  - ID of the test run.
- **testId**
  - ID of the test which was executed.
- **testName**
  - Name of the test.
- **location**
  - Location of the agent which excuted the test.
- **initiated**
  - Date and time when the test was initiated.
- **duration**
  - Total duration of the test run in seconds.
- **status**
  - Overall result of the test.
- **reportUrl**
  - URL to the test run report.
- **results**
  - A wrapper object containing the results of the test run.
  - Child Elements:
    - **warningsCount**
      - Count of the HTTP warnings returned by the test assertions.
    - **failureCount**
      - Count of the HTTP status code responses that are greater than 400.
    - **httpFailures**
      - Description of failures whose HTTP Status response code is greater than or equal to 400.
    - **criticalFailures**
      - Description of failures whose HTTP Status response code is greater than or equal to 500.

- `assertions`
  - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receieve a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test reults with a build pipline such as Jenkins, via the JUnit plugin.

```
<?xml version="1.0" encoding="UTF-8"?>
<testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
<testcase name="" classname="" time="">
  <failure message="" type="" />
</testcase>
</testSuite>
```

Response Description

- `<testSuite>`
  - Child Elements: `<testCase>`
  - Attributes:
    - `name`
      - Test Suite name.
    - `tests`
      - Number of published tests ran.
    - `disabled`
      - Number of disabled tests.
    - `errors`
      - Number of errors.
    - `failures`
      - Number of tests within the test suite that failed.
    - `timestamp`
      - Date and time the tests were ran.
    - `time`
      - Total duration of all test runs in seconds.
- `<testCase>`
  - Child Elements: `<failure>`
  - Attributes:
    - `name`
      - Test name.
    - `classname`
      - ID of the test which was executed.
    - `time`
      - Total duration of the test run in seconds.
- `<failure>`
  - Attributes:
    - `message`
      - Failure message containing the expected and actual response.
    - `type`
      - Type of failure.

Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Run Published Test By ID

Description

The Run Published Test By ID endpoint executes a single specified test within an API Hook's scope.

HTTP Request

```
POST <API-Hook-URL>/tests/{Test-ID}/run
```

Sample Method Invocation

```
curl -X POST \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
-H Content-Type:application/json \
-d '
    {
      "options": {
          "allAssertions": boolean,
          "JUnitFormat": boolean
      },
      "variables": {
          string: string,
      }
    }
  ' \
<API-Hook-URL>/tests/{Test-ID}/run
```

Parameters	**Path Parameters** Test-ID: The ID of the Test to execute. **Header Parameters** API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.

Request Body	**MIME type: application/json**
	
	`{ options: { allAssertions: boolean, JUnitFormat: boolean }, variables: { string: string, } }`
	
	Body Parameters
	
	• `options` (Only required if providing a child element)
	  ◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted.
	  ◦ Child Elements:
	  ▪ `allAssertions` (Optional)
	  ▪ When `false`, only the results of failing assertions in the test are returned. When `true`, all assertions in the test are returned. `allAssertions` is `false` by default.
	  ▪ `JUnitFormat` (Optional)
	  ▪ When `false`, `application/json` format is returned for the test results. When `true`, `text/xml` JUnit format is used for the test results (see `text/xml` response). `JUnitFormat` is `false` by default.
	• `variables` (Optional)
	  ◦ The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.

Response Content	**MIME type: application/json** `application/json` is the default response from the endpoint. `[{ testRunId: string, testId: string, testName: string, location: string, initiated: string, duration: integer, status: enum['passed' or 'failed'], reportUrl: string, results: { warningsCount: integer, failureCount: integer, httpFailures: array[object], criticalFailures: array[object], assertions: array[object] }`

```
    }
    ]
```

Response Description

- `testRunID`
  - ID of the test run.
- `testId`
  - ID of the test which was executed.
- `testName`
  - Name of the test.
- `location`
  - Location of the agent which excuted the test.
- `initiated`
  - Date and time when the test was initiated.
- `duration`
  - Total duration of the test run in seconds.
- `status`
  - Overall result of the test.
- `reportUrl`
  - URL to the test run report.
- `results`
  - A wrapper object containing the results of the test run.
  - Child Elements:
    - `warningsCount`
      - Count of the HTTP warnings returned by the test assertions.
    - `failureCount`
      - Count of the HTTP status code responses that are greater than 400.
    - `httpFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 400.
    - `criticalFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 500.
    - `assertions`
      - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receieve a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test reults with a build pipline such as Jenkins, via the JUnit plugin.

```
    <?xml version="1.0" encoding="UTF-8"?>
    <testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
    <testcase name="" classname="" time="">
      <failure message="" type="" />
    </testcase>
    </testSuite>
```

Response Description

- `<testSuite>`
  - Child Elements: `<testCase>`
  - Attributes:
    - `name`
      - Test Suite name.
    - `tests`
      - Number of published tests ran.
    - `disabled`
      - Number of disabled tests.
    - `errors`
      - Number of errors.
    - `failures`
      - Number of tests within the test suite that failed.
    - `timestamp`
      - Date and time the tests were ran.
    - `time`
      - Total duration of all test runs in seconds.
- `<testCase>`
  - Child Elements: `<failure>`
  - Attributes:
    - `name`

	▪ Test name. ▪ `classname` ▪ ID of the test which was executed. ▪ `time` ▪ Total duration of the test run in seconds. • `<failure>` ○ Attributes: ▪ `message` ▪ Failure message containing the expected and actual response. ▪ `type` ▪ Type of failure.
Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Test definition syntax

The test is defined as a YAML file with the following sections:

```
 requirements: {}

info:
  title: "New Configuration YAML File"
  version: 2

configs:
  globalVariables:
    protocol: https://
    domain: sample-api.us-east-a.apiconnect.automation.ibm.com
    basePath: /bank

  inputs:
    - default:
        value: string
        type: array
    - second:
        value: number
        type: string

  steps:
    - type: request
      method: get
      url: "{{ configs.globalVariables.protocol }}{{ domain }}{{ globalVariables.basePath }}/branches"
      var: branches
      mode: json

    - type: assert-is
      expression: branches
      value: "{{ type }}"

    - type: assert-exists
      expression: branches.[1]
      stoponfail: true

    - type: assert-is
      expression: branches.[0].type
      value: string
      stoponfail: true

    - type: assert-is
      expression: branches.[0].address.city
      value: string
      stoponfail: true

    - type: assert-compares
      expression1: branches.[0].type
      expression2: branches.[7].type

    - type: request
      method: get
      url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/orders/order/AB1234
      var: payload
      mode: json

    - type: assert-equals
      expression: payload_response_statusCode
      value: 200
      ifexists: false
      stoponfail: false

    - type: assert-equals
      expression: payload_response_header_Content-Type
      value: application/json

    - type: assert-in
      expression: payload_response_header_Content-Type
      values:
        - application/json
```

```
      - application/swagger+yaml

  - type: assert-contains
    expression: payload_response_header_Content-Type
    value: app

  - type: assert-matches
    expression: payload_response_header_Content-Type
    value: ^[a-z]+/json

  - type: assert-exists
    expression: "payload"
    stoponfail: false

  - type: assert-is
    expression: "payload.tracking_reference"
    value: "string"
    ifexists: "false"
    stoponfail: false

  - type: assert-exists
    expression: payload.shipped_at
    stoponfail: false

  - type: assert-exists
    expression: payload.status
    stoponfail: false

  - type: assert-exists
    expression: payload.created_at
    stoponfail: false
```

Table 1. Summary of the parameters supported by the type attribute

Parameters	Description	Sub-attributes
globalVariables	Global variables are settings that remain consistent across the entire test and typically do not change between runs.	You can define any attributes here based on your requirements. For example: - portocol: Specifies the protocol (for example, `https://`) used in all requests, ensuring secure communication. - domain: Specifies the primary server address for API requests. - basepath: Defines the base path for all API endpoints (for example, `/bank`), which is appended to the domain for constructing request URLs.
inputs	Defines various sets of input parameters used across multiple test scenarios.	You can create multiple data sets with any attributes needed for specific test scenarios. For example, default and second are two data sets, each with its own attributes tailored for different scenarios. Note: At least one data set must be present to run the test.
request	Make an HTTP request.	- method: Defines the HTTP method to use. - url: Defines the URL to make the request to. - params: Defines the key value mapping of parameters to send. - headers: Defines the key value mapping of headers to send. - var: Defines the name of the variable to store the response in. - mode: Defines what type of data to expect and how to parse it (supported: json). For example: - type: request - method: get - url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches - var: branches - mode: json
assert-is	Assert that the type of variable from the response is value.	- expression: Defines the variable to test. - value: Defines the type we expect in response. For example: - type: assert-is expression: branches value: array
assert-exists	Assert that a particular variable specified in expression exists.	- expression: Defines the variable to test. - stoponfail: If one of the tests fails, the stoponfail attribute stops the execution of the remaining tests. For this, stoponfail must be set to true. For example: - type: assert-exists expression: branches.[1] stoponfail: true
assert-equals	Assert that a variable is equal to value.	- expression: Defines the variable to test. - value: Defines the value to compare against. For example: - type: assert-equals expression: payload_response_header_Content-Type value: application/json

Parameters	Description	Sub-attributes
assert-greater	Assert that the variable is greater than value.	- expression: Defines the variable to test. - value: Defines the value to compare against. For example: - type: assert-greater expression: payload_temperature value: application/json
assert-less	Assert that the variable is lesser than value.	- expression: Defines the variable to test. - value: Defines the value to compare against. For example: - type: assert-less expression: payload_temperature value: application/json
assert-in	Assert that the element identified by a given expression matches at least one item from a given list.	- expression: Defines the variable to test. - value: Defines an array of values to compare against. For example: - type: assert-in expression: payload_response_status value: application/json
assert-matches	Assert that the value of the element identified by a given expression matches a specified format.	- expression: Defines the variable to test. - value: Defines the regex value to compare against. For example: - type: assert-matches expression: payload_response_header_Content-Type value: [1]+/json
assert-compares	Assert that two elements are equivalent in some way.	- expression1: Defines the path to the first element for comparison. - expression2: Defines the path to the second element for comparison. For example: - type: assert-compares expression1: branches.[0].type expression2: branches.[7].type
assert-contains	Assert that the value of the element identified by a given expression contains a specific substring.	- expression: Defines the variable to test. - value: Defines the substring to compare against. For example: - type: assert-contains expression: payload_response_header_Content-Type value: app
each	Loop over the array referenced in the expression carrying out the sub-steps for each item found.	- expression: Defines the variable to test. For example: - type: each expression: "analytics.events"

if	If the specified condition (defined in the expression) is met, the assertions in the if-condition steps will be executed; otherwise, they will be skipped.	- expression: condition to test
		- steps: sub-steps that ATM executes if the condition succeeds
		For example,
		`- type: if`
		`expression: "{{payload_response_statusCode}} == 200"`
		`steps:`
		`- type: assert-is`
		`expression: "payload.tracking_reference"`
		`value: "string"`
		`stoponfail: false`

Tutorial: Invoking test cases from Jenkins with JUnit result format

Before you begin

You must have the Automated API behavior testing application enabled and have created and published at least one test. You must have a Jenkins instance that you can create a new build in with the JUnit Plugin installed

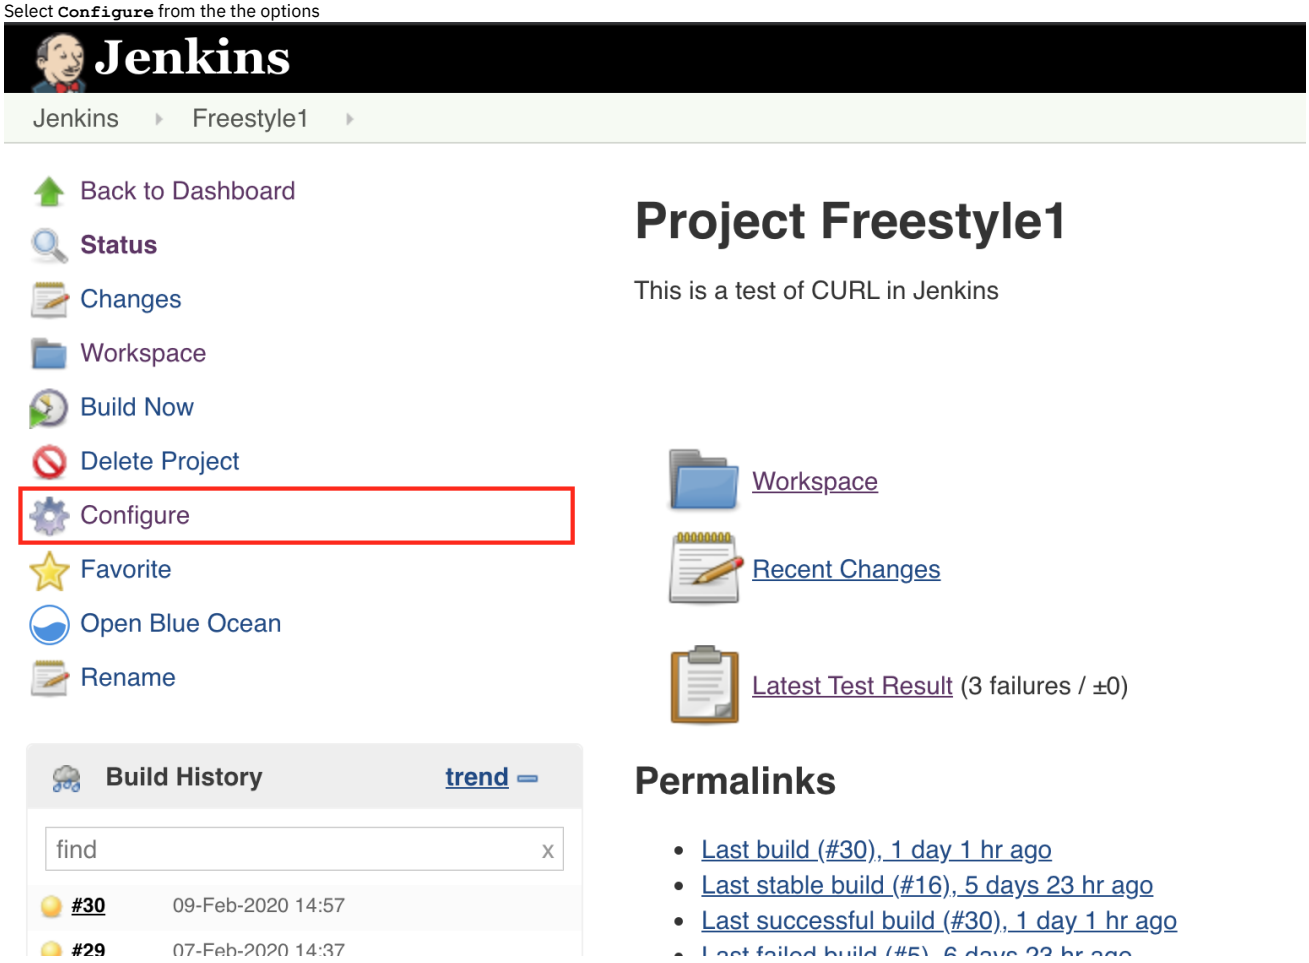
About this tutorial

In this tutorial, you invoke a test case using injected variables from a jenkins pipeline

This tutorial takes you through the following steps

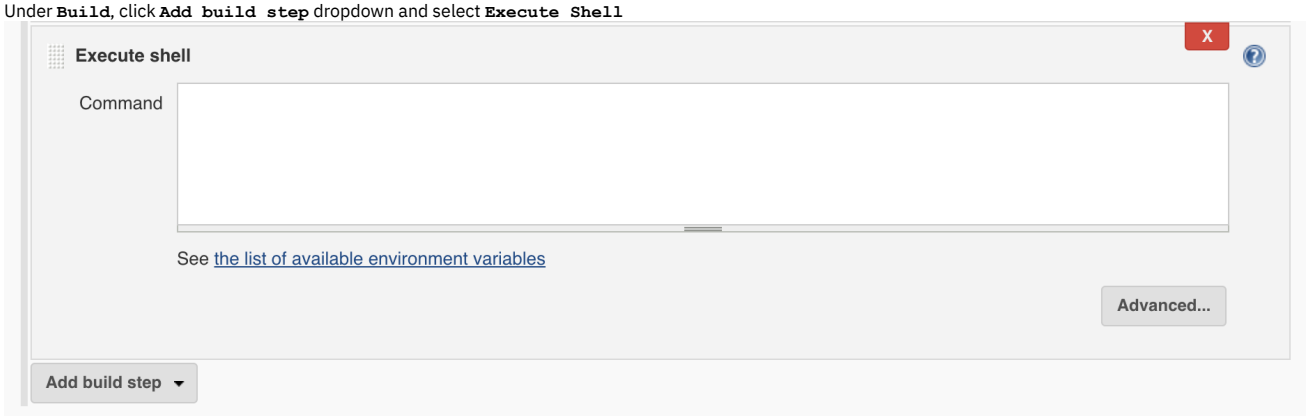
1. Creating an API Hook
2. Creating an API Key and Secret
3. Creating a Jenkins build that invokes the API Hook
4. Executing the build and reviewing the test results

Creating an API Hook



See Creating an API Hook

Creating an API Key and Secret

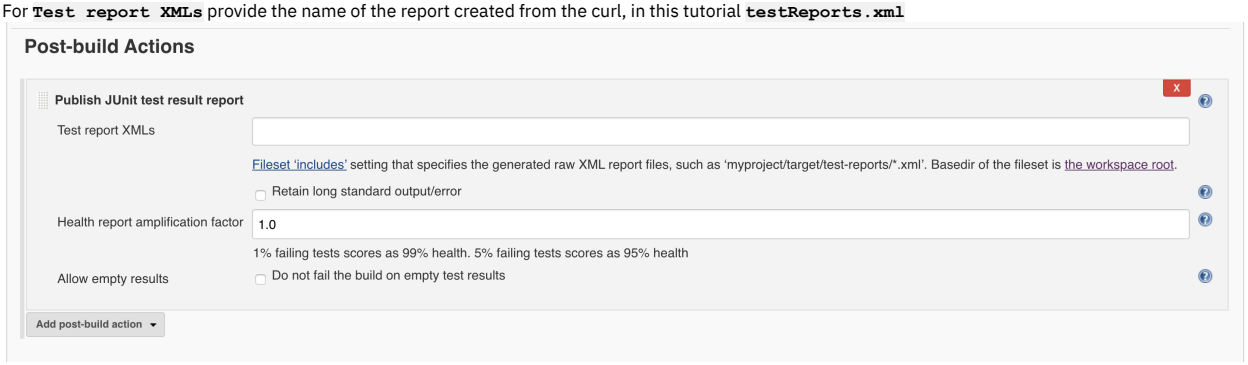


See Creating an API Key and Secret

Creating a Jenkins build that invokes the API Hook

1. Create a Jenkins Project or navigate to an existing one
2. Select **`Configure`** from the the options

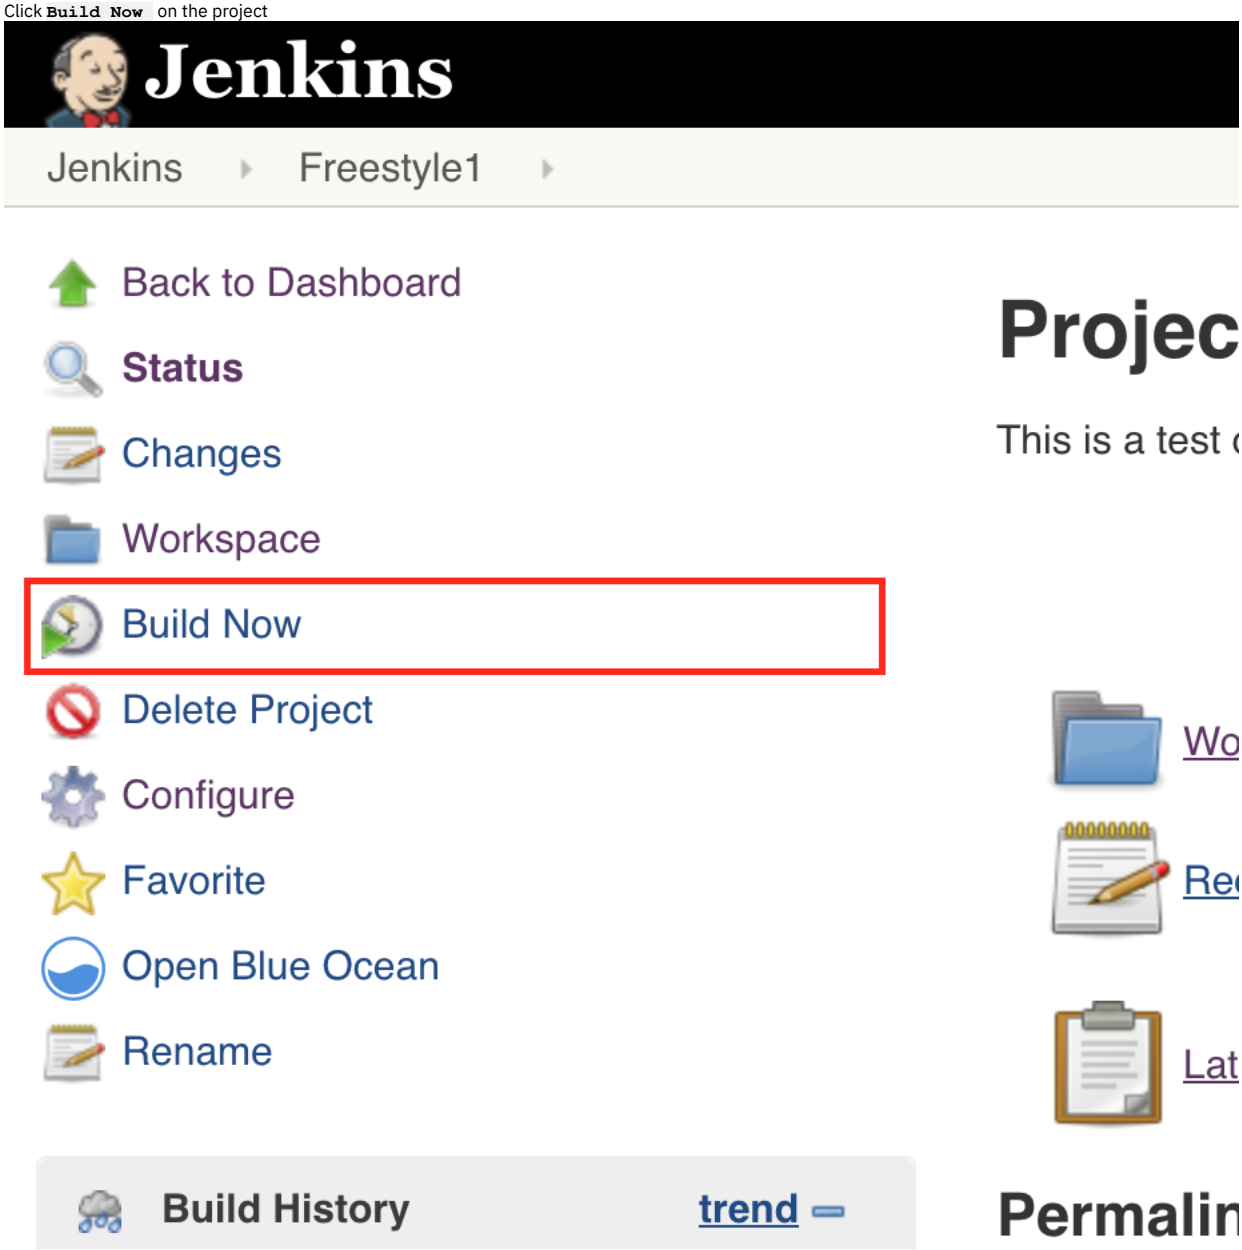
3. Under **`Build`**, click **`Add build step`** dropdown and select **`Execute Shell`**



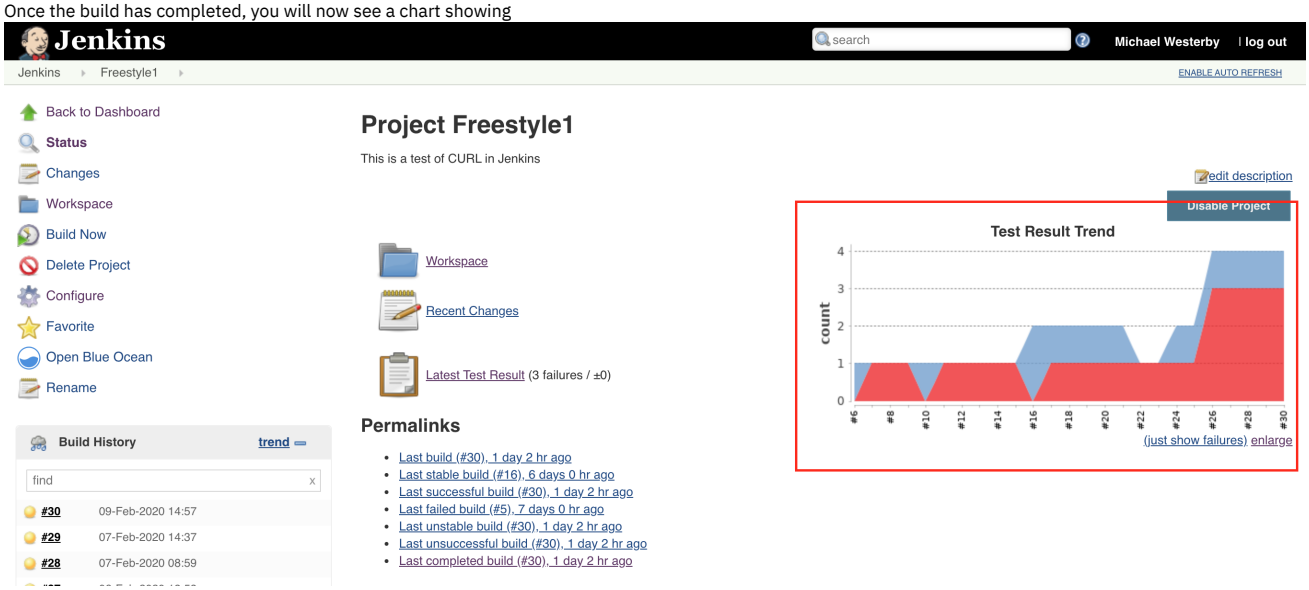
4. Within the **`Execute shell`** block paste a **`curl`** command that will invoke the hook that was created in step 1

```
curl -XPOST
-H 'x-api-key: <API-KEY>'
-H 'x-api-secret: <API-SECRET>'
-H "Content-type: application/json"
```

```
-d '{ options: { JUnitFormat: true }}'
'<API-HOOK-URL>/tests/run'
>| testReports.xml
```

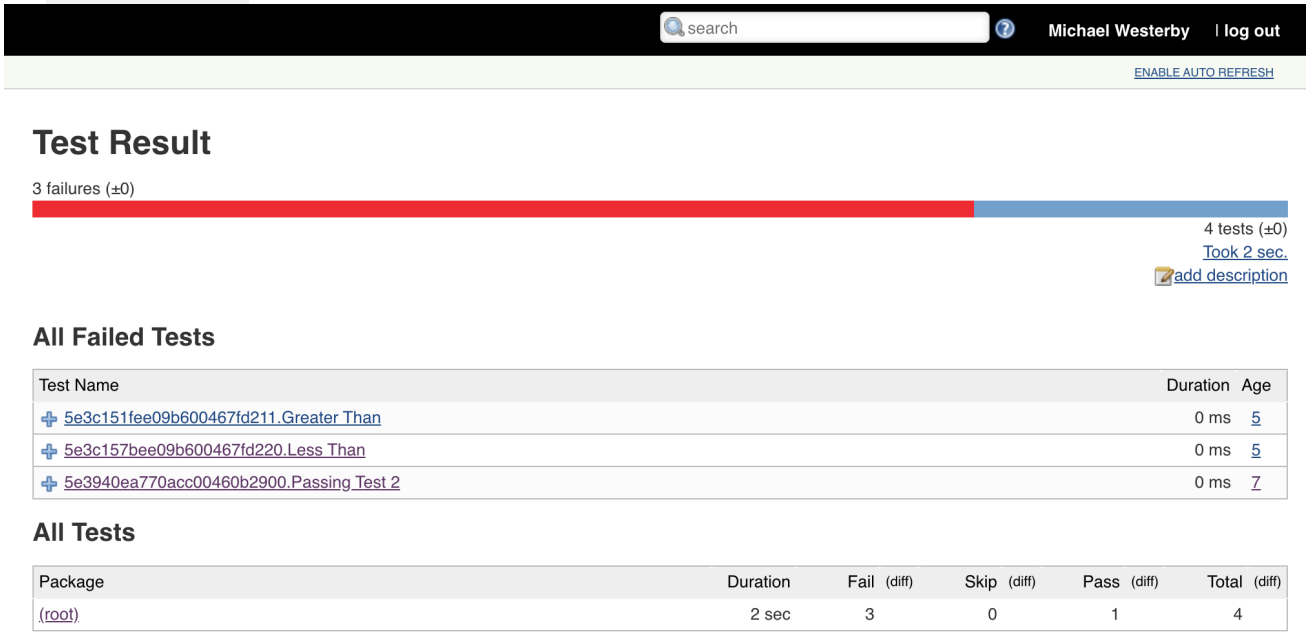


5. Under **`Post-build Actions`**, click **`Add post-build action`** and in the dropdown select **`Publish JUnit test results report`**.
    1. For **`Test report XMLs`** provide the name of the report created from the curl, in this tutorial **`testReports.xml`**



6. Save the project

Executing the build and reviewing the test results



1. Click **`Build Now`** on the project

2. Once the build has completed, you will now see a chart showing

3. Click **`Latest Test results`** and review the Junit results

To expand upon this tutorial additional options and steps can be found under Using API Hooks

What you did in this tutorial

In this tutorial you completed the following activities:

- Created a API Hook
- Created a Key and Secret used for authenicating with a hook
- Invoked the API Hook using the Key and Secret to start a test and process the results

AutoTest Assist

The AutoTest assistant exercises your API by sending it a series of randomly-generated requests, guided by the API definition and any custom rules that you provide, and alerts you about any conformance errors and server-side errors that it observes.

You control the auto-tester by creating and running an AutoTest *profile,* and you can create multiple profiles against the same API to cover different use-cases. A profile specifies how the auto-tester should run, which endpoints it should test, and what kind of data it should send. A default profile is constructed so that you can get immediate feedback by providing no more than a target URL and credentials.

The AutoTest assistant is especially useful while an API is under development as it can quickly identify errors in an implementation without you having to write test cases. It is also valuable later in the cycle for spotting regressions, as the random nature of its requests can provide coverage that your existing test cases do not match. However, it is not meant as a replacement for other testing tools in API Connect, but is rather complementary, and the information it provides when it identifies an error is often a good starting point for creating a test case.

Follow these steps to create and run your first profile:

- Creating a profile
- Modifying a profile
- Deleting a profile
- Running a profile
- Viewing the report

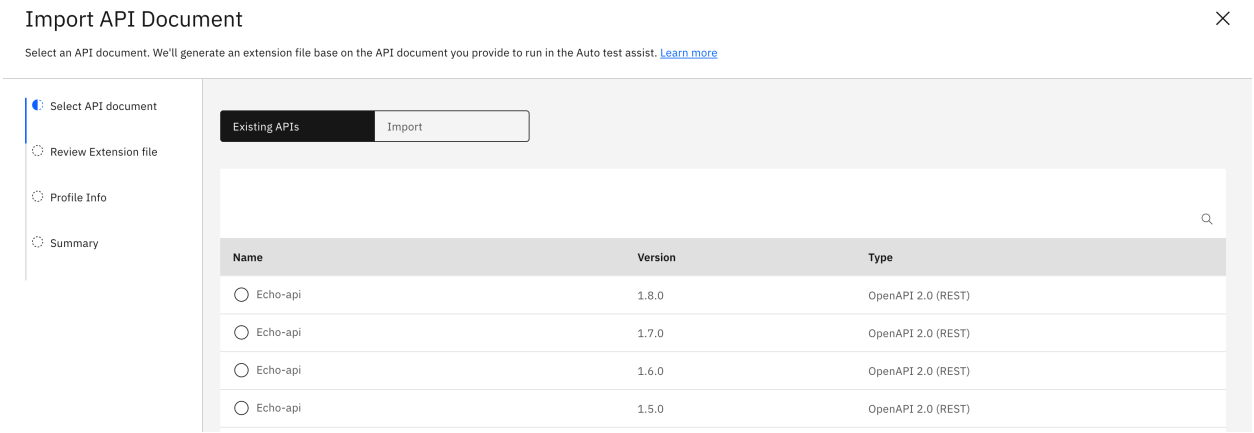
Consult these additional guides for detailed instructions on how to configure the auto-tester to support your use case:

- Profile Configuration
- Profile Security
- Data Generation Rules

Known limitations

- When using AutoTest Assist, do not use a parameter location of type **`formdata`** in an OpenAPI 2.0 specification. Doing so will result in an error.
- The API definition must conform to OpenAPI 2.0 (Swagger 2.0)
- The API definition document must have a **`.json`** or **`.yaml`** extension (you cannot select a document with another extension)
- If there are errors in the API definition then you will see only a blank screen, and the errors are not reported
- You must provide either a username and password, or a bearer token, to authenticate against the target API; other authentication methods are not supported
- You can run only one profile at a time

Creating an AutoTest profile



An AutoTest profile exists within a test suite, alongside your test cases.

To add an AutoTest profile to a test suite:

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. Go to the **Tests** > **AutoTest Profiles** tab.
5. Click **Add**.
6. Create an AutoTest profile using one of the following methods:

Existing APIs

1. Select a predefined API.

2. Click **Next**.
3. Review the read-only extension file.
4. Enter the profile name, description, and tags.
5. Click **Next**. You will see the message that the extension file and the AutoTest configuration has been generated.

Import

1. Drag and drop a JSON or YAML file that contains the API test case definition, or enter a URL for the API test case and provide a username and password if required for authentication.
2. Click **Next**.
3. Review the extension file and click **Next**.
4. Enter the profile name, description, and tags.
5. Click **Next**. You will see the message that the extension file and the AutoTest configuration has been generated.

What to do next

- Next topic: Running an AutoTest profile

Modifying an AutoTest profile

To edit an AutoTest profile in a test suite:

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. Go to the **Tests** > **AutoTest Profiles** tab.
5. Select an AutoTest profile.
6. Go to the **Info** tab, update the profile name, description, and tags, then click **Save**.
7. To edit the extension file, click the extension file, update the settings, and click **Save**. For more information, see API Extensions

What to do next

- Next topic: Running an AutoTest profile

API Extensions

An **API Extension** augments an OpenAPI definition with semantic information designed to improve the automatic generation of test cases. Extensions are used primarily by the AutoTest assistant to refine its randomly-generated test cases, but have wider applicability.

An extension comes in two parts:

- Resources identify the key resource types managed by the API, and their methods
- Properties attach semantic categories to schema properties, to constrain the format of values suggested for those fields

An extension is associated with a specific OpenAPI document and uses JSON Pointer notation to locate terms in that document.

Resources

The `resources` section contains a set of resource definitions, where each definition contains at least the following:

- a name for the resource
- a pointer to a schema of type `object` that models the resource
- a collection of methods that operate on the resource

Typically, a resource definition also identifies a field within the schema that stores a unique identifier for instances of that type.

For example, consider this extract from an API extension:

```
resources:
  Book:
    schemas:
      primary:
        json_ptr: '#/definitions/Book'
    properties:
      id_name: '$.book_id'
    operations:
      create:
        - json_ptr: '#/paths/~1books/post'
      retrieve:
        - json_ptr: '#/paths/~1books~1{book_id}/get'
        - json_ptr: '#/paths/~1books/get'
      update:
        - json_ptr: '#/paths/~1books~1{book_id}/put'
      delete:
        - json_ptr: '#/paths/~1books~1{book_id}/delete'
```

The `resources` section contains a single resource definition with the following properties:

- it defines a resource named `Book`
- a book is modeled by a schema of the same name located in the OpenAPI document under `definitions`
- each book has a property `book_id` that holds its unique ID
- there are operations defined in the OpenAPI document under `paths` that create, retrieve, update and delete books

The correspondence between the resource name and the schema name is common but not required: a resource name can be anything, as long as it is unique within the API.

The unique ID field for a book is identified by a simplified form of JSON Path expression that locates a property (`book_id`) within the primary schema.

Operations (or methods) on a resource are grouped by category:

- Create
- Retrieve
- Update

- Delete

There can be multiple operations in each. In this example there are two operations that retrieve books: one that returns a single book by ID, and another that returns a list of books, and this is common. A different definition might have **`patch`** as well as (or instead of) **`put`** under **`update`**.

JSON Pointer expressions in a resource definition all refer implicitly to the associated OpenAPI document, so the prefix **`#`** introduces a relative location within that document. JSON Pointer syntax uses the string **`~1`** to stand for a forward slash character (**`/`**) to prevent confusion with the same character used as a separator, so the operation defined in the OpenAPI document by the term:

```
paths:
  /books/{book_id}:
    get:
```

is identified here by the JSON Pointer:

```
#/paths/~1books~1{book_id}/get
```

Dependencies

A resource definition may also describe a dependency from one resource type to another.

For example:

```
  Order:
    schemas:
      primary:
        json_ptr: '#/definitions/Order'
    properties:
      id_name: '$.order_id'
    dependencies:
      - name: Book
        required: true
        references:
          - name: $.book_id
            in: body
        dependee_deletion: disabled
      - name: Customer
        required: true
        references:
          - name: customer_id
            in: path
        dependee_deletion: mutual
    operations:
      create:
        - json_ptr: '#/paths/~1customers~1{customer_id}~1orders~1{order_id}/post'
      # rest omitted for brevity
```

This definition says that the resource **`Order`** has dependencies on two other resources **`Customer`** and **`Book`** (which must be defined in the same extension).

Both dependencies are **required** in the sense that an order cannot exist unless there is a customer (to place the order) and at least one book (to buy).

An order refers to an existing book through the property **`book_id`** in the primary schema, and to a customer through the path parameter **`customer_id`**, as in the **`create`** method shown (and in other methods omitted).

A customer *owns* a set of orders; this is a hierarchical relationship implicit in the path:

```
/customer/{customer_id}/orders/{order_id}
```

When a customer is deleted, all their orders are also deleted, and this behavior is indicated by the **`mutual`** value of the deletion property.

A different relationship applies to books: a book cannot be deleted until all the orders which refer to it have been deleted, so deletion is indicated as **`disabled`** in that case.

There are three possible values for the **`dependee_deletion`** property:

- **`enabled`**: a referenced resource can be deleted even while dependent resources that refer to it still exist
- **`disabled`**: a referenced resource cannot be deleted until all dependent resources that refer to it have been deleted
- **`mutual`**: deleting a referenced resource deletes all the dependent resources that refer to it: this is typical where the dependent is owned by or contained in the referent

Pure resources

A pure resource is one that has no instances, or at least no instances that can be tracked with unique IDs, and is used as a placeholder for operations that do not behave as resource methods.

A pure resource differs from a standard resource in the following ways:

- it has no ID field (because there are no instances)
- dependencies have no **`dependee_deletion`** (for the same reason)
- all operations are grouped under a single **`pure`** category

For example:

```
ServiceAvailability:
  schemas:
    primary:
      json_ptr: '#/definitions/ServiceAvailability'
    operations:
      pure:
        - json_ptr: '#/paths/~1service~1status/get'
```

`ServiceAvailability` is a type that is returned as the result of a service status request but has no unique, persistent state.

Properties

The **properties** section assigns semantic categories to schema properties occurring in operation payloads, to constrain the range of values interpolated into generated request bodies.

For example:

```
properties:
  - json_ptr: '#/definitions/CardPayment'
    items:
      - name: card_number
        semantic: credit_card_number
      - name: expiry_date
        semantic: expiry
      - name: security_code
        semantic: cvv
```

The JSON Pointer expression locates a schema named **CardPayment** in the API document under **definitions**; the schema must have **object** type with at least the properties **card_number**, **expiry_date** and **security_code** which are specified here to have particular semantics that will guide the auto-generation of appropriate values wherever a **CardPayment** occurs in a request payload.

Semantic categories must be drawn from the following set:

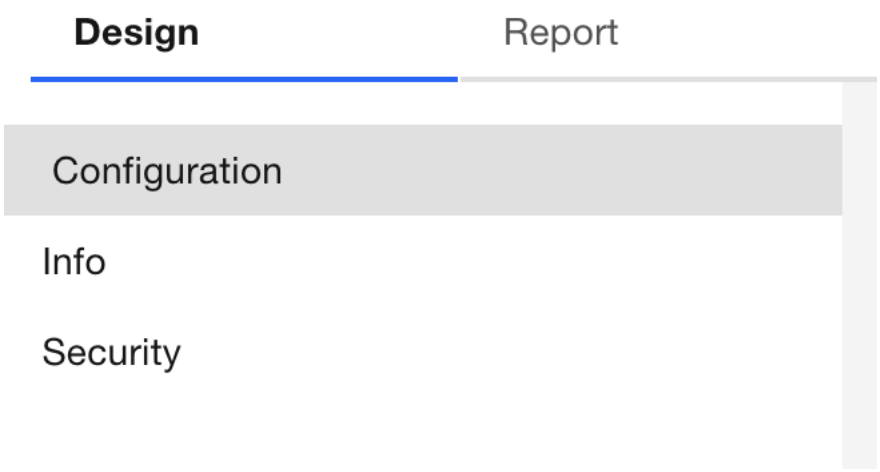
address	cvv	latitude	state_code
age	date	longitude	street
area_code	domain	minutes	temperature
birthday	email	month	time
certificate	expiry	name	timestamp
charset	first_name	number	token
cidr	gender	paragraph	twitter
city	geo_location	percentage	url
color	hours	phone	user_agent
content_encoding	humidity	phone_number	username
content_type	iban	prefix	uuid
coordinates	id	pressure	version
country	identity_provider	price	year
country_code	ip_address	revision	zip_code
credit_card_number	language	sentence	
currency	language_code	social_security_number	
currency_code	last_name	state	

Collection points to a schema that describes a set of resources. It's typically used to retrieve a list of resources.

Deleting an AutoTest profile

To delete an AutoTest profile in a test suite:

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. Go to the **Tests** > **AutoTest Profiles** tab.
5. On the **Tests** > **AutoProfiles** tab, locate the AutoTest profile you want to delete, click the **Options** icon > **Delete** option.

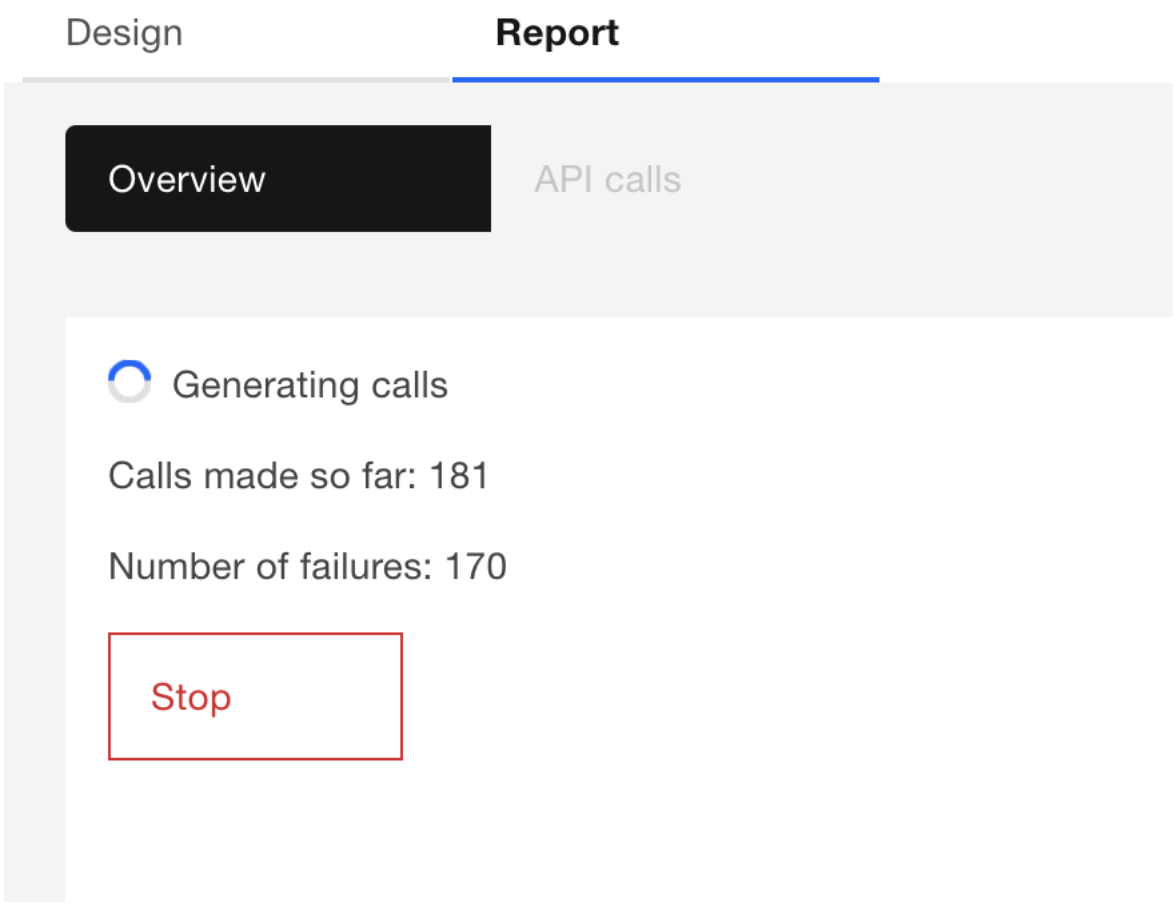


What to do next

- Next topic: Running an AutoTest profile

Running an AutoTest profile

To be able to run an AutoTest profile you will need to configure it first. Make sure to set the ServerURL parameter correctly otherwise all the generated API calls will fail. For more information please refer to AutoTest Profile Configuration. At any point during this process you can click on the save button to maintain your progress.



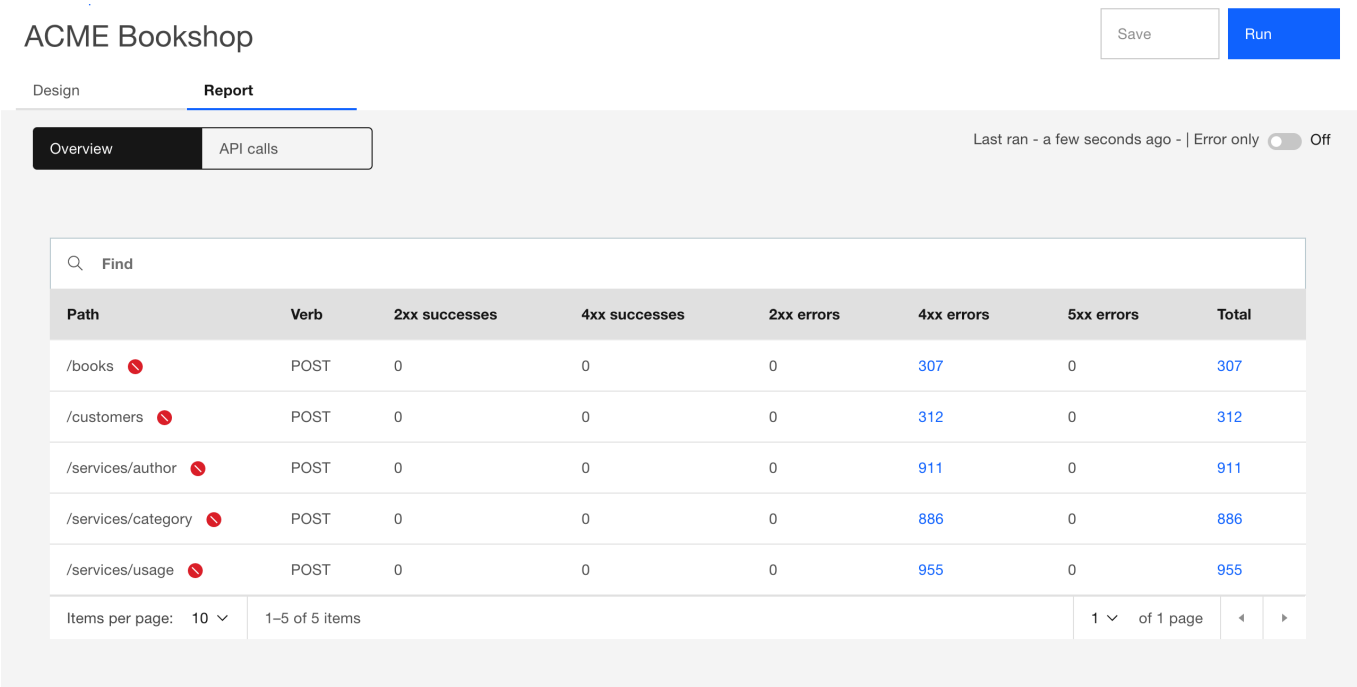
Once you have made your changes in the configuration panel, go to the security panel to set your authentication.

For more information read through AutoTest Profile Security.

Once you have made all your changes to the configuration and security. You can either save, or click on the run button.

This will take you to the report page where the exerciser will generate calls to test the API.

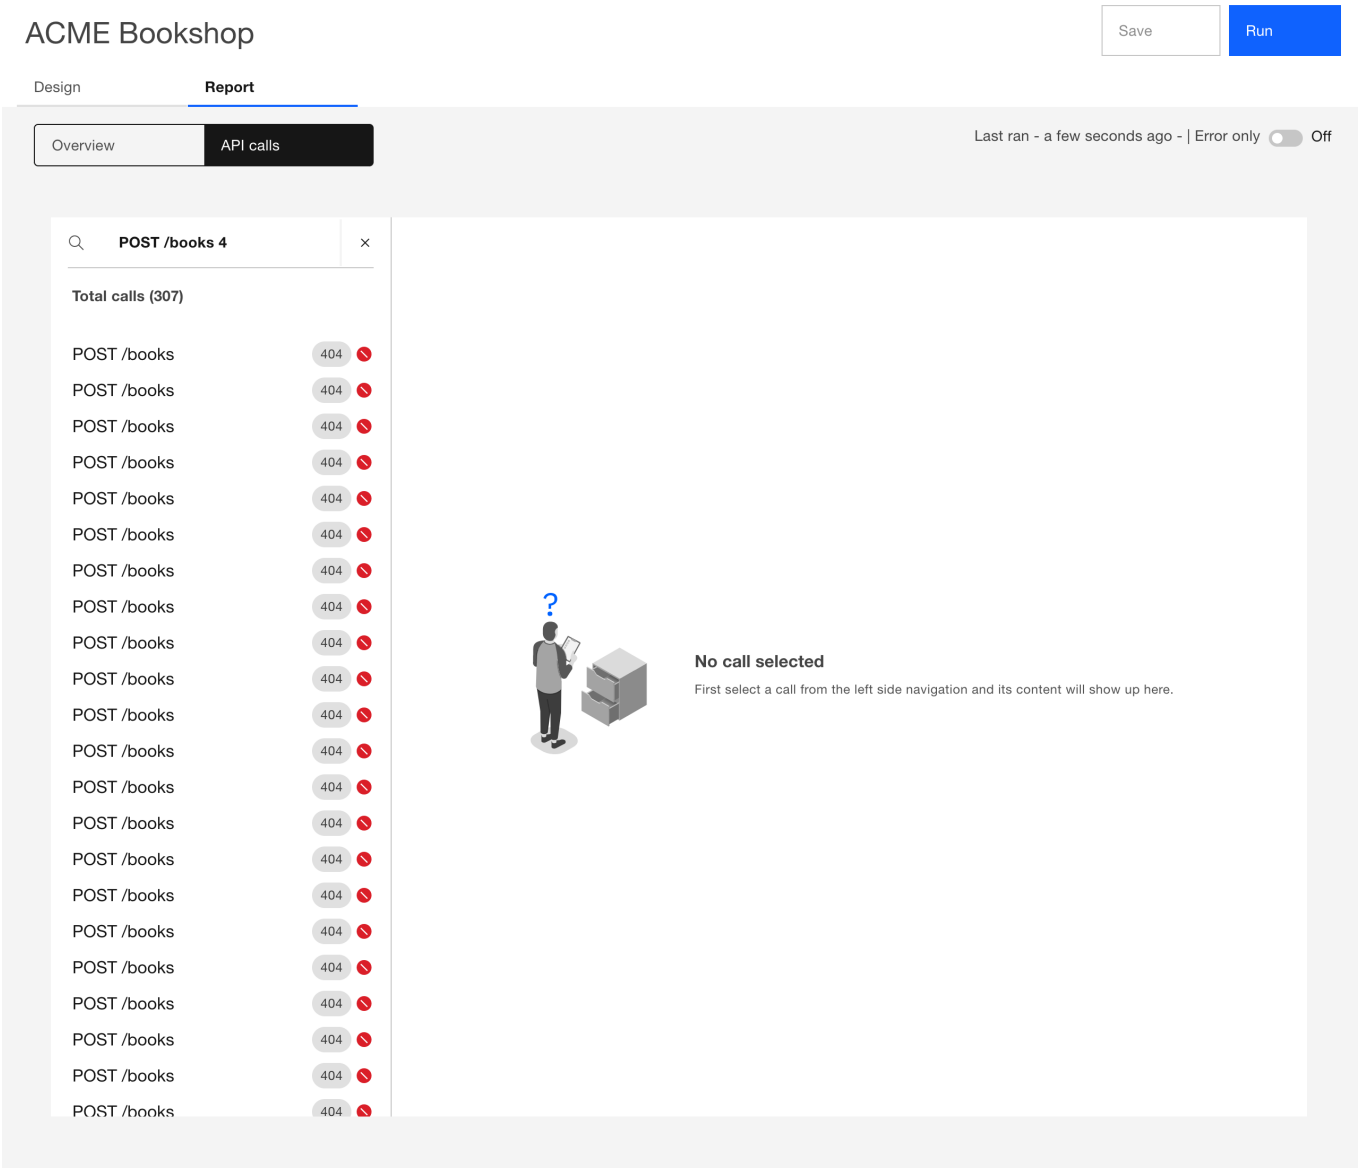
Once the generation has finished, it will take you to the next step AutoTest Report



What to do next

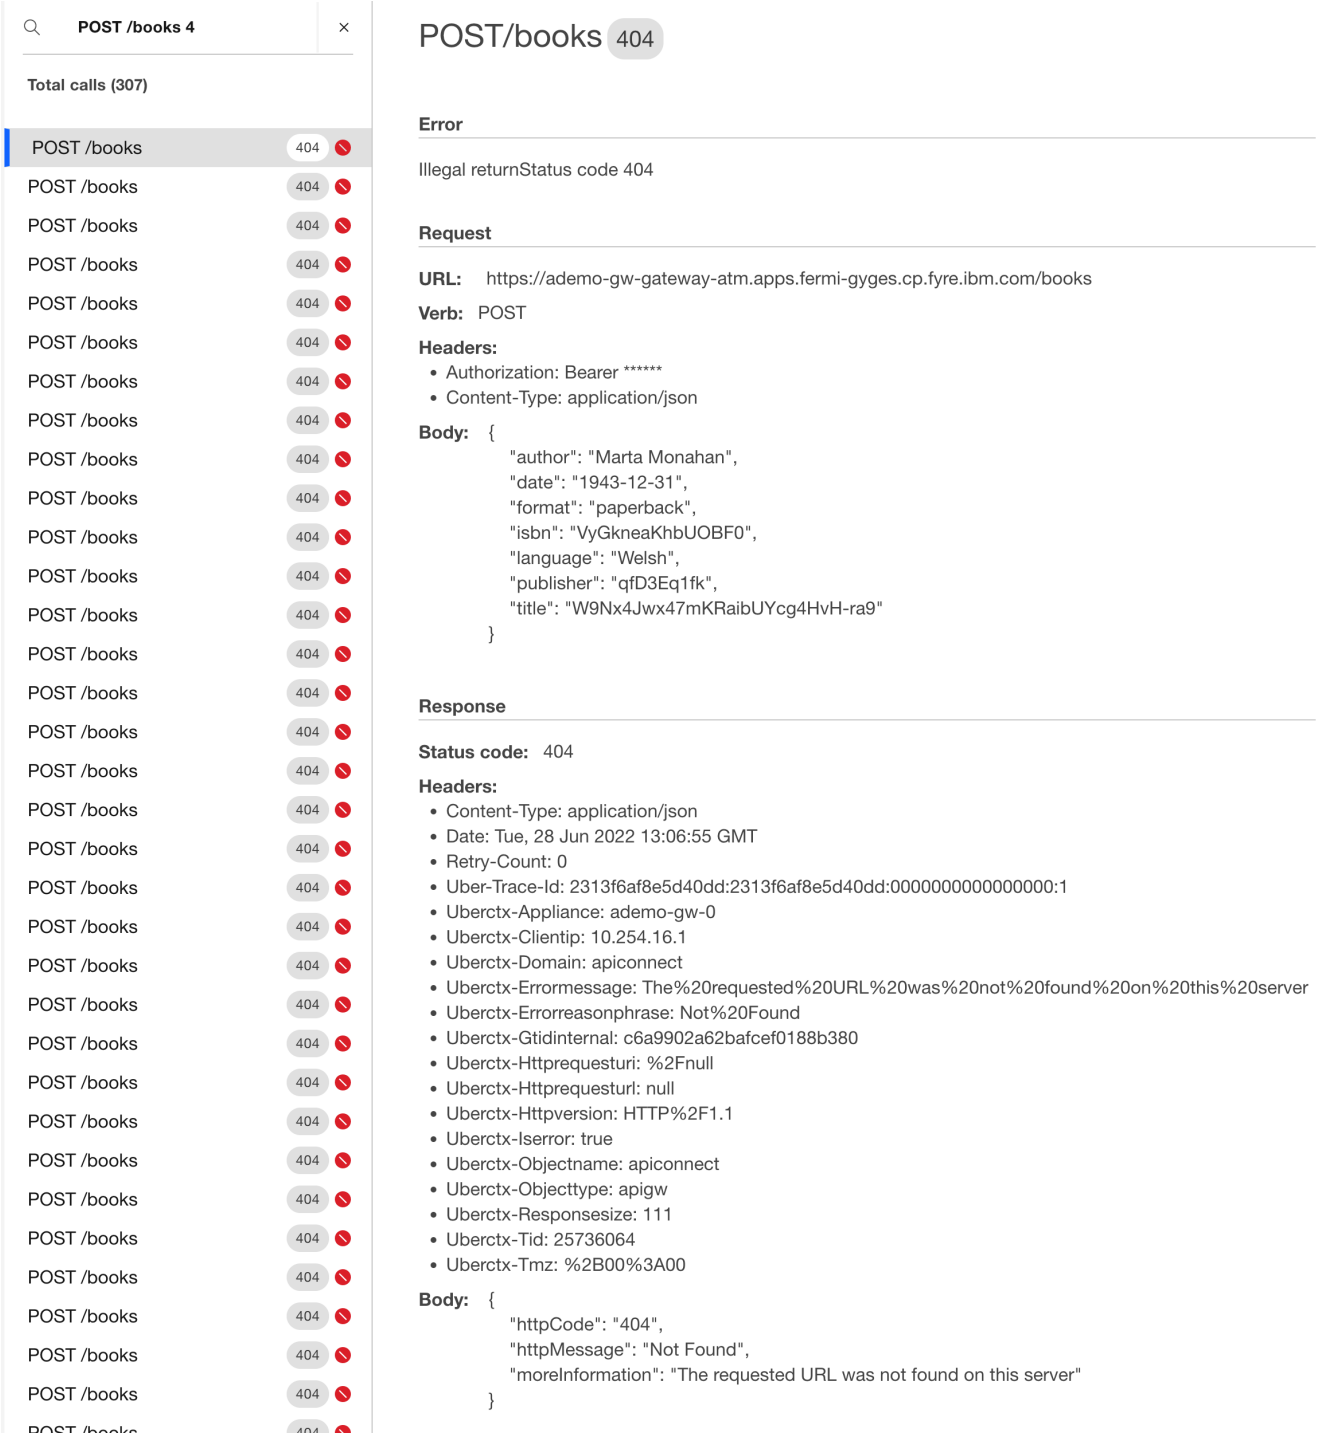
- Next topic: Viewing the AutoTest Report

Viewing the AutoTest report



Once the AutoTest run has completed (either stopped manually or the configured time to run threshold has been reached) you will be presented with the **Report** section, where you will be able to view the results of the run.

First up is the **Overview** tab, which contains a table displaying all the paths defined in the AutoTest profile's API specification, alongside their associated HTTP methods (verbs), and followed by the number of each class of responses received throughout the course of the AutoTest profile run.

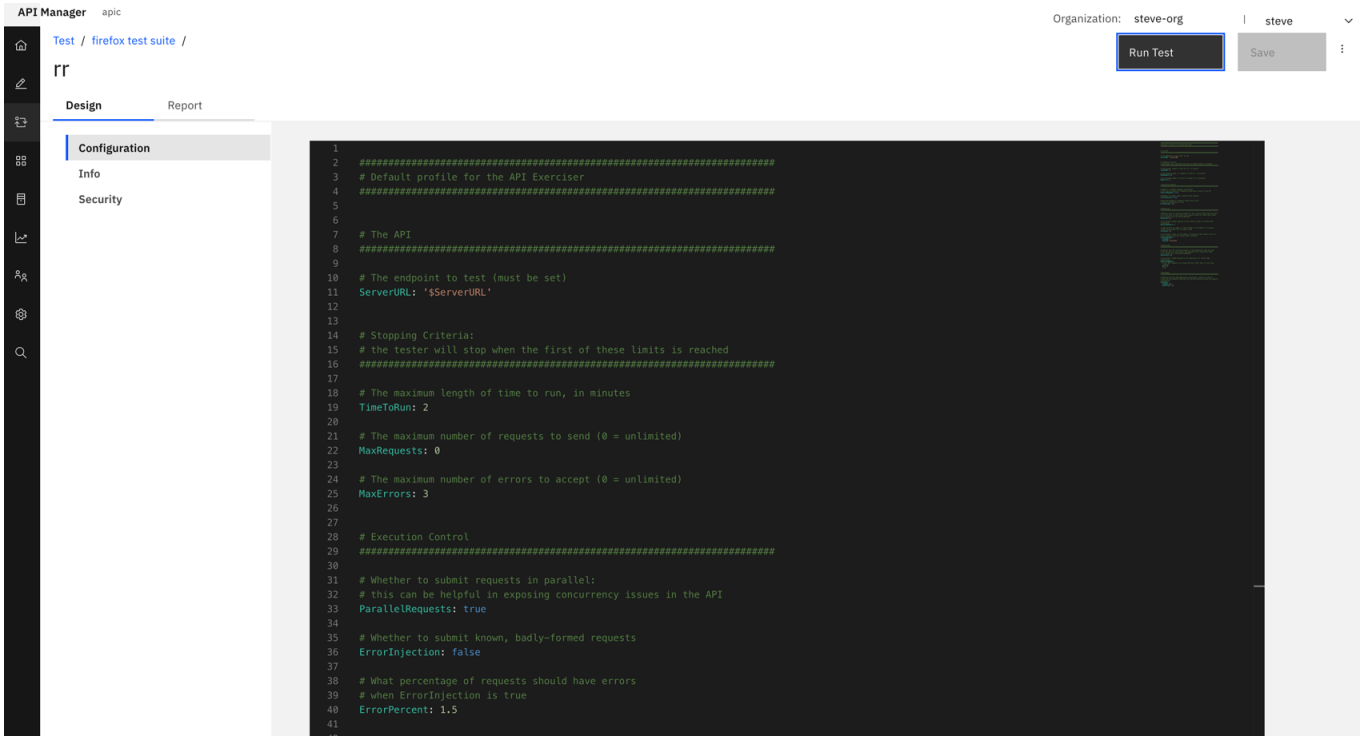


The **API calls** tab contains a more detailed view of every API call made by the run. The left side contains the list of the calls and their respective response statuses; the search bar lets you filter on the HTTP method, the path, and the response code; this should make it relatively easy to find specific requests amongst the potentially large number of API calls.

You can also get to the details view by clicking on any of the non-zero numbers in the overview table; this will automatically filter the list of API calls by the appropriate class of responses (or just the path and verb if the total tally is clicked on), as shown below.

*Either of the two views lets you apply a global **Errors only** filter by interacting with the toggle in the top right corner, under the **Save** and **Run** buttons. This will apply a filter to both the overview table and the detailed API calls list so that they will either display only errored or all requests.*

Selecting one of the calls from the list will render the details of that call on the right hand side. As seen below information such as headers and bodies for both the request and response is shown. This lets you closely exmaine precisely how a specific API endpoint had been called and the response the request received.



Profile Configuration

The configuration controls the execution of your profile; it determines for how long the test should run, and what kinds of requests it should generate. A newly-created profile includes a default configuration that you can run immediately to check that the auto-tester works with your API. The one thing you may have to set or change before you can run is the target Server URL which must point to your test deployment; the default value is copied from the API definition, where one is provided. You must also specify appropriate authentication settings on the separate **`Security`** tab (see Profile Security).

The configuration is in YAML format. The editor highlights syntactic errors as you type, and verifies the content for consistency with the API definition each time you press **`Save`**. If there is an error in the configuration, then the profile cannot run.

The Profile Configuration editor

Sections in the configuration:

- The API
- Stopping Criteria
- Execution Control
- Resources
- Operations
- Datatypes

The API

ServerURL

The server URL is the single endpoint to which all requests are sent. It must be a valid URL, reachable from your namespace, and include at least a scheme and a server address; it may also include a port number and a path prefix. It must not include a trailing slash. The server URL is prefixed to an operation path from the API definition to create the target of a request. For example, given this URL definition from the configuration:

```
ServerURL: https://api-host:8000/apis
```

And this operation path from the API definition:

```
paths:
  /movies:
    post:
```

The auto-tester will send **POST** requests to this target URL:

```
https://api-host:8000/apis/movies
```

Stopping Criteria

The profile stops running as soon as any of these criteria are met.

TimeToRun

The maximum length of time to run, in minutes: the auto-tester stops sending requests once this time period has elapsed. The overall running time will be longer because it includes additional time for setup and teardown.

For example, to set a maximum running time of ten minutes:

```
TimeToRun: 10
```

MaxRequests

The maximum number of requests to send: the auto-tester stops issuing requests once this number has been reached. The final total of requests may be greater if additional requests are needed for setup and teardown.

Set this to zero to disable the request limit, and then the auto-tester will issue as many requests as fit into the allotted time period.

For example, to set a maximum of two thousand requests:

```
MaxRequests: 2000
```

MaxErrors

The maximum number of error responses to allow: the auto-tester stops issuing requests once this number has been reached.

An error in this context is not an API error indicated by a **4xx** (or even, sometimes, a **5xx**) response, which is to be expected if the profile exercises all execution paths through the implementation. An error here is one where the response to a request is inconsistent with the API definition, which is a defect. Common cases include:

- the status code is not documented
- the payload does not conform to the schema
- any 500 error

There should be no such errors in a mature implementation so the limit is typically set low, so that the profile can terminate early if they occur. You can set the limit to zero and disable this stopping condition, which might be appropriate for a development environment where you know that some operations have defects (or you can disable those operations from ever being called as described under Operations).

For example, to set the error limit to three:

```
MaxErrors: 3
```

Execution Control

ParallelRequests

If this is **true** then the auto-tester spawns threads to issue multiple requests concurrently, otherwise it issues just one request at a time. The concurrent option increases throughput and can be helpful in exposing synchronization issues in the API.

The number of concurrent threads is fixed and cannot be changed.

For example, to disable concurrent requests:

```
ParallelRequests: false
```

ErrorInjection

If this is **true** then the auto-tester issues a certain percentage of malformed requests to further exercise the validation logic of the API, otherwise it only issues requests that are well-formed according to the API definition.

The percentage of requests is specified as **ErrorPercent**.

For example, to enable malformed requests:

```
ErrorInjection: true
```

ErrorPercent

The percentage of malformed requests, when **ErrorInjection** is **true**.

For example, to include 2% of malformed requests:

```
ErrorPercent: 2.0
```

Resources

The AutoTest execution model is based around the notion of "resources", where a resource has a schema (of object type) and a set of operations (or methods). Resources are defined in the API extensions.

The auto-tester only exercises operations that belong to resources. To decide which operation to execute next, the auto-tester first picks a resource type at random, and then an operation from that type (again, at random).

You control the frequency with which resources are selected by assigning them weights. The selection frequency for a given resource is computed as the weight for that resource divided by the sum of all the weights.

A zero weight means that the resource will never be selected, and you can use this to exclude certain resources from testing; for example, when you know that they are not yet fully implemented. It is an error for all weights to be zero which would leave nothing to test.

Use the **Resources** key to assign weights to specific resources, and **ResourceDefault** to set the default weight for any resources not specified.

Resources

The weights assigned to specific resource types. The value is an object, where the keys are resource names, and the values are non-negative integer weights. Resource names must be declared in the API extensions.

For example, to increase the test focus on **Customer** operations, and exclude **Order** operations entirely:

```
Resources:
  Customer: 2
  Order: 0
```

ResourceDefault

The default weight for any resource type not mentioned explicitly under **Resources**. The weight can be any non-negative integer value, but there are two common use cases:

- if the weight is 1 then all resources are selected with equal frequency, except where specified otherwise under **Resources**
- if the weight is 0 then all resources are disabled, except for those specified otherwise under **Resources**

For example, to disable all resources by default:

```
ResourceDefault: 0
```

In this case there must be at least one non-zero weight under **Resources**.

Instances

Upper and lower bounds on the number of resource instances that should exist at any time. The value is an object, where the keys are resource names, and the values specify lower and upper bounds for those resource types. Resource names must be declared in the API extensions, and the bounds must be non-negative integers that together define a non-empty range. The upper bound may also be **unlimited** in which case the number of instances depends upon the balance of create and delete requests issued for that type.

The auto-tester keeps track of the instances it creates for each resource type, in order to provide valid references and avoid too many 404 responses, and makes best efforts to keep the number of instances within any specified bounds.

For example, to place an upper bound on the number of **Customer** instances that should exist at any time:

```
Instances:
  Customer:
    maximum: 25
```

InstanceDefault

The default instance bounds for any resource type not mentioned explicitly under **Instances**.

For example, to make the default unlimited:

```
InstanceDefault:
  minimum: 1
  maximum: unlimited
```

Operations

Once the auto-tester has selected a resource type, it uses a similar weighting strategy to choose an operation from that type.

You control the frequency with which operations are selected by assigning them weights. Use the **Operations** key to assign weights to specific operations, and **OperationDefault** to set the default weight for any operations not specified.

A zero weight disables an operation entirely, and if all the operations are disabled for a resource then the resource itself is also disabled.

Operations

The weights assigned to specific operations. The value is an object whose schema follows the pattern established by the **Paths** object in OpenAPI, but the values assigned to each operation are non-negative integer weights.

For example, to increase test focus on the **put_customer** operation, and avoid **patch_customer** completely:

```
Operations:
  /customers/{customer_id}:
    put: 10
    patch: 0
```

The special key _ can be used to match all methods defined on a path that are not called out explicitly. For example, to disable all but the **put_customer** operation:

```
Operations:
  /customers/{customer_id}:
    put: 10
    _: 0
```

Remember that the weights are interpreted only across operations within the same resource type, and not across all operations in the API, so the overall distribution is determined by both the weight on the resource and the weight on the operation.

OperationDefault

The default weight for any operations not mentioned explicitly under **Operations**. The value is an object where the keys are method names and the values are the default weights for those methods where they occur under any path. The special key _ matches all method names that are not listed separately.

For example, to disable all operations by default:

```
OperationDefault:
  _: 0
```

In this case there must be at least one non-zero weight under **Operations**.

Datatypes

Place here any custom rules that guide the auto-tester in generating values for operation parameters and payloads. These rules override the default rules derived from the API definition and any semantic annotations in the API extensions.

Rule syntax is described in Data Generation Rules.

Schemas

Data generation rules for named schemas found under **definitions** (OpenAPI 2.0) or **components/schemas** (OpenAPI 3.0).

For example, given the schema definition:

```
Movie:
  type: object
  properties:
```

```
    title:
      type: string
    release_date:
      type: string
      format: date
    language:
      description: Two-letter ISO 639-1 language code
      type: string
      pattern: '[a-z]{2}'
```

The default generation rule for the **language** property, derived from this schema, will produce random string values that match the specified pattern (two lower-case alphabetic characters) but many of these will not be valid language codes, potentially giving rise to an excessive number of 400 responses.

To override the default generation rule and specify instead some particular language codes sufficient for testing:

```
Datatypes:
  schemas:
    Movie:
      properties:
        language:
          enum:
            - en
            - fr
            - de
```

To inject a small percentage of invalid values:

```
Datatypes:
  schemas:
    Movie:
      properties:
        language:
          choice:
            - enum:
                - en
                - fr
                - de
              weight: 98
            - const: xx
              weight: 2
```

Operations

Data generation rules for operation parameters and payloads described by inline (or unnamed) schemas and types. The value is an object whose schema follows the pattern established by the **Paths** object in OpenAPI.

Note that the auto-tester only supports **path** and **query** parameters at present, and other parameter types are ignored.

For example, given these (abbreviated) operation definitions:

```
paths:
  /movies:
    get:
      parameters:
        - name: limit
          in: query
          description: Sets an upper bound on the number of movies returned
          schema:
            type: integer
    post:
      requestBody:
        content:
          application/json:
            schema:
              type: object
              allOf:
                - $ref: '#/definitions/Movie'
                - properties:
                    keywords:
                      type: array
                      items:
                        type: string
```

To set values for the **limit** query parameter, and the **keywords** property of the payload to **post**:

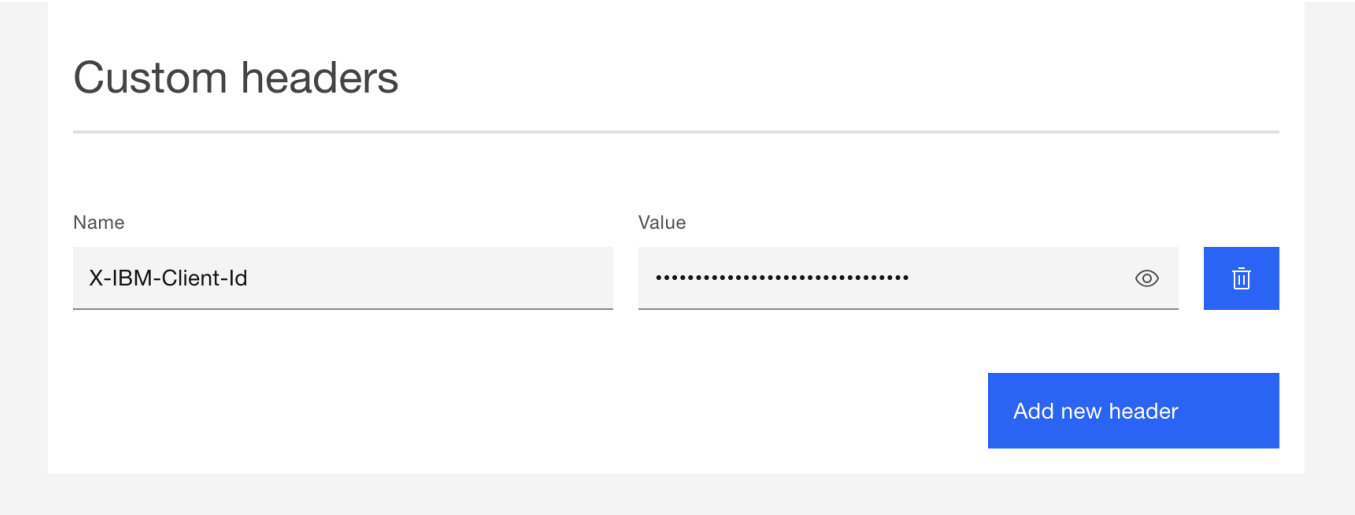
```
Datatypes:
  operations:
    /movies:
      get:
        parameters:
          - name: limit
            in: query
            data:
              # pick a random value between 0 and 500 (inclusive)
              minimum: 0
              maximum: 500
      post:
        requestBody:
          content:
            application/json:
              data:
                properties:
                  keywords:
                    # pick up to 3 items from the following list
                    items:
```

```
                    enum:
                      - avant-garde
                      - dystopia
                      - epic
                      - postmodern
                      - remake
                      - shootout
                  minItems: 0
                  maxItems: 3
```

Profile Security

Security is where you set credentials for the API under test. The auto-tester supports only **Basic** authentication (username and password) and **Bearer** (or **Token**) authentication; it does not support other authentication methods such as **OAuth,** or the use of custom headers.

Select your security type from the dropdown and enter the required information:



Security Type	Description	Credentials
None	Unsecured endpoint	n/a
Basic	Basic HTTP authentication	Username/Password
Basic-url	Same as **Basic** but omits the word `Basic` from the Authorization header	Username/Password
Bearer	Bearer (or Token) authentication	Token

If you provide incorrect credentials then they will not prevent the profile from running, but you can expect to see all requests fail, typically with the response **401 Unauthorized** or **403 Forbidden.**

If you provide a bearer token then be sure that it has a sufficient lifetime to cover the full period of the test, which is determined by the stopping criteria in the profile configuration. Otherwise, once the token expires, you can expect to see authentication failures as described earlier.

Custom headers

You can also confiure custom security headers should your APIs require them for authentication/authorization. Simply add the required header(s) and the appropritate value(s) under the custom headers section like so:

Data Generation Rules

This feature is available only in API Connect Enterprise as a Service

Data generation rules guide the auto-tester in choosing values to populate the parameters and payloads of its requests.

There are default rules derived from the API definition and extensions, but sometimes you want to override these, either to improve the general accuracy of the auto-tester or to tailor its requests to a specific use case, and you do that by adding custom rules to the Datatypes section of the profile configuration.

A data generation rule binds a **data generator** to a schema or type in the API definition such that, when the auto-tester assembles the data for a request and encounters that schema or type, it uses the generator to provide an appropriate value at that point.

Data generators

A **data generator** describes a never-ending sequence of values, and whenever the auto-tester calls on a generator it takes the next value from the sequence.

The syntax for generation rules reuses terms from JSON Schema where the implied constraints on a schema are sufficient to guide the auto-tester in generating conformant values. Such constraints occurring in the API definition help inform the default rules.

Constant

The **constant** generator always returns the same value, which can be of any simple type.

```
const: 0

# ==> 0, 0, 0, ...

const: Thursday

# ==> "Thursday", "Thursday", "Thursday", ...
```

Enumeration

The **enumeration** generator returns values selected at random from a given list, which can be of any simple type.

```
enum:
  - 0
  - 1
  - 2

# ==> 1, 0, 2, 0, ...

enum:
  - Thursday
  - Friday
  - Saturday

# ==> "Friday", "Saturday", "Saturday", ...
```

Pattern

The **pattern** generator returns string values that match a given regular expression.

```
pattern: '[0-9]{3}'

# ==> "884", "924", "121", ...

pattern: '[a-z][a-z_]{0,15}'

# ==> "dbe", "kg_cfsv", "dhbfgbjxavmsaxq", ...
```

Range

The **range** generator returns numeric values uniformly distributed over a given range (inclusive).

```
minimum: 0
maximum: 10

# ==> 10, 6, 8, ...
```

If either endpoint is omitted then it defaults to the most negative or most positive value of the type:

```
minimum: 0

# ==> 10029625, 3162517758, 841054690, ...
```

Semantic

The **semantic** generator returns values that conform to some pre-defined semantic category, covering names, addresses, credit card numbers, etc. The set of categories is the same as that allowed in the API extensions.

```
semantic: email

# ==> "herbertschaden@fahey.net", "emmyfarrell@cruickshank.com", "vilmaprohaska@zboncak.org", ...

semantic: first_name

# ==> "Antwan", "Connie", "Modesto", ...
```

Resource

The **resource** generator returns values that are unique identifiers of resource instances of a given type, selected at random from the pool of existing instances. The identifier of an instance is taken from the **id_name** property of the resource type defined in the API extensions and its type and format will vary accordingly.

```
resource: Customer

# ==> "e5537298-9041-47fc-b97e-c910d8f9d971", "f60521c8-2ccb-4036-a742-9f350271675f", "e5537298-9041-47fc-b97e-c910d8f9d971",
...
```

Array

The **array** generator returns array values whose contents are populated from a data generator defined recursively. The length of the array is chosen at random between **minItems** and **maxItems** inclusive.

```
items:
  pattern: '[0-9]{3}'
minItems: 3
maxItems: 3

# ==> ["770", "496", "219"], ["431", "895", "331"], ["864", "130", "204"], ...

items:
  enum:
    - 0
    - 1
minItems: 0
```

```
maxItems: 5

# ==> [], [1, 0, 1, 1], [0], ...
```

Object

The **object** generator returns object values whose properties are populated from named data generators, defined recursively.

```
properties:
  x:
    minimum: 0
    maximum: 100
  y:
    minimum: 0
    maximum: 100

# ==> {"x": 59, "y": 63}, {"x": 22, "y": 8}, {"x": 95, "y": 57}, ...
```

```
properties:
  code:
    pattern: '[0-9]{3}'
  language:
    enum:
      - en
      - fr
      - de

# ==> {"code": "452", "language": "fr"}, {"code": "504", "language": "en"}, {"code": "846", "language": "fr"}, ...
```

If a property is not required by the target schema then it may be marked with an **optional** attribute which specifies a frequency (between **0.0** and **1.0**) that determines how often the property is included in the generated object (where 0 means never, and 1 means always).

```
properties:
  code:
    pattern: '[0-9]{3}'
  language:
    optional: 0.5
    enum:
      - en
      - fr
      - de
  tag:
    optional: 0.0

# ==> {"code": "452", "language": "fr"}, {"code": "504", "language": "en"}, {"code": "846"}, ...
```

Choice

The **choice** generator returns values selected at random from a given list of data generators, using optional weights to bias the outcome. The alternatives must be simple generators, which excludes **array** and **object** generators.

```
choice:
  # bias the selection towards English
  - const: en
    weight: 5
  - const: fr
  - const: de

# ==> "en", "en", "en", ..., "de", "en", ...
```

```
choice:
  # normal values in the range 1-10
  - minimum: 1
    maximum: 10
    weight: 98
  # with a small percentage of outliers
  - const: 999
    weight: 2

# ==> 6, 3, 9, 1, ..., 999, 6, ...
```

Data generation rules

A **data generation rule** binds a data generator to a schema occurring in the API definition so that the auto-tester knows how to generate values for that schema in an API call. Rules are specified in the Datatypes section of the profile configuration, and override the default rules derived from the API definition and extensions.

Schemas occur widely in the OpenAPI specification, but there are three key locations which have most relevance to the auto-tester where the profile allows override rules:

- Named schemas
- Parameters
- Inline request bodies

Named schemas

A schema rule assigns a data generator to a named schema from the API definition, found either under **definitions** (OpenAPI 2.0) or **components/schema** (OpenAPI 3.0). The auto-tester will use the specified generator wherever the named schema occurs in a request.

Schema rules appear in the schemas section of the profile configuration, under **Datatypes**.

Because this is an *override,* the generator may be incomplete for the original schema, and the auto-tester will fall back to using the default rules to cover any gaps. In particular, if the schema describes an object type then the generator need only name a subset of the object properties, and the auto-tester will apply the override for those properties but use default rules for the rest.

For example, given this named schema in the API definition:

```
Movie:
  type: object
  properties:
    title:
      type: string
    release_date:
      type: string
      format: date
    language:
      description: Two-letter ISO 639-1 language code
      type: string
      pattern: '[a-z]{2}'
```

The default rule derived from the schema returns values such as:

```
{
  "title": "mkLHM22Ohabb6YG4-wdZFUwxQa7dn",
  "release_date": "2018-09-14",
  "language": "jq"
}
```

You can refine this by overriding the default rules for the **title** and **language** properties:

```
Datatypes:
  schemas:
    Movie:
      properties:
        title:
          semantic: sentence
        language:
          enum:
            - en
            - fr
            - de
```

This rule binds an object generator (introduced by the keyword **properties**) to the schema named **Movie** which -- combined with the default rule for **release_date** -- returns values such as:

```
{
  "title": "What dog everybody am myself hourly meeting how group over example her",
  "release_date": "2094-06-31",
  "language": "de"
}
```

Parameters

A parameter rule binds a data generator to a named parameter within an operation found under **paths** in the API definition.

Parameter rules appear in the operations section of the profile configuration, under **Datatypes**.

For example, given this parameter definition on **GET /movies** in the API definition that restricts the number of movies returned in a single call:

```
paths:
  /movies:
    get:
      parameters:
        - name: limit
          in: query
          description: Sets an upper bound on the number of movies returned
          schema:
            type: integer
```

The default rule derived from this definition will return values from the full integer range, but you can override this with a rule in the profile configuration that specifies a more realistic range, with occasional outliers to check the validation logic:

```
Datatypes:
  operations:
    /movies:
      get:
        parameters:
          - name: limit
            data:
              choice:
                - minimum: 1
                  maximum: 500
                  weight: 95
                - const: 0
                  weight: 3
                - const: 8000000
                  weight: 2
```

The format of the rule follows the format of the original definition but with the keyword **data** in place of **schema** to introduce the data generator.

In OpenAPI, a parameter is uniquely identified by a name *and a location* (so the same name could be used in, say, both query and header) so the parameter rules allow the **in** property as optional where needed to disambiguate. It's not used in this example because the query parameter is the only one named **limit**.

The auto-tester only supports parameters of type **query** and **path** at present (and **body** in OpenAPI 2.0). Rules bound to other parameter types are ignored.

Request body

A request body rule binds a data generator to the body of a request where the corresponding schema is specified directly as part of the operation in the API definition, rather than via a reference to a named schema.

Request body rules appear in the operations section of the profile configuration, under **Datatypes**.

For example, given this definition of the payload to a **POST** request:

```
paths:
  /movies:
    post:
      requestBody:
        content:
          application/json:
            schema:
              type: object
              allOf:
                - $ref: '#/components/schemas/Movie'
                - properties:
                    keywords:
                      type: array
                      items:
                        type: string
```

The following rule generates some appropriate keywords to attach to a new movie (where the movie itself is covered by the rules discussed earlier):

```
Datatypes:
  operations:
    /movies:
      post:
        requestBody:
          content:
            application/json:
              data:
                properties:
                  keywords:
                    # pick up to 3 items from the following list
                    items:
                      enum:
                        - avant-garde
                        - dystopia
                        - epic
                        - postmodern
                        - remake
                        - shootout
                    minItems: 0
                    maxItems: 3
```

As with the parameter rules, the format follows that of the original definition but with **data** in place of **schema**. The definition is in the style of OpenAPI 3.0, but the rule can work for OpenAPI 2.0 as well as long as the content type is consistent; alternatively, starting from an OpenAPI 2.0 definition, you can use a **body** parameter rule to specify the payload, but that does not work for 3.0.

Testing an API with the policies editor

IBM® API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note:

- If you are testing an OpenAPI 2.0 API, you can use either the Policies editor test tool that is described here, or you can use the Test tab. If you are testing an OpenAPI 3.0 API, only the Test tab is available; see Using the Test tab to debug your API.
- If you are testing an API that contains references to API properties, only those references that are defined inside the API assembly are resolved and replaced with their corresponding values when you call the API in the assembly test tool. The property references that are defined outside of the API assembly are not resolved during the test. For more information on API properties, see Setting API properties (OpenAPI 2.0) or Setting API properties (OpenAPI 3.0).
- Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.

Procedure

To test an API, complete the following steps.

1. If you are using API Designer, set the mode to Online using the Options menu ⋮ on the main page.
2. In the navigation pane, click Develop, then select the APIs tab.
3. Click the title of the API that you want to work with.
4. Click the Gateway tab then, in the navigation pane, click Policies.
5. If you are testing the API for the first time and, when you created the API definition, you selected the Activate API option, your test setup will already be configured and you can proceed immediately to the next step to test your API. Otherwise, click Offline to toggle the API to the Online state. If you are retesting your API after modifying the API, the modified APIs are republished automatically on saving.
6. Click the Test icon ▷.
   Note:
   - The Test icon is active only if you have toggled your API to the Online state, as described in step 5.
   - The Catalog, Product, Plan, and application details that are displayed in the Setup pane reflect your configured API testing preferences; see Specifying the testing preferences for an API,

7. In the Operation section, select the API operation that you want to test, then click Invoke.
   The API response is displayed in the Response section.
   Note: If you receive a message that is associated to an untrusted certificate, perform the following steps:
   a. Click the link that is provided.
   b. Accept the certificate.
   c. Return to the test environment.
   d. Click Invoke again.
   The message also mentions a lack of CORS support on the server that is one of the possible causes for the connection failure.

Testing an API with the Local Test Environment

Use the Local Test Environment (LTE) to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.

API Connect provides the following methods for testing an API on your local machine:

- Invoke the API from the API Designer UI application running in Online mode as described in Testing an API.
- Call the API in the Local Test Environment with a cURL command, as described in the following sections.

Prerequisites

- The API Connect developer toolkit, including the API Designer user interface, installed. For installation and running instructions, see Installing the toolkit.
- The Local Test Environment and the API Designer must be from the same API Connect fix pack release in order for them to work together.
- Docker installed.
  Note: The Local Test Environment is not supported with Docker Version 18.09.x.
- A minimum of 4 GB of RAM available to Docker if a single gateway type is used, or 6 GB if both the DataPower® API Gateway and DataPower Gateway (v5 compatible) are used.
  Note: As you increase the number of APIs that are published to your gateways, you will need to allocate further memory to Docker. You will also need to start the Local Test Environment with a larger database; see `apic-lte start`.
- If you are using Windows, ensure that your C: drive (or the drive on which your HOME directory is located, if different), is enabled as a shared drive so that the Local Test Environment files are accessible to the Docker containers.

Installing the Local Test Environment

There are two options for installing the Local Test Environment:

- Each user downloads the Local Test Environment images to their local machine and installs the Local Test Environment from there.
- One user downloads the Local Test Environment images and uploads them to a private Docker registry, from where any user can install the Local Test Environment.

To install the Local Test Environment from your local machine, complete the following steps:

1. Open a browser and visit the API Connect announcement page, search for your product version, and locate the "Downloads" table on the product announcement page. In the table, click the link to download each of the following files:
   - apic-lte-images-*version*.tar.gz, which contains all required Docker images.
     Example: apic-lte-images-10.0.2.tar.gz
   - apic-lte-*platform*-*version*, which are binary files for the macOS, Linux®, and Windows platforms.
     Examples:
     - macOS: apic-lte-osx-10.0.2
     - Linux: apic-lte-linux-10.0.2
     - Windows: apic-lte-win-10.0.2
2. On the macOS or Linux platform, use the `chmod` command to make the binary file executable; for example:

   ```
   chmod +x linux-apic-lte
   ```

3. Load the Docker images into your local Docker image repository by entering the following command:

   ```
   docker load < apic-lte-images.tar.gz
   ```

Note: In all Local Test Environment commands that are used on the remainder of this page, replace *platform* with `macOS`, `linux`, or `windows`, depending on your platform, as follows:

- macOS: replace `platform-apic-lte` with `osx-apic-lte`
- Linux: replace `platform-apic-lte` with `linux-apic-lte`
- Windows: replace `platform-apic-lte` with `win-apic-lte`

To upload the Local Test Environment images to a private Docker registry, complete the following steps:

1. Download the `IBM_API_CONNECT_LOCAL_TEST_ENVIRO.zip` file as described in step 1.
2. Distribute the appropriate binary file to all users, according to the platform.
3. Upload the Local Test Environment to your private Docker registry; enter the following command:

   ```
   platform-apic-lte registry-upload apic-lte-images.tar.gz registry_host
   ```

   where *registry_host* is the host name or IP address of your private Docker registry. Now, any user can install and run the Local Test Environment as follows:
   a. If the private Docker registry requires authentication, log in by entering the following command:

      ```
      docker login registry_host
      ```

   b. Load the Docker images into your local Docker image repository by entering the following command:

```
platform-apic-lte init registry_host
```

Starting the Local Test Environment

1. Start the Docker images by running the following command:

   ```
   platform-apic-lte start
   ```

   Note:
   - By default, the `platform-apic-lte start` command starts only a DataPower API Gateway. To also start a DataPower Gateway (v5 compatible), enter the following command:

     ```
     platform-apic-lte start --datapower-gateway-enabled --datapower-api-gateway-enabled
     ```

   - The Local Test Environment might fail to start with an error message that includes the strings `Error: certificate is not yet valid` and `CERT_NOT_YET_VALID`. The most likely cause is that the date and time setting is incorrect on the machine that is the running the Local Test Environment. Ensure that the date and time setting is correct, before attempting the start command again. If you are using Docker for Windows, the clock in the Docker containers can become out of sync with the system clock, especially after a machine has been put in sleep mode. In this case, restarting Docker should fix the clock discrepancy; for more information, see https://github.com/docker/for-win/issues/4526.
   - By default, the LTE starts with an empty backend database that does not contain the APIs and Products that might have been published during an earlier run of the LTE. To start the LTE with the backend database that was used during the previous run, use the flag `--keep-config`, for example, `platform-apic-lte start --keep-config`. When you use `--keep-config` any other flag that is specified for the start is ignored. Instead the same flags that were used during the earlier start are used, in particular the same gateways are enabled.
2. Verify that the Local Test Environment is installed and running correctly by running the following commands:
   a. Check the status of the LTE components:

      ```
      platform-apic-lte status
      ```

      This output from this command shows the status of all components, and provides endpoint and authentication details, and should be similar to the following:

      ```
      Container                      Status
      ---------                      ------
      apic-lte-apim                  Up 3 minutes
      apic-lte-datapower-gateway     Not Running
      apic-lte-datapower-api-gateway  Up 2 minutes
      apic-lte-db                    Up 3 minutes
      apic-lte-juhu                  Up 3 minutes
      apic-lte-lur                   Up 3 minutes

      - Platform API url: https://localhost:2000
      - Admin user: username=admin, password=7iron-hide
      - 'localtest' org owner: username=shavon, password=7iron-hide
      - 'localtest' org sandbox test app credentials client id: 80963e74076afe50d346d76401c3c08a
      - Datapower API Gateway API base url: https://localhost:9444/localtest/sandbox/
      ```

   b. Log in to the management server:

      ```
      apic login --server localhost:2000 --username shavon --password 7iron-hide --realm provider/default-idp-2
      ```

      This command confirms that you can log in to the management server, and the response should be as follows:

      ```
      Logged into localhost:2000 successfully
      ```

      Known issue: If you receive an error during the login, stop and then restart the LTE; then log in again.

Note: To configure the toolkit credentials for Local Test Environment, use the following command:

```
apic client-creds:set ~/.apic-lte/credentials.json
```

Preparing an API for testing in the Local Test Environment

To prepare an API for testing in the Local Test Environment, you must publish it to the Sandbox Catalog in the Local Test Environment. If you want to test an API that you already published, proceed to Testing an API in the Local Test Environment., otherwise, complete the following steps:

1. Launch the API Designer user interface with the following command:

   ```
   APIC_DESIGNER_CREDENTIALS=~/.apic-lte/credentials.json <path-to-designer>
   ```

2. Open the required local directory; this is the directory in which your API and Product definition files will be stored.
3. Connect to the Local Test Environment. If you haven't previously connected to the Local Test Environment, click Add Another Cloud, then complete the following steps:
   a. In the HOST URL field, enter `https://localhost:2000`, then click Next.
   b. In the Username field, enter `shavon`, in the Password field enter `7iron-hide`, then click Sign in.
   Note:
   - If you are not able to connect to the Local Test Environment using `https://localhost:2000`, enter `https://127.0.0.1:2000` instead in the HOST URL field.
   - If you receive an error during the login, stop and then restart the LTE; then log in with API Designer again.

   If you have previously connected to the Local Test Environment, click the existing tile to log in immediately.

   The API Designer welcome page opens.

4. Click Develop APIs and Products, then click the API that you want to test. For details on how to configure an API definition, see Developing your APIs and applications.
5. You must publish your API before testing. For instructions on how to publish an API, See Publishing a draft Product
   Note: Whenever you make any changes to an API, you must republish it before retesting.

Testing an API in the Local Test Environment.

To test an API in the Local Test Environment, issue a REST API call to the following URL:

**`https://localhost:9444/localtest/sandbox/`*`basepath/operation_path`*`?client_id=`*`lte_client_id`*

where:

- *basepath* is the base path that is configured in the API definition.
- *operation_path* is the path for the operation that you want to invoke, as configured in the API definition.
- *lte_client_id* is the client ID for the test application in the local test environment, as returned by the ***`platform`*`-apic-lte status`** command in step 2.

The following example show how to test the API that is created in the tutorial Creating a proxy REST API definition, by using the **`curl`** utility; the API returns the details of bank branches:

```
curl -k https://localhost:9444/localtest/sandbox/branches/details?client_id=80963e74076afe50d346d76401c3c08a
[{"id":"0b3a8cf0-7e78-11e5-8059-a1020f32cce5","type":"atm","address":{"street1":"600 Anton Blvd.","street2":"Floor

```

Local Test Environment commands

The following table summarizes the Local Test Environment commands; use the **`help`** command to get full usage details for any command.

Table 1. Local Test Environment command summary

Command	Description
***`platform`*`-apic-lte help `*`command`**	Display help information for any command.
***`platform`*`-apic-lte init`**	Download the Local Test Environment Docker images.
***`platform`*`-apic-lte start`**	Start the Local Test Environment Docker images. Use the **`--database-max-heap-size`** parameter to set the size of the Local Test Environment database, in bytes; for example: **`linux-apic-lte start --database-max-heap-size 4096M`** **`linux-apic-lte start --database-max-heap-size 1G`** **`linux-apic-lte start --database-max-heap-size 1048576K`** **`linux-apic-lte start --database-max-heap-size 1073741824`** The default value is **`1024M`**. Tip: By default, the ***`platform`*`-apic-lte start`** command deletes all previous data and re-initializes the Local Test Environment configuration, so all your previous configuration, including published Products, is deleted. To retain the previous configuration, and to apply the same command parameters that were used in the previous ***`platform`*`-apic-lte start`** command, supply the **`--keep-config`** parameter.
***`platform`*`-apic-lte status`**	Display status information for the Local Test Environment components, and endpoint and authentication details.
***`platform`*`-apic-lte stop`**	Stop the Local Test Environment Docker images.
***`platform`*`-apic-lte version`**	Display Local Test Environment version information.

Troubleshooting the Local Test Environment

You can consult the log file for each Local Test Environment microservice or database by using the following command:

`docker logs `*`container-name`*

where *container-name* is one of the following:

- **`apic-lte-juhu`**: the authentication gateway
- **`apic-lte-apim`**: the API Management service
- **`apic-lte-lur`**: the Local User Registry
- **`apic-lte-db`**: the Postgres database of the API Management service
- **`apic-lte-datapower-api-gateway`**: the DataPower API Gateway
- **`apic-lte-datapower-gateway`**: the DataPower Gateway (v5 compatible)

You can access the gateway logs in either of the following ways:

- Use the gateway administration web UI:
  1. Open the page **`https://localhost:`*`web_ui_port`*** in a browser; for details of the required port value, see Local Test Environment port values.
  2. Select the apiconnect domain and the WebGUI interface, and log in with user name `admin` and password `admin`.

3. Click View Logs.

- Use the gateway administration CLI:
  1. Open an SSH connection by using the following command:

     ```
     ssh -p gateway-ssh-port localhost
     ```

     For details of the required port value, see Local Test Environment port values. The user name is `admin` and the password is `admin`.
  2. Enter the command **switch domain apiconnect**.
  3. To view the gateway log, enter the command **show log**.
  4. To view the log for the communication between the gateway and the API management system, enter the command **show logging gwd-log**.

Local Test Environment port values

If any of the default port values for the Local Test Environment components conflict with ports already in use on your system, you can change them when you start the Local Test Environment by passing one or more `--component port_value` parameters to the `platform-apic-lte start` command, where:

- *component* is the Local Test Environment component whose port value you want to change.
- *port_value* is the required value.

For example:

```
platform-apic-lte start --datapower-api-gateway-api-port 9445
```

The following table lists the components, together with the corresponding *component* parameters, and the default port values:

Component	*component* parameter	Default port value
DataPower API Gateway API port	`datapower-api-gateway-api-port`	9444
DataPower API Gateway API Connect service port	`datapower-api-gateway-apic-service-port`	3001
DataPower API Gateway REST management port	`datapower-api-gateway-rest-management-port`	5555
DataPower API Gateway SSH port	`datapower-api-gateway-ssh-port`	9023
DataPower API Gateway administration web UI	`datapower-api-gateway-web-gui-port`	9091
DataPower API Gateway XML management port	`datapower-api-gateway-xml-management-port`	5551
DataPower Gateway (v5 compatible) API port	`datapower-gateway-api-port`	9443
DataPower Gateway (v5 compatible) API Connect service port	`datapower-gateway-apic-service-port`	3000
DataPower Gateway (v5 compatible) REST management port	`datapower-gateway-rest-management-port`	5554
DataPower Gateway (v5 compatible) SSH port	`datapower-gateway-ssh-port`	9022
DataPower Gateway (v5 compatible) administration web UI	`datapower-gateway-web-gui-port`	9090
DataPower Gateway (v5 compatible) XML management port	`datapower-gateway-xml-management-port`	5550
Platform API port	`platform-api-port`	2000

Testing an API with the Explorer tab

Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal . You can also use the Try it tool to test the behavior of the API.

Before you begin

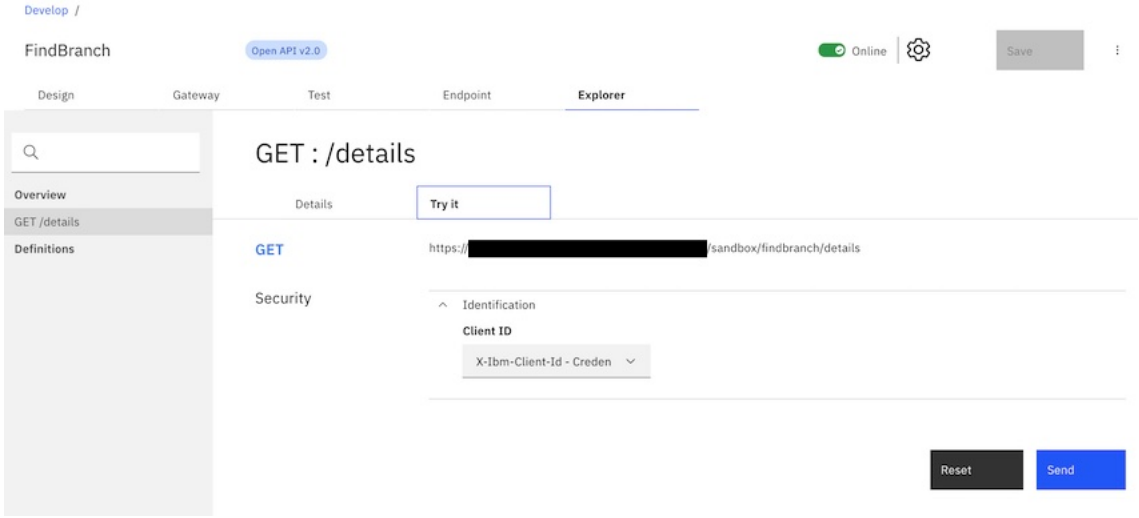
To test an API in the Try it test tool, the API must be auto-published. If the API is not auto-published, the Try it tool isn't enabled in the Explorer.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

About this task

The Explorer tab in the API editor of the API Designer UI and API Manager UI enables you to view how your APIs look to an API consumer in the Developer Portal. You can check the descriptions of the different artifacts, and as well as any schemas or examples, and you can also test the behavior of the API by using the Try it tool.

Note:



- You cannot use the Try it tool to test non-enforced APIs.

Procedure

To test an API by using the Try it tool, complete the following steps.

1. If you are using API Designer, set the mode to Online using the Options menu ⋮ on the main page.
2. In the navigation pane, click Develop, then select the APIs tab.
3. Click the title of the API that you want to work with.
   The API editor is displayed.
4. Click the Explorer tab.
   An Overview of the API is displayed.

5. Click the API artifacts in the side menu bar to explore the operations and definitions that are available in the API, including reviewing any examples and schemas.
6. To test API behavior, click an operation in the side menu bar, and click the Try it tab.
   The test pane for the operation is displayed, as shown in the following example:

7. Provide any required API parameters, and click Send.
   The API response is displayed in the Response section.
   Note: If you receive a message relating to an untrusted certificate, click the link that is provided, accept the certificate, then return to the test environment and click Send again.

What to do next

When you are happy with the look and behavior of your API, you can stage the API to a Product in a Catalog. For more information, see Staging an API.

Staging an API

The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Staging is not available when working offline in API Designer.

A Catalog is a staging target, and behaves as a logical partition of the DataPower® Gateway, and the Developer Portal.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can stage an API either from the Develop listing page, or from within the API definition itself.
   a. To stage an API from the Develop listing page, click the options menu icon alongside the required API, and then select Stage.
   b. To stage an API from within the API definition, complete the following steps:
      i. Click the title of the API that you want to work with.
      ii. Click the options menu icon:

      iii. Click Stage.
4. Choose one of the following actions:
   - To stage the API by adding it to a new Product:
     - Select New Product - Publish using a new product.
     - When prompted, enter a Title and Version.
     - The Product Name is automatically entered. The Name is the used to refer to the product in CLI commands. See the toolkit CLI reference documentation.
     - Click Next.
   - To stage the API by adding it to an existing Product:
     - Select Existing Product - Publish using an existing product
     - Select the Product you want to use.
     - Click Next.
5. On the Stage To page, select the Catalog to which you want to stage the Product.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.

6. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
7. Click Stage.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Publishing an API

The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Manage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can publish an API either from the Develop listing page, or from within the API definition itself.
   a. To publish an API from the Develop listing page, click the options menu icon ⋮ alongside the required API, and then select Publish.
   b. To publish an API from withing the API definition, complete the following steps:
      i. Click the title of the API that you want to work with.
      ii. On the Develop page, click the Menu icon (three dots), adjacent to the API that you want to edit, and then click Edit API.
      iii. Click the Test tab and then select Target Configuration.
      The Preferences dialog box is displayed.
      iv. Set the Auto-publish option to On.
   Remember: The auto publish setting is not associated with individual APIs. If you activate the auto publish setting for one API, it applies to all other APIs, regardless of the catalogue or the gateway. Therefore, it is highly recommended that you select a single set of settings for all the APIs instead of changing the settings individually for each API.
4. Choose one of the following actions:
   - To publish the API by adding it to a new Product:
     - Select New Product - Publish using a new product.
     - When prompted, enter a Title and Version.
     - The Product Name is automatically entered. The Name is the used to refer to the product in CLI commands. See toolkit CLI reference documentation.
     - Click Next.
   - To publish the API by adding it to an existing Product:
     - Select Existing Product - Publish using an existing product
     - Select the Product you want to use.
     - Click Next.
5. Select the Catalog to which you want to publish the Product.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.
7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. Click Publish.

Results

Your Product is published to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click  Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the Pending state; the Product is published in the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see Publishing a Product.

For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Notes:

- If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.
- If the Product contains an API that includes a user-defined policy that has not been imported into this Catalog, the publish will fail. The user-defined policy must be available in the required Catalog for the Product to be published successfully. For detailed instructions on how to import a user-defined policy into a Catalog, see Importing a user-defined policy into a Catalog.

Creating a new version of an API definition

You can create multiple versions of an API definition and edit the versions independently by using IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: If you want to publish a modified API to a production Catalog, you **must** create a new version of the API. You cannot publish an API to a production Catalog if there is already a published API with the same name and version.

Procedure

To create a new version of an API definition, complete the following instructions:

1. In the navigation pane, click Develop, then select the APIs tab.
2. You can create a new version of an API definition either from the Develop page, or from within the API definition itself.
   a. To create a new version of an API definition from the Develop page, complete the following steps:
      i. Alongside the API version that you want to work with, click the options icon ⋮, then click Save as a new version. The Save API as a new version window opens.
      ii. Enter your new version number, then click Save.
   b. To create a new version of an API definition from within the API definition itself, complete the following steps:
      i. Click the title of the API definition that you want to create a new version of.
      ii. Click the options menu icon:

      iii. Click New Version, enter your new version number, then click Submit.

   Note: The version corresponds to the **`info.version`** property value of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended, for example `1.0.0`.

Results

You have created a new version of your API definition, which you can now edit independently of other versions. Each version of the API definition is listed separately on the APIs and Products page.

Related tasks

- Creating an API definition

Updating an API definition from a file

You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The update operation completely replaces the previous API definition.

Procedure

To update an API from a file, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to update.

3. Click the options menu icon:

4. Click Update, then either drag and drop the file or click the link to select the file from your local file system.
5. Click Submit, then click Save.

Updating a SOAP API

You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.

About this task

You complete this task by using the browser based API Manager UI.

You can also use the API Connect developer toolkit CLI to update a SOAP API; for more information see API development and management commands.

When you initiate the update action, the specified WSDL is parsed to find a service that matches the name of the API that you are updating. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed.

Only those sections of the API that are affected by the new WSDL are replaced, the other sections are unchanged.

Procedure

To update a SOAP API from a WSDL file or a .zip archive, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the SOAP API that you want to update.
3. Click the options menu icon:

4. Then click Update WSDL, and either drag and drop the file or click the link to select the file from your local file system.
   The format of the WSDL file is validated. If the format is invalid, an error message is displayed.
5. Click Next.
   The services in the selected API are displayed. If no match is found, an error message is displayed.
6. Click Upload.
   The SOAP API is updated from the specified WSDL definition.
7. Click Save to save the updates.
8. If you updated a previously published API, you must publish it again for the change to take effect:
   a. Click the Online/Offline toggle (shown in step 3) to set the API as Offline.
   b. Click the toggle again to set the API back to Online, which publishes the API again.

Related tasks

- Creating an API definition

Renaming an API definition

By renaming an API definition, you change the **`name`** property that, together with the version, is used to uniquely identify the API definition in API Connect. The **`name`** property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Click the options menu icon:

4. To rename the API, select Rename.
   Only this version of the API is renamed.
5. Enter the new name, then click Submit.
   Note: If you previously added the API to a Product, it will no longer be recognized by that Product. You must open the Product and modify the `apis:` section on the Source tab as appropriate; for example:

```
apis:
  newname1.0.0:
    name: 'newname:1.0.0'
```

Changing an API rate limit

When you activate an API to make it available for testing, as described in Activating an API, no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Note:

- For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.
- If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the **Target product rate limit** option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied. for more information, see Defining rate limits for an API operation.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Select Test tab and click Target Configuration.
4. On the Preferences page, locate the Target product rate limit and click Edit.
5. Select Unlimited to allow unrestricted calls to the API, or select Custom to define the required rate limit; use the supplied fields to define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute.
   Note:
   The system clock determines the start time for rate, and burst limits. The intervals are configured as follows:
   - 1-second interval starts at each new second.
   - 1 minute interval starts at the beginning of each minute.
   - 1 hour interval starts at the beginning of each hour.
   - 1 day interval starts at midnight UTC.
   - 1 week interval starts on Thursday at 00:00:00 UTC.
6. Click Choose Rate Limit when done.
7. Click Save Preferences.

Results

You have successfully updated the rate limit period for the API.

Adding an OpenAPI extension to an API

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.

Before you begin

Import the OpenAPI extension into the Sandbox Catalog, or into any Catalog to which the API that you are adding the extension to will be published; see Importing an OpenAPI extension into a Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Select the Gateway tab, expand Gateway and portal settings, then click Extensions.
4. Select the OpenAPI extensions that you want to use with this API, then click Save.
   Note: The OpenAPI extensions listed are those that have been imported into the Catalog and gateway service defined in the testing preferences for the API; see Importing an OpenAPI extension into a Catalog and Specifying the testing preferences for an API. You will also need to import the OpenAPI extension into any Catalog to which the API will be published.
5. Update the OpenAPI source for the API definition with the values for the fields as defined in your selected OpenAPI extension schema files, as follows:
   a. Click the Source icon </>.
   b. Add a property whose name must begin with `x-` and references the name of the OpenAPI extension that you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file.
      For an example, see Referring to an extension in an API definition
   c. Click Save when done.

Downloading an API definition

You can download the details of your API definitions so that you can store them for later recovery.

Before you begin

To complete this task, you must have created an API definition. For more information, see Creating an API definition.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Drafts:View`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

You can download REST APIs that were created by using Creating a REST proxy API from a target service for example. This download creates a .yaml file that defines the API.

You can download SOAP APIs that were created by using Creating a REST proxy API from an existing WSDL service , or Creating a SOAP proxy API from an existing WSDL service for example. This download creates a .zip file that contains the WSDL definition and the YAML file that defines the API.

You can use the downloaded .yaml and .zip files to re-create your API. For information about creating an API from a .yaml file, see Adding a REST API by importing an OpenAPI definition file. For information about creating an API from a .zip file, see Adding a SOAP API by importing a zip file.

Procedure

To download a .yaml, or .zip file that contains the details of your API, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Alongside the API version that you want to work with, click the options icon ⋮ and then click Download.
3. Save the file to the required location.

Results

You downloaded a .yaml, or .zip file with a representation of your API.

Deleting an API definition

You can delete an API definition that is no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. You can delete an API either from the Develop listing page, or from within the API definition itself.
   a. To delete an API from the Develop listing page, click the options menu icon ⋮ alongside the required API, and then select Delete.
   b. To delete an API from within the API definition, complete the following steps:
      i. Click the title of the API definition that you want to work with.

ii. Click the options menu icon:

iii. To delete just this version of the API, select Delete. To delete all versions of this API, select Delete API.

Note: If a Product was previously generated automatically from the API, by using the Activate API option, that Product will be deleted together with the API; such Products have the title *api_title* auto product.

3. Click Delete to confirm.

Using an options file when importing a WSDL service

When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.

You can use an options file when importing a .zip file while performing any of the following tasks:

- Creating a REST proxy API; see Creating a REST proxy API from an existing WSDL service.
- Creating a SOAP proxy API; see Creating a SOAP proxy API from an existing WSDL service.
- Adding a target WSDL service to an API definition; see Editing an API definition.

The options file is a YAML file, and must have the file name apiconnect.yaml.

You can include the following fields in the file:

Table 1. Fields that can be included in the apiconnect.yaml file

Field name	Value	Default	Description
`suppressExamples`	`true` or `false`	`false`	Suppress auto-generation of examples.
`wssecurity`	`true` or `false`	`true`	Enable generation of definitions for WS-Security headers.
`implicitHeaderFiles`	Array of XSD file locations		Additional schema files, not referenced in the WSDL, that are used to define additional SOAP headers.
`port`	The `name` attribute for a `wsdl:port` in a `wsdl:service` definition.		Create the API by using the information for the specified port. If the specified port does not exist, or refers to a REST/XML port rather than a SOAP port, the API creation fails. If no `port` field is present in the options file, API Connect creates the API by using the first SOAP port that it finds in the `wsdl:service` definition.

Example

```
suppressExamples: true
wssecurity: false
implicitHeaderFiles:
  - xsdDir/schema1.xsd
  - xsdDir/schema2.xsd
```

Variable references in API Connect

In API Connect you can reference different variables in your API definition.

When defining an API, creating a custom policy, or configuring another policy or logic construct, you can include references to context variables and properties.

Variable references are resolved either when the API is staged in a Product, for static variables that are fixed upon staging, or when the API is called, for variables that can change with each API call.

Types of variables

Context variables

A context variable is a variable relevant during an API call, for example, the input of the call, the path of the call, or the message during the call. A context variable is one of the variables that makes up that particular context.
Context variables can consist of more than one part, for example, `request.headers`.

For a list of available context variables, see API Connect context variables.

API properties

An API property is a variable in an API where its value depends upon the Catalog in which the API is staged or published. By referencing an API property, you can use the same API definition in different Catalogs where there are small differences between the instances of the API between the Catalogs. For example, an assembly might contain an `if` construct that runs its case when a particular Catalog is used, determined from the value of the API property. API properties can also be used to hide a value such as a password by encoding the value.
API properties are referenced by name.

For a list of API properties, see API properties

For more information, see Setting API properties (OpenAPI 2.0) or Setting API properties (OpenAPI 3.0).

Note: Once defined, an API property is read only.

Catalog properties

A Catalog property is specific to a Catalog. And can be referenced in any of the API definitions in that Catalog. For more information, see Creating and configuring Catalogs.

Notes:

- If you change the value of a Catalog property, any API that references that property must be republished for it use the new value.
- Catalog properties and API properties are not supported with global policies. Therefore, if you use such properties in a global policy, they are not replaced with the values that are specified in the Catalog or API property definitions.

Methods of referencing variables

You can get, or set, the value for a referenced variable.

- Get the value for a variable in either of the following ways:
  - Through the GatewayScript policy, run the `apim.getvariable()` API.
  - API Gateway only Through the GatewayScript policy, use the `context.get()` function; for more information, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.
  - Through the XSLT policy, run a stylesheet that uses the `apim:getVariable` extension function.
  - In an assembly policy field that supports variable references, use the following syntax:

    `$(variable)`

- Set the value for a variable in either of the following ways:
  - Through the Set Variable policy.
  - Through the GatewayScript policy, use the `apim.setvariable()` API.
  - API Gateway only Through the GatewayScript policy, use the `context.set()` function; for more information, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.
  - Through the XSLT policy, run a stylesheet that uses the `apim:setVariable` extension element.

GatewayScript references

When you want to reference a variable in a GatewayScript context, use one of the following methods:

`apim.getvariable(variable)`

where *variable* is the name of the context variable or API property that you want to reference.

`apim.setvariable(variable, value, action)`

where

- *variable* is the name of the context variable or API property that you want to reference.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, use the following code:

  ```
  var contentType = apim.getvariable('request.headers.content-type');
  apim.setvariable(variable, contentType, 'set');
  ```

  This property is required only when `set` or `add` is specified as the action.
- *action* is the action that you want to apply to the variable. Valid options are:
  - `set`
  - `add`
  - `clear`

  If no option is set, the default option of `set` is applied.

Use the `getvariable` method to retrieve the value of a context variable or API property, and the `setvariable` method to change one.

Some of the situations where you would use this type of reference are:

- GatewayScript policies. -For more information, see GatewayScript.
- `if` logic constructs. For more information, see if.
- User-defined policies. For more information, see Authoring policies.

Stylesheet references

You can reference a variable by using functions and elements in an XSLT policy with the following syntax:

```
<xsl:variable name="variable_name" select="apim:getVariable(variable)" />
```

where *variable* is a literal value, another variable, or a valid XSLT XPath statement.

```
<xsl:call-template name="apim:setVariable">
    <xsl:with-param name="varName" select="variable"/>
    <xsl:with-param name="value" select="value"/>
    <xsl:with-param name="action" select="action"/>
</xsl:call-template>
```

where

- *variable* is the name of the context variable or API property that you want to reference. This can be a literal value, another variable, or a valid XSLT XPath statement.
- *value* is the string value that you want to set the variable to. This can be a literal value, another variable, or a valid XSLT XPath statement. This property is required only when `set` or `add` is specified as the action.
- *action* is the action that you want to apply to the variable. This can be a literal value, another variable, or a valid XSLT XPath statement. Valid options are:
  - `set`

- `add`
- `clear`

If no option is set, the default option of `set` is applied.

The following example sets a named variable to the value of the Content-Type header in a request:

```
<xsl:variable name="contentType" select="apim:getVariable('request.headers.content-type')" />
<xsl:call-template name="apim:setVariable">
    <xsl:with-param name="varName" select="'variable'"/>
    <xsl:with-param name="value" select="$contentType"/>
    <xsl:with-param name="action" select="'set'"/>
</xsl:call-template>
```

Inline references

In many situations you can make a simpler reference, by using the following syntax:

`$(variable)`

where *variable* is the name of the context variable or API property that you want to reference.
Some of the situations where you would use this type of reference are:

- The URL is called by an Invoke or Proxy policy. For more information about the policies, see Invoke or Proxy.
- A Map policy. For more information, see Map.

Notes: The map policy can reference the following variables inline:

- Variables that are defined as inputs to the map policy and specified in the from field of a mapping.
- Context variable or API properties, provided that the `x-ibm-gateway-map-resolve-apic-variables` API property is not set to `false`. If an inline reference in a map policy resolves to a context variable or API property, it is immediately replaced by the corresponding value. For more information on the `x-ibm-gateway-map-resolve-apic-variables` API property, see Properties controlling the map policy.

For more information on the use of inline references, and examples, see the following About inline references section.

About inline references

When you use an inline reference for a property value in an assembly policy, the variable reference is replaced with the corresponding string value at run time, before the property is evaluated. For example, consider the following incoming request, which has two headers and two query parameters (a **curl** command is used to illustrate the request):

```
curl --data-binary @request.json \
   -H 'Content-Type: application/json' \
   -H 'X-Environment: test' \
   http://apiserver/org/catalog/petstore/getPetDetails?petid=285&storeid=z03
```

If an `invoke` policy is configured as follows:

```
 invoke:
    target-url: https://backend/GetPetInfo/$(request.parameters.storeid)/$(request.parameters.petid)
```

then the value of the `target-url` property is evaluated as `https://backend/GetPetInfo/z03/285`, and this is therefore the URL to which the `invoke` policy sends its request.

DataPower Gateway (v5 compatible) only You can also use an inline reference in the `condition` property of a `switch` policy. Consider the following example:

```
- switch:
    case:
        - condition: "$(request.headers.X-Environment)" == "production"
          execute:
              - invoke:
                  http://www.finance.com/base/stockquote
        - condition: "$(request.headers.X-Environment)" == "test"
          execute:
              - invoke:
                  http://testserver1.finance.com/stockquote
```

Using the incoming request referred to previously, the value of the `X-Environment` header is `"test"`. The inline references are first evaluated, then the conditions are evaluated as JavaScript. Therefore, the first condition is evaluated as `"test" == "production"`, returning `false`, and the second condition is evaluated as `"test" == "test"`, returning `true`, so the `invoke` policy sends its request to `http://testserver1.finance.com/stockquote`.
Important: This example, which encloses the inline references inside double quotes, assumes that the API is deployed to the DataPower API Gateway. If you deploy the API to the DataPower Gateway (v5 compatible), then the double quotation marks are added implicitly when the inline references are evaluated, and you must therefore omit them from the `condition` property; the two conditions in this example would therefore be

```
condition: $(request.headers.X-Environment) == "production"
```

and

```
condition: $(request.headers.X-Environment) == "test"
```

However, as an alternative to using an inline reference in a `condition`, you can instead use pure JavaScript, as follows:

```
- switch:
    case:
        - condition: request.headers["X-Environment"] == "production"
          execute:
              - invoke:
                  http://www.finance.com/base/stockquote
        - condition: request.headers["X-Environment"] == "test"
          execute:
```

```
                - invoke:
                    http://testserver1.finance.com/stockquote
```

in which case the policy configuration works correctly as-is in both types of gateway.
For more information on the types of gateway, see API Connect gateway types.

In addition to single strings, you can use an inline reference for a complete object. Consider the following example, which uses an inline reference in a **set-variable** policy:

```
- set-variable:
    actions:
        - set: saved.reqHdrs
          value: $(request.headers)
          type: string
```

Here, the **request.headers** structured JSON object is substituted with its corresponding string representation, and a variable that is named **reqHdrs** is therefore created, under the **saved** object, with a string value of **{"Content-Type":"application/json","X-Environment":"test",...}**. However, if you are using the DataPower API Gateway, you can specify **type: any**, in which case the **set-variable** policy copies the value as-is, and **saved.reqHdrs** is created as a JSON object rather than a string:

```
- set-variable:
    actions:
        - set: saved.reqHdrs
          value: $(request.headers)
          type: any
```

You can reference a property in a JSON or XML request directly by name, by using the following syntax:

$(request.body.*property_name*)

for example, if the request contains **{ "account-number": 123 }** or **<account-number>123</account-number>** you can retrieve the value **123** by using the following inline reference:

$(request.body.account-number)

if the property value is within a nested property structure, you can reference it by concatenating the property names. For example, if the request contains **{ "account": { "balance": 123 } }** or **<account><balance>123</balance></account>** you can retrieve the value **123** by using the following inline reference:

$(request.body.account.balance)

Similarly, you can reference a property in a JSON or XML response by using the following syntax:

$(message.body.*property_name*)

Restriction: If you are using the DataPower API Gateway, you can reference properties in this way only if the format of the request or response is JSON; the mechanism is not supported by XML request or response formats. If the you are using the DataPower Gateway (v5 compatible) the mechanism is supported by both JSON and XML formats.

API properties

Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.

In IBM® API Connect, you can create API properties that consist of Catalog-specific values to eliminate the need for source code modifications. You can then reference the properties elsewhere in your API definition.

Pre-supplied API properties

Pre-supplied API properties for various policies are shown in the tables.

A list of invoke related API properties that control the behavior of the invoke policy.

Table 1. Properties controlling the invoke policy

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-decode-request-params	No	If set to a value of **true**, any request parameters that are referenced by a variable definition on an invoke target-url are URL-decoded. The default behavior is to not decode any parameters, thereby sending them to the target URL without alteration.	Boolean

Property	Required	Description	Data type

DataPower Gateway (v5 compatible) only
x-ibm-gateway-invoke-suppress-clientid
	No	When set with a value of **true**, or not specified, the X-IBM-Client-Id HTTP header (if specified on the API request) is suppressed from being sent to the invoke target URL. When set with a value of **false**, the X-IBM-Client-Id HTTP header is no longer suppressed from being sent to the invoke target URL.
		This property is supported only by the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a **header-control** property to the **invoke** policy configuration in the OpenAPI definition for your API, as in the following examples.
		
		Suppress the **X-Client-ID** header as follows:
		
		`- invoke:`
		`  target-url: http://myhostname/mypath`
		`  header-control:`
		`  type: blacklist`
		`  values:`
		`  - ^X-Client-ID$`
		
		Suppress the **userId** query parameter as follows:
		
		`- invoke:`
		`  target-url: http://myhostname/mypath`
		`  parameter-control:`
		`  type: blacklist`
		`  values:`
		`  - ^userId$`
			Boolean

DataPower Gateway (v5 compatible) only x-ibm-gateway-optimize-invoke	No	If set to `false`, prevents the replacement of the last invoke in a policy with proxy. Any value other than `false` (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-queryparam-encode-plus-char	No	If set to a value of **true**, all "+" characters in the query parameter values of the target-url of the Invoke and Proxy policies are encoded to "%2F". The default value is **false**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-api-enforce-response-limits	No	If set to a value of **true**, allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned. Note: The x-ibm-gateway-api-enforce-response-limits property is supported by the DataPower Gateway (v5 compatible) but not by the DataPower API Gateway. However, if you are using the DataPower API Gateway, consider using a Parse policy in your API assembly to enforce these limits. For information on the different types of gateway, see API Connect gateway types.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-emulate-v4-soap-error	No	IBM API Management Version 4.0 initiates a DataPower error when a SOAP fault is returned from a web service. IBM API Connect provides a mechanism to catch SOAP errors and does not initiate a DataPower error. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to **true** only in the case where a gateway extension is expecting to handle a SOAP error in a post error rule. The default value is **false**. Note: This property is deprecated in favor of x-ibm-gateway-invoke-emulate-v4-invoke-error.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-keep-payload	No	If set to a value of **true**, the invoke policy sends a payload on an HTTP DELETE method. This property is available for use with IBM DataPower Gateway version 7.7.1.1 and later. The default value is **false**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-emulate-v4-invoke-error	No	IBM API Management Version 4.0 initiates a DataPower error when a backend server error is returned, either a SOAP fault returned from a web service or a JSON or XML (non-SOAP) error from a restful service. IBM API Connect provides a mechanism to catch SOAP errors and operation errors and does not initiate a DataPower error when they occur. If no catch policy is configured, a generic error message is generated. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to **true** only in the case where a gateway extension is expecting to handle a backend server error in a gateway extension post error rule or if the client of the API is expecting the backend server error to be returned. The default value is **false**.	Boolean

A list of map-related API properties that control the behavior of the map policy.

Table 2. Properties controlling the map policy

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-array-first-element-value	No	In IBM API Management Version 4.0, if a mapping source value is from an array then only the first value is output. In API Connect, the default behavior is to return an array of all array element values. To maintain compatibility with IBM API Management Version 4.0, set this API property to **true** to only return the first array element value.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-resolve-apic-variables	No	By default, any API Connect variable that is found in the map configuration is resolved. For example, **$(request.headers.content-type)** resolves to the request's content type header. Because searching for variables in every map property can be CPU intensive, you can choose not to resolve variables by setting this API property to `false`. If this property is not configured or is set to any other value, the existing behavior to search for these variables continues. Note that variable usage within a map value JavaScript snippet is not changed provided that the variables that are referenced come from a configured map input.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-create-empty-array	No	This property controls how the map policy handles the output of an empty array; it can have the following values: • **all**: Output all empty arrays, including empty children arrays. This is the default value if the property is not configured or has an invalid value. • **parent**: Output only the current property's empty array value. Children map actions of this property are not attempted. • **none**: Prevent any empty output array values from being produced.	String

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-optimize-schema-definition	No	Set the value of this property to **`true`** to provide a performance improvement to the map policy when a very complex schema definition is referenced by a policy output definition; for example, some very complex schemas that are generated by importing a very complex WSDL schema. The map policy builds a schema from an API definition when a referenced definition is provided as the value of the schema. If the schema does not have references that generate a circular reference, setting this property to **`true`** might provide a performance benefit while generating the same schema as would otherwise have been generated. However, in cases where the schema is very complex, with many potentially circular references, the generated schema could be different because the enhanced schema handling processes circular references differently. In such cases therefore, you should examine the resulting output to determine if the performance benefit gained is not at the expense of a change in the map policy output. The default value of this property, is **`false`**, maintaining the existing behavior and performance.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-null-value	No	Set the value of this API property to **`true`** to allow a property from a map policy's input data with a value of **`null`** to be mapped to the output document. By default, a property from a map policy's input data with a value of **`null`** is not mapped to the output document.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-resolve-xmlinput-datatypes	No	XML input elements with numeric or boolean data have no metadata to indicate whether this data should be mapped as a string value or as the specific data type. If you set the value of this property to **`false`**, XML input elements are always mapped as a string. If you set the value to **`true`**, numeric or boolean XML input elements are mapped as the corresponding data type from the input schema. The default value is **`false`**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-xml-empty-element	No	This property controls how the map policy handles XML input empty elements and impacts JSON output when the input document is XML; it can have the following values: • **`string`**: The value for an empty XML element is considered to be an empty string. This is the default value if the property is not configured or has an invalid value. • **`null`**: The value for an empty XML element is considered to be null. A mapping of this element to a JSON output property does not occur unless the API property x-ibm-gateway-map-null-value is also specified with a value of **`true`**. • **`none`**: The empty XML element is ignored. • **`string-badgerfish`**: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. • **`null-badgerfish`**: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the API property **`x-ibm-gateway-map-null-value`** is also specified with a value of **`true`**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-schema-definition-reference-limit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String

Property	Required	Description	Data type

DataPower Gateway (v5 compatible) only
x-ibm-gateway-map-emulate-v4-default-required-properties
	No	Set this property to true to have default values generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
		• An array consists of objects that contain one or more required properties.
		• An object which is optional has one or more child properties that are required.
		By default, these required properties are not present in the output. If you set the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property to **true**, these required properties will be present in the output. If the output schema defines a **default** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:
		• String: empty string ("")
		• Number: 0
		• Boolean: false
		• Object: empty object
		• Array: empty array
		Example 1
		The input data has the following array of objects:
		`[{"a": "value1"}, {"a": "value2", "b": "value3"}]`
		The output schema defines the output object as having two properties, **a** and **b**, of which **b** is required. The map policy defines the following mappings:
		• `input.array.a` to `output.array.a`
		• `input.array.b` to `output.array.b`
		If the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property is set to **true**, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:
		`[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]`
		Example 2
		The output schema defines the following structure:
		`{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }`
		Property **b** is optional but property **d** within **b** is required.
		The map policy defines a mapping to `output.a.b.c`.
		If the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property is set to **true**, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:
		`{"a" : {"b" : {"c" : "value1", "d" : ""} } }`
		If the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property is not specified or does not have a value of **true**, these required properties are **not** created in the output with their default values.
			Boolean

DataPower Gateway (v5 compatible) only x-ibm-gateway-map-post-process-json-output	No	Set the value of this property to **true** to enable post processing of mapped JSON output. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set the value to **false** for no post processing of mapped JSON output. The default value is **false**.	Boolean

DataPower Gateway (v5 compatible) only
x-ibm-gateway-map-emulate-v4-empty-json-object
	No	If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set the value of this property to **true** to create an empty object for the parent of the target mapping, emulating the behavior of IBM API Management Version 4.0.
		Example
		The map policy defines a mapping to `output.a.b.c`.
		If input data is present, the output is as follows:
		`{ "a": { "b": { "c": "inputvalue" } } }`
		If there is no input data, and the **x-ibm-gateway-map-emulate-v4-empty-json-object** API property is set to **true**, the output is as follows:
		`{ "a": { "b": { } } }`
		Properties **a** and **b** are created but the value of **b** is an empty object.
		The default value is **false**.
			Boolean

DataPower Gateway (v5 compatible) only A list of proxy-related API properties that control the behavior of the proxy policy.

Table 3. Properties controlling the proxy policy

Property	Required	Description	Data type

x-ibm-gateway-proxy-suppress-clientid	No	A setting of `false` activates the injection of the X-IBM-Client-Id HTTP header (if it is specified on the API request), or the **`client_id`** query parameter in the request URL, to the proxy target-url. If not specified, or set with a value of `true`, suppresses the sending of this parameter to the proxy target-url.
		This property is supported only by the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a **`header-control`** property to the **`invoke`** policy configuration in the OpenAPI definition for your API, as in the following examples.
		
		Suppress the **`X-Client-ID`** header as follows:
		
		`- proxy:`
		`  target-url: http://myhostname/mypath`
		`  header-control:`
		`  type: blacklist`
		`  values:`
		`  - ^X-Client-ID$`
		
		Suppress the **`userId`** query parameter as follows:
		
		`- proxy:`
		`  target-url: http://myhostname/mypath`
		`  parameter-control:`
		`  type: blacklist`
		`  values:`
		`  - ^userId$`
			Boolean

x-ibm-gateway-optimize-invoke	No	If set to `false`, prevents the replacement of the last invoke in a policy with proxy. Any value other than `false` (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean
x-ibm-gateway-queryparam-encode-plus-char	No	If set to a value of **`true`**, all "+" characters in the query parameter values of the target-url of Invoke and Proxy policies are encoded to "%2F". The default value is **`false`**.	Boolean
x-ibm-gateway-api-enforce-response-limits	No	If set to a value of **`true`**, allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned.	Boolean

A list of API properties that control the behavior of the rate limit policy.

Table 4. Properties controlling the rate limit policy

Property	Required	Description	Data type
x-ibm-gateway-emulate-v4-plan-rate-limit	No	By default in IBM API Connect Version 10, if you configure a rate limit only for a Plan and not for the API operations within the Plan then a single rate limit threshold is set for the API as a whole, regardless of which operation in the API is requested. This behavior differs from IBM API Management Version 4.0 where the rate limit is set **individually** for **each** operation in the API. To change the Version 10 behavior to emulate the Version 4.0 behavior, set this API property to a value of **`true`**.	Boolean

A list of API properties that control the behavior of multiple policies.

Table 5. Properties controlling multiple policies

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-sourcecode-resolve-apic-variables	No	If set to **`true`**, API Connect variable references are resolved. Set to **`false`** if you want the policy to ignore API Connect variable references. The default value is **`true`**. This property applies to the following policies: • Map • GatewayScript • XSLT • if • switch Note: This property setting is overridden by the x-ibm-gateway-map-resolve-apic-variables API property setting for the Map policy.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-api-json-parse-error-handling	No	If an API request or response payload includes valid JSON content that contains characters that cannot be represented in the JSONX XML internal syntax that is used by the DataPower Gateway, set this property to **`escape-unicode`** to allow the payload to be accepted without parsing errors. If this property is not configured or is set to any other value, the payload is rejected as invalid JSON. This property applies to the API request payload, and to the API response payload when **`x-ibm-gateway-api-enforce-response-limits`** is enabled.	String
DataPower Gateway (v5 compatible) only x-ibm-gateway-framework-preserve-escaped-reverse-solidus	No	By default, the string `\\` in a policy property is converted to a single `\` character. Set this property to **`true`** to preserve the string `\\`.	Boolean

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-inspect-request-headers	No	Causes an inspection of the HTTP headers in the API request to check for characters in the header values that are illegal XML characters; it can have the following values: • **`default`**: There is no inspection for these characters in the header values. If one is present, the API request fails with an HTTP 500 Internal Server Error. • **`sanitize`**: Any illegal XML characters in header values are replaced with a **`?`** character. The API processing will continue. Any API that attempts to read **`request.headers.<headername>`** will see the **`?`** character in the value. However, the original protocol headers representing **`message.headers`** will still have the original character, which will be sent to an invoke or proxy backend server. • **`bad-request`**: There will be an inspection for these characters in the header values. If one is present, the API request fails with an HTTP 400 Bad Request. The default value is **`default`**.	Boolean

API policies and logic constructs

Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.

Policies are the building blocks of assembly flows, and they provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

Logic constructs behave in a similar way to policies, but they affect how and which parts of the assembly are implemented without modifying the data flow of the assembly.

IBM® API Connect provides the following ways that you can create, configure, and apply policies and logic constructs:

Policies associated with a Plan
: A Plan provides a mechanism for grouping API operations or subsets of operations from one or more APIs. You can set rate limiting policies on a Plan to specify how many requests an application is allowed to make during a specified time interval. You can also configure a policy for each operation that is included in a Plan. For more information, see Working with Products.

Built-in policies
: A built-in policy enables you to apply a pre-configured policy statement to an assembly to control processing capabilities in the Gateway server. Built-in policies are applied by using the API Designer assembly editor to add a built-in policy to your assembly and to configure the properties for that policy. For more information, see Built-in policies.
Note: You can also apply built-in policies to your APIs by adding an **`assembly`** extension to your OpenAPI definition file. For more information, see IBM extensions to the OpenAPI specification.

Logic constructs
: A logic construct enables you to control the flow of data through your assembly during an API call. Like policies, logic constructs are applied to an API by using the API Designer assembly editor to add a logic construct to your assembly and to configure the behavior of the construct. For more information, see Logic Constructs.
Note: You can also apply logic constructs to your APIs by adding an **`assembly`** extension to your OpenAPI definition file. For more information, see IBM extensions to the OpenAPI specification.

User-defined policies
: A user-defined policy enables you to create your own policies to control extra processing features in the Gateway server, such as security, or routing of requests. User-defined policies are created outside of API Connect and then imported into one or more Catalogs, so they can be applied to an operation in the same way as built-in policies. For more information, see Authoring policies.

- **Built-in policies**
  IBM API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing in the Gateway server when an API is invoked.
- **Logic Constructs**
  IBM API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.
- **Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway**
  In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.
- **User-defined policies**
  Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

- execute

Built-in policies

IBM® API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing in the Gateway server when an API is invoked.

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

- DataPower Gateway Indicates that the policy can be run on the DataPower Gateway (v5 compatible).

- API Gateway Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see API Connect gateway types.

Built-in policies are configured in the context of an API. You can use the API Designer assembly editor to add a built-in policy to an API and to configure the properties for that policy.

You can also add built-in policies to an API by creating an OpenAPI definition file. For more information, see Creating an OpenAPI definition file.

The following table shows the list of built-in policies that are available. The table contains links to configuration information for both the built-in policy definitions, and the OpenAPI policy definitions. The policies are the same, but they are created in different ways.

Table 1. Built-in policies

Built-in policy	OpenAPI policy	Description	DataPower Gateway	API Gateway
Activity Log	activity-log	Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity. Note: The Activity Log policy is not supported in the assembly for an API whose gateway type is DataPower API Gateway. Instead, you configure activity logging in the API design settings. For details, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).	✓	✓ Functionality provided in the API design; see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0)
Client Security	client-security	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	✗	✓
Extract	extract	Use the Extract policy to extract and transform data from fields in your API.	✗	✓
GatewayScript	gatewayscript	Use the gatewayscript policy to execute a specified DataPower GatewayScript program.	✓	✓
Generate JWT	jwt-generate	Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).	✓	✓
GraphQL Cost Analysis	graphql-cost-analysis	Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.	✗	✓
GraphQL Execute	graphql-execute	Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.	✗	✓
GraphQL Introspect	graphql-introspect	Use the GraphQL Introspect policy to introspect a GraphQL schema.	✗	✓
if	if	Use the if policy to apply a section of the assembly when a condition is fulfilled.	✓	✓ Functionality provided by switch
Invoke	invoke	Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.	✓	✓
JSON to XML	json-to-xml	Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.	✓	✓
Log	log	Use the Log policy to customize or override the default activity logging configuration for an API.	✗	✓
Map	map	Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.	✓	✓
OAuth	oauth	Use the OAuth policy to policy to perform OAuth processing based on defined OAuth provider settings.	✗	✓
operation-switch	operation-switch	Use the operation-switch policy to apply a section of the assembly to a specific operation.	✓	✓
Parse	parse	Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	✗	✓
Proxy	proxy	Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the `message.body` and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.	✓	✓ Functionality provided by Invoke
Rate Limit	ratelimit	Use the Rate Limit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	✗	✓
Rate Limit Info	ratelimitinfo	Use the Rate Limit Info policy to return information about your rate limits.	✗	✓
Redaction Redaction - DataPower API Gateway Redaction - DataPower Gateway (v5 compatible)	redact - DataPower API Gateway redact - DataPower Gateway (v5 compatible)	Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	✓	✓
Set Variable	set-variable	Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.	✓	✓
switch	switch	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	✓	✓
throw	throw	Use the throw policy to throw an error when it is reached during the execution of an assembly flow.	✓	✓

Built-in policy	OpenAPI policy	Description	DataPower Gateway	API Gateway
User Security	user-security	Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	✗	✓
Validate Validate - DataPower API Gateway Validate - DataPower Gateway (v5 compatible)	validate - DataPower API Gateway validate - DataPower Gateway (v5 compatible)	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	✓	✓
Validate JWT	jwt-validate	Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.	✓	✓
Validate Username Token	validate-usernametoken	Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.	✓	✗
XML to JSON	xml-to-json	Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).	✓	✓
XSLT	xslt	Use the XSLT policy to apply an XSLT transform to the payload of the API definition.	✓	✓

Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 3.0 API assembly

- **Activity Log**
  Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.
- **Client Security**
  The Client Security policy can be used to extend client authentication access for your APIs.
- **Extract**
  Use the Extract policy to extract and transform data from fields in the API context.
- **GatewayScript**
  Use the gatewayscript policy to execute a specified DataPower GatewayScript program.
- **Gemini invoke**
  Use the Gemini invoke policy to invoke Gemini operations.
- **Generate JWT**
  Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).
- **GraphQL Cost Analysis**
  Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.
- **GraphQL Execute**
  Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.
- **GraphQL Introspect**
  Use the GraphQL Introspect policy to introspect a GraphQL schema.
- **IBM Cloud Authentication**
  Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.
- **Invoke**
  Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.
- **JSON to XML**
  Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.
- **Lambda**
  Use the Lambda policy to directly trigger AWS Lambda functions from API without using the Amazon API Gateway.
- **Log**
  Use the Log policy to customize or override the default activity logging configuration for an API.
- **Map**
  Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.
- **OAuth**
  An OAuth policy performs the requested OAuth processing based on the defined OAuth provider settings.
- **openai invoke**
  Use the OpenAI invoke policy to invoke OpenAI operations.
- **Azure openai invoke**
  Use the Azure OpenAI invoke policy to invoke Azure OpenAI operations.
- **Parse**
  Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.
- **Proxy**
  Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the `message.body` and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.
- **Rate Limit**
  Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.
- **Rate Limit Info**
  Use the Rate Limit Info policy to return information about rate limits, burst limits, and count limits. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.
- **Redaction - DataPower API Gateway**
  Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.
- **Redaction - DataPower Gateway (v5 compatible)**
  Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

- **Set Variable**
  Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.
- **Token Mediation**
  The Token Mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.
- **User Security**
  Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.
- **Validate - DataPower API Gateway**
  Use the Validate policy to validate the payload in an assembly flow against a schema.
- **Validate - DataPower Gateway (v5 compatible)**
  Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.
- **Validate JWT**
  Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.
- **Validate Username Token**
  Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.
- **watsonx.ai invoke**
  Use the watsonx.ai invoke policy to invoke watsonx.ai operations.
- **Websocket Upgrade**
  Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.
- **XML to JSON**
  Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).
- **XSLT**
  Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Activity Log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see activity-log.

Note that if you are using the DataPower API Gateway, you can configure your logging preferences by using the API design editor. For more information, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).

About

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is `activity` for when API execution completes successfully, and `payload` for when API execution completes with an error code. Apply the Activity Log policy to your assembly to change the type of content to log in these API event records. For more information about API event records, see API event record field reference.
Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled. Enable buffering as follows in the API YAML:

```
x-ibm-configuration:
  ...
  activity-log:
    enabled: true
    error-content: payload
    success-content: payload
  ...
  buffering: true
```

Note:
Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but does not log successful cases.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Activity Log policy properties

Property label	Required	Description	Data type
Title	Yes	A title for the policy is required, but a default value, `activity-log` is provided.	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
Content	Yes	Defines the type of content to be logged when the operation is successful. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **activity**.	string
Error content	No	Indicates what content to log if an error occurs. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **payload**.	string

Client Security

The Client Security policy can be used to extend client authentication access for your APIs.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see client-security.

About

You use the Client Security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
  - For all methods except HTTP, use the ID Name and the Secret Name properties to specify the location that contains the ID and the location that contains the secret.
    - When Cookie, specify which cookie.
    - When Context Variable, specify which runtime context variable.
    - When Form, specify the form data.
    - When Header, specify which header.
    - When Query, specify which query parameter.
  - For the HTTP method, use the HTTP Type property to specify the format of the authorization header, which expects the Basic form in the **basic base64_id:secret** format.
- Define the method to authenticate the extracted client credentials. The supported methods are Native (this means by using IBM® API Connect), or by using a specified Third party user registry.
  - If Third party, use the User Registry Name property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Client Security policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **client-security**.	string

Property label	Required	Description	Data type
Description	No	A description of the policy.	string
Stop on Error	Yes	If this setting is enabled, assembly processing stops if client security fails, and an error is returned. The check box is selected by default.	boolean
Secret Required	Yes	If this setting is enabled, the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID. The check box is selected by default.	boolean
Credential Extraction Method	Yes	Select one of the following options to define how the calling application authenticates: • Header: client ID and client secret credentials must be supplied in the request header. • Query: client ID and client secret credentials must be supplied as query parameters in the request URL. • Form: client ID and client secret credentials must be supplied as form data sent in a POST request. • Cookie: client ID and client secret credentials must be supplied in a header called `Cookie`. • HTTP: the calling application must authenticate by using basic authentication. • Context Variable: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a GatewayScript policy for example. The names of these context variables are determined by the values that you supply in the ID Name and Secret Name properties of the Client Security policy. The default value is Header.	string
ID Name	Yes, unless the selected value of Credential Extraction Method is HTTP	The name of the parameter whose value specifies the client ID. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
Secret Name	Yes, if Secret Required is enabled and the selected value of Credential Extraction Method is other than HTTP	The name of the parameter whose value specifies the client secret. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
HTTP Type	Yes, if the selected value of Credential Extraction Method is HTTP	The authentication type. Currently, the only available option is Basic.	
Authenticate Client Method	Yes	Select one of the following options: • Native: only client ID and client secret are used to authenticate the client. If the selected value of Credential Extraction Method is HTTP then the calling application must supply the client ID for the user name, and the client secret for the password. • Third party: a user registry is used to authenticate the client. If the selected value of Credential Extraction Method is other than HTTP then the calling application must supply the user name for the client ID, and the password for the client secret. The default value is Native.	string
User Registry Name	Yes, if the selected value of Authenticate Client Method is Third party	Select the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

API Gateway only

Extract

Use the Extract policy to extract and transform data from fields in the API context.

Before you begin

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly editor. For details about how to configure the policy in your OpenAPI source, see extract.

About this task

The Extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see Constructing JSONata expressions to extract and transform data.

The input to the Extract policy must be parsed data. One way to produce parsed data is to add a Parse policy before the Extract policy in your assembly.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Extract policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 2. Extract policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **extract**.	string
Description	No	A description of the policy.	string
Root	Yes	The data source that contains the content to transform. The default value is **message.body**.	string
Capture	Yes	The path expression that identifies the field. The default setting is **$**, which indicates the entire input.	string
Transform	Yes	The expression that defines how to transform the content.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - extract:
      version: 2.0.0
      title: extract
...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

Transform the contents of the **account** field to include only the last 4 characters.

```
- extract:
    version: 2.0.0
    title: extract
    root: message.body
    extracts:
      - capture: $.members.policy.**.account
        transform: $substring($,-4)
    description: Include only the last 4 characters of the account field.
```

- **Constructing JSONata expressions to extract and transform data**
  To extract and transform data from fields in the API context when using the Extract policy with the DataPower API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

API Gateway only

Constructing JSONata expressions to extract and transform data

To extract and transform data from fields in the API context when using the Extract policy with the DataPower® API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - **$eval()**
  - **$sift()**
  - **$each()**
  - **$error()**
  - **$assert()**
- **$fromMillis()** is supported with the following restrictions:
  - The **$fromMillis()** parameter supports numbers in the range -5364662400000 - 2903299199000.
    - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
    - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- **$now()** is supported with the following restrictions:
  - The following component specifiers are not supported:
    - **W** = Week in year
    - **w** = Week in month
    - **X** = ISO week-numbering year
    - **x** = ISO week-numbering month

- Representing numbers as words are not supported, so the following presentation modifiers are not supported:
  - **W** = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
  - **w** = Lowercase word (for example: [Yw] => two thousand and twenty-four)
  - **Ww** = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
- Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
$apiCtx()	Generic access to an API context	The **$apiCtx()** extension gives generic access to an API context. • Sample transform field in an extract action: **"$apiCtx().request.uri"** • Sample condition of a case in a switch action: **"$apiCtx().request.path = '/simple/apictx-function'"**
$header(name)	**message.headers.name**	Message header
$httpVerb()	**request.verb**	HTTP method of the request
$operationID()	**api.operation.id**	ID of the operation
$operationPath()	**api.operation.path**	Path of the operation
$queryParameter('name')	• **request.parameters.*name*.locations** The supported keyword is **query**. • **request.parameters.*name*.values**	Searches for the index of **query** in **request.parameters.*name*.locations** and returns **request.parameters.*name*.values[index]**, where **[index]** is the value for **query** in locations. Parameter values are not URL decoded.
$statusCode()	**message.status.code**	Status code
$storageType([arg])	***variable*.body** You can specify any variable in the API context. When no variable is specified, the default variable **message.body** is used.	Storage type of the message. The supported values are **binary**, **empty**, **graphql**, **json**, **stream**, or **xml**.
$urlParameter('name')	• **request.parameters.*name*.locations** The supported keywords are **path** and **query** • **request.parameters.*name*.values**	Searches for the index of **path** and **query** in **request.parameters.*name*.locations** and returns a single array that contains both **path** and **query** values from **request.parameters.*name*.values**. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. **http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese** The **$urlParameter('breed')** URL returns the following array of values. **[cats, adopt, Sphynx, Siamese]** In this example, the URL includes an API path that is configured as **/petstore/{breed}/{breed}**, where **breed** is configured to be a path parameter of the API path. As a result, **cats** and **adopt** are included in the output.
$xpath(path, xpathExpression)	You can specify any writable variable in the API context. The **xpathExpression** must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. **$xpath($, '//price')**

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
$gqlActiveOperation([graphql_message])	**message.body**	Gets the active operation found in the specified GraphQL message. The **operationName** must be the same as the name of the active operation.
$gqlAlias(graphql_field_node)	**message.body**	Gets the alias of a GraphQL field node.
$gqlFragments([graphql_message])	**message.body**	Gets the fragments found in the specified GraphQL message.
$gqlName([graphql_node])	**message.body**	Gets the node name. For operations, the node name is the **operationName**. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the **operationName** of **message.body** is retrieved.
$gqlOperations([graphql_message])	**message.body**	Gets the operations found in the specified GraphQL message.
$gqlType([graphql_node])	**message.body**	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the **&** (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- **`query`**
  The entire GraphQL query including operations and fragments.

- ***`operationName`***
  For an anonymous operation, ***`operationName`*** can be empty.

- ***`~fragmentSpreadName`***
- ***`on~typeCondition`***
- ***`~~fragmentDefinitionName`***

GatewayScript

Use the gatewayscript policy to execute a specified DataPower® GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see gatewayscript.

About

The gatewayscript policy gives you built-in access to the DataPower Gateway module via variable **`apim`**.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. gatewayscript policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`gatewayscript`**.	string
Description	No	A description of the policy.	string

Source	Yes	The GatewayScript source code to execute. For example:
		
		`var message = [ 'Hello', 'World!' ];`
		`console.debug(message.join(' '));`
			string

Examples

The following examples show how the full OpenAPI for the policy looks in the source code.

Example one:

```
gatewayscript:
  title: writes message to DataPower log
  source: console.debug('Hello World!');
```

Example two:

```
gatewayscript:
  title: script written in multiple lines
  source: |
    var message = [ 'Hello', 'World!' ];
    console.debug(message.join(' '));
```

For more code examples, see GatewayScript code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- GatewayScript APIs for API management
- Accessing and manipulating a variable in the API context
- OAuth context variables

Errors

The following error can be thrown while the policy is being executed:

- **`JavaScriptError`** - a generic error that captures all errors that occur during the execution of the policy.
- **GatewayScript code examples**
  Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Related tasks

- Creating a new REST OpenAPI definition

GatewayScript code examples

Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing a GatewayScript policy or user-defined policy for a new API Gateway API, use the mechanisms described in Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The GatewayScript functions that are listed here use the common name **`apim`** to call the methods. However, you can change the common name to one of your choice by using one or other of the following function calls depending on your gateway type:

  DataPower Gateway (v5 compatible)
  ```
  var name = require('local:///isp/policy/apim.custom.js');   // v5-Compatible Gateway
  ```
  API Gateway
  ```
  var name = require('apim');                                 // DataPower API Gateway
  ```

  where *name* is your chosen name; for example:

  ```
  var apim = require('apim');
  ```

Access the assembly context

The following code snippets show examples of how to access the assembly context.
Example one returns the **`request`** context:

```
apim.getvariable('request');
```

Example two returns the header named **`myheader`**:

```
apim.getvariable('request.headers.myheader');
```

Example three shows how to set, add, or clear a context variable, in this case a message header:

```
apim.setvariable('message.headers.name', value, action)
```

where

- *name* is the name of the message header that you want to set, add, or clear.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the *value* as **`request.headers.content-type`**. This property is only required when **`set`** or **`add`** is specified as the action.
- *action* is the action that you want to apply to the variable. Valid options are:
  - **`set`**
  - **`add`**
  - **`clear`**

  If no option is set, the default option of **`set`** is applied.

For a complete list of context variables, see API Gateway context variables, and for more information about how to reference context variables in IBM API Connect see Variable references in API Connect. If you are using the DataPower® API Gateway, see also Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Accessing OpenAPI extensions in GatewayScript

The following example demonstrates how to access custom extensions (like **x-banking**) in the OpenAPI (Swagger) document from GatewayScript:

```
if (context.swagger) {
    context.swagger.readAsJSON(function(error, swaggerDoc) {
        if (error) {
            // Handle error case
            context.set('message.body', error);
            context.message.statusCode = 500;
        }
 else {
    extensionContent = swaggerDoc["x-banking"]
}
```

Read input synchronously

The following code snippets show examples of how to read input synchronously by using the **apim.getvariable** function to read data direct from a context. JSON input is returned as a JavaScript object. XML data is returned as a NodeList object (DOM).
Example one returns a synchronous read of the original request body into the variable that is called *json*:

```
var json = apim.getvariable('request.body');
```

Example two returns a synchronous read of the current message into the variable that is called *xml*:

```
var xml = apim.getvariable('message.body');
```

Note: If the content type of the data is neither XML nor JSON, the **apim.getvariable()** function returns a NodeList object consisting of one binary node, which must be converted to a string. If the content really is XML or JSON, you must then parse this string, as illustrated in the following example:

```
var data = apim.getvariable('request.body');

// if a nodelist was returned and the type is 13 (BLOB/Binary Node), convert it
// to a Buffer, which can then be converted to a string
if ((data.item && data.length > 0 && data.item(0).nodeType === 13)) {
  data = data.item(0).toBuffer().toString();
}

// if the string really is XML or JSON, then now add code to parse it with
// the appropriate XML or JSON parse function
      .
      .
      .
```

Read input asynchronously

The following code snippets show the **apim.readInput()** calls that you can use to perform a JavaScript callback function to read input data asynchronously into a variable. JSON input is returned as a JavaScript object. XML data is returned as a NodeList object (DOM). Other types of input are returned as a Buffer object.

```
apim.readInput(callback(err,input) {});
apim.readInputAsJSON(callback(err,json) {});
apim.readInputAsXML(callback(err,nodelist) {});
apim.readInputAsBuffer(callback(err,buffer) {});
```

Note: The **apim.readInput()** function attempts to determine the input data type and call the appropriate **apim.readInputAs*type*()** function in order to return the data in the correct format. However, to ensure that the correct data type is returned, use the **apim.readInputAs*type*()** function.
The **apim.readInputAs*type*()** function reads the data from either the INPUT context (for example **session.INPUT**), or from a policy output context (for example **policy.output**), depending on whether a previous policy had been called that had written output to a policy output context. This function then calls the underlying IBM DataPower GatewayScript **readAs*type*** method on the relevant context to read the data, and then use JavaScript callbacks to return the data to a variable. For more information about DataPower methods, see Gateway programming model and GatewayScript.

The following is an example of how to use the **apim.readInputAsJSON()** callback function to get data into a variable that is called *json*:

```
apim.readInputAsJSON(function (error, json) {
if (error)
{
// handle error
}
else
{
// the json parameter will contain the json data that has been read
// process the json object in some way and write to the output context
if (json.test=='true')
{
// if json data contains a variable called test that is set to true, then also add some test data
json.data = 'This is my test data'
}
session.output.write(json);
// write to the output context
}
});
```

Configure error information

The following code block shows an example of how to configure the policy implementation to produce error information by using the **apim.error()** function. In this example, **MyError** is thrown to the assembly flow. If there is a catch handler it catches this error, otherwise the assembly skips the execution of the flow and sends a **500 Internal Error** response.

```
apim.error('MyError', 500, 'Internal Error', 'Some error message');
```

where:

- `MyError` is the name of the error.
- `500` is the HTTP code of the required error message.
- `Internal Error` is the HTTP reason phrase for the error.
- `Some error message` is the suggested action for the user.

Accessing the caught exception in a catch block

The following example shows how, in the `catch` block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

```
let exception = apim.getError();
```

The function returns a JSON object; for example:

```
{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}
```

Write output

The following example shows how to write data into the output, in this case the JSON data `'{ "status": "created" }'`, by using the `session.output.write` variable:

```
session.output.write('{ "status": "created" }');
```

The `session.output.write` variable is a standard GatewayScript method that writes data to the output context. For more information, see Contexts and sessions.
Use the following function to set the format of the content that is written to the `session.output` variable:

```
apim.output('application/type');
```

For example, if you were creating a policy that called:

```
session.output.write('<test>this is some xml data</test>');
```

the policy would write XML data to the output context. You would need to configure the policy to also call

```
apim.output('application/xml');
```

to tell the system that the output is XML. It can cause issues in the processing of the policy if the actual output context format, and the format that is specified in `apim.output`, are different.
Note: If you use `apim.setvariable` to manipulate `message.body`, you must immediately follow the `apim.setvariable` function call with an `apim.output` function call that specifies the content type of the payload that was written to `message.body` by `apim.setvariable`.

API Gateway only

Gemini invoke

Use the Gemini invoke policy to invoke Gemini operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see gemini-invoke.

About

The Gemini invoke policy provides access to six Gemini operations:

- `POST models/[model]:generateContent`
- `POST models/[model]:countTokens`
- `POST models/[model]:embedContent`
- `POST models/[model]:batchEmbedContents`
- `GET models/[model]`
- `GET models`

The Gemini invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Gemini invoke policy properties

Property label	Required	Description	Data type
Title	No	Gemini invoke chat completions	string
Description	No	A description of the policy.	string
Gemini Operation	Yes	The Gemini operation to invoke; must be one of the following operations: • **`POST models/[model]:generateContent`** An HTTP POST operation for **`generateContent`**. See Generating Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:countTokens`** An HTTP POST operation for **`/countTokens`**. See Counting tokens in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:embedContent`** An HTTP POST operation for **`embedContent`**. See Embed Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:batchEmbedContents`** An HTTP POST operation for **`batchEmbedContents`**. See Batch Embed Content in the Gemini API documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the Gemini API documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the Gemini API documentation for sample response examples.	string
Gemini API Key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Gemini requests.	string
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the Gemini service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the Gemini service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
Gemini Operation Path Parameters	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
Gemini Operation Query Parameters	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the Gemini response. By default, this property uses message as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Generate JWT

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see jwt-generate.

About

JSON Web Token (JWT) is a compact, URL-safe way of representing claims that are to be transferred between two parties. The Generate JWT policy enables you to generate claims and configure whether they are to be used as the payload of a JSON Web Signature (JWS) structure, or as the plain text of a JSON Web Encryption (JWE) structure. Specifying the cryptographic material for both the JWS and the JWE produces a nested JWT that is both digitally signed and encrypted. The JWT is then assigned to the Authorization header as a Bearer token (the default option), or to the runtime variable in the JSON Web Token (JWT) property, if specified.

Note:

- For algorithm types HS256, HS384, and HS512 the cryptographic objects referenced must be a Shared Secret Key.
- For algorithm types RS256, RS384, RS512, ES256, ES384, ES512, PS256, PS384, PS512 the cryptographic objects referenced must be a Crypto Key (private key).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to sign the JWT.

Prerequisites

The following prerequisites apply:

- If you are using one or more cryptographic objects (crypto objects), they must be located in the API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or certificate that is needed to encrypt or sign the JWT contents.
- If a JSON Web Key (JWK) is being used, it must be referenced by a runtime variable.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Generate JWT policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`jwt-generate`**.	string
Description	No	A description of the policy.	string
JSON Web Token (JWT)	No	Runtime variable in which to place the JWT that is generated. The default value is: **`generated.jwt`**. However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
JWT ID Claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to **`true`**, and a UUID is generated and set as the JTI claim value.	boolean
Issuer Claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: **`iss.claim`**	string
Subject Claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string
Audience Claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
Validity Period	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is **`3600`**.	integer
Private Claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
Sign JWK variable name	No	Runtime variable that contains the JWK that is used to sign the JWT.[1]	string

Property label	Required	Description	Data type
Cryptographic Algorithm	No	The cryptographic algorithm to use. Valid values are: • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512	string
Sign Crypto Object	No	The cryptographic object to use to sign the JWT.[1]	string
Sign KID value	No	The customized `kid` value for JWT signing.	string
Encryption Algorithm	No	The encryption algorithm to use. Valid values are: • A128CBC-HS256 • A192CBC-HS384 • A256CBC-HS512	string
Encrypt JWK variable name	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string
Key Encryption Algorithm	No	The key encryption algorithm to use. Valid values are: • RSA1_5 • RSA-OAEP • RSA-OAEP-256 • dir • A128KW • A192KW • A256KW	string
Encrypt Crypto Object	No	The cryptographic object to use to encrypt the claim.	string
Encrypt KID value	No	The customized `kid` value for JWT encryption.	string

Example

```
    - jwt-generate:
        version: 2.1.0
        title: jwt-generate
        description: New jwt-generate v2.1.0 policy.
        jwt: generated.jwt
        jti-claim: true
        iss-claim: iss.claim
        sub-claim: sub.claim
        aud-claim: aud.claim
        exp-claim: 3600
        private-claims: private.claims
        jws-jwk: jws.jwk
        jws-alg: HS256
        jws-crypto: jwsCryptoObjectName
        custom-kid-value-jws: jws.kid
        jwe-enc: A128CBC-HS256
        jwe-jwk: jwe.jwk
        jwe-alg: RSA1_5
        jwe-crypto: jweCryptoObjectName
        custom-kid-value-jwe: jwe.kid
```

Errors

The following error can be thrown while the policy is being executed:

- `RuntimeError` - a generic error that captures all errors that occur during the execution of the policy. Upon failure, the detailed error message that is received from the underlying JOSE module is written to the default system log as an error message. This detailed error message is also assigned to the runtime variable jwt-generate.error-message, so it can be retrieved via catch.

If a catch is not configured, in the case of a failure the Generate JWT policy returns an HTTP code 500 `Invalid-JWT-Generate` failure. The detailed error message from the underlying JOSE module can be found in the system log.
Attention: If you are an API developer who is troubleshooting a failure that one of your customers had with your API, consider the security risks before sending a customer the exact content of the log message. You can avoid the possibility of someone launching an attack based on the information that they receive from the log message by sending the customer only general information about the message.

Related information

- Introduction to JSON Web Tokens

[1] A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used. If you are using one or more cryptographic objects (crypto objects), they must be located in the API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or certificate that is needed to encrypt or sign the JWT contents.

GraphQL Cost Analysis

Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-cost-analysis.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Cost Analysis policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`graphql-introspect`**.	string
Description	No	A description of the policy.	string
Input	No	A variable in the API context that contains the input to the GraphQL cost analysis. The content of the body field of the variable is the GraphQL cost query. By default, the variable name is **`message`**. The query should be in the format as specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **`__cost`**.	string
Output	No	A variable in the API context where the results of the GraphQL cost analysis are stored. The content of the body field of the variable is the result of GraphQL cost analysis. The default variable name is the same as that of the variable specified for the input field. Therefore, by default, the input of the GraphQL cost analysis is overwritten by the output.	string
Target	No	A variable in the API context that contains the target for the GraphQL cost analysis. The content of the body field of the variable is the GraphQL context. By default, the variable name is **`graphql_execute_args`**. The target context specifies the query to analyze and, optionally, the result of the query execution.	string

GraphQL Execute

Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 (DataPower API Gateway Version 10.0.4.0 and later) 2.1.0 (DataPower API Gateway Version 10.5.2.0 and later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-execute.

About

The GraphQL Execute policy executes a GraphQL query by using sub-queries. The policy splits up the original GraphQL query into different sub-queries that can then be processed in different ways. The GraphQL Execute policy supports the following four different sub-queries as targets:

1. **`root`**; contains the core GraphQL query that you want to invoke on the backend.
2. **`__introspection`**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend.
3. **`__rateLimit`**; contains the **`__rateLimit`** query that specifies the different rate limit data that you want to receive.
4. **`__cost`**; contains the **`__cost`** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **`__cost`**.

The **`root`**, **`__rateLimit`**, and **`__introspection`** targets can be executed in any order, or at the same time. The **`__cost`** target can be executed at any time if no response data is expected. If response data is expected, then the **`__cost`** target is executed after the **`root`** target in order to accurately return correct response cost data. After all the targets are executed, the GraphQL Execute policy combines all of the responses together. To enable the responses of the individual targets to be correctly merged with each other into a final, single response, the GraphQL Execute policy must include all of the introspection types that are associated with each level of the response data.

Note: If the request includes the header **introspectionOnly**, the GraphQL Execute policy will execute only the introspection related sub queries including **_introspection**, **_rateLimit**, and **_cost** without invoking the backend for the root query. This behavior allows the gateway to return schema metadata, rate limit information, and cost analysis results locally.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Execute policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **graphql-execute**.	string
Description	No	A description of the policy.	string
Target	No	The target for the sub-queries. Valid values are: • **root**; contains the core GraphQL query that you want to invoke on the backend. • **__introspection**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend. • **__rateLimit**; contains the **__rateLimit** query that specifies the different rate limit data that you want to receive. • **__cost**; contains the **__cost** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.	string

GraphQL Introspect

Use the GraphQL Introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-introspect.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Introspect policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **graphql-introspect**.	string
Description	No	A description of the policy.	string
Input	No	A variable in the API context that contains the input to introspect. The content of the **body** field of the variable is the input to introspect. By default, the variable name is **message**.	string
Output	No	A variable in the API context where the results of the introspection are stored. The content of the **body** field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified in the Input field. Therefore, by default, the input of the introspection is overwritten by the output.	string

API Gateway only

IBM Cloud Authentication

Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ibm-cloud-authentication.

About

The IBM Cloud Authentication policy provides an API key to the IBM Access Manager and, if successfully authenticated, returns a Bearer token to be used by all subsequent watsonx.ai operation requests. The Bearer token is cached and will be valid for approximately 60 minutes. A new token is retrieved when a response for the API key was not cached. or expired.

The IBM Cloud Authentication policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. IBM Cloud Authentication policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy; the default value is `ibm-cloud-authentication`. The title displays in the API assembly editor in the UI.	string
Description	No	A description of the policy.	string
API key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate subsequent watsonx.ai requests.	string

Invoke

Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.

Note: The Invoke policy does not support responses with multipart form data, that is, when the response is set to `Content-Type: multipart/related`.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.1 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

- **Configuring the Invoke policy for DataPower API Gateway**
  Follow these steps to configure the Invoke policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Invoke policy for DataPower Gateway (v5 compatible)**

API Gateway only

Configuring the Invoke policy for DataPower API Gateway

Follow these steps to configure the Invoke policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Invoke policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Invoke policy for DataPower Gateway (v5 compatible). For information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see invoke.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Invoke policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Invoke policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`invoke`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Invoke URL value is pre-supplied from information that is defined in the imported WSDL.	string
Backend type	No	Select one of the following options to determine how the payload is sent to the backend. Detect Detect the message type and send the payload to the backend accordingly. XML Package the payload as XML and send. If the message type is not XML, the operation fails. JSON Package the payload as JSON and send. If the message type is not JSON, the operation fails. Binary Package the payload as binary and send, regardless of the message type. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. The default value is Detect.	string
GraphQL send type(policy version 2.2.0 and later)	Yes, if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep	Select one of the following values to determine how the GraphQL payload is sent to the back end. Detect Detect the message type and send the payload to the back end accordingly. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. JSON Package the payload as JSON and send. If the message type is not GraphQL, the operation fails. Note: GraphQL send type is supported only if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply from the endpoint (in seconds). The default value is **`60`**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this checkbox, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this checkbox, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the Invoke. The following values are valid. • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **`GET`**. However, if set to **`Keep`**, or the property is removed from the source, the HTTP method from the incoming request is used.	string
HTTP Version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Select one of the following values. • HTTP/1.0 • HTTP/1.1 • HTTP/2 The default value is HTTP/1.1.	string
HTTP/2 Required (policy version 2.1.0 and later)	No	Select this checkbox to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non-TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if HTTP Version is set to HTTP/2.	boolean

Property label	Required	Description	Data type
Compression	No	Select this checkbox to enable Content-Encoding compression on upload. The checkbox is cleared by default.	boolean
Cache Type	No	The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are: Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL. Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option. No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings. Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached. The default value is Protocol.	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to **`Time to Live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Allow WebSocket Upgrade (policy version 2.1.0 and later)	No	Select this checkbox to allow an HTTP or HTTPS connection to be upgraded to the WebSocket protocol if the request received by the corresponding HTTP or HTTPS handler on the DataPower API Gateway uses WebSocket (ws) or WebSocket Secure (wss). Note: • This setting is available only for GraphQL APIs. • The Allow WebSocket Upgrade setting is deprecated. To allow WebSocket upgrade requests that can manage API processing data, define an assembly WebSocket upgrade policy. For more information, see Websocket Upgrade.	boolean
Inject proxy headers	No	If you select this checkbox, the **`invoke`** policy injects the **`X-Forwarded-For`**, **`X-Forwarded-To`**, **`X-Forwarded-Host`**, and **`X-Forwarded-Proto`** headers to the request that is sent to the target URL. The checkbox is cleared by default.	boolean
Decode Request Params	No	If you select this checkbox, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The checkbox is cleared by default.	boolean
Queryparam Encode	No	If you select this checkbox, all "+" characters in the query parameter values of the target URL are encoded to %2F. The checkbox is cleared by default.	boolean
Keep Payload	No	If you select this checkbox, the invoke policy sends a payload on an **`HTTP DELETE`** method. The checkbox is cleared by default.	boolean
Restrict to HTTP 1.0 (policy version 2.0.0 only)	No	If you select this checkbox, HTTP transactions are restricted to version 1.0. The check box is cleared by default.	boolean
Allow chunked uploads	No	If you select this checkbox, chunked-encoded documents are sent to the server. When the HTTP 1.1 protocol is used, the body of the document can be delimited by either **`Content-Length`** or chunked encoding. While all servers can interpret **`Content-Length`**, many applications fail to understand chunked-encoded documents. For this reason, **`Content-Length`** is the standard method. The use of **`Content-Length`** interferes with the ability of the DataPower Gateway to fully stream. If you must stream full documents to the target server, enable this property. When enabled, the server must be RFC 2616 compatible. Unlike all other HTTP 1.1 features that can be negotiated down at run time, you must know beforehand that the target server is RFC 2616 compatible. The check box is selected by default. Note: Chunked encoding is not supported by the HTTP 1.0 protocol.	boolean

Property label	Required	Description	Data type
Persistent Connection (policy version 2.3.0 and later)	No	Select this checkbox to enable HTTP persistent connections, allowing connection re-use. The checkbox is selected by default.	boolean
Header control	No	Specifies the headers in `message.headers` that you want to copy to the target URL. To prevent headers from being copied, complete the following steps. a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. To specify headers that you want to be copied, complete the following steps. a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. The values that you specify are in regular expression format. For example, to specify the Content-Type header, enter `^Content-Type$` By default, Blocklist is selected, with no blocklist entries, meaning that **all** headers are copied.	string

Parameter control	No	Specifies the parameters in the incoming request that you want to be copied to the target URL.
		To prevent parameters from being copied, complete the following steps.
		a. Select Blocklist.
		b. Click Add blocklist.
		c. In the empty field that is displayed, enter the parameter name.
		d. To add further parameters, repeat the previous steps.
		To specify parameters that you want to be copied, complete the following steps.
		a. Select Allowlist.
		b. Click Add allowlist.
		c. In the empty field that is displayed, enter the parameter name.
		d. To add further parameters, repeat the previous steps.
		The values that you specify are in regular expression format.
		
		For example, if the incoming request is
		
		`http://apigw/org/sandbox/petstore/base?petid=100&display=detailed`
		
		and you specify a white list entry of `^petid$`, the target URL at run time will be
		
		`http://myhost/mypath?storeid=3&petid=100`
		
		By default, Allowlist is selected, with no allowlist entries, meaning that **no** parameters are copied.
			string

Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a `catch` flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable *message*. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as Map. Note: If you want the response to be saved in *message*, leave the Response object variable property blank, do **not** supply the value `message`.	string
Buffering	No	Select Buffering to specify whether to buffer the payload. If Buffering is selected, the payload is buffered, and the Invoke policy can check the type of the payload. If Buffering is not selected, the payload is streamed, and the Invoke policy cannot check the payload type. Note: If you enable Buffering, you must also configure a Parse policy to interpret the payload. Without a Parse policy, the payload remains an uninterpreted buffer, and the Invoke policy succeeds if the backend service accepts payloads of type `binary` or `detect`. If a Parse policy is configured, it implicitly disables streaming, even if buffering is off, because parsing requires the full payload to be buffered. For more information, see Parse.	boolean

6. Specify a version for the policy by clicking the Source icon </>, and completing the `version` section of the policy YAML. For example:

```
execute:
  - invoke:
      version: 2.0.0
      title: invoke
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

```
- invoke:
    version: 2.0.0
    title: get the account status
    target-url: https://example.com/accounts/{id}?status={status}
    cache-response: time-to-live
    cache-putpost-response: true
    tls-profile: MyTLSProfile:1.0.0
    verb: POST
```

```
    timeout: 60
    compression: false
    username: MyUser
    password: MyPassword
    stop-on-error:
      - ConnectionError
      - OperationError
```

DataPower Gateway (v5 compatible) only

Configuring the Invoke policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Invoke policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Invoke policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Invoke policy for DataPower API Gateway. For information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see invoke.

You might notice that the last invoke in their policy is replaced by a proxy. The replacement is sometimes done automatically by the IBM® API Connect DataPower Gateway to improve performance. The proxy is functionally equivalent to the invoke, but the API caller might notice the following differences when proxy is used.

- If the HTTP request made by the invoke or proxy gets a redirect (`3xx`) response:
  - invoke returns the response from following the redirect response.
  - proxy does not follow `3xx` responses, and the redirect response is returned.
- The IBM API Connect test tool shows that proxy was used, but invoke appears in the analytics latency records.
- The response from the proxy can contain different whitespace or escaping than a response from invoke. Despite the differences in the response, it is still valid.

If you want to prevent replacement of the last invoke in the assembly with proxy, you can set the API property api.properties.x-ibm-gateway-optimize-invoke to `false`.
For more information, see API properties.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Invoke policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Invoke policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`invoke`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Invoke URL value is pre-supplied from information that is defined in the imported WSDL.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply from the endpoint (in seconds). The default value is **`60`**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this checkbox, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this checkbox, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the Invoke. The following values are valid. • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **`GET`**. However, if set to **`Keep`**, or the property is removed from the source, the HTTP method from the incoming request is used.	string
Compression	No	Select this checkbox to enable Content-Encoding compression on upload. The checkbox is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are: Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL. Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option. No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings. Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached. The default value is Protocol.	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to **`Time to Live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a **`catch`** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable *message*. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as Map. Note: If you want the response to be saved in *message*, leave the Response object variable property blank, do **not** supply the value `message`.	string
Buffering	No	Select Buffering to specify whether to buffer the payload. If Buffering is selected, the payload is buffered, and the Invoke policy can check the type of the payload. If Buffering is not selected, the payload is streamed, and the Invoke policy cannot check the payload type. Note: If you enable Buffering, you must also configure a Parse policy to interpret the payload. Without a Parse policy, the payload remains an uninterpreted buffer, and the Invoke policy succeeds if the backend service accepts payloads of type **`binary`** or **`detect`**. If a Parse policy is configured, it implicitly disables streaming, even if buffering is off, because parsing requires the full payload to be buffered. For more information, see Parse.	boolean

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - invoke:
      version: 1.0.0
      title: invoke
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

```
- invoke:
          version: 1.0.0
          title: get the account status
          timeout: 60
          verb: POST
          cache-response: time-to-live
          cache-ttl: 900
          stop-on-error:
            - ConnectionError
            - OperationError
```

```
        tls-profile: MyTLSProfile
        target-url: https://example.com/accounts/{id}?status={status}
        username: MyUser
        password: MyPassword
```

JSON to XML

Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

The JSON to XML policy uses a simple convention, based on BadgerFish, to convert your API context payload from JSON to XML. The policy expects the JSON input to be in the same format as the BadgerFish convention, so the structure can be rebuilt in XML. No additional configuration is required. For more information about the BadgerFish convention, see BadgerFish.
Note: The JSON to XML policy does convert the JSON structure `{ "a" : "hello" }` (which is not BadgerFish convention) into `<a>hello</a>`.
Use the IBM® API Connect API Designer assembly view when you are creating your API definition to add a built-in policy to the flow.

The policy must be attached to the flow at the point at which you require the conversion to be performed. For example, if you need to convert a JSON-formatted request into an XML-formatted request, the policy must be attached to the request flow.

The policy reads input from the **`message.body`**, if that context exists, otherwise from the **`request.body`**, and then writes the output to the **`message.body`**.

Note: If you are using the DataPower API Gateway, the input to the JSON to XML policy must be parsed data. One way to produce parsed data is to use a Parse policy before a JSON to XML policy in your assembly flow, which provides explicit control of the parse action.

- **Configuring the JSON to XML policy for DataPower API Gateway**
  Follow these steps to configure the JSON to XML policy for DataPower API Gateway in the assembly user interface.
- **Configuring the JSON to XML policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the JSON to XML policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the JSON to XML policy for DataPower API Gateway

Follow these steps to configure the JSON to XML policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the JSON to XML policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the JSON to XML policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. For information about how to configure the policy in your OpenAPI source, see json-to-xml.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the JSON to XML policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`json-to-xml`**.	string
Description	No	A description of the policy.	string
Input	No	The input message to convert. Specify the name of a variable in the API context. ***`variableName`*`.body`**, the message payload, represents the JSON input to convert. The default value of the variable is **`message`** and **`message.body`** is the default input.	string
Output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***`variableName`*`.body`** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **`message.body`**. Otherwise, when the input message is the variable **`my-message-variable`**, for example, the default output is **`my-message-variable.body`**. The variable cannot be any read-only in the API context.	string

Property label	Required	Description	Data type
Conversion type	No	The conversion type that determines the target format of the output. The following options are available: • None: No conversion of the output takes place. • badgerFish: BadgerFish convention is used to determine the target conversion format of the output.	string
Root XML Element Name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the Always output the root element checkbox is selected. The default value is **`json`**.	string
Always output the root element	Yes	Select this checkbox if you always want the policy to output the root element, even if it is not required to make the XML document well formed. The default value is **`false`**.	boolean
Element name for JSON array elements	No	The XML element name to be used for JSON array elements.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - json-to-xml:
      version: 2.0.0
      title: json-to-xml
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For example, the following simple JSON object

```
{ "a": { "$" : "hello" } }
```

becomes

```
<a>hello</a>
```

The following JSON object with an attribute

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

becomes

```
<a type="world">hello</a>
```

DataPower Gateway (v5 compatible) only

Configuring the JSON to XML policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the JSON to XML policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the JSON to XML policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the JSON to XML policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see json-to-xml.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the JSON to XML policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`json-to-xml`**.	string
Description	No	A description of the policy.	string
Root XML Element Name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the Always output the root element checkbox is selected. The default value is **`json`**.	string

Property label	Required	Description	Data type
Always output the root element	Yes	Select this checkbox if you always want the policy to output the root element, even if it is not required to make the XML document well formed. The default value is **`false`**.	boolean
Element name for JSON array elements	No	The XML element name to be used for JSON array elements.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - json-to-xml:
      version: 1.0.0
      title: json-to-xml
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For example, the following simple JSON object

```
{ "a": { "$" : "hello" } }
```

becomes

```
<a>hello</a>
```

The following JSON object with an attribute

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

becomes

```
<a type="world">hello</a>
```

API Gateway only

Lambda

Use the Lambda policy to directly trigger AWS Lambda functions from API without using the Amazon API Gateway.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	1.3.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see Lambda.

About

The Lambda policy lets you trigger AWS Lambda functions from within an API's assembly without requiring you to use the Amazon API Gateway. When you add the policy to an API assembly, you can specify the Lambda function to invoke and provide credentials for using it. The credentials can be either an AWS IAM role, or an Access Key ID/Secret Access Key pair. You can download the lambda policy from Lambda policy fix pack.

To enable API Connect to invoke a Lambda function, complete the following tasks:

1. Configure access to the Lambda function in AWS as explained in the Setting up permissions and trust in AWS section of this topic.
2. Define an API policy in API Connect using the policy properties in the Properties section of this topic.

Note:

- The Lambda policy uses VPC endpoints to ensure that the communication from the gateway to the Lambda service is over the AWS private backbone.
- For information about Lambda and instructions for using the Lambda features, see the AWS Lambda documentation.

Setting up permissions and trust in AWS

To use a Lambda policy, you must set up a role in your AWS account, specifying a permissions policy and a trust relationship, so that API Connect can invoke the AWS Lambda function. There is one authentication option when using the AWS Lambda policy:

- Access Key ID/Secret Access Key

Use the instructions for the option that best suits your needs.

Access Key ID/Secret Access Key

Provide the AWS Access Key ID/AWS Secret Access Key pair of an account with permission to invoke one or more Lambda functions. The permissions of this account should be as narrowly-scoped as possible; the account should be a service account with no other permissions other than the ability to invoke one or more Lambda functions. For more information, see the Identity-Based IAM Policies for Lambda documentation.
To use the Access Key ID/Secret Access Key authentication option, complete the following steps to use your account's IAM service and create an IAM service account with appropriate permissions to facilitate limited communication with API Connect:

1. Sign in to the AWS Management Console and open the IAM console.
2. On the AWS IAM console, click Users in the navigation list, and then click Add users.
3. When prompted to "Set user details", provide a User name (unique within your AWS account) and select Access key - Programmatic access.
   You can select the Password - AWS Management Console access option, but it is not required for interaction with API Connect.

   There are a variety of options for defining permissions for the new user account. See the AWS Identity and Access Management User Guide for information on adding the user to a user group, or attaching a policy directly to the user.

   A straightforward method of defining user permissions that adheres to the least-privilege principle is to create an IAM user with no permissions, and then add that user to the permissions configuration of a specific Lambda function, as demonstrated in the following steps.

4. On the "Set user details" page, click Next: Tags without making any changes to the new User account.
5. Create the desired Tags and then click Next: Review.
6. Review your settings and click Create user.
   Ignore the warning that **`This user has no permissions`** because you will assign permissions in the remaining steps.

7. Click Download .csv to save the new user's Access key ID and Secret access key, and store them in a safe place. These values will be used as the AWS Access Key ID and AWS Secret Access Key when configuring the Lambda policy of your API in API Connect.
8. Update the Lambda function to provide permissions for the new user:
   a. In the Lambda console, open the Functions page.
   b. Select the function that API Connect will invoke.
   c. Click Configuration.
   d. In the Resource-based policy statements section, click Add permissions.
   e. Select AWS account and add a unique Statement ID.
   f. Set Principal to the ARN of the new user.
      `arn:aws:iam::<AWS_account_ID>:user/<username>`, available on the Users > *<username>* page.

   g. Set the Action to **`lambda:InvokeFunction`**.
   h. Click Save.

   Repeat this step for every Lambda function that the user account will invoke.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`lambda`**.	string
Description	No	A description of the policy.	string
AWS Access Key ID	Yes	AWS Access keys are long-term credentials for an AWS IAM user. Required if the AWS Assume Role ARN is not provided instead. For instructions on creating the access key pair in AWS, see Access Key ID/Secret Access Key in this topic.	string
AWS Secret Access Key	Yes	The secret access key that corresponds to the specified AWS Access Key ID.	string
Function	Yes	The name or Amazon Resource Name (ARN) of the AWS Lambda function to execute, using one of the following formats: • Function name; for example: **`my-function`** • Function ARN; for example: **`arn:aws:lambda:us-east-a:123456789012:function:my-function`** • Partial ARN – **`123456789012:function:my-function`** For more information, see **`FunctionName`** in the AWS Lambda Developer Guide.	string
Region	Yes	The AWS region where the Lambda function is hosted.	string
Qualifier	No	The alias or version of the Lambda function that you want to execute. For more information, see **`Qualifier`** in the AWS Lambda Developer Guide.	string

API Gateway only

Log

Use the Log policy to customize or override the default activity logging configuration for an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see log.

About

By default, the logging of activity when an API is called, and the sending of the log data to the analytics server, is determined by the settings in the API definition, as described in Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0). However, you can customize activity logging by adding a Log policy to the API assembly flow.

The Log policy enables you to gather all API analytics data for processing in your assembly, and to control what activity log data is sent to the analytics server. Here are some examples of the ways in which you can use the Log policy to customize API activity logging:

- Gather activity log data, use a Redaction policy to redact sensitive fields in the data, then send to the analytics server.
- Send different levels of analytics data depending on certain conditions; for example, the API operation that was called.
- Configure custom activity logging in a global policy that is applied to every API in a Catalog. For more information on global policies, see Working with global policies.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Log policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`log`**.	string
Description	No	A description of the policy.	string

Mode	Yes	Select one of the following options:
		• Gather-only: gather all analytics data and write it to the **`log`** context variable, which populates the API event record on completion of the API execution. For more information on the fields in the **`log`** context variable, and the consequent API event record, see API event record field reference.
		• Send-only: perform the following actions:
		  ◦ Read the data from the **`log`** context variable.
		  ◦ Truncate all message payloads and convert to a textual representation.
		  ◦ Send the data to the analytics server.
		• Gather-and-send: perform a **`gather-only`** operation, immediately followed by a **`send-only`** operation.
		If you use the Send-only or Gather-and-send option, data is buffered and sent to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information, see Configuring an analytics endpoint in the DataPower knowledge center.
		Note: If you are offloading to a third party analytics server, you can redact any aspect of the event data. If you are using API Connect analytics, you can redact only request and response payloads.
			string

API Gateway only Log Level	No	The type of content to log. Enter one of the following values: • `none`: Indicates no logging. • `activity`; Logs the invocation only, which is only the resource URI. • `header`: Logs activity and header. • `payload`:Logs activity, header, and payload. • `default`; Use the log level setting defined in the API definition; for more information, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0). This is the default value. • `$(value)`: An inline parameter in the format **`$(value)`** to retrieve a value from the API context.	

Map

Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.5.0.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see map.

About

Be aware that MAP decodes all parameter values to an ASCII character equivalent. If a MAP parameter contains entries such as %nn, the MAP output contains decoded values.

For information about the structure of a Map policy and its behavior, see The Map policy structure.

For information about configuring a Map policy by using the user interface, see Configuring the Map policy in the user interface.

For examples of YAML representations of different Map policy configurations, see Map policy examples.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Map policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The field is visible when editing inputs. The default value is **map**.	string
Description	No	A description of the policy. The field is visible when editing inputs.	string
Inputs	Yes	A list of variables that are inputs of the policy.	array (string)
Outputs	Yes	A list of variables that are outputs of the policy.	array (string)
Value	Yes	A GatewayScript program to be performed by the policy in order to map its inputs to its outputs, or to set the value of outputs.	string

Note: The map policy has other properties that are not displayed in the user interface. For a complete list of properties, see map.

The Map policy structure

The Map policy uses a structure within its OpenAPI definition to specify the behavior of the policy.

This topic contains the following sections:

- Structure
- Input and output definitions
- Actions
- Script
- Fields
- References to inputs and outputs
- Accessing other contexts

For map policy examples, see Map policy examples.

Note: If you deploy your API to the DataPower® Gateway (v5 compatible) then, with the exception of client ID and client secret, the passing of form input as a parameter into an API is not supported. This restriction does not apply if you deploy your API to the DataPower API Gateway.

Structure

In addition to its title and description, a Map policy has the following four main sections:

`inputs`
: A list of variables that form the input of the Map policy. Each input has a context variable in which the input variable is found, the variable's name within the Map policy, the content type of the variable, and the definition of the variable or a schema defining its structure.

`outputs`
: A list of variables that form the output of the Map policy. These include a context variable where the output variable is found or should be created, the variable's name at output, and the definition of the variable or a schema defining its structure.

`action`
: An array containing details of the actions to be performed in order. Each entry includes either a **`set`** or **`create`** field, which specifies the output variable or variables that are part of the action. An action can also contain a **`from`** field, which specifies the input variable or variables that are part of the action.

  Each action also contains either a **`value`** field, when the output is set or created, or a **`foreach`** field and a new **`actions`** section, when further actions are nested within the first to set or create elements in a nested array.

`options`
: The following property options are available for you to select:

- Include empty. If the check box is selected (the default option), empty XML elements are included in the output of the map policy. Clear the check box if you do not want empty XML elements to be included in the output of the map policy.
- Namespace inheritance. If the check box is selected (the default option), XML namespaces are inherited from the parent element. Clear the check box if you want the map policy to use explicit namespaces.
- Namespace inlining. If the check box is selected (the default option), XML namespaces will be inserted into the document where they are first used. Clear the check box if you want namespaces to all be defined on the root element.
- API Gateway only Resolve XML input data type. If the check box is selected, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Clear the check box (the default option) if you want all XML element values to be returned as a string.
- API Gateway only Parse XML output: If the check box is selected, the map policy will write XML output to **`message.body`** as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string.
- API Gateway only Empty XML element handling. This property controls how the map policy handles the output of an empty XML element. The following choices are available:
  - String (the default option): An empty XML element is handled as an empty string.
  - Null: An empty XML element is handled as a null value.
  - None: The data is ignored.
  - API Gateway only String Badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property.
  - API Gateway only Null Badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the Allow null value option is selected.
- API Gateway only Use only first array element. If the check box is selected, if an array is encountered in the traversal of the input, only the first element is used. Clear the check box (the default option) if you want the map policy to use all array elements.
- API Gateway only Resolve API Connect variable references. If the check box is cleared (the default option), the map policy ignores API Connect variable references in the map properties. Select the check box if you want API Connect variable references found in the map properties to be resolved.
- API Gateway only Allow null value. If the check box is selected, an input property value with a null value is mapped to the output document. Clear this check box (the default option) if you want the map policy to ignore null input values.
- API Gateway only Optimize schema definition. If the check box is selected, complex schema types evaluation handles circular type references in an optimized manner. Clear this check box (the default option) to evaluate these schema types in a standard manner.
- API Gateway only Create required child properties for array objects and mapped optional objects. If the check box is selected, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
  - An array consists of objects that contain one or more required properties.
  - An object which is optional has one or more child properties that are required.

  By default, these required properties are not present in the output. If you select this option, these required properties will be present in the output. If the output schema defines a **`default`** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:
  - String: empty string ("")
  - Number: 0
  - Boolean: false
  - Object: empty object
  - Array: empty array

  Example 1

  The input data has the following array of objects:

  ```
  [{"a": "value1"}, {"a": "value2", "b": "value3"}]
  ```

  The output schema defines the output object as having two properties, **`a`** and **`b`**, of which **`b`** is required. The map policy defines the following mappings:

  - **`input.array.a`** to **`output.array.a`**
  - **`input.array.b`** to **`output.array.b`**

  If the check box is selected, and **`b`** is either not mapped or has no input data present, then **`b`** is assigned a default value of an empty string, and the output is as follows:

  ```
  [{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]
  ```

  Example 2

  The output schema defines the following structure:

  ```
  {"a" : {"b" : {"c" : "value1", "d" : "value2"} } }
  ```

  Property **`b`** is optional but property **`d`** within **`b`** is required.

  The map policy defines a mapping to **`output.a.b.c`**.

  If the check box is selected, and **`d`** is not mapped, then **`d`** is assigned a default value of an empty string, and the output is as follows:

  ```
  {"a" : {"b" : {"c" : "value1", "d" : ""} } }
  ```

  If the check box is not selected, these required properties are **not** created in the output with their default values.

- API Gateway only Empty JSON array handling. This property controls how the map policy handles the output of an empty array. The following choices are available:
  - All (The default value): Output all empty arrays, including empty children arrays.
  - Parent: Output only the current property's empty array value. Children map actions of this property are not attempted.
  - None: Prevent any empty output array values from being produced.
- API Gateway only Enable JSON post processing. Select this check box to enable post processing of mapped JSON output. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output

property values that have a Badgerfish JSON syntax due to object mapping of an XML input. The check box is cleared by default, meaning that there is no post processing of mapped JSON output.

- API Gateway only Schema definition circular reference limit. Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition.
  The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5.
- Severity level for input data log messages; This property specifies the severity level for log messages that relate to input data. The following choices are available:
  - error
  - warn
  - info
- API Gateway only Create empty parent object for failed mapping. If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Select this check box to create an empty object for the parent of the target mapping, emulating the behavior of IBM® API Management Version 4.0.

  Example

  The map policy defines a mapping to `output.a.b.c`.
  If input data is present, the output is as follows:

  ```
  {
    "a": {
      "b": {
        "c": "inputvalue"
      }
    }
  }
  ```

  If there is no input data, and the Create empty parent object for failed mapping option is selected, the output is as follows:

  ```
  {
    "a": {
      "b": {
      }
    }
  }
  ```

  Properties `a` and `b` are created but the value of `b` is an empty object.
  The check box is cleared by default.

Input and output definitions

You define the inputs and outputs of your Map policy in their own sections. Each input or output is an element in the array inputs or outputs and is defined by a name, a schema definition or reference, and a variable within the context from which it should be read or to which it should be written. After they have been defined, inputs and outputs are referenced by the name provided in the definition, not by the name of the variable.

The following example shows the inputs and outputs sections of a Map policy.

```
inputs:
  input_string:
    schema:
      type: string
    variable: request.parameters.name_in
  input_integer:
    schema:
      type: integer
    variable: request.parameters.age_in
outputs:
  output:
    schema:
      $ref: '#/definitions/output'
    variable: message.body
```

The schema field specifies the schema that describes the variable and can be a simple type, a reference to a definition, or an inline schema definition.

The variable field describes the variable and the context that should be assigned to the input or output variable during the execution of the map policy.

Actions

The fields included in the `actions` section are used in the following ways:

`set`
: Use the `set` field when you want to assign the result of the `value` field to the output variable specified in the `set` field, replacing the existing value of the output variable. You can specify only one output variable, although this variable can be an array or object.

`create`
: Use the `create` field when you want to use the result of the `value` field to create a new entry for the output array specified in the `create` field, appending it to the array. You can specify only one output variable, although this variable can be an array or object.

`from`
: Specify which variables are used in the action as either a single variable or an array of variables, where a variable can be an array or an object. The `from` field is not included if no inputs are used.

`value`
: Use GatewayScript to provide a script that produces output variables. When a single input is mapped to a single output, the `value` field can be omitted and the variable in `from` is set or created as the variable in `set` or `create` respectively.

`default`
: Provide a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see Inline references.

foreach
Specify a variable if you want to execute the associated **actions** field for each entry of the array. The variable can be from the input or output of the Map policy.

actions
Use the **actions** field to nest actions within an action. Because another action could achieve the same result if applied only once, it is primarily for use with the **foreach** field.

Script

In a **value** or **default** field, use GatewayScript to write the behavior of the action to which the **value** field belongs.

Include the script in single quotation marks. For example: **'4 + 5'** or ***'variable_1*.toUpperCase()'**.

For information about GatewayScript, see Gateway programming model and GatewayScript

Fields

from, **set**, and **create**
Each action must have a single **set** or **create** field that specifies the output variable to which the action is applied. Each action can also have a **from** field containing one or more entries that are used to specify the input variable or variables that are used in the action.

The **set** and **create** fields are both used to assign values to the output variable.

- **set** replaces the current value of the output variable or creates the variable if it does not already exist.
- **create** appends a new array entry to the output variable.

For **set** and **create**, use ***output_variable_name*.*variable_name*** to specify which of your defined output variables to use, where *output_variable_name* is as defined in the outputs section of the Map policy and *variable_name* refers to an optional field that belongs to the output variable.

For **from**, use ***input_variable_name*.*variable_name*** to specify which of your defined output variables to use, where *input_variable_name* is as defined in the outputs section of the Map policy and *variable_name* refers to an optional field that belongs to the output variable.

foreach
Use the **foreach** field to specify an input array for which the following **actions** or **value** field will be executed for each entry of the array.

For example:

```
foreach: input.in
actions:
   actions
```

where *input.in* is an input variable that is an array and *actions* is one or more actions in the same format as the parent section. In this example the instructions specified in *actions* are executed once for each array entry of *input.in*.
Referencing the input variable specified in the **foreach** field references the array entry that the current iteration corresponds to.

If a single variable is used in the **foreach** field instead of an array, the following **actions** or **value** field will be applied to or based upon the single variable once and then the loop will terminate.

References to inputs and outputs

Reference variables from the **from** field either by name or by using a number preceded by a '$' and enclosed in parentheses. The variables are numbered from 1, where 1 is the first variable in the array, or the only variable when the **from** field lists only a single variable. For example:

```
value: '$(1) + $(2)'
```

or

```
value: '$(variable_1) + $(variable_2)'
```

where each *variable* is a variable that is included in the **from** field.
During a **foreach** loop, you can reference **$(0)**. The **$(0)** variable begins a **foreach** loop empty but, after an iteration, becomes equivalent to the output of the iteration and can then be referenced again. In this manner, you can apply an array to a single value. For example:

```
- set: out.total
from: in.input
foreach: in.input
value: '$(0) + $(in.input)'
```

where *out.total* is referenced by **$(0)**. In each iteration, the current value of *out.total* and the current array entry of *in.input* are summed, and the value of *out.total* is set as this summation.
When using a foreach to operate on an array, if the elements of the array do not have named fields, you can use **$(this)** to reference the current level of nesting.

Accessing other contexts

At any point within your Map policy's **value** or **default** fields, you can access the context of the API call using the syntax **$(*context*.*variable*)**.

Alternatively, you can include the variables from other contexts when you define an input to your map policy and then reference it as you would any other input variable.

For a list of available context variables, see API Connect context variables.

Configuring the Map policy in the user interface

The assemble view in API Designer provides a visual representation of the relations between the inputs and outputs of your Map policy.

Procedure

To configure your Map policy, complete the following steps:

1. Click the Map policy in the canvas of the Assemble view.
   The property sheet opens.
2. Click the Edit inputs icon in the Input column.
3. Add an input variable.
   a. Click + input.
   b. In the Context variable field for an input, provide the location of your input variable in the context of the assembly. For a list of context variables, see API Connect context variables.
   c. In the Name field for an input, provide a name for your input for use within only the Map policy.
      Note:
      You must ensure that the name that you provide does not exactly match the value of the Context variable field, or the result might be unpredictable.
   d. Optional: In the Content type field, specify the type of your input. If None is selected, the content type is treated as JSON.
   e. In the Definition field for an input, provide the type of the variable.
      The type can be one from a standard set of types, a definition that you have created for your API, or you can select Inline schema to provide a schema as one of the following options:
      - YAML
      - JSON
      - Generate from sample JSON
      - Generate from sample XML

      .
      If you select Object or Array, you can create a schema through the user interface after you have clicked Done and returned to the main view of the property sheet.
4. Optional: To remove a variable, click the corresponding Remove input icon .
5. After you have added all of your input variables, click Done.
6. Click the Edit outputs icon in the Output column.
7. Add an output variable.
   a. Click + output.
   b. In the Context variable field for an output, provide the location of your output. This location can be a new context or one already established during the assembly. For a list of context variables, see API Connect context variables.
   c. In the Name field for an output, provide a name for your variable to use within the Map policy and when it is included in its context at output.
      Note:
      You must ensure that the name that you provide does not exactly match the value of the Context variable field, or the result might be unpredictable.
   d. Optional: In the Content type field, specify the type of your input. If None is selected, the content type is treated as JSON.
   e. In the Definition field for an output, provide the type of the variable.
      The type can be one from a standard set of types, a definition that you have created for your API, or you can select Inline schema to provide a schema as one of the following options:
      - YAML
      - JSON
      - Generate from sample JSON
      - Generate from sample XML

      If you select Object or Array, you can create a schema through the user interface after you have clicked Done and returned to the main view of the property sheet.
8. Optional: To remove a variable, click the corresponding Remove output icon .
9. After you have added all of your output variables, click Done.
10. Optional: If you selected Object or Array for the type of an input or output, create an inline schema definition through the user interface by completing the following steps:
    a. For an Array, click add item. Provide a type for the item and then click the Add icon .
    b. For an Object, click add property. Provide a name and type for the property and then click the Add icon .

    For objects and arrays that are created in this manner, you can continue to add items and properties, which can themselves be objects and arrays.
11. To connect an input variable to an output variable, click the circle that is directly before the input variable and then click the circle that is directly before the output variable.
    A green line is drawn, linking the two variables together. You can connect multiple inputs to a single output, and a single input can be connected to multiple outputs.
12. To configure an output, whether it has inputs that are connected to it or not, click the circle directly before the output variable without first clicking a circle for an input variable.
    The Configure mapping window opens.
13. Optional: In the Mapped from section of the window, you can view which inputs are mapped to the output you are editing. To remove an input, click the Remove input icon alongside the input.
    If the output is part of an array, further configuration options are available. The array, or levels of array in the case of a multidimensional array, can be created by iterating arrays on the input side of the mapping. For each level of your array, select which array on the input side is to be iterated. In the Value field, you can use `$(this)` to reference elements of an array that are not named within the array.
14. Optional: In the Value field, use GatewayScript to configure how any inputs are transformed to produce the output.
    For more information about valid code, see the Script section of the The Map policy structure topic.
15. Optional: In the Default field, provide a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see Inline references.
16. Optional: To delete all mappings to the output, click Delete.
17. When you have configured your outputs, click OK.
18. Optional: Click the Settings icon in the Map column.

a. Optional: Provide a Title and Description for your Map policy.
b. To control the XML output of the map policy, select the following options as required:

Include empty
: If the check box is selected (the default option), empty XML elements are included in the output of the map policy. Clear the check box if you do not want empty XML elements to be included in the output of the map policy.

Namespace inheritance
: If the check box is selected (the default option), XML namespaces are inherited from the parent element. Clear the check box if you want the map policy to use explicit namespaces.

Namespace inlining
: If the check box is selected (the default option), XML namespaces will be inserted into the document where they are first used. Clear the check box if you want namespaces to all be defined on the root element.

Resolve XML input data type
: If the check box is selected, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Clear the check box (the default option) if you want all XML element values to be returned as a string.

Parse XML output
: If the check box is selected, the map policy will write XML output to **`message.body`** as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string.

Note: These options effect the XML output only and have no effect on the JSON data.

c. 

From the Empty XML element handling list, select one of the following options to control how the map policy handles the output of an empty XML element:

- String (the default option): An empty XML element is handled as an empty string.
- Null: An empty XML element is handled as a null value.
- None: The data is ignored.
- 

String Badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property.
- 

Null Badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the Allow null value option is selected.

d. 

Select the following general configuration options as required:

Use only first array element
: If the check box is selected, then if an array is encountered in the traversal of the input, only the first element is used. Clear the check box (the default option) if you want the map policy to use all array elements.

Resolve API Connect variable references
: If the check box is cleared (the default option), the map policy ignores API Connect variable references in the map policies. Select the check box if you want API Connect variable references found in the map properties to be resolved.

Allow null value
: If the check box is selected (the default option), an input property value with a null value is mapped to the output document. Clear this check box (the default option) if you want the map policy to ignore null input values.

Optimize schema definition
: If the check box is selected, complex schema types evaluation handles circular type references in an optimized manner. Clear this check box (the default option) to evaluate these schema types in a standard manner.

Enable JSON post processing
: If the check box is selected, post processing of mapped JSON output is enabled. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. The check box is cleared by default, meaning that there is no post processing of mapped JSON output.

Create empty parent object for failed mapping
: 

Use this setting to control the behavior if a mapping fails because its input is not present and there is no default mapping configured.
The default behavior is to make no change to the output, but if you select this check box an empty object is created for the parent of the target mapping, emulating the behavior of IBM API Management Version 4.0.

Example
: The map policy defines a mapping to **`output.a.b.c`**.
If input data is present, the output is as follows:

```
{
  "a": {
    "b": {
      "c": "inputvalue"
    }
  }
}
```

If there is no input data, and the Create empty parent object for failed mapping option is selected, the output is as follows:

```
{
  "a": {
    "b": {
    }
  }
}
```

Properties **`a`** and **`b`** are created but the value of **`b`** is an empty object.
The check box is cleared by default.

Create required child properties for array objects and mapped optional objects

If the check box is selected, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:

- An array consists of objects that contain one or more required properties.
- An object which is optional has one or more child properties that are required.

By default, these required properties are not present in the output. If you select this option, these required properties will be present in the output. If the output schema defines a `default` property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:

- String: empty string ("")
- Number: 0
- Boolean: false
- Object: empty object
- Array: empty array

Example 1

The input data has the following array of objects:

```
[{"a": "value1"}, {"a": "value2", "b": "value3"}]
```

The output schema defines the output object as having two properties, **a** and **b**, of which **b** is required. The map policy defines the following mappings:

- `input.array.a` to `output.array.a`
- `input.array.b` to `output.array.b`

If the check box is selected, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:

```
[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]
```

Example 2

The output schema defines the following structure:

```
{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }
```

Property **b** is optional but property **d** within **b** is required.

The map policy defines a mapping to `output.a.b.c`.

If the check box is selected, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:

```
{"a" : {"b" : {"c" : "value1", "d" : ""} } }
```

If the check box is not selected, these required properties are **not** created in the output with their default values.

e. API Gateway only From the Empty JSON array handling list, select one of the following options to control how the map policy handles the output of an empty array:
   - All (the default option): Output all empty arrays, including empty children arrays.
   - Parent: Output only the current property's empty array value. Children map actions of this property are not attempted.
   - None: Prevent any empty output array values from being produced.

f. From the Severity level for input data log messages list, select one of the following options to specify the severity level for log messages that relate to input data:
   - error
   - warn
   - info

g. API Gateway only Set the Schema definition circular reference limit field to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5.

h. Click Save when done.

Results

You have configured a Map policy to transform and map variables in your assembly flow.

Map policy examples

Examples of the OpenAPI definitions of Map policies.

- One to one mapping
- Many to one mapping
- A simple transformation using the value field
- Mapping from multiple contexts into a new context
- Mapping to an inline schema definition
- Mapping with a default value
- Mapping an array into a single value
- Mapping array elements to an array
- Using the advanced XML options
- Increasing parse settings of the Map policy

One to one mapping

The following example:

- maps parameters from the request's query to an object in the message body.
- maps one strings directly to a single string.
- maps one integer directly to a single integer.

The referenced definition, `output`, defines an object containing a string, name, and an integer, age.

```
      - map:
          title: 1-1 map
          inputs:
            input_string:
              schema:
                type: string
              variable: request.parameters.name_in     # the location of the variable, named "name_in" and found in the query
parameters of the request
            input_integer:
              schema:
                type: integer
              variable: request.parameters.age_in    # another variable in the query parameters of the request
          outputs:
            output:
              schema:
                $ref: '#/definitions/output'    # a schema definition reference to use for the output. The schema is for the
whole of the message body.
              variable: message.body
          actions:
            - set: output.name_out    # in the actions section, variables are referenced by their name within the map policy
              from: input_string      # if a value field is not used, the mapping is direct with the input value used for the
output variable
            - set: output.age_out     # because the 'output' variable is itself an object, further references are made to
variables that it contains
              from: input_integer
```

Many to one mapping

The following example:

- maps parameters from the request's query to an object in the message body.
- maps two strings to a single string by concatenating them.
- maps two integers to a single integer by summing them.

The referenced definition, `output`, defines an object containing a string and an integer.

```
      - map:
          title: many-1 map
          inputs:
            input_string_1:
              schema:
                type: string
              variable: request.parameters.first_name
            input_string_2:
              schema:
                type: string
              variable: request.parameters.last_name
            input_integer_1:
              schema:
                type: integer
              variable: request.parameters.balance_1
            input_integer_2:
              schema:
                type: integer
              variable: request.parameters.balance_2
          outputs:
            output:
              schema:
                $ref: '#/definitions/output'
              variable: message.body
          actions:
            - set: output.full_name
              from:
                - input_string_1
                - input_string_2
               value: |
                 var retValue = undefined;
                 if ($(input_string_1) !== undefined && $(input_string_2) !== undefined) {
                   retValue = $(input_string_1).toUpperCase() + ' ' + $(input_string_2).toUpperCase()"
                 }
                 retValue;
            - set: output.total_balance
              from:
                - input_integer_1
                - input_integer_2
              value:  |
                var i1 = 0;
                var i2 = 0;
                if ($(input_integer_1) !== undefined) i1 = $(input_integer_1);
                if ($(input_integer_2) !== undefined) i2 = $(input_integer_2);
                i1 + i2;
```

A simple transformation using the value field

The following example:

- maps a parameter from the request's query to an object in the message body.
- maps one string featuring lowercase characters to a single string containing only uppercase characters.

The referenced definition, `output`, defines an object containing a single string.

```
      - map:
          title: Uppercase map
          inputs:
            input_lowercase:
              schema:
                type: string
              variable: request.parameters.name_in
          outputs:
            output_uppercase:
              schema:
                $ref: '#/definitions/output'
              variable: message.body
          actions:
            - set: output_uppercase.name_out
              from: input_lowercase
              value: $(input_lowercase).toUpperCase()    # the input variable is referenced and calls the toUpperCase method to
produce a value for the output variable
```

Mapping from multiple contexts into a new context

The following example:

- maps an integer from the request's header to an integer in a new message body.
- maps a string from the message's body to the body of a new custom context, named *new_context*.

```
      - map:
          title: Context map
          inputs:
            input_integer:
              schema:
                type: integer
              variable: request.headers.age_in      # the 'age_in' header of the request is used as an input
            input_string:
              schema:
                type: string
              variable: message.body.name_in      # as is the 'name_in' field of the request body
          outputs:
            output_integer:
              schema:
                type: integer
              variable: message.body.age_out
            output_string:
              schema:
                type: string
              variable: new_context.body.name_internal    # the context named 'new_context' is created by the map policy and
exists only while the assembly is processed
          actions:
            - set: output_string
              from: input_string
            - set: output_integer
              from: input_integer
```

Mapping to an inline schema definition

The following example:

- maps parameters from the request's headers to an object in the message body, which is defined within the map policy.
- maps one string directly to a single string.
- maps one integer directly to a single integer.

```
      - map:
          title: Inline schema map
          inputs:
            input_integer:
              schema:
                type: integer
              variable: request.headers.age_in
            input_string:
              schema:
                type: string
              variable: request.headers.name_in
          outputs:
            output:
              schema:                    # instead of a simple type or a reference to a definition, an inline YAML definition
is used
                type: object
                properties:
                  name_out:
                    type: string
                    name: name_out
                  age_out:
                    type: integer
                    format: int32
                    name: age_out
                title: output
              variable: message.body
          actions:
```

```
            - set: output.age_out
              from: input_integer
            - set: output.name_out
              from: input_string
```

Mapping with a default value

The following example:

- maps one string directly to a single string.
- provides a default value for the output string if a valid input string is not provided.

```
      - map:
          title: Default Map
          inputs:
            input_string:
              schema:
                type: string
              variable: request.headers.name_in
          outputs:
            output_string:
              schema:
                type: string
              variable: message.body.name_out
          actions:
            - set: output_string
              from: input_string
              default: John Smith            # the default field is specified in the same way as a value, in this case
providing a fixed value
```

Mapping an array into a single value

The following map policy:

- maps a single array of integers into a single integer.
- sums the integers in the array.
- `$(0)` represents the accumulated output because map evaluates all array element values.

```
      - map:
          title: Summation map
          inputs:
            input:
              schema:
                $ref: '#/definitions/balance_array_in'
              variable: request.body
          outputs:
            output:
              schema:
                type: integer
              variable: message.body.total_balance_out    # instead of using a full schema definition of the message body, a
single variable in the message body is specified
          actions:
            - set: output
              from: input
              foreach: input      # the foreach field specifies that each value of the array 'input' is to be iterated over
              value: $(0)+$(input) # the $(0) reference is the accumulated value of the 'output' variable
```

Mapping array elements to an array

The following map policy:

- maps an array, whose elements are objects containing two integers, to an array, whose entries contain a single integer field.
- maps an array to an array of the same length.
- takes the difference of the values of the integers in each array element to create a single integer in each array element.

```
      - map:
          title: Array summation
          inputs:
            input:
              schema:
                $ref: '#/definitions/balance_and_credit_array'
              variable: request.body
          outputs:
            output_array:
              schema:
                type: array
              variable: message.body
          actions:
            - create: output_array
              from: input
              foreach: input
              actions:
                - set: total_balance_out
                  from:                          # inside the actions section, variables inside the array elements being
iterated over are used
                    - integer_in_1
                    - integer_in_2
                  value: $(integer_in_1)-$(integer_in_2)      # the difference of the variables is taken for each array entry
of 'input'
```

Using the advanced XML options

The following example:

- does not include empty elements in the output of the map policy.
- uses explicit name spaces rather than inheriting name spaces from the parent element
- indicates that all namespace declarations will be placed on the root XML element.
- uses all array elements rather than only the first
- ignores API Connect variable references
- maps input property values with a null value to the output document
- handles circular type references in an optimized manne

```
      actions:
          - set: output, two
            from: input, one
      options:
          includeEmptyXMLElements: false
          namespaceInheritance: false
          inlineNamespaces: false
          mapArrayFirstElementValue: false
          mapResolveApicVariables: false
          mapNullValue: true
          mapOptimizeSchemaDefinition: true
          mapCreateEmptyArray: parent
```

Increasing parse settings of the Map policy

To increase the parse-settings-reference, you can update the YAML source with the desired parse settings. Using the following example, you can update the YAML source with the necessary parse settings.

```
      - map:
        version: 2.1.0
        title: map
        inputs: {}
        outputs: {}
        actions: []
        parse-settings-reference:
          parse-settings:
            document_type: detect
            max_doc_size: 8388608
            max_nesting_depth: 512
            max_width: 8192
            max_name_length: 256
            max_value_length: 8192
            max_unique_names: 1024
            max_unique_prefixes: 1024
            max_unique_namespaces: 1024
            max_number_length: 128
        options:
          mapEmulateV4EmptyJSONObject: false
          mapEmulateV4DefaultRequiredProps: true
          mapEnablePostProcessingJSON: false
          mapReferenceLimit: 1
```

For more information, see Creating parse settings.

OAuth

An OAuth policy performs the requested OAuth processing based on the defined OAuth provider settings.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see oauth.

About

By adding an assembly OAuth policy, you specify the OAuth provider settings to use to perform the requested OAuth processing and the supported OAuth processing components.

Note: You add an OAuth policy to the assembly in a native OAuth provider. For more information, see the following topics:

- Editing the native OAuth provider configuration using the API Editor (Cloud Manager UI)
- Editing the native OAuth provider configuration using the API Editor (API Manager UI)

You can specify the settings through one or more of the following methods.

- URL reference
- Literal configuration
- Object reference

When you use more than one method to specify the same aspect of the OAuth provider settings, the following precedence rules apply to enforce the settings dynamically for the incoming transactions.

- URL reference takes precedence over any existing literal configuration or object reference.
- Literal configuration takes precedence over any existing object reference.

You can configure the policy to support one or more of the following processing components:

Validate request
: Validates the authorization request from the client.

Generate authorization code
: Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource.

Verify authorization code
: Verifies the authorization code from the client.

Verify refresh token
: Verifies the refresh token that is presented by the client.

Generate access token
: Generates the access token to the client when the authorization code or refresh token is verified.

Introspect token
: Introspects the token to determine its state and, when active, its metadata.

When the policy does not support a processing component but that processing is requested, the unsupported component is not run.

You can include multiple OAuth policies in your OAuth provider assembly. For example, your assembly might include the following flow:

1. OAuth policy that validates the request.
2. GatewayScript policy.
3. OAuth policy that generates authorization code.

For more information, see Example - using multiple OAuth policies in an OAuth provider assembly and OAuth context variables.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OAuth policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **oauth**.	string
Description	No	A description of the policy	string
Default OAuth Provider Settings Object	Yes	The name of an existing OAuth provider that defines the required settings.	string
Dynamic OAuth configuration from a URL	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings.	string
Dynamic OAuth configuration from a literal string	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings.	string
Supported OAuth components	No	Select the OAuth components that are supported by this policy.	string

Overriding the default OAuth provider settings

You can use either the Dynamic OAuth configuration from a literal string property or the Dynamic OAuth configuration from a URL property to dynamically override any OAuth provider configuration settings defined by the Default OAuth Provider Settings Object property.

For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the **OAuthProviderSettings** management schema, defined in the xml-mgmt.xsd file located in the store: directory on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of **gatewayscript** policies that use OAuth context variables to manipulate the OAuth flow. For details on creating a native OAuth provider, see Configuring a native OAuth provider.

It has the following assembly flow:

The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download multiple_oauth_policies.txt.

Sample policy to add a custom scope

The **add_scope** policy is a **gatewayscript** policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: add_scope
    source: |-
      // Add another custom scope to the request
      let scope = context.get("request.parameters.scope.values[0]");
      if (scope)
        context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first **process_request** policy is an **oauth** policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the oauth.processing context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: process_request
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect protocol steps
      that are needed for OAuth Validation by default. The inputs and
      outputs of each of the steps are driven by documented context
      variables. Add or remove the Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthValidateRequest
```

Sample policy to modify the scope

The **modify_scope** policy is a **gatewayscript** policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: modify_scope
    source: |-
      let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

      // Check application and modify the scope
      let app = context.get("oauth.processing.client_id");
      let scope = context.get("oauth.processing.scope");
      if (app === admin_id) {
```

```
        context.set("oauth.processing.scope", scope + " admin");
      } else {
        context.set("oauth.processing.scope", scope + " customer");
      }
```

Branch conditionally according to the OAuth path

The **path_branch** policy is a **switch** policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
    version: 2.0.0
    title: path_branch
    case:
      - condition: ($operationPath() = '/oauth2/token')
        execute:
            .
            .
            .
          definition of the user_security and other_grants policies
            .
            .
            .
      - condition: ($operationPath() = '/oauth2/authorize')
        execute:
            .
            .
            .
          definition of the user_password and implicit_authcode policies
            .
            .
            .
      - otherwise:
            .
            .
            .
          definition of the other_endpoints policy
            .
            .
            .
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The **user_password** policy for password grant type processes the user name and password from the **x-www-form-urlencoded** body. The authentication method is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **other_grants** policy is an **oauth** policy that enables the **OAuthGenerateAccessToken**, **OAuthVerifyAZCode**, **OAuthVerifyRefreshToken**, and **OAuthCollectMetadata** components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_password
    version: 2.0.0
    description: ''
    factor-id: default
    extract-identity-method: context-var
    user-context-var: request.parameters.username.values
    pass-context-var: request.parameters.password.values
    ei-stop-on-error: false
    user-auth-method: auth-url
    au-stop-on-error: false
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
- oauth:
    title: other_grants
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for token path by default.
      The inputs and outputs of each of the steps are driven by
      documented context variables. Add or remove the Supported
      OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAccessToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
      - OAuthCollectMetadata
```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The **user_security** policy configuration is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **implicit_authcode** policy is an **oauth** policy that enables the **OAuthGenerateAZCode**, **OAuthGenerateAccessToken**, and **OAuthCollectMetadata** components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_security
    version: 2.0.0
    description: >-
      This user security policy performs EI(basic) and AU(auth
      url) check for oauth assembly. Change the security check
      method as required
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: auth-url
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
- oauth:
    title: implicit_authcode
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for az code path by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthCollectMetadata
```

Process all other endpoints

The **otherwise** condition catches all other endpoints such as the introspect and revoke endpoints. The **other_endpoints** policy in the **otherwise** condition is an **oauth** policy that enables the **OAuthIntrospectToken**, and **OAuthRevokeTokencomponents** components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: other_endpoints
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for all other paths by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthIntrospectToken
      - OAuthRevokeToken
```

openai invoke

Use the OpenAI invoke policy to invoke OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see openai-invoke.

About

The OpenAI invoke policy provides access to four OpenAI operations:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

The OpenAI invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OpenAI invoke policy properties

Property label	Required	Description	Data type
Title	No	`OpenAI` invoke chat completions	string
Description	No	A description of the policy.	string
OpenAI Operation	Yes	The OpenAI operation to invoke; must be one of the following operations: • `POST /chat/completions` An HTTP POST operation for `/chat/completions`. See Create chat completion in the OpenAI documentation for sample request and response examples. • `POST embeddings` An HTTP POST operation for `/embeddings`. See Create embeddings in the OpenAI documentation for sample request and response examples. • `GET models` An HTTP GET operation for `/models`. See List Models in the OpenAI documentation for sample response examples. • `GET models/[model]` An HTTP GET operation for `/models/[model]`. See Retrieve model in the OpenAI documentation for sample response examples.	string
OpenAI API Key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate OpenAI requests.	string
OpenAI Organization Id	No	An optional property where you can specify the organization identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy requests specifying this property will count as usage by the organization specified.	string
OpenAI Project Id	No	An optional property where you can specify the project identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy request specifying this property will count as usage by the project specified.	string
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
OpenAI Operation Path Parameters	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation `GET models/[model]`, the path parameter property would be specified as `model:somename`. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string

Property label	Required	Description	Data type
OpenAI Operation Query Parameters	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the OpenAI response. By default, this property uses message as the value, which enables the response to be accessible by subsequent API policies in `message.body` and `message.headers`.	string

API Gateway only

Azure openai invoke

Use the Azure OpenAI invoke policy to invoke Azure OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see Azure openai-invoke.

About

The Azure OpenAI invoke policy provides access to four Azure OpenAI operations:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

The Azure OpenAI invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Azure OpenAI invoke policy properties

Property label	Required	Description	Data type
Title	No	Azure OpenAI invoke chat completions	string
Description	No	A description of the policy.	string
Azure OpenAI Operation	Yes	The Azure OpenAI operation to invoke; must be one of the following operations: • `POST /chat/completions` An HTTP POST operation for `/chat/completions`. See Create chat completion in the Azure OpenAI documentation for sample request and response examples. • `POST embeddings` An HTTP POST operation for `/embeddings`. See Create embeddings in the Azure OpenAI documentation for sample request and response examples. • `GET models` An HTTP GET operation for `/models`. See List Models in the Azure OpenAI documentation for sample response examples. • `GET models/[model]` An HTTP GET operation for `/models/[model]`. See Retrieve model in the Azure OpenAI documentation for sample response examples.	string
Azure OpenAI API Key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Azure OpenAI requests.	string
Azure OpenAI Resource Id	Yes	Serves as part of endpoint of URL that points to your provisioned resources.	string
Azure OpenAI Deployment ID	Yes	Path parameter - the name of project/deployment in Azure where model is deployed.	string

Property label	Required	Description	Data type
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the Azure OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
Operation Version	No	The operation version specifies the version of the OpenAI operation (such as completions, chat/completions, embeddings) that the policy applies to. It is defined using YYYY-MM-DD format.	
Azure OpenAI Operation Path Parameters	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation `GET models/[model]`, the path parameter property would be specified as `model:somename`. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
Azure OpenAI Operation Query Parameters	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the Azure OpenAI response. By default, this property uses message as the value, which enables the response to be accessible by subsequent API policies in `message.body` and `message.headers`.	string

Parse

Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later) 2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see parse.

About Parse

With the parse policy, you can retrieve parse settings by using the following methods in increasing order of precedence.

1. Specify a valid parse settings configuration from which to retrieve its properties as the default parse settings.
   Note: If you change the default name, you must separately configure a corresponding ParseSettings object on the DataPower API Gateway.
2. Specify a literal string as serialized XML or JSON properties as parse settings. These properties take precedence over any existing default properties. The literal string must be XML or JSON formatted.
   - The XML format is `"<ParseSettings><propertyName>propertyValue</propertyName></ParseSettings>"`.
   - The JSON format is `"{ \"ParseSettings\" : { \"propertyName\" : propertyValue } }"`.
3. A URL that represents a named context from which to retrieve the serialized XML or JSON properties as parse settings. These properties take precedence over any existing literal or default properties.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Parse policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is `parse`.	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
Use Content Type	No	If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the **`Content-Type`** specified in the request headers. If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the **`Content-Type`** specified in the request headers and fails if the **`Content-Type`** in the request headers does not match the parse setting. Enabling this setting is applicable only when the expected **`Content-Type`** is either JSON or XML. If this setting is not enabled, the parse operation uses either the document type that is specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type. The check box is cleared by default.	boolean
Parse settings object reference	No	An existing valid object from which to retrieve default property values for the dynamic object.	string

Document type	No	The type of document to parse. Select one of the following options:
		• Detect: the document type is detected and the payload is parsed accordingly. This type is the default option.
		• JSON: the payload is parsed as JSON.
		• XML: the payload is parsed as XML.
		• Graphql: parsing is performed in one of the following ways:
		  ◦ As GraphQL in the body of a POST request. The GraphQL is in the following format:
		`{ me { name } }`
		  ◦ As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format:
		`{ "query": "query MyData ($idVar: Int!) { user (id: $idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} }`
		  ◦ Through the URL query of a GET request. The URL is in the following format:
		`https://myapi/graphql?query={me{name}}`
		The following example includes the **`variables`** and **`operationName`** properties, with URL encoding (line-breaks are for table formatting only, your value will not include line-breaks):
		`https://hostname/basepath/graphql?query=query%20fetchAccounts %20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}} &variables={"limit":100}&operationName=fetchAccounts`
		Note: If the Buffering is selected in Invoke policy, the document type is detected, and the payload is parsed accordingly. For more information, see Configuring the Invoke policy for DataPower API Gateway and Configuring the Invoke policy for DataPower Gateway (v5 compatible).
		
		Query variables in a GET request can be sent as a JSON string in a query parameter called **`variables`**. If the query contains several named operations, an **`operationName`** query parameter is required to determine which operation is to be executed.
			string

Maximum document size	No	Optionally, the maximum document size in bytes of a JSON, XML, or GraphQL input document that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. The default value is 4194304.	integer
Maximum nesting depth	No	Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message. • When XML, it is the maximum level of element depth. • When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. • When GraphQL, it is the maximum level of nested selection sets. Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth. The default value is 512.	integer

Property label	Required	Description	Data type
Maximum width	No	Optionally, the maximum width of the payload that the parse operation accepts. • When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. • When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. • When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document. The default value is 4096.	integer
Maximum name length	No	Optionally, the maximum name length in bytes in a document that the parse operation accepts. • For XML, it is the length of the name portion of a tag. • For JSON, it is the length of the label portion of the JSON label-value pair. • For GraphQL, it is the maximum length of the identifiers, including field names and directive names. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document. The default value is 256.	integer
Maximum value length	No	Optionally, the maximum value length in bytes in a document that the parse operation accepts. • For XML, it is the length of an attribute or the length of a text value. • For JSON and GraphQL, it is the length of a string value. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document. The default value is 8192.	integer
Maximum number of unique names	No	Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts. • For XML, it is the number of unique XML local names. • For JSON, it is the number of unique JSON labels. Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document. The default value is 1024.	integer
Maximum number of unique prefixes	No	Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document. The default value is 1024.	integer
Maximum number of unique namespaces	No	Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document. The default value is 1024.	integer
Maximum number length	No	Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document. The default value is 128.	integer
Parse settings literal configuration	No	A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.	string
Parse settings URL reference	No	A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.	string
Message for parsing	No	The name of a variable in the API context. The content of the **`body`** field of the variable is the input to the policy. The default variable name is **`message`**.	string
Message for resulting parsed data	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

Use the YAML source to set the following option.

Property	Required	Description	Data type

Property	Required	Description	Data type
strict-utf8-encoding	No	For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document. • When **on**, the entire document is checked for valid UTF-8 encoding. • When **off**, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. The default value is **off**.	boolean

For examples, see parse.

Proxy

Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the **message.body** and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see proxy.

About

Only one Proxy policy is permitted to be run per unique flow of your assembly. More than one Proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.

You can use the Proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, Proxy must be the last policy in the assembly, otherwise the response that is received can be manipulated during subsequent steps, thereby causing the multipart form data to be lost.

The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the invoke policy rather than the proxy policy.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Proxy policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **proxy**.	string
Description	No	A description of the policy.	string
Invoke URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Proxy URL value is pre-supplied from information that is defined in the imported WSDL.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the proxy. Valid values are: • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **Keep**. By using **Keep**, or removing the property from the source, the HTTP method from the incoming request is used.	string
Compression	No	Select this check box to enable Content-Encoding compression on upload. The check box is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are: Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL. Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option. No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings. Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached. The default value is Protocol.	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to **`Time to Live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a **`catch`** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. This variable can then be referenced in other actions, such as 'Map'.	string
X-Forwarded header	No	This header can be provided by 1. If **`X-Forwarded-Host`** exists, processing continues. If it does not exist prior to calling the proxy policy, it is set with the value of the **`Host`** header. 2. The **`X-Forwarded-For`** header is always set, in all cases. This header maintains breadcrumbs, showing a comma-separated list of IPs, from the client through any preceding proxy. 3. If all three of **`X-Forwarded-Host`**, **`X-Forwarded-Port`**, and **`X-Forwarded-Proto`** headers are missing at the time of calling the proxy policy, they are set automatically. To prevent this, set **`X-Forwarded-Host`** header to some value before calling the proxy policy.	string

API Gateway only

Rate Limit

Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.5.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ratelimit.

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a Rate Limit policy is placed before an Invoke policy, and the call made by the Invoke policy exceeds the limits defined by the Rate Limit policy, the API call itself fails.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`ratelimit`**.	string
Description	No	A description of the policy.	string
Source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Select one of the following options: • Catalog by Name: the limits to be applied are defined in the appropriate **`api-collection`** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the **`api-collection`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan by Name: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a Plan by Name rate limit policy: ◦ Every Plan that contains the API that is being limited must have the named rate limit applied. ◦ A Plan by Name rate limit policy cannot be used with automatically generated Products. • Gateway by Name: the limits to be applied are defined in the **`apigw`** object, named **`apiconnect`**, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the **`apigw`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan Default: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies.	string
Rate Limit Name	Yes[1]	If Source property is set to Catalog by Name, the name of a rate limit as defined in the DataPower API Gateway configuration, To display the Rate Limit Name field, click Add Rate Limit; you can add as many rate limits as you want. [1]You must provide at least one rate, burst, or count limit.	string

Property label	Required	Description	Data type
Burst Limit Name	Yes[2]	If Source property is set to Catalog by Name, the name of a burst limit as defined in the DataPower API Gateway configuration. If Source is set to Plan by Name, the name of an assembly burst limit in a Plan. To display the Burst Limit Name field, click Add Burst Limit; you can add as many burst limits as you want. [2]You must provide at least one rate, burst, or count limit.	string
Count Limit Name	Yes[3]	If Source property is set to Catalog by Name, the name of a count limit as defined in the DataPower API Gateway configuration. If Source is set to Plan by Name, the name of an assembly count limit in a Plan. To display the Count Limit Name field, click Add Count Limit; you can add as many count limits as you want. [3]You must provide at least one rate, burst, or count limit.	string
Operation	No	For a rate limit, select one of the following options: • Consume: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. • Replenish: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55. Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1. The default value is Consume. For a count limit, select one of the following options: • Increment: the current count is incremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. • Decrement: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway. The default value is Increment. For a burst limit, the only option is Consume, meaning that the limit applied is that defined in the burst limit specified in the Burst Limit Name field.	string

- **Configuring a rate, burst, or count limit on the DataPower API Gateway**
  If you want to include a rate limiting policy in your API assembly flow, you must first configure the required rate, burst, and count limits on the Gateway. Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

Configuring a rate, burst, or count limit on the DataPower API Gateway

If you want to include a rate limiting policy in your API assembly flow, you must first configure the required rate, burst, and count limits on the Gateway. Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

About this task

You configure rate, burst, and count limits on the DataPower® API Gateway by defining them in one or more configuration files that you package and then add to the Gateway as a Gateway extension.

You define *Catalog scoped* rate, burst, and count limits in the appropriate **api-collection** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. The defined rate, burst, and count limits will be available to be included in Rate Limit policies in the assembly flows of all the APIs that are published to that Catalog.

You define *Gateway scoped* rate, burst, and count limits in the appropriate **apigw** object on the DataPower API Gateway. The defined rate, burst, and count limits will be available to be included in Rate Limit policies in the assembly flows of all the APIs that are published to that Gateway.

The system clock determines the start time for rate, burst, and count limits. The intervals are configured as follows:

- 1-second interval starts at each new second.
- 1 minute interval starts at the beginning of each minute.
- 1 hour interval starts at the beginning of each hour.
- 1 day interval starts at midnight UTC.
- 1 week interval starts on Thursday at 00:00:00 UTC.

Note:

- Only one Gateway extension can be in use at any one time, so you should package all required rate, burst, and count limits in a single Gateway extension.
- To apply a Catalog scoped or Gateway scoped rate, burst, or count limit, it must be referenced in a Rate Limit policy in an API assembly.
- You should ensure that all rate, burst, and count limit names are unique across all your Plans and Catalogs. When an API is called, information about any rate, burst, or count limits (such as name, limiting criteria, and remaining number of calls) is returned in the HTTP headers of the response. If two or more limit definitions with exactly the same name are applied during the invocation of an API, information about only **one** of them is returned. However, **all** limiting criteria are applied.

Procedure

1. Create a .cfg file that includes the DataPower API Gateway CLI commands that define the rate, burst, or count limit.
   To define a rate limit, use the **assembly-rate-limit** command. To define a burst limit, use the **assembly-burst-limit** command. To define a count limit, use the **assembly-count-limit** command. For details of the command parameters, see assembly-rate-limit, assembly-burst-limit, and assembly-count-limit in the DataPower product documentation.

   Example 1: Configuring a Catalog scoped rate limit

   ```
   top; config;
   switch apiconnect;

   api-collection myorg_mycatalog_collection
     assembly-rate-limit  30per1min 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-
   amount"
   exit
   ```

   In this example, the **assembly-rate-limit** command specifies a rate limit name, and the API call limits that you want to impose, 30 calls per minute in this case. The final, optional argument, **"my.vars.expected-amount - my.vars.actual-amount"**, is a weight expression. You use weight expressions in cases where you want to restore an appropriate amount of remaining rate limit balance when an earlier usage calculation in your assembly flow turns out to be too high. You define two rate limiting policies in your assembly flow, one with a **consume** operation, and a subsequent one with a **replenish** operation that restores some of the remaining rate limit balance if appropriate. The weight expression calculates the amounts to be consumed or replenished; for more information, see Rate Limit.

   The **api-collection** command specifies the **api-collection** object in which you want to configure the rate, burst, or count limits. The name of the **api-collection** object has the following format:

   ***org_catalog*_collection**

   where:
   - *org* is the name of the provider organization that contains your Catalog.
   - *catalog* is the name of the Catalog.

   This **api-collection** object name is assigned automatically by the Gateway the first time that a Product is published to the Catalog.

   Example 2: Configuring a Catalog scoped count limit

   ```
   top; config;
   switch apiconnect;

   api-collection myorg_mycatalog_collection
     assembly-count-limit  maxsixty 60 1 on on off off off off "" "1" off
   exit
   ```

   The final argument is the **autodecrement** property that controls whether the count limit is automatically decremented at the end of an API assembly. The default value is **on**, meaning that at the end of the assembly the count limit is automatically decremented by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly.

   Example 3: Configuring a Gateway scoped rate limit

   ```
   top; config;
   switch apiconnect;

   apigw apigw_object_name
     assembly-rate-limit  30per1min 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-
   amount"
   exit
   ```

   The **apigw** command specifies the name of the **apigw** object in which you want to configure the rate, burst, or count limits; the **apigw** object name is the same as the name of the API Connect domain in your DataPower API Gateway configuration.

2. Package the .cfg file in a **.zip** file.
   You can package multiple .cfg files in a single **.zip** file if you want; the .cfg files must all be at the root of the **.zip** file.
3. Add the **.zip** file to the DataPower API Gateway as a Gateway extension. For details, see Configuring your Gateway server extensions.

What to do next

Apply the rate, burst, or count limits to an API by adding a Rate Limit policy to the API assembly flow.

Related information

- Gateway extension guidelines - DataPower API Gateway.

API Gateway only

Rate Limit Info

Use the Rate Limit Info policy to return information about rate limits, burst limits, and count limits. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ratelimitinfo.

About

The Rate Limit Info policy returns information about the rate limits, burst limits, and count limits that are applied to the API.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit Info policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`ratelimitinfo`**.	string
Description	No	A description of the policy.	string
Input	No	The input context that specifies what rate limit information is requested.	string
Output	No	The destination of rate limit information.	string

API Gateway

Redaction - DataPower API Gateway

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the Redaction policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Redaction - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see redact - DataPower API Gateway.

Note: With the DataPower API Gateway, the input to the Redaction policy must be parsed data. One way to produce parsed data is to use a Parse policy before a Redaction policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`redact`**.	string
Description	No	A description of the policy.	string
Root	No	Specifies the data source that contains the content to redact or remove. If no value is entered in the Root field, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of `message.body`. The actual content to which the action is applied then depends on the positioning of the Redaction policy in the overall assembly flow; for example: • If positioned at the beginning, the action is applied to the client request. • If positioned after an Invoke policy, the action is applied to the response from the back end. • If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the Redaction policy is used after a Log policy that specifies Gather-only mode, specify a Root value of `log.request_body` for the logged request payload, or `log.response_body` for the logged response payload.	string
Path	Yes	Specifies a JSONata path expression that identifies the content to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
Action	No	Specifies whether you want to remove or redact the content. Choose one of the following options: • Remove: Completely removes the specified fields. • Redact: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is Redact. Note: If a numerical value is being redacted, the redacted value is depicted as `******` and the type is changed to **`string`**.	string

Tip: You can optionally click Add action to specify JSONata expressions for additional fields that you want to remove or redact from the specified content source.

- **Constructing JSONata expressions to redact fields**
  To define a field for redaction or removal when using the Redaction policy with the DataPower API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

Constructing JSONata expressions to redact fields

To define a field for redaction or removal when using the Redaction policy with the DataPower® API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - **`$eval()`**
  - **`$sift()`**
  - **`$each()`**
  - **`$error()`**
  - **`$assert()`**
- **`$fromMillis()`** is supported with the following restrictions:
  - The **`$fromMillis()`** parameter supports numbers in the range -5364662400000 - 2903299199000.
    - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
    - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- **`$now()`** is supported with the following restrictions:
  - The following component specifiers are not supported:
    - **`W`** = Week in year
    - **`w`** = Week in month
    - **`X`** = ISO week-numbering year
    - **`x`** = ISO week-numbering month
  - Representing numbers as words are not supported, so the following presentation modifiers are not supported:
    - **`W`** = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
    - **`w`** = Lowercase word (for example: [Yw] => two thousand and twenty-four)
    - **`Ww`** = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
  - Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description

`$apiCtx()`	Generic access to an API context	The `$apiCtx()` extension gives generic access to an API context.
		• Sample transform field in an extract action:
		`"$apiCtx().request.uri"`
		• Sample condition of a case in a switch action:
		`"$apiCtx().request.path = '/simple/apictx-function'"`

`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation
`$queryParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keyword is `query`. • `request.parameters.`*`name`*`.values`	Searches for the index of `query` in `request.parameters.`*`name`*`.locations` and returns `request.parameters.`*`name`*`.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*`variable`*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

`$urlParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keywords are `path` and `query`
	• `request.parameters.`*`name`*`.values`
		Searches for the index of `path` and `query` in `request.parameters.`*`name`*`.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.`*`name`*`.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values.
		`http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese`
		The `$urlParameter('breed')` URL returns the following array of values.
		`[cats, adopt, Sphynx, Siamese]`
		In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.

`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- **`query`**
  The entire GraphQL query including operations and fragments.

- ***`operationName`***
  For an anonymous operation, ***`operationName`*** can be empty.

- ***`~fragmentSpreadName`***
- ***`on~typeCondition`***
- ***`~~fragmentDefinitionName`***

You can define the path using either of the following options:

- Use a JSONata expression
- Use the **`$xpath()`** JSONata extension

Using a JSONata expression

The path specified by the JSONata expression is relative to any value specified for the **`root`** property of the Redaction policy. If the **`root`** property has no value or is absent, begin the expression with the absolute content path. If the **`root`** property has a value then you can either begin the expression with **`$`** to use the **`root`** path directly, or you can provide a sub-path relative to the **`root`** path.

Note: If you use a JSONata expression to redact fields and soft linked copies of a field exist in different locations, the Redaction policy can cause content from all of the linked fields to be redacted.
JSONata expressions can be used with content that is in either JSON or XML format.

Example 1
: If the **`root`** property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the **`price`** field in the request and response data:

```
message.body.**.price
```

Example 2
: If the **`root`** property of the Redaction policy has the value **`log.request_body`**, use the following expression to redact or remove all occurrences of the **`price`** field, specifically within an **`item`** element, in the logged request payload:

```
$.item.price
```

Example 3
: If the **`root`** property of the Redaction policy has the value **`log`**, use the following expression to redact or remove all occurrences of the **`price`** field in the logged response payload:

```
response_body.**.price
```

The **`**`** descendant wildcard traverses all descendants at all hierarchical levels.

Using the `$xpath()` JSONata extension

The **`$xpath()`** function has the following format:

```
$xpath(content_path, xpath_expression)
```

where:

- *content_path* is the path to the content that contains the field that you want to redact or remove.
- *xpath_expression* is the XPath expression that defines the field that you want to redact or remove.

The *content_path* is relative to any value specified for the **`root`** property of the Redaction policy. If the **`root`** property has no value or is absent, provide the absolute content path. If the **`root`** property has a value then you can either provide the value **`$`** for the *content_path* parameter to use the **`root`** path directly, or you can provide a sub-path relative to the **`root`** path.

The **`$xpath()`** function can be used only with content that is in XML format.

Example 1
: If the **`root`** property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the **`price`** field in the request and response data:

```
$xpath(message.body, '//price')
```

Example 2

If the **root** property of the Redaction policy has the value **log.request_body**, use the following expression to redact or remove all occurrences of the **price** field, specifically within an **item** element, in the logged request payload:

```
$xpath($, 'item/price')
```

Example 3

If the **root** property of the Redaction policy has the value **log**, use the following expression to redact or remove all occurrences of the **price** field in the logged response payload:

```
$xpath(response_body, '//price')
```

The **//** expression in the second parameter selects all occurrences anywhere in the content.

DataPower Gateway (v5 compatible)

Redaction - DataPower Gateway (v5 compatible)

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This topic describes the Redaction policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Redaction - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see redact - DataPower Gateway (v5 compatible).

About

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **redact**.	string
Description	No	A description of the policy.	string
Path	Yes	Specifies an XPath expression that defines the field to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields.	string
Action	Yes	Specifies whether you want to remove or redact the field. Valid values: • **remove**: Completely removes the specified field. • **redact**: Redacts (obfuscates with "*"s) the field to block out the data. The default value is **redact**. Note: If a numerical value is being redacted, the redacted value is depicted as ****** and the type is changed to **string**.	string

Property label	Required	Description	Data type
From	Yes	Specifies where to remove or redact the specified field from. Valid values: • `all`: Removes or redacts the specified field from the Request body, the Response body, and the activity logs. • `request`: Removes or redacts the specified field from the Request body. • `response`: Removes or redacts the specified field from the Response body. • `logs`: Removes or redacts the specified field from the activity logs. The default value is `all`. Optionally click Add item to specify additional values.	string

Tip: You can optionally click Add item to specify XPath expressions for additional fields that you want to remove or redact from the Request body, Response body, and logs.

- **Constructing XPath expressions to redact fields**
  To define a field for redaction when using the DataPower Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

DataPower Gateway (v5 compatible) only

Constructing XPath expressions to redact fields

To define a field for redaction when using the DataPower® Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

About this task

The following sections provide examples for constructing XPath expressions to redact a field; examples are provided for API responses in both XML and JSON format:

XPaths for XML

Consider the following example of an XML response:

```
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>412 Brooklyn Avenue</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

To redact "streetAddress" in the preceding example the XPath expression would be: `//streetAddress`
where the components of the expression have the following meaning:

Expression	Meaning
`//`	search anywhere in the XML structure
`//streetAddress`	search anywhere in the XML structure for an element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New Jersey</city>
```

```
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Both incidences of "streetAddress" have been redacted.
To redact one specific incidence of "streetAddress" in the initial example, the XPath expression would be: `//secondaryAddress/streetAddress`
where the components of the expression have the following meaning:

Expression	Meaning
`//secondaryAddress`	search anywhere in the XML structure for an element of type "secondaryAddress"
`//secondaryAddress/streetAddress`	search under the preceding element for a child element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Only the secondary address has been redacted.
XPaths for JSON
Consider the following example of a JSON response:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "412 Brooklyn Avenue",
    "city": "New Jersey",
    "state": "NJ",
    "postalCode": 12302
  }
}
```

Unlike the preceding XML example, to construct an XPath for this example you must use the corresponding DataPower XML representation, JSONx. The JSONx equivalent of this JSON response is as follows:

```
<json:object xsi:schemaLocation="http://www.datapower.com/schemas/json jsonx.xsd"
xmlns:json="http://www.ibm.com/xmlns/prod/2009/jsonx" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <json:object name="primaryAddress">
    <json:string name="streetAddress">21 2nd Street</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
  <json:object name="secondaryAddress">
    <json:string name="streetAddress">412 Brooklyn Avenue</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
</json:object>]
```

To redact the element "streetAddress" from the preceding JSONx structure, the XPath expression would be: `//*[@name='streetAddress']`
where the components of the expression have the following meaning:

Expression	Meaning
`//*`	find any element anywhere in the structure
`[@name='streetAddress']`	this element has a 'name' property with value "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: All incidences of "streetAddress" have been redacted in the preceding JSON structure.
To redact a specific occurrence of the "streetAddress" element, the XPath expression would be: `//*[@name='secondaryAddress']/*[@name='streetAddress']`

where the components of the expression have the following meaning:

Expression	Meaning
`//*`	find any element anywhere in the structure
`//*[@name='secondaryAddress']`	find an element anywhere in the structure that is named "secondaryAddress"
`//*[@name='secondaryAddress']/*[@name='streetAddress']`	find a child element of any type (`/*`) where the child element has a name of "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: Only the street address for the secondary address has been redacted.

What to do next

See Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly to learn how to apply a redact policy using XPath.

Set Variable

Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see set-variable.

- **Configuring the Set Variable policy for DataPower API Gateway**
  Follow these steps to configure the Set Variable policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Set Variable policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the Set Variable policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the Set Variable policy for DataPower API Gateway

Follow these steps to configure the Set Variable policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Set Variable policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. For information about how to configure the policy in your OpenAPI source, see set-variable.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.

3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`set-variable`**.	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set , add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: • any • string • number • boolean For all values other than any, the value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when **`Set`** or **`Add`** is specified as the action. For example, to *set* a named variable of **`billing-hostname`** to a literal value, you can specify the Value as **`acme.com`**. As another example, to *set* a named variable to the value of the Content-Type header in a request, you can specify the Value entry as **`$(request.headers.content-type)`**. If the selected value of the Type field is boolean, select the Value check box to indicated a value of **`true`**. Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - set-variable:
      version: 2.0.0
      title: set-variable
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For examples, see set-variable.

DataPower Gateway (v5 compatible) only

Configuring the Set Variable policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Set Variable policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Set Variable policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see set-variable.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.

5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`set-variable`**.	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set , add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: • string • number • boolean The value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when **`Set`** or **`Add`** is specified as the action. For example, to *set* a named variable of **`billing-hostname`** to a literal value, you can specify the Value as **`acme.com`**. As another example, to *set* a named variable to the value of the Content-Type header in a request, you can specify the Value entry as **`$(request.headers.content-type)`**. If the selected value of the Type field is boolean, select the Value check box to indicated a value of **`true`**. Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - set-variable:
      version: 1.0.0
      title: set-variable
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For examples, see set-variable.

API Gateway only

Token Mediation

The Token Mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.

Table 1. Gateway support

Gateway	Policy version
DataPower® API Gateway	2.0.0

Note: The Token Mediation policy will only work for the DataPower API Gateway. The DataPower firmware version that the API Gateway is running on must be **LTS 10.6.0.0 (or later) or CD firmware release 10.6.3 (or later).**
This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see token-mediation.

Prerequisites

Before using the Token Mediation policy, ensure that distributed variable settings are enabled. Distributed variables allow you to read from or write to DataPower® facilities across transactions or domains. They serve as an alternative to system variables and must be enabled for the registration process to function end-to-end (E2E). For more details, see Configuring settings to manage distributed variables.

About

The Token Mediation policy (token-mediation_2.0.0) serves as a mediator for OAuth tokens by caching the token received from an OAuth Token Endpoint and exchanging it for a session cookie, which is sent to the Client Application via a **`Set-Cookie`** header. Depending on the policy configuration, this session token can be used to (A)

retrieve the original token from the cache or (B) instruct the policy to set the HTTP Authorization header for seamless access to resources on the Resource Server.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Token Mediation policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy.	string
Description	No	A description of the policy.	string
Cookie Name	Yes	The name of session cookie returned to the client application.	string
Token Endpoint URL	Yes	The URL of the OAuth provider's Token Endpoint.	string
Token Endpoint TLS Profile	No	The TLS profile used for connecting to the Token Endpoint URL. Note: The Token Endpoint TLS Profile property is optional for this policy but may be required by the Token Endpoint, and it is the responsibility of the policy user to determine its necessity. The policy must match the exact DataPower object name. For TLS profiles created by API Connect, the DataPower object follows this naming convention: **`<provider-org>_<catalog>_<tls-profile-name>V<tls-profile-version>`**. **Example:** **`myorg_mycatalog_my-tls-profile1.0.0`**.	string
Authorization Endpoint URL	Yes	The URL of the OAuth provider's Authorization Endpoint.	string
Output	No	The output context that receives the Authorization header. Note: The **`output`** parameter plays a key role in policy behavior. When specified, the policy retrieves the Access Token Response from the cache, extracts the access token (if available), and sets the Authorization header in the designated output message context. If the **`output`** parameter is not specified, the policy writes the Access Token Response to the **`message`** context and sets the **`Content-Type`** header to **`application/json`**.	string

User Security

Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see user-security.

About

When you define an assembly user security action, you can define the processing for identity-extraction, authentication, and authorization or you can selectively disable any of these this aspects of processing. When disabled, this processing aspect is skipped.

When identity-extraction is enabled, the following methods are supported.

- Use basic authentication, which requires no additional configuration.
- Use context variables. For this method, specify which variable contains the user name and password.
- Use a redirect. For this method, specify the URL fragment to redirect to, and the time allowed to process.
- Use an HTML login form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

When authentication is enabled, the following methods are supported.

- Contact an LDAP server. For this method, specify which server to contact.
- Send a request to an authentication endpoint. For this method, specify the URL of the endpoint, the TLS client profile to secure the connection, the pattern to select which response header to add, and the response header that contains the authenticated credentials.

When authorization is enabled, the following methods are supported.

- Implicitly accept any previously authenticated users, which requires no additional configuration.
- Use an HTML authorization form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

You can attach this policy to the REST API flow.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. User Security policy properties

Property label	Required	Description	Data type

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`user-security`**.	string
Description	No	A description of the policy.	string
Factor ID	No	The identity that identifies the results of factor-authentication in the API context.	string
Extract Identity Settings	Yes	Select the method that is used to extract the user credentials. The following options are available: Basic Use basic authentication; no additional configuration is required. Context Variable The credentials are provided by API Connect context variables; specify the following properties: • Username content variable: the context variable that is used to obtain the user name. • password context variable: the context variable that is used to obtain the password. HTML Form Use forms based identity-extraction. Select whether to use the default form or a custom form. For a custom form, specify the following properties: • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. In the HTML form time limit field, specify the time allowed to submit the form. Redirect Use a redirect for identity-extraction; specify the following properties: • Redirect URL: the URL fragment to which to redirect the request to obtain user credentials. • Redirect time limit: the time allowed for the transaction to complete. Disabled Identity-extraction is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of identity-extraction failure.	string
Authenticate User Settings	Yes	Select the authentication method. The following options are available: Authentication URL The credentials are authenticated by an external endpoint; specify the following properties: • Authentication URL: the URL of the authentication endpoint. • Authentication TLS profile: the TLS client profile that is used to secure the connection to the authentication endpoint. • Authentication response header pattern: the pattern that is used to select which response headers to add to the API context. • Authentication response header credential: the response header that contains the authenticated user credentials. LDAP The credentials are authenticated by an LDAP user registry; from the LDAP registry list, select the required registry. Disabled Authentication is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of authentication failure.	string
Authorize User Settings	Yes	Select the authorization method. The following options are available: authenticated Implicitly accept any previously authenticated users; no additional configuration is required. HTML Form The user provides authorization through an HTML form. Select whether to use the default form or a custom form. For a custom form, specify the following properties: • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. In the Dynamic table entries field, enter the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form. In the HTML form time limit field, specify the time allowed to submit the form. Disabled Authorization is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of authorization failure.	string

API Gateway

Validate - DataPower API Gateway

Use the Validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the Validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Validate - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.4.0 (DataPower API Gateway Version 10.0.4.0 or later) 2.5.0 (DataPower API Gateway Version 10.5.0.0 or later) 2.6.0 (DataPower API Gateway Version 10.5.0.2 or later 2.7.0 (DataPower API Gateway Version 10.5.0.3 or later

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate - DataPower API Gateway.

About

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

Note: With the DataPower API Gateway, the input to the Validate policy must be parsed data. One way to produce parsed data is to use a Parse policy before a Validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **validate**.	string
Description	No	A description of the policy.	string
Input	No	Specifies the name of a variable in the API context. The content of the **body** field of the variable, which is represented by ***variable_name*.body**, is the input data to validate. By default, the variable name is **message**.	string
Output	No	Specifies the name of a variable in the API context. • If the validation passes, the body field of the output variable, which is represented by ***variable_name*.body**, stores the output of the assembly validate action. • If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. • If the validation fails, no output is stored. • If an output variable is not specified, the results of the assembly validate action are not saved.	string

Property label	Required	Description	Data type
Validate against	Yes	Specifies the schema to be used for validating the payload. Select one of the following values: • **`definition`**: Select this value if you want to use a previously defined schema to validate the payload that is returned from other invoke actions or tasks in the assembly flow. From the Definition Object list, select the required schema. For information on defining a schema for an OpenAPI 2.0 API definition, see Defining schema definitions for an API. For information on defining a schema for an OpenAPI 3.0 API definition, see Defining schema components. • **`URL`**: the schema is identified by a URL location. ◦ In the JSON Schema URL field, enter the URL of the JSON schema to be used for validating a JSON payload. ◦ From the XML Validation Mode list, select how XML validation is to be performed: ▪ **`None`**: no XML payload validation is required. ▪ **`xsd`**: an XML schema will be used to validate an XML payload. In the XML Schema URL field, enter the URL of the XML schema. ▪ **`wsdl`**: a WSDL schema will be used to validate a SOAP payload. In the WSDL URL field, enter the URL of the WSDL schema. ▪ **`soap-body`**: validate the body of a SOAP message against the XML schema only. Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported. ▪ Maximum of 6,500 lines. Each key and each item in an array count as a line. ▪ Maximum recursion depth of 250. ▪ Maximum of 3,000 items in **`enum`** lists. • **`WSDL`**: (available with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. • **`body-param`**: validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Defining parameters for an operation. • **`response-param`**: validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Defining responses for an operation. • **`GraphQL`**: (available for a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables.	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property label	Required	Description	Data type
Validate message body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow xsi:type='SOAP-ENC:Array' rule	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
Wildcards ignore xsi:type rule	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

For examples, see validate - DataPower API Gateway.

Related tasks

- Defining Paths for an API

DataPower Gateway (v5 compatible)

Validate - DataPower Gateway (v5 compatible)

Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.

Gateway support

Note: This topic describes the Validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Validate - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate - DataPower Gateway (v5 compatible).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the `message.body` variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then `message.body` is not set, and validate is not able to act.
- If you use the `multipleOf` keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
  - The value must not be less than `0.00000099999999999999848869`.
  - If the value is greater than 1, the amount before the decimal point must not be greater than `99999999999999934463`.

About

You can attach this policy to the following API flow:

- REST

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

You can apply a different OpenAPI schema definition to each Validate policy either by choosing from the set of schema definitions that is specified at the API level, or the schema definition at the operation level.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is `validate`.	string
Description	No	A description of the policy.	string
Definition	Yes	Specifies the schema definition to be used for validating the payload. Valid values: • `request`: Select this value to validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. • `response`: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. • `#/definitions/definition_name`: Select this value for a previously defined schema definition to be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. For information on defining a schema for an API definition, see Editing an API definition.	string

Validate JWT

Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see jwt-validate.

About

JSON Web Token (JWT) is a compact, URL-safe way of representing claims that are to be transferred between two parties. The Validate JWT policy enables you to secure access to your APIs by using JWT validation. For example, when an input request that contains a JWT in the header is received, the Validate JWT policy extracts the token, verifies, and decrypts (if appropriate) the signature, and validates the claim. If valid, the claim is put in a runtime variable (for subsequent use if required), and access is allowed to the API. If the claim is not valid, access is denied.

All claims that are specified in the Validate JWT policy are validated, but this is not necessarily all the claims that are contained in the JWT. Not all claims that are in the JWT must be validated, but if any one of the claims that are specified in the Validate JWT policy fail, the whole validation fails. If the validation succeeds, the full set of claims that are contained in the JWT are written to the runtime variable specified in the Output Claims property. Thereby allowing any subsequent action to use this runtime variable to further validate the full set of claims that were in the JWT, as necessary.

Note:

- If the original message was signed with a Shared Secret Key, the cryptographic object that is specified must also be a Shared Secret Key.
- If the original message was signed with a Private Key, the cryptographic object that is specified must be a Crypto Certificate (public certificate).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If a JWK header parameter is included in the header of the JWT, the parameter must match the JWK or cryptographic object that is specified in the policy, or the JWT validation will fail.
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to decrypt or verify the JWT.
- The JWT validate action on the DataPower API Gateway can verify a JWT by using either a single JWK, or a JWK set.

Prerequisites

The following prerequisites apply:

- IBM® DataPower V7.5 with the Application Optimization (AO) option.
- If you are using one or more cryptographic objects (crypto objects), they must be located in the IBM API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or public certificate that is needed to decrypt the JWT contents or verify the signature.
- If a JSON Web Key (JWK), or JWK set, is being used, it must be referenced by a runtime variable.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate JWT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`jwt-validate`**.	string
Description	No	A description of the policy.	string
JSON Web Token (JWT)	Yes	Context or runtime variable that contains the JWT to be validated. The default value is: **`request.headers.authorization`**. However, if this property is not set, the policy looks for the JWT in the **`request.headers.authorization`** location by default. Note: The format of the authorization header must be: **`"Authorization: Bearer jwt-token"`** where *jwt-token* is the encoded JWT.	string
Output Claims	Yes	Runtime variable to which the full set of claims that are contained in the JWT is assigned. The default value is: **`decoded.claims`**.	string
Issuer Claim	No	The Perl Compatible Regular Expressions (PCRE) to use to validate the Issuer (iss) claim.	string
Audience Claim	No	The PCRE to use to validate the Audience (aud) claim.	string
Decrypt Crypto Object	No	The cryptographic object (a shared key or certificate) to use to decode the claim.[1]	string
Decrypt Crypto JWK variable name	No	Runtime variable that contains the JWK to use to decrypt the JWT.[1]	string

Property label	Required	Description	Data type
Verify Crypto Object	No	The cryptographic object (a shared key or certificate) to use to verify the signature.[2]	string
Verify Crypto JWK variable name	No	Runtime variable that contains the JWK, or JWK set, to use to verify the signature.[2]	string

Example

```
- jwt-validate:
    version: 1.0.0
    title: jwt-validate
    jwt: request.headers.authorization
    output-claims: decoded.claims
    iss-claim: "'^data.*'"
    aud-claim: "'^id.*'"
    jwe-crypto: jweCryptoObjectName
    jwe-jwk: jwe.jwk
    jws-crypto: jwsCryptoObjectName
    jws-jwk: jws.jwk
```

Errors

The following error can be thrown while the policy is being executed:

- **`RuntimeError`** - a generic error that captures all errors that occur during the execution of the policy. Upon a validation failure, the detailed error message that is received from the underlying JOSE module is written to the default system log as an error message. This detailed error message is also assigned to the runtime variable jwt-validate.error-message, so it can be retrieved via catch.

If a catch is not configured, in the case of a validation failure the Validate JWT policy returns an HTTP code 500 **`Invalid-JWT-Validate`** failure. The detailed error message from the underlying JOSE module can be found in the system log.
Attention: If you are an API developer who is troubleshooting a failure that one of your customers had with your API, consider the security risks before sending a customer the exact content of the log message. You can avoid the possibility of someone launching an attack based on the information that they receive from the log message by sending the customer only general information about the message.
For examples, see jwt-validate.

Related information

- Introduction to JSON Web Tokens

[1] A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used. If you are using one or more cryptographic objects (crypto objects), they must be located in the IBM API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or public certificate that is needed to decrypt the JWT contents or verify the signature.
[2] A JWK, or JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.

Validate Username Token

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate-usernametoken.

About

A WS-Security UsernameToken enables a user identity to be passed securely over a multi-point message path. The Validate Username Token policy extracts the UsernameToken element from the request payload, authenticates the extracted username and password, and provides access to the protected resource based on the authentication result. The policy has two authentication methods: Lightweight Directory Access Protocol (LDAP) user registry, or Authentication URL.

The Validate Username Token policy supports both passwordText and passwordDigest types of password. When the authentication method is Authentication URL with a passwordDigest, a basic authentication header that contains a Base64 encoded username and passwordDigest is sent to the URL. In addition, a custom header named X-IBM-PasswordType is set with a value of digest. The following table shows the authentication process based on password type:

Table 2. Authentication URL process by password type

passwordText	passwordDigest
Authentication: Basic base64(username:password)	Authentication: Basic base64(username:passwordDigest) X-IBM-PasswordType: 'digest'

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate Username Token policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate Username Token policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate Username Token policy after the task that collates the response.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 3. Validate Username Token policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **validate-usernametoken**.	string
Description	No	A description of the policy.	string
Authentication type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: • **Authentication URL**: Select this value to validate the user credentials against an authentication URL. • **LDAP registry**: Select this value to validate the user credentials against an LDAP user registry. The default value is: **Authentication URL**.	string
Authentication URL (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to **Authentication URL**.	string
TLS profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to **Authentication URL**.	string
LDAP registry name (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. You can select a name from the drop-down list, or type a name manually. Note: This property is required only if Authentication type is set to **LDAP registry**.	string
User Registry Name (policy version 1.1.0 and later)	Yes	Select the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
LDAP search attribute[1]	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "LDAP Registry"
    ldap-registry: "wstest"
    ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "Authentication URL"
    auth-url: "https://www.google.com"
    tls-profile: "default-ssl-profile"
```

Errors

The policy returns an HTTP `200` status code when successful, and the input payload is copied to the output flow. For all failure types the policy returns an HTTP `500` status code, and the output contains the SOAP fault.

Tip: If there are authentication failures, try verifying the LDAP user registry configuration as follows:

- Ensure Search (DN) is set as the communication method.
- Ensure Authenticated Bind is set so that specific permissions are required to search the registry.
- Ensure the Admin DN and Password fields are correctly completed for the Distinguished Name (DN) of a user authorized to carry out searches in the LDAP directory.
- Ensure that a combination of Base DN, Prefix, and Suffix are set, such that they fully describe the user DN. For example:
  - For a user named: **cn=alice**, **dc=ibm**, **dc=com**

    ```
    BaseDN: dc=ibm
    Prefix: cn=alice
    Suffix: dc=com
    ```

    where the user DN is calculated as: Prefix + BaseDN + Suffix.

Related information

- Creating an LDAP registry
- Authenticating by using your enterprise user registry

[1] When authenticating with LDAP and passwordText, the policy uses the username and password as LDAP bind credentials. However, when authenticating with LDAP and passwordDigest, the digest itself cannot be used for authentication. Instead, an LDAP search for the username is performed by using the administrator's distinguished name (DN) and password, and an attribute corresponding to the contents of the ldap-search-attribute is retrieved. A hash of the contents of this attribute (along with the Nonce and Created attributes, as in the WS-Security UsernameToken profile specification) is then compared to the passwordDigest.

API Gateway only

watsonx.ai invoke

Use the watsonx.ai invoke policy to invoke watsonx.ai operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see watsonx-ai-invoke.

About

The watsonx.ai invoke policy provides access to three watsonx.ai operations:

- `POST /text-generate`
- `POST /tokenize`
- `GET /deployment-models`

The watsonx.ai invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. watsonx.ai invoke policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy; the default value is `watsonx-ai-invoke text generation`.	string
Description	No	A description of the policy.	string
watsonx.ai Operation	Yes	The watsonx.ai operation to invoke; must be one of the following operations: • `POST text-generate` An HTTP POST operation for `/text-generate`. See Infer text in the watsonx.ai documentation for sample request and response examples. • `POST tokenize` An HTTP POST operation for `/tokenize`. See Text tokenization in the watsonx.ai documentation for sample request and response examples. • `GET deployment-models` An HTTP GET operation for `/deployment-models`. See List the available foundation models in the watsonx.ai documentation for sample response examples. If the request payload contains a `project_id` property, it is ignored and the policy's own `project_id` property is used.	string
watsonx.ai Operation Version	Yes	The watsonx.ai API operation version, using the format `yyyy-mm-dd`. To see the available version dates, refer to Active Version Dates in the watsonx.ai API documentation. For information on API versioning in watsonx.ai, see Versioning in the same documentation.	string
watsonx.ai Project Id	Yes	The ID of the watsonx.ai project used for resolving API requests.	string
watsonx.ai Region	Yes	The IBM Cloud region where watsonx.ai requests are sent.	string

Property label	Required	Description	Data type
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the watsonx.ai service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the watsonx.ai service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the watsonx.ai response. By default, this property uses `message` as the value, which enables the response to be accessible by subsequent API policies in `message.body` and `message.headers`.	string

Websocket Upgrade

Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

- **Configuring the Websocket Upgrade policy for DataPower API Gateway**
  Follow these steps to configure the Websocket Upgrade policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the Websocket Upgrade policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the Websocket Upgrade policy for DataPower API Gateway

Follow these steps to configure the Websocket Upgrade policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types.
For information about how to configure the policy in your OpenAPI source, see websocket-upgrade.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is `websocket-upgrade`.	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is `60`.	integer

Property label	Required	Description	Data type
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this check box, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this check box, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the **`invoke`** policy injects the **`X-Forwarded-For`**, **`X-Forwarded-To`**, **`X-Forwarded-Host`**, and **`X-Forwarded-Proto`** headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
Queryparam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean
Header control	No	Specifies the headers in **`message.headers`** that you want to copy to the target URL. To prevent headers from being copied, complete the following steps: a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. To specify headers that you want to be copied, complete the following steps: a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. The values that you specify are in regular expression format. For example, to specify the Content-Type header, enter **`^Content-Type$`** By default, Blocklist is selected, with no blocklist entries, meaning that **all** headers are copied.	string
Parameter control	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. To prevent parameters from being copied, complete the following steps: a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. To specify parameters that you want to be copied, complete the following steps: a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. The values that you specify are in regular expression format. For example, if the incoming request is **`http://apigw/org/sandbox/petstore/base?petid=100&display=detailed`** and you specify a white list entry of **`^petid$`**, the target URL at run time will be **`http://myhost/mypath?storeid=3&petid=100`** By default, Allowlist is selected, with no allowlist entries, meaning that **no** parameters are copied.	string
Request assembly	No	The request processing assembly. For details on configuring an assembly in the **`execute`** section, see execute. For example: **`request-assembly:`** **`  execute`** `.` `.` `.` ***`  policy assembly`*** `.` `.` `.`	object
Response assembly	No	The response processing assembly. For details on configuring an assembly in the **`execute`** section, see execute. For example: **`response-assembly:`** **`  execute`** `.` `.` `.` ***`  policy assembly`*** `.` `.` `.`	object

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - websocket-upgrade:
      version: 2.0.0
      title: websocket-upgrade
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Websocket Upgrade policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Websocket Upgrade policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types. For details on how to configure the policy in your OpenAPI source, see websocket-upgrade.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **websocket-upgrade**.	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **301 Moved Permanently**. If you select this check box, the **invoke** policy follows the URL redirection by making a further call to the URL specified in the **Location** header in the response. If you clear this check box, the **invoke** saves the **301** status code and the API call is considered to be complete. Note: The **follow-redirect** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **invoke** always follows the URL redirection; the **proxy** policy (not supported by the DataPower API Gateway) saves the **301** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the **invoke** policy injects the **X-Forwarded-For**, **X-Forwarded-To**, **X-Forwarded-Host**, and **X-Forwarded-Proto** headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
Queryparam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean

Request assembly	No	The request processing assembly. For details on configuring an assembly in the **execute** section, see execute. For example:
		`request-assembly:`
		`  execute`
		`  .`
		`  .`
		`  .`
		`  policy assembly`
		`  .`
		`  .`
		`  .`
			object

Property label	Required	Description	Data type

Response assembly	No	The response processing assembly. For details on configuring an assembly in the **execute** section, see execute. For example:
		`response-assembly:`
		`  execute`
		`  .`
		`  .`
		`  .`
		`  policy assembly`
		`  .`
		`  .`
		`  .`
			object

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - websocket-upgrade:
      version: 1.0.0
      title: websocket-upgrade
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

XML to JSON

Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

The XML to JSON policy uses a simple convention, based on BadgerFish, to convert your API context payload from XML to JSON. The XML content is preserved, including the attributes and namespaces. No additional configuration is required. For more information about the BadgerFish convention, including some examples, see BadgerFish.

Use the API Designer assembly view when you are creating your API definition to add a built-in policy to the flow.

The policy must be attached to the flow at the point at which you require the conversion to be performed. For example, if you need to convert an XML-formatted request into a JSON-formatted request, the policy must be attached to the request flow.

The policy reads input from the **message.body**, if that context exists, otherwise from the **request.body**, and then writes the output to the **message.body**.

Note: If you are using the DataPower API Gateway, the input to the XML to JSON policy must be parsed data. One way to produce parsed data is to use a Parse policy before an XML to JSON policy in your assembly flow, which provides explicit control of the parse action.

Examples

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For examples, see xml-to-json.

- **Configuring the XML to JSON policy for DataPower API Gateway**
  Follow these steps to configure the XML to JSON policy for DataPower API Gateway in the assembly user interface.
- **Configuring the XML to JSON policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the XML to JSON policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the XML to JSON policy for DataPower API Gateway

Follow these steps to configure the XML to JSON policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Set Variable policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xml-to-json.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`xml-to-json`**.	string
Description	No	A description of the policy.	string
Input	No	The input message to convert. Specify the name of a variable in the API context. ***`variableName`*`.body`**, the message payload, represents the XML input to convert. The default value of the variable is **`message`** and **`message.body`** is the default input.	string
Output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***`variableName`*`.body`** represents the result of conversion from XML format to JSON format. When the specified input message is the default message, the default output is **`message.body`**. Otherwise, when the input message is the variable **`my-message-variable`**, for example, the default output is **`my-message-variable.body`**. The variable cannot be any read-only in the API context.	string
Conversion type	No	The conversion type that determines the target format of the output. The following options are available: • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. • apicv5: apicv5 convention is used to determine the target conversion format of the output.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - xml-to-json:
      version: 2.0.0
      title: xml-to-json
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For more examples, see xml-to-json.

DataPower Gateway (v5 compatible) only

Configuring the XML to JSON policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XML to JSON policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the XML to JSON policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xml-to-json.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

   Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **xml-to-json**.	string
Description	No	A description of the policy.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - xml-to-json:
      version: 1.0.0
      title: xml-to-json
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For examples, see xml-to-json.

XSLT

Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xslt.

Note: If you are using the DataPower API Gateway, the input to the XSLT policy must be parsed data. One way to produce parsed data is to use a Parse policy before an XSLT policy in your assembly flow, which provides explicit control of the parse action.
For examples of the OpenAPI definitions of XSLT policies, see XSLT policy examples.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Errors

The following error can be thrown while the policy is being executed:

- **TransformError** - a generic error that captures all errors that occur during the execution of the policy.

- **Configuring the XSLT policy for DataPower API Gateway**
  Follow these steps to configure the XSLT policy for DataPower API Gateway in the assembly user interface.
- **Configuring the XSLT policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the XSLT policy for DataPower Gateway (v5 compatible) in the assembly user interface.
- **XSLT policy examples**
  Examples of the OpenAPI definitions of XSLT policies.
- **Implementation code examples**
  Example XSLT and GatewayScript code snippets.

API Gateway only

Configuring the XSLT policy for DataPower API Gateway

Follow these steps to configure the XSLT policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the XSLT policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types.
For information about how to configure the policy in your OpenAPI source, see xslt.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XSLT policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`xslt`**.	string
Description	No	A description of the policy.	string
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Serialize output	No	If you select this option, the output tree that is generated by the XSLT policy is serialized. The content of **`message.body`** is updated with the serialized binary data rather than the XML tree. The check box is cleared by default, which indicates that the output tree is not serialized.	boolean
Source	Yes	The XSLT transform source to execute.	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property label	Required	Description	Data type
Validate message body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow xsi:type='SOAP-ENC:Array' rule	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
Wildcards ignore xsi:type rule	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - xslt:
      version: 2.1.0
```

```
      title: xslt
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

DataPower Gateway (v5 compatible) only

Configuring the XSLT policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XSLT policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the XSLT policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see xslt.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XSLT policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **xslt**.	string
Description	No	A description of the policy.	string
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Source	Yes	The XSLT transform source to execute.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - xslt:
      version: 1.0.0
      title: xslt
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

XSLT policy examples

Examples of the OpenAPI definitions of XSLT policies.

- Simple example with no context current payload
- Concatenation and transformation
- Obtain query parameter values and refer to context variables
- Return DataPower object name associated with a client TLS profile

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing an XSLT policy or user-defined policy for a new API Gateway API, use the mechanisms described in Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The XML specification https://www.w3.org/TR/xml/ does not specify a preferred order for XML namespace (XMLNS) attributes. Best practice is to not rely upon the sequence of XMLNS attributes if you write custom parsing code.

Simple example with no context current payload

The following is an example of where the XSLT input document does not use the context current payload (there is no input):

```
- xslt:
  title: example xslt
  source: |
    <xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
```

```
    <xsl:template match="/">
      <Hello>World!</Hello>
    </xsl:template>
  </xsl:stylesheet>
```

Concatenation and transformation

The following example shows a more complex XSLT transform source, where the stylesheet concatenates two input strings and transforms the third input string to the IP address of the client:

```
- xslt:
  title: xslt
  input: true
  source: |
    <?xml version="1.0" encoding="UTF-8"?>
    <xsl:stylesheet
        xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
        xmlns:xalan="http://xml.apache.org/xslt"
        xmlns:fn="http://www.w3.org/2005/xpath-functions"
        xmlns:dp="http://www.datapower.com/extensions"

```

Obtain query parameter values and refer to context variables

The following example shows a complete OpenAPI source file. The API includes an XSLT policy that obtains a query parameter value in XSLT, and also uses the **getvariable** method to retrieve the value of the context variable **request.headers.user-agent**.

        <dp:url-open target="{$targetUrl}" response="responsecode" timeout="20" http-headers="$httpHeaders" ssl-proxy="
{$tlsClientProfile}"/>
      </xsl:template>

    </xsl:stylesheet>
```

Note that references to the "v5c" (v5-compatible) gateway do not apply to API Connect Enterprise as a Service.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower® API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Implementation code examples

Example XSLT and GatewayScript code snippets.

Note: If you are using GatewayScript, you must include one or other of the following commands depending on your gateway type:

DataPower Gateway (v5 compatible) `var apic = require(./apim.custom.js);`

API Gateway `var apic = require('apim');`

where *apic* is the common name used for the GatewayScript examples in this topic. However, *apic* could be any given name of your choice, for example you could use:

```
var apim = require(./apim.custom.js);
```

and then you would start your calls with **apim**.

- Access to input properties code snippet
- Access to runtime context code snippet

- Access to input payload code snippet
- Access to HTTP headers code snippet
- Modify the payload code snippet
- Configure error information code snippet
- Accessing the caught exception in a catch block
- Set variables code snippet

Access to input properties code snippet

The following code block shows an example of how to access the input properties by using the XSLT `policyProperties()` function. The example defines a property that is named `a_property`, which is declared as an integer value, but is retrieved in XSLT as text.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:apigw="http://www.ibm.com/xmlns/datapower/2017/11/apigateway"
  exclude-result-prefixes="dp func apim apigw"
  extension-element-prefixes="dp func apim apigw">

  <!-- Contains the APIM functions -->
    DataPower Gateway (v5 compatible) <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
    API Gateway <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="p" select="apim:policyProperties()" />
    <xsl:message>
      The value of my input property is
      <xsl:value-of select="$p/a_property" />
      <apigw:set-variable name="'propfound'" value="'true'"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getPolicyProperty(propertyName)
```

where ***propertyName*** is the name of the input property that you want to access. If the input property name is blank, the action will return all input properties.

Access to runtime context code snippet

The following code block shows an example of how to access the runtime context by using the XSLT `getContext()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
    DataPower Gateway (v5 compatible) <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
    API Gateway <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="client-id" select="apim:getContext('client.app.id')" />
    <xsl:message>
      The calling application is
      <xsl:value-of select="$client-id" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getContext(varName)
```

where ***varName*** is the name of the context variable that you want to access.
For a complete list of context variables, see API Gateway context variables. If you are using the DataPower® API Gateway, see also Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Access to input payload code snippet

The following code block shows an example of how to access the input payload by using the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="input" select="apim:payloadRead()" />
    <xsl:message>
      The input payload is
      <xsl:copy-of select="$input" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.readInput(callback)
```

A callback is required because the actual payload read is asynchronous. The callback method is called when the payload is ready.
This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.
The following example shows how to use the **payloadType()** function to determine what type of payload (XML or JSONx) will be returned by the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="payloadType" select="apim:payloadType()" />
    <xsl:message>
      <xsl:text>Payload type is [</xsl:text>
      <xsl:value-of select="$payloadType" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

Access to HTTP headers code snippet

The following code block shows an example of how to access the HTTP headers in XSLT by using the **getContext()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
```

```
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="content-type" select="apim:getContext('request.headers.content-type')" />
    <xsl:message>
      The request content type is
      <xsl:value-of select="$content-type" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getContext(request.headers.headerName)
```

where ***headerName*** maps to the name of the header you want to access.
Note: Access or modification of HTTP headers by using DataPower extensions, such as `dp:set-request-header`, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.

Modify the payload code snippet

The output from a user-defined policy must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. The following code block shows an example of how to modify the payload in XSLT. To assist the API Gateway policy framework to accept the new or transformed message, call the `apim-output` template, as shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:jsonx="http://www.ibm.com/xmlns/prod/2009/jsonx"
  exclude-result-prefixes="apim"
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
```

DataPower Gateway (v5 compatible)

```
<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
```

API Gateway

```
<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <!-- Creates a JSON document (empty object is for simplicity) -->
    <jsonx:object>
    </jsonx:object>

    <!-- Indicates the media type of the output being produced -->

    <xsl:call-template name="apim:output">
      <xsl:with-param name="mediaType" select="'application/json'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where `mediaType`:

- `'application/json'` is when the output is written in JSONx format.
- `'application/xml'` is when the output is written in XML format.

If you are using GatewayScript, call the following function:

```
apic.output(mediaType)
```

where ***mediaType*** is:

- `application/json` is when the output is written in JSONx format.
- `application/xml` is when the output is written in XML format.

Specifying the media type allows the next steps in the assembly flow to understand how to process the new payload.

Tip: The output from a user-defined policy must be XML or JSONx. JSONx is an IBM standard format to represent JSON as XML. One way to convert output GatewayScript JSON data into JSONx, is to add a `Convert Query Params to XML` action to follow the GatewayScript action within the same policy rule. The `Convert Query Params to XML` action must have an `Input Conversion` with the `Default Encoding` set to `JSON`. The output from the GatewayScript action must be the input for the `Convert Query Params to XML` action for JSONx to be produced.

Configure error information code snippet

The following XSLT code block shows an example of how to configure the policy implementation to produce error information by calling the `apim-error` template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="apim"
```

```
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
```
DataPower Gateway (v5 compatible)
```
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
```
API Gateway
```
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <!-- Indicates this policy has a failure and provides
       additional information for the client application -->
  <xsl:template match="/">
    <xsl:call-template name="apim:error">
      <xsl:with-param name="httpCode" select="'401'" />
      <xsl:with-param name="httpReasonPhrase" select="'Unauthorized'" />
      <xsl:with-param name="errorMessage" select="'Please select a Plan'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **errorMessage** is the suggested action for the user.

If you are using GatewayScript, call the following function:

```
apic.error(name, httpCode, httpReasonPhrase, message)
```

where:

- **name** is the name of the error.
- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **message** is the suggested action for the user.

Accessing the caught exception in a catch block

The following XSLT code block shows an example of how, in the **catch** block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

For DataPower Gateway (v5 compatible):

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  extension-element-prefixes="dp"
  exclude-result-prefixes="dp apim">

  <xsl:output method="xml" />

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">

    <xsl:variable name="exception" select="apim:getError()"/>
    <!-- output desired error message based on the exception -->
    <myError>
       <errorReason><xsl:value-of select="$exception/error/message"/></errorReason>
    </myError>

    <!-- Propagate the HTTP status code and reason phrase from the exception -->
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.code'"/>
      <xsl:with-param name="value" select="$exception/error/status/code"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.reason'"/>
      <xsl:with-param name="value" select="$exception/error/status/reason"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    </xsl:template>

</xsl:stylesheet>
```

For API Gateway:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
```

```
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:apigw="http://www.ibm.com/xmlns/datapower/2017/11/apigateway"
  extension-element-prefixes="dp apim apigw"
  exclude-result-prefixes="dp apim apigw">

  <xsl:output method="xml" />

  <!-- Contains the APIM functions -->
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">

    <xsl:variable name="exception" select="apigw:get-error()"/>
    <!-- output desired error message based on the exception -->
    <myError>
       <errorReason><xsl:value-of select="$exception/error/message"/></errorReason>
    </myError>

    <!-- Propagate the HTTP status code and reason phrase from the exception -->
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.code'"/>
      <xsl:with-param name="value" select="$exception/error/status/code"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.reason'"/>
      <xsl:with-param name="value" select="$exception/error/status/reason"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    </xsl:template>

</xsl:stylesheet>
```

The `apim:getError()` and `apigw:get-error()` functions return an XML node set; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<error>
    <name>RuntimeError</name>
    <message>This is a thrown Runtime Error</message>
    <policyTitle>Throw Runtime Error</policyTitle>
    <status>
        <code>500</code>
        <reason>Internal Server Error</reason>
    </status>
</error>
```

If you are using GatewayScript, call the following function:

```
apim.getError()
```

which returns a JSON object; for example:

```
{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}
```

Set variables code snippet

The following XSLT code block shows an example of how to set a runtime variable to a specified string value by calling the `setVariable` template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
    DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
    API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="" select="'https://endpoint.host.com/data'" />
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'serviceEndpoint'" />
```

```
      <xsl:with-param name="value" select="$targetUrl" />
      <xsl:with-param name="action" select="'set'" />
    </xsl:call-template>
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$targetUrl" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$targetUrl}" response="xml" http-method="get"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **varName** is the name of the runtime variable that you want to set a value to.
- **value** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **value** as **$(request.headers.content-type)**.

If you are using GatewayScript, call the following function:

```
apic.setvariable(varName, varValue, action)
```

where:

- **varName** is the name of the runtime variable that you want to set a value to, or that you want to add or clear.
- **varValue** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **varValue** as **request.headers.content-type**. This property is only required when **set** or **add** is specified as the action.
- **action** is the action that you want to apply to the variable. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

The following XSLT example shows how to retrieve the value of a runtime variable by using the **getVariable()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
```

DataPower Gateway (v5 compatible)

```
<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
```

API Gateway

```
<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="varValue" select="apim:getVariable('serviceEndpoint')" />
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$varValue" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$varValue}" response="xml" http-method="get"/>
  </xsl:template>

</xsl:stylesheet>
```

where

- **varValue** is the name of the runtime variable that you want to retrieve a value for.

If you are using GatewayScript, call the following function:

```
apic.getvariable(varName)
```

where ***varName*** is the name of the runtime variable that you want to retrieve a value for.

Logic Constructs

IBM® API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.

Logic constructs are configured in the context of an API. You can use the API Designer assembly editor to add a logic construct to an API and to configure the properties for that construct.

The logic constructs are described in the following subtopics:

- **if**
  Use the if construct to apply a section of the assembly when a condition is fulfilled.
- **operation-switch**
  Use the operation-switch component to apply a section of the assembly to a specific operation.
- **switch**
  Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.
- **throw**
  Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Related concepts

- The assembly editor

if

Use the if construct to apply a section of the assembly when a condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see if.

An if construct provides a way to branch an API's assembly when a specified condition is fulfilled. Each if construct contains a section of the assembly that is only executed when the script within the construct returns a **`true`** value.

When using the assemble view's property sheet, use the Condition field to write your condition that returns **`true`** or **`false`**.

If you want one or more policies or constructs to be executed when the condition of the if construct is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the if construct. Constructs and policies included in the if construct are part of the case that is executed when the condition of the if construct is returned as true.

For information about the OpenAPI implementation of an if construct, see if.

In the Condition field, use the form **`apim.getvariable('`*`context.location.variable`*`')`** to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of an if construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, **`if`** is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
Condition	Yes	Use GatewayScript to provide conditions. A list of context variables that you can use to generate conditions can be found in API Connect context variables.

operation-switch

Use the operation-switch component to apply a section of the assembly to a specific operation.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see operation-switch.

An operation-switch component provides a way to branch an API's assembly depending on the operation that is called. For each case, a separate piece of the assembly is applied to the operations that belong to the case.

When using the assemble view's property sheet, click the Case field to view suggested operations. Type in the Case field to refine the list of suggested operations.

Each case behaves as an assembly. To add components to a case, drag the component from the palette to the area included in the operation-switch component. Dashed boxes are displayed where the component can be included in the case.

For information about the OpenAPI implementation of an operation-switch component, see operation-switch.

Restriction: Nesting an operation-switch component inside an if or switch construct, or another operation-switch component, is **not** supported.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of an operation-switch component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, `operation-switch` is used by default.
Description	No	A description of your component, it is not displayed on the canvas.
Case	Yes	Each case includes one or more operations to which the branch provided by the operation switch applies.

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see switch.

A switch construct provides a way to branch an assembly based on multiple conditions. Each switch component contains multiple cases, each corresponding to a section of the assembly that is only executed when the condition or operation specified by the case is met or used. Additionally, an otherwise case executes when no other case is fulfilled.

Add new cases by clicking + Case and add an "otherwise" case by clicking + Otherwise.

If multiple cases are fulfilled, the highest priority case will be executed. Change the priority of cases by clicking the Move up ↑and Move down ↓ icons.

To configure a case to be executed if a specific operation is called, use the search operations field and select your operation from the list. You can refine the results of the search by typing in the search operations field.

To configure a case to be executed based on a GatewayScript condition, click edit condition and enter your script in the "Condition editor" window. When you have supplied a script, you can edit your script either in the Condition field or by clicking edit condition.

If you are using the DataPower Gateway (v5 compatible), you enter your condition as GatewayScript directly in a code area in the Condition editor. If you are using DataPower API Gateway, the Condition editor provides a script builder to help you construct your condition script; for more information, see Using the switch policy condition editor.

To delete a case, click the Remove case icon 🗑.

If you want one or more policies or constructs to be executed when the condition of a case is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the case's section of the switch construct.

Note: A switch case **must** contain at least one policy, otherwise the Gateway server returns an error.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of a switch construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, `switch` is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
case	Yes (one or more)	Specify one or more operations or write a script for a condition. API Gateway Use the Condition editor to construct your condition script. See Using the switch policy condition editor. DataPower Gateway (v5 compatible) Use GatewayScript to provide conditions. You can reference variables by using the form `apim.getvariable('context.location.variable')`, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable. A list of context variables that you can use to generate conditions can be found in API Connect context variables.

Property	Required	Description
otherwise	No	Add an otherwise case if you want to execute a section of the assembly when no other cases are fulfilled.

- **Using the switch policy condition editor**
  The switch policy condition editor provides a user interface to help you build the conditions for the `case` clauses in a switch policy.

API Gateway only

Using the switch policy condition editor

The switch policy condition editor provides a user interface to help you build the conditions for the `case` clauses in a switch policy.

You build a condition script by using the Add Group and Add Condition options, together with operator selections, and pre-supplied function selections. The Output field shows the resultant condition script, and updates dynamically as you build your condition.

Adding conditions

When you open the policy condition editor, an initial condition is pre-supplied ready for you to configure.

Use the drop-down list to select the function that you want to begin your condition.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - `$eval()`
  - `$sift()`
  - `$each()`
  - `$error()`
  - `$assert()`
- `$fromMillis()` is supported with the following restrictions:
  - The `$fromMillis()` parameter supports numbers in the range -5364662400000 - 2903299199000.
    - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
    - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- `$now()` is supported with the following restrictions:
  - The following component specifiers are not supported:
    - `W` = Week in year
    - `w` = Week in month
    - `X` = ISO week-numbering year
    - `x` = ISO week-numbering month
  - Representing numbers as words are not supported, so the following presentation modifiers are not supported:
    - `W` = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
    - `w` = Lowercase word (for example: [Yw] => two thousand and twenty-four)
    - `Ww` = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
  - Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description

`$apiCtx()`	Generic access to an API context	The `$apiCtx()` extension gives generic access to an API context.
		• Sample transform field in an extract action:
		`"$apiCtx().request.uri"`
		• Sample condition of a case in a switch action:
		`"$apiCtx().request.path = '/simple/apictx-function'"`

`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation

Extension	Variable	Description
`$queryParameter('name')`	• `request.parameters.name.locations` The supported keyword is `query`. • `request.parameters.name.values`	Searches for the index of `query` in `request.parameters.name.locations` and returns `request.parameters.name.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*variable*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

`$urlParameter('name')`	• `request.parameters.name.locations` The supported keywords are `path` and `query`
	• `request.parameters.name.values`
		Searches for the index of `path` and `query` in `request.parameters.name.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.name.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values.
		`http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese`
		The `$urlParameter('breed')` URL returns the following array of values.
		`[cats, adopt, Sphynx, Siamese]`
		In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.

`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- ***operationName***
  For an anonymous operation, ***operationName*** can be empty.

- ***~fragmentSpreadName***
- **on~*typeCondition***
- ***~~fragmentDefinitionName***

After you select the function, additional fields are displayed, depending on the selected function, so that you can complete the condition. For example, if you select the function **$httpVerb()**, a comparison operator selection list is displayed (**=** or **!=**), together with a list of HTTP verbs to select on the right hand side of the expression (**GET**, **PUT**, **POST**, **DELETE**, **HEAD**, **OPTIONS**, or **PATCH**).

If you select NOT, your condition is negated with a **$not** function.

To add further conditions, click Add Condition; you then select whether to insert an **and** or an **or** operator between this condition and the preceding one.

To group two or more conditions inside parentheses, click Add Group, then add your conditions to the group; you then select whether to insert an **and** or an **or** operator between this group and the preceding condition or group.

To write your own condition from scratch, select Custom, then enter your script in the field provided.

Example

To build the following condition:

```
($statusCode() != 200 and ($httpVerb() = 'GET' or $httpVerb() = 'PUT'))
```

complete these steps in the condition editor:

1. Select **$statusCode()**, select **!=** for the comparison operator, and enter **200** in the field on the right hand side of the condition.
2. Click Add Group.
3. In the new group sub pane that is displayed, click Add Condition.
4. Select **httpVerb()**, leave the comparison operator as **=**, and select **GET** on the right hand side of the condition.
5. Click Add Condition in the group sub pane again.
6. Select **httpVerb()**, leave the comparison operator as **=**, and select **PUT** on the right hand side of the condition.
7. For the comparison operator between the two conditions, select **or**.

Simple condition statements

The following examples show conditions that use a single function.

This example uses the **$httpVerb()** extension to specify the HTTP method of the request.

```
$httpVerb()="GET"
```

This example uses the **$operationPath()** extension to specify the path of the operation.

```
$operationPath()="/base/path-2"
```

This example uses the **$operationID()** extension to specify the operation ID.

```
$operationID()="test-gatewayscript-GET"
```

This example uses the **$statusCode()** extension to specify the message status code.

```
$statusCode()=200
```

This example uses the **$header(name)** extension to specify the content type of the message header.

```
$header("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use **and** and **or** operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to **test-gatewayscript-GET**.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a **POST** or **PUT** request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to **test-gatewayscript_POST** and a message status code equal to **200**, or an API operation ID equal to **test-gatewayscript-GET** and a message status code equal to **500**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and
$statusCode()=500)
```

This example specifies an API operation ID equal to **test-gatewayscript-POST** and a message status code equal to **200** with an API operation path equal to **/base/path-2**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to **text/plain** and a message header length equal to **300**, or a message status code equal to **200**.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

Note: When users sign in by using the Toolkit login path (a URL that includes `?from=TOOLKIT`), the generated API key has a fixed time-to-live (TTL) of 5 minutes.

throw

Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see throw.

When the throw policy is encountered, the specified error and error message is produced.

If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

If no catch is triggered by the thrown error, then a `500 Internal Server Error` is returned to the API caller.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of a throw component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, `throw` is used by default.
Error name	Yes	The error name that is thrown by the policy.
API Gateway only Error status code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the `$(variable)` format to reference the `error.status.code` API context variable.
API Gateway only Error status reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the `$(variable)` format to reference the `error.status.reason` API context variable.
Error message	No	The error message that is returned with the error name.

API Gateway only

Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway

In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.

All API context variables are stored in a JSON-like tree; each context variable is a node in this tree. A non-leaf node can be either an object or an array, while a leaf node can be a number, string, boolean, or document; a document can contain an XML document, BLOB, Stream, or another JSON document.

Each context variable has a name and a value. You can access a context variable by name when using the GatewayScript and XSLT APIs. Dot notation is used to access a context variable, reflecting the position of the corresponding node in the JSON-like tree; for example, `request.headers.Host`. Where a node name contains special characters, bracket notation is supported; for example, `request.headers['Content-Type']`.

For the GatewayScript policy, all the APIs for the DataPower® API Gateway are in the `context` module, which is a global module. You can therefore access the `context` module directly, you do not need to use the `require()` function first.

For the XSLT policy, the APIs are in the `http://www.ibm.com/xmlns/datapower/2017/11/apigateway` namespace; to use these APIs you must declare this namespace.

Note: If you are using apigw extension elements, you must specify the "apigw" namespace prefix in the "extension-element-prefixes" attribute of the xsl:stylesheet. This prefix must also be added to the "exclude-result-prefixes" attribute to make sure that this namespace is not added to any XML output that is the result of this stylesheet. Attention: The mechanisms described here for interacting with the API Connect context are preferred and provide the best performance if you are writing new GatewayScript or XSLT policies, or if you are authoring user-defined policies. However, for v5-compatible gateways and v5 compatibility for APIs created for the API Gateway, the preferred mechanisms are as described in GatewayScript code examples and XSLT policy examples.

- Accessing context variables
- About payloads
- Manipulating the message headers
- Manipulating the message status - examples
- Accessing the message body
- Rejecting the session

Accessing context variables

GatewayScript examples

To read the `client.app.id` context variable:

```
var clientID = context.get('client.app.id');
```

To set the value of a context variable:

```
context.set('my.vars.amount', 100);
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
context.clear('my.vars');
```

The resulting tree has the following structure:

```
{ "my": { } }
```

XSLT examples

To read the `client.app.id` context variable:

```
<xsl:variable name="clientID" select="apigw:get-variable('client.app.id')"/>
```

To set the value of a context variable:

```
<apigw:set-variable name="'my.vars.amount'" value="100"/>
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
<apigw:clear-variable name="'my.vars'"/>
```

The resulting tree has the following structure:

```
{ "my": { } }
```

About payloads

When the assembly flow for an API call begins, the following two message objects are predefined in the API context tree:

- `request`: holds the information for the original payload; the `request` message is a read-only object.
- `message`: holds the information for the current payload.

Typically, a message object has `headers` and `body` properties. For the current payload, the `message` message object might have `variables` and `status` properties, and other properties created during the execution of the assembly.
The following example shows the general structure of a typical message:

```
{
  "headers": {
    "Content-Type": "application/xml",
    "X-Client-ID": "1234567890"
  },
  "variables": {
    "amount": 123,
    "name": "xyz"
  },
  "status": {
    "code": 200,
    "reason": "OK"
  },
  "body": <XML/Blob/Stream/JSON Document>
}
```

Manipulating the message headers

GatewayScript examples

To delete a header:

```
context.message.header.remove('X-My-Header');
```

To read a header:

```
var reqType = context.request.header.get('Content-Type');
var currType = context.message.header.get('Content-Type');
```

To set a header:

```
context.message.header.set('Content-Type', 'application/json');
```

To iterate through the headers:

```
var reqHdrs = context.request.headers;
for (var h in reqHdrs) {
   console.log('>>> Reading the request header: ', h, '=', reqHdrs[h]);
}

var currHdrs = context.message.headers;
for (var h in currHdrs) {
   console.log('>>> Reading the current header: ', h, '=', currHdrs[h]);
}
```

To create a message context called **headersContext**, if one doesn't already exist, and add to it a boolean context variable called **HelloWorld**, with the value **true**:

```
var ctx = context.getMessage("headersContext") || context.createMessage("headersContext");
ctx.setVariable('HelloWorld', true);
```

The **setVariable** call writes the variable into **headersContext.variables.HelloWorld**; therefore a condition statement in any subsequent **switch** policy should check for **headersContext.variables.HelloWorld** rather than **headersContext.HelloWorld**.
To read the context variable in any subsequent **gatewayscript** policy, use the following call:

```
ctx.getVariable("HelloWorld")
```

Note: If you are either migrating an API from IBM® API Connect Version 5.0, or from the DataPower Gateway (v5 compatible), to the DataPower API Gateway, or you are configuring a new API for the DataPower API Gateway, creating a message context, rather than using the context variable mechanism described in Accessing context variables, is the preferred option. In the case of migration, it most closely matches the behavior of IBM API Connect Version 5.0, and **setVariable** and **getVariable** calls will continue to work without modification.
Creating a message context is also the preferred option if you are creating a new API for the DataPower API Gateway because it most closely aligns the API context with the way that various native DataPower API Gateway policies process it.

XSLT examples

To delete a header:

```
<apigw:clear-header message="'message'" name="'X-My-Header'"/>
```

To read a header:

```
<xsl:variable name="reqType" select="apigw:get-header('request', 'Content-Type')"/>
<xsl:variable name="currType" select="apigw:get-header('message', 'Content-Type')"/>
```

To set a header:

```
<apigw:set-header name="'Content-Type'" value="'text/xml'"/>
```

To get all headers:

```
<xsl:variable name="allReqHdrs" select="apigw:all-headers('request')"/>
<xsl:variable name="allCurrHdrs" select="apigw:all-headers('message')"/>
```

Manipulating the message status - examples

Note: Only the **message** object has the status property, not the **request** object.

GatewayScript examples

To read the status code and reason phrase:

```
var code = context.message.statusCode;
var reason = context.message.reasonPhrase;
```

To update the status code:

```
context.message.statusCode = 400; //integer, update the code, with default reason
```

To update the status code and reason phrase in a single operation:

```
context.message.statusCode = '200 Wonderful'; //string, update code along with customized reason
```

Note: The **context.message.reasonPhrase** context variable is read-only.

XSLT examples

To read the status code and reason phrase:

```
<xsl:variable name="code" select="apigw:get-variable('message.status.code')"/>
<xsl:variable name="reason" select="apigw:get-variable('message.status.reason')"/>

<apigw:set-variable name="'message.status.code'" value="200"/>
<apigw:set-variable name="'message.status.reason'" value="'OK'"/>
```

Accessing the message body

Note: The request body is read-only.

GatewayScript examples

To read the request body:

```
context.request.body.readAsJSON(function(error, json) {});
context.request.body.readAsXML(function(error, xml) {});
context.request.body.readAsBuffer(function(error, buffer) {});
```

To read the message body:

```
context.message.body.readAsJSON(function(error, json) {});
context.message.body.readAsXML(function(error, xml) {});
context.message.body.readAsBuffer(function(error, buffer) {});
```

To write the message body and update the content type accordingly:

```
// text response
context.message.body.write("Hello world.");
context.message.header.set('Content-Type', "text/plain");

// JSON response
var pet = { "kind": "dog", "age": 3, "color": "black" };
context.message.body.write(pet);
context.message.header.set('Content-Type', "application/json");

// XML response
var resp = "<order><id>100</id><timestamp>20181231</timestamp><status>fulfilled</status></order>";
context.message.body.write(resp);
context.message.header.set('Content-Type', "text/xml");
```

XSLT examples

Note:

- There is no XSLT API to write the message body; the output of the stylesheet transformation is used to update **message.body**.
- To read the request body or the message body, you must parse **message.body** with a Parse policy before the XSLT policy is executed. At the beginning of the assembly flow, **message.body** contains **request.body** so, after parsing **message.body**, you can then read the request from **message.body**.
- If the XSLT input document uses the context current payload, **message.body** is used for the input document **'/'** that can be accessed from the XSLT policy if **message.body** has been parsed as XML in advance; this is determined by the **input** property of the XSLT policy, see xslt.

Read the message body:

```
<xsl:variable name="currentPayload" select="apigw:read-payload('message')" />
```

Read the message body when the **input** property of the XSLT policy is set to **true**:

```
<xsl:variable name="currentPayload" select="/" />
```

Rejecting the session

Note: After the session is rejected, the API assembly flow is stopped and a fault response is returned, unless a catch handler is defined.

GatewayScript example

To reject the session with an error name and message, and update the status reason and code:

```
context.reject('CustomError', 'You are not authorized to make this API call');
context.message.statusCode = '401 Unauthorized';
```

XSLT example

To reject the session with an error name and message, and update the status reason and code:

```
<apigw:reject identifier="'CustomError'" status-code="401" reason="'Unauthorized'">You are not authorized to make this API call</apigw:reject>
```

- **Manipulating attachments in a message object**
  The message object provides APIs and properties to manipulate message attachments.

API Gateway only

Manipulating attachments in a message object

The message object provides APIs and properties to manipulate message attachments.

If the assembly includes a parse policy, attachments in the request or response of a multipart message can be manipulated and sent back to the client. By default, the response is sent to the client in multipart format.
Restriction: You cannot add an attachment to a request or response which does not contain existing attachments.
Alternatively, you can clear **context.message.attachments** to discard the attachments and send only **message.body** to the client.
Note: If the assembly does not include a parse policy, the following processing rules apply.

- For a multipart request where the **message.body** variable is not changed, the invoke policy keeps and passes the attachments to the server.
- For a multipart request or response where the **message.body** variable is not changed, the result API action passes the attachments as the final response.
- If the **message.body** variable is changed, attachments are discarded.

- Retrieving an attachment
- Appending an attachment to the message
- Retrieving the number of attachments in an array
- Removing an attachment from the message
- Reading, accessing, and manipulating the body of an attachment
- Manipulating the headers of an attachment

Retrieving an attachment

GatewayScript examples

Retrieve the attachment by index location.

`context.message.attachments[1]`

Retrieve the attachment by looking up the value of `pic1` in the `Content-Id` header.

`context.message.attachments['cid:pic1']`

Retrieve the attachment by looking up the value of `uri1` in the `Content-Location` header.

`context.message.attachments['uri1']`

Appending an attachment to the message

GatewayScript example

```
var headers = JSON.parse ( '{ "Content-Type": "text/xml; charset=utf-8", "Content-Id": "<data>" }' );
context.message.attachments.append(headers, 'Hello world.');
```

Retrieving the number of attachments in an array

Example

```
for (var i = 0; i < context.message.attachments.count; i++) {
  context.message.attachments[i].header.set('X-Foo', 'bar');
}
```

Removing an attachment from the message

GatewayScript examples

Remove the attachment by index location.

`context.message.attachments.remove(1)`

Remove the attachment by looking up the value of `pic1` in the `Content-Id` header.

`context.message.attachments.remove('cid:pic1')`

Remove the attachment by looking up the value of `uri1` in the `Content-Location` header.

`context.message.attachments.remove('uri1')`

Reading, accessing, and manipulating the body of an attachment

GatewayScript examples

To read the payload of an attachment in binary and return the contents as either a `Buffer`, `Buffers`, `JSON`, or `XML NodeList` object:

```
context.message.attachments[0].body.readAsBuffer(function(errorObject,bufferObject){})
context.message.attachments[0].body.readAsBuffers(function(errorObject,buffersObject){})
context.message.attachments[0].body.readAsJSON(function(errorObject,jsonObject){})
context.message.attachments[0].body.readAsXML(function(errorObject,nodeList){})
```

To write content `Hello world` to the current payload of the attachment:

`message.attachments[0].body.write("Hello world")`

Manipulating the headers of an attachment

GatewayScript examples

To retrieve the values of the whole attachment headers:

`context.message.attachments[0].headers`

To retrieve the value of the named header of the attachment:

`context.message.attachments[0].header.get();`

To delete the current `Content-Type` header of the attachment.

`context.message.attachments[0].header.remove('Content-Type');`

You can set the value of the named header of an attachment. The header can be coalesced and noncoalesced. Take the following code as an example.

`context.message.attachments[0].header.set('MyCookie', ['cookie1', 'cookie2']);`

If the value type is array, the `MyCookie` header is noncoalesced and it is present with different entries in HTTP header.

```
MyCookie: cookie1
MyCookie: cookie2
```

User-defined policies

Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

A policy is a configuration element that controls a specific aspect of processing in the Gateway server during an API invocation at run time. IBM® API Connect provides built-in policies for many capabilities, including logging, redaction, proxy, and transformations, but you can also create user-defined policies to provide more processing control.

The following information outlines how to create and manage user-defined policies:

Creating a user-defined policy
: A user-defined policy is created outside of API Connect by using a standard development tool, but the policy must conform to a particular schema. For information about how to create a policy, see Authoring policies.
Note: If you run your policies on a DataPower® Gateway, ensure that the user-defined policy controls processing supported by the version ofIBM DataPower Gateway on which the policy runs. When using the GatewayScript actions, the minimum DataPower firmware version 7.2.0 or late.

Importing a user-defined policy into API Connect
: To make a user-defined policy available to an API, the policy must be imported into one or more Catalogs in the API Manager. If you also want to be able to apply the policy to your policy assembly in API Designer, you must import that policy into the developer toolkit environment.
Make your policy accessible to API Designer by using the developer toolkit. For detailed instructions, see Packaging and importing your policies into IBM API Connect.

  Make your policy available by using the API Manager UI. For detailed instructions, see:

  - Importing a user-defined policy into a Catalog. If you want to create a new Catalog and import a user-defined policy as part of the configuration, follow the instructions in Creating and configuring Catalogs.
  - Packaging and importing your policies into IBM API Connect.

  Note: Import a user-defined policy into every Catalog in API Manager that you require the policy to run in.

Applying a user-defined policy to an API
: Apply a user-defined policy to an API definition by using the assemble view in API Designer or API Manager to add the component to your assembly and configure its properties. For detailed instructions, see Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly.

Deleting a user-defined policy
: Delete a user-defined policy from a Catalog, by clicking the Delete icon next to the policy in the associated Catalog in API Manager.

Tags in API Connect

There are a number of forms of tagging in IBM® API Connect.

- You can create tags in an API that are visible in its OpenAPI definition and can be used to filter operations in the Developer Portal.
- You can tag items in the Developer Portal so that they can be searched for.

Tags within an API

The OpenAPI specification allows the inclusion of tags in an API definition, and you can create these tags through the API Manager user interface. You can assign tags to an operation within an API.

Tags that are assigned to an operation can be used to group the operations of an API in the Developer Portal, by using the filter options for the API. These tags are visible to anyone who can view any of the Products to which the API belongs.

For more information, see Editing an OpenAPI 2.0 API definition and Configuring an operation.

Note: Though you can tag the API itself in the API Setup section, by using this method the tag is not visible in the Developer Portal.

Tags in the Developer Portal

An administrator can assign tags to items in the Developer Portal, which are then available through the API Products search function in the Developer Portal.

For more information, see Editing tags for a specific item and Managing tags in the Developer Portal.

Working with Products

In IBM® API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The following diagram demonstrates how Products, Plans, and APIs relate to one another.
Note: Plans belong to only one Product, but they can possess different APIs to other Plans within the same Product, and they can share APIs with Plans from any Product.

Figure 1. The hierarchy of Products, Plans, and APIs.

Products provide a method by which you can group APIs into a package that is intended for a particular use. Additionally, they contain Plans, which can be used to differentiate between different offerings. Plans can share APIs, but whether subscription approval is required depends upon the Plan itself. Additionally, you can enforce rate limits through these Plans, or through operations within the APIs of a Plan that override the rate limit of the Plan. You can also assign different subscription costs to your Plans to differentiate the rates of API calls. For more information, see Monetizing your Products.

To make an API available to an application developer, it must be included in a Plan. You can create Plans only within Products, and these Products are then published in a Catalog. A lifecycle manager can then control the availability and visibility of APIs and Plans through the API Manager. By using the API Manager, you can specify the Plans that an application developer is able to subscribe to through the Developer Portal. The application developer can only subscribe to one Plan from a specific Product. Multiple Plans within a single Product are useful in that they can fulfill similar purposes but with differing levels of performance and cost. For example, you can have a "Demo Plan", which makes a single API available free of charge, and a "Full Plan" which makes several APIs available with a monthly subscription cost.

As well as controlling which APIs an application developer can use, different Plans can be used to implement different rate limits. A rate limit can be implemented as a default rate that is shared across an entire Plan, or can be set for specific operations of an API within that Plan, exempting them from the shared Plan rate limit. Different Plans can have differing rate limits, both between operations and for the overall limit. This is useful for providing differing levels of service to customers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note:

- Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
- The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see Working with Catalogs

API Connect also supports the implementation of multiple versions of Products. You can choose version numbers and use them to aid the development of your Products and Plans.
Note: The version for a Product is distinct from the version of any APIs that are contained in the associated Plans. Plans cannot themselves have their own version, they use the version of their parent Product.

- **Creating a draft Product**
  Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.
- **Downloading a draft Product**
  You can download the details of your draft Product so that you can store them for later recovery.
- **Importing a draft Product**
  You can create a Product by importing a Product definition in a .yaml file.
- **Searching for a draft Product**
  Quickly locate a draft API or Product by searching on the title and version.
- **Editing a draft Product**
  After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.
- **Staging a draft Product**
  Stage a draft Product to a Catalog to create a specific version of that Product before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- **Publishing a draft Product**
  Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- **Creating a new version of your Product**
  You can have multiple versions of a Product in IBM API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.
- **Specifying the gateway type for a Product**
  You can edit the Product configuration to specify a gateway type.
- **Deleting a draft Product**
  You can delete draft Products that are no longer required.
- **Organizing your Products into categories**
  You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal , in their defined categories.

Related information

- Working with Products in the API Manager

Creating a draft Product

Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.

Before you begin

Define your APIs. For more information, see Creating an API definition.
Tip: As well as using the method described in this task, you can also create a Product when you create an API. If you create an API by using the developer toolkit command line editor, a Product is automatically created for you. You can then change any of the Product settings by opening your new Product in the Products page of the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you first create your Product, it has *draft* status. When you have finished configuring your draft Product, you stage it to a Catalog so that the APIs in the Product can be made available to your application developers.

Procedure

To create a Product, complete the following steps:

1. In the navigation pane, click Develop, select the Products tab, then click Add > Product.
   The Add Product page opens.
2. Select New Product, then click Next.
3. On the Info page, complete the following steps:
   a. Enter the Title and Version of the Product and, optionally, a description. A Name is entered automatically.
      Note: The value in the Name field is a single string that is used to identify the Product in developer toolkit CLI commands. The Title is used for display.
      To view the CLI commands to manage draft Products, see the toolkit CLI reference documentation.

   b. Click Next.
4. On the APIs page, select the APIs that you want to include in the Product. For staging, you can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled. The APIs for which the Enforced option is disabled are not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see API Connect gateway types, Specifying the gateway type for a Product, and Specifying the gateway type for an API definition.
5. Click Next.
6. On the Plans page, complete the following steps:
   a. Optional: Change the Title, Description, or Rate limit settings for the default Plan.
   b. Optional: To add further Plans, click Add, then scroll down and modify the Plan settings as required.
   c. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
   Note: The publish option is not available in the API Designer UI.
8. If Publish product is selected, you can select which gateway service the Product is published to. By default, the Product is published to all relevant gateway services.
9. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

   Visibility can also be set at the Catalog or Space level. For more information, see Configuring Product visibility in a Catalog.

10. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
    If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
    Note: If you select custom visibility or subscribability, the consumer organizations and consumer organization groups that you can choose from are those in the Sandbox Catalog for the management server and provider organization that you are connected to. If you want to specify consumer organizations or groups that are in another Catalog, or in a Space, publish the Product to that Catalog or Space, then configure the visibility or subscribability there; for details, see Changing the availability of a Product.
    If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

    If you are working offline in API Designer, you must type in the exact name of the organization or group.

    For more information about consumer organizations in a Catalog, see Administering Consumer organizations.

11. Click Next to create your Product.
    a. To further configure your Product, click Edit Product.

For details, see Editing a draft Product

b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task.
For details on how to configure your Product later, see Editing a draft Product.

Results

You have created a draft Product, and specified a set of APIs and Plans into one offering that you can now make available to your developers.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

Related tasks

- Creating a new version of your Product

Downloading a draft Product

You can download the details of your draft Product so that you can store them for later recovery.

Before you begin

To complete this task, you must have created a draft Product. For more information, see Creating a draft Product.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Product-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

You can download the details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to export an entire implementation. For information about creating a Product from a .yaml file, see Importing a draft Product.

Procedure

To download a .yaml file containing details of your Product, complete the following instructions:

1. In the navigation pane, click  Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon ⋮ and then click Download.
4. Save the file to the required location.

Results

You have downloaded a .yaml representation of your Product.

Related tasks

- Importing a draft Product

Related information

- Creating a Product

Importing a draft Product

You can create a Product by importing a Product definition in a .yaml file.

Before you begin

To complete this task, you must have a .yaml representation of a Product. This can be created as described in the Downloading a draft Product task.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can import details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to import an entire implementation.

You can import the file from your local file system.

Procedure

To create a Product from a .yaml file, complete the following instructions:

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Click Add > Product.
4. Select Existing Product, then click Next.
5. To import a file from your local file system, you can either drag and drop your files, or click Browse and select the file that you want to use.
   The wizard checks the validity of the YAML, and displays a message indicating successful validation.
6. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
8. Click Next to create your Product.
   a. To further configure your Product, click Edit Product.
      For details, see Editing a draft Product
   b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task.
      For details on how to configure your Product later, see Editing a draft Product.

Results

You have imported a Product from a .yaml file. If the same APIs and versions of APIs as referenced in the file are present, then they will be included in the Product.

Importing a Product in this way does not include the API definitions, only references to them.

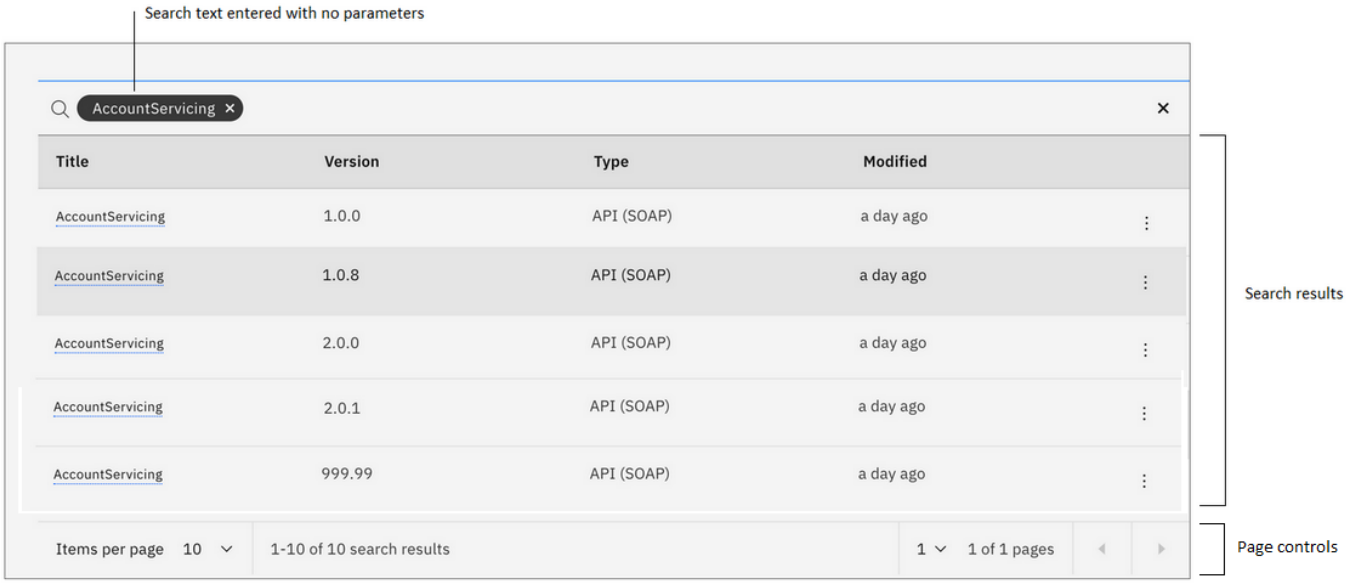
- Downloading a draft Product



Searching for a draft Product

Quickly locate a draft API or Product by searching on the title and version.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

On the Develop page, type your search string into the search field and click (or press Enter) to run the search.

The search returns a list of APIs (or Products) that most closely resemble your keywords, rather than limiting the results to identical matches. The following image shows a search string that includes "AccountServicing". The results include all draft APIs and Products with a title that is similar to the search text, with duplicates sorted by creation date.

Resources with a name, title, or version that doesn't match the search text are excluded from the results. If you select a resource type to search for but do not specify any keywords, the results are sorted by title and then by creation date. For example, if you search for Products but do not include any keywords, then all Products appear in the results table.

Search text

The search is case insensitive. Trailing spaces and accents (for example: é, è, â) are ignored. For best results, provide as much of the title and version as possible in your search text. Detailed search strings return more accurate results. Results include all titles that are similar to your search string, and not just identical matches.

What's included in the search?

The scope of the search includes the API or Product Title, Name, and Version fields. The search applies only to the current provider organization (displayed in the product banner's Organization field).

You can optionally restrict your search to Products only, or to a specific type of API. Click in the search field and then in the "Types" list that displays, select Product or an API type (REST or SOAP).

How are results displayed?

Search results display as a table, which is sorted by API or Product title and version. If the results overflow onto additional pages, navigate between pages using the standard page controls that follow the table. When you clear the search, APIs and Products are listed alphabetically by title and, within each title, by newest version first.

Editing a draft Product

After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.

About this task

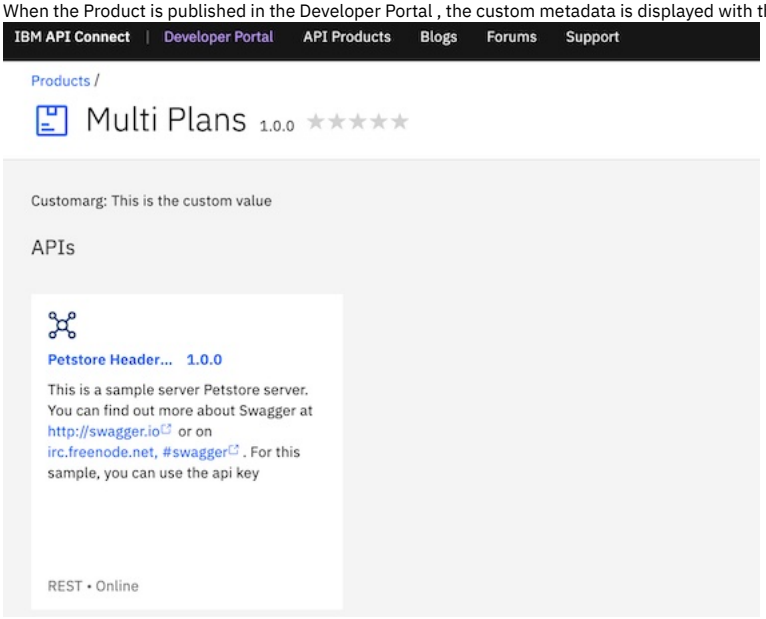
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

Procedure

To edit a draft Product, complete the following steps:

1. Access the Product Setup page in one of the following ways:
   - After completing the initial creation of the Product, click Edit Product.
   - In the navigation pane, click Develop, then select the Products tab.
   - Click the title of the Product that you want to edit.
2. On the Product Setup page, you can make the following configuration changes:
   a. In the Info section, change the Title, Version, or Summary.
   b. Use the Contact, Terms of Service, and License sections to enter the corresponding details as required.
   c. Change the gateway type. For more information, see API Connect gateway types and Specifying the gateway type for a Product.
   d. Click Save to save your changes.
3. Optional: Specify Product metadata to be displayed with the Product in the Developer Portal :
   a. Click the Source tab to see the OpenAPI source for the Product.
   b. Add the custom attribute `x-name: value` into the `info` section. For example:



```
info:
  version: 1.0.0
  title: Multi Plans
  name: multi-plans
```

```
  x-customarg: This is the custom value
...
```

Where `customarg` is the name of the custom metadata, and `This is the custom value` is the information content.

c. Click Save.

When the Product is published in the Developer Portal , the custom metadata is displayed with the Product. For example:

4. Click Visibility, then make the following changes as required:
   a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, complete the following steps:
      - Select the Catalog for which you want to control visibility.
      - Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. If needed, you can enter the name of a consumer organization or organization group that doesn't currently exist but will be added in the future. Later, create it using the same name. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

   b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
   If you select Custom, complete the following steps:
      - Select the Catalog for which you want to control subscribability.
      - Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If needed, you can enter the name of a consumer organization or organization group that doesn't currently exist but will be added in the future. Later, create it using the same name. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

   Note:
      - If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
      - Although the title of each organization or group is displayed, followed by the name in parentheses, in the table of selected organizations and groups only the name is displayed

   a. Click Save to save your changes.

   Note: You can change the visibility and subscribability settings when you publish the Product; see Publishing a draft Product. You can also change the settings in the Catalog to which the Product is published; see Changing the availability of a Product.
5. To specify the APIs that you want to include in the Product, click APIs, then complete the following steps:.
   a. Click Edit.
   All draft APIs are listed.
   b. Select the APIs that you want to include. For staging, you can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled. The APIs for which the Enforced option is disabled are not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see API Connect gateway types, Specifying the gateway type for a Product, and Specifying the gateway type for an API definition.
   c. Click Save when done.
   The selected APIs are listed.

   Note: To make an API available to application developers, you must include it in a Plan.
6. Optional: Add billing integration to the Product. Click Plans, and in the Billing integration section, select the billing integration resource that you want to apply to the Product.
   In the Plans section, you can then either edit the Default Plan to add pricing information, or create a new Plan with pricing information. For more information about billing integration, see Monetizing your Products.
7. Optional: Add one or more Plans to the Product, or modify an existing Plan. Note that a default plan is automatically created for you, with a rate limit of 100 API calls per hour.
   a. Click Plans.
   b. To add a new Plan, click Add. To modify an existing Plan, click the options icon ⋮ alongside the required Plan, then click Edit.
   c. Specify the Title of the Plan and, optionally, a description. A Name is entered automatically.
   Note: The value in the Name field is a single string that is used to identify the Plan in developer toolkit CLI commands. The Title is used for display.

d. Specify whether your Plan requires subscription approval. If you want subscriptions by developers to require approval, select the Approval check box; otherwise, ensure the check box is cleared.
Note:
To view the subscription tasks history, complete the following steps:
- In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
- Click Tasks tab.
- Click Approvals history from the navigation pane.

e. In the Plan pricing section, you can add pricing information by completing the following steps:
i. Change the toggle to On for Plan pricing. The Plan pricing definition section is displayed.
ii. If you want to include any free trial days in your Plan, select Include free trial days, and then enter the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.
iii. Select the Currency for the billing process use.
iv. Enter the Price per month to bill the subscriber for. If the selected currency supports fractional units, enter the price including any fractional units, such as cents.

For more information about Product billing integration, see Defining a Product with billing integration.

f. In the Plan Rate Limits section, you can modify a rate limit, and click Add to add further rate limits. You can set multiple rate limits, at second, minute, hour, day, and week time intervals. To remove a rate limit, click the corresponding delete icon .
Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

g. In the Plan Burst Limits section, you can modify a burst limit, and click Add to add further burst limits. You use burst limits to prevent usage spikes that might damage infrastructure. You can set multiple burst limits, at second and minute intervals. To remove a burst limit, click the corresponding delete icon .
Rate and burst limits work together to manage network traffic for the APIs covered under a Plan. A Plan can have multiple rate and burst limits, but it is recommended that each time interval be assigned only one set of limits. Adjust the rate and burst limits to allow for maximum traffic without overloading your network. The **rate limit** sets the maximum amount of sustainable, ongoing traffic for accessing the APIs on your network within a time interval (for example, one day). The **burst limit** sets the maximum short-term traffic volume for your network within a time interval (per second or minute).

The **burst limit** allows for short bursts of increased traffic. When the **burst limit** is exceeded, all subsequent API calls are rejected until the start of the next **burst limit interval**. The **burst limit counter** is reset to zero at the start of the next interval, which allows API calls to be accepted again. These API calls count toward the **rate limit counter**, but the resetting of the **burst limit counter** does not affect the **rate limit counter**.

The **rate limit** is the number of API calls allowed in a time interval, for example, 1000 calls per day. When the **rate limit** is exceeded, and Hard limit is enabled, all subsequent API calls will be rejected. The **rate limit counter** is reset to zero at the start of the next **rate limit interval**, which allows API calls to be accepted again. If Hard limit is disabled, all subsequent API calls are still accepted, and a message is logged stating that the **rate limit** has been exceeded. This is referred to as a "soft limit."

Hard limit affects only the **rate limit**, as illustrated by the following scenarios:

Scenario A

Table 1. Hard limit enabled

Hard limit	Burst limit	Rate limit
ON	100 calls/minute	1000 calls/day

- If a user calls an API 100 times in one minute, the **burst limit** is reached. The 101st call (and any subsequent calls) within the same minute will be rejected. Once the minute is up, the **burst limit counter** is reset. All API calls are tallied toward the **rate limit** of 1000 calls per day. The resetting of the **burst limit counter** does not affect the **rate limit counter**.
- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day rate limit, and the 1001st call will be rejected until the end of the same one day **rate limit interval**. During the period of time when API calls are rejected due to the daily **rate limit** being exceeded, the **burst limit** will not be activated since the calls are already rejected.
- Both **burst limits** and **rate limits** are applied per consumer.

Scenario B

Table 2. Hard limit disabled

Hard limit	Burst limit	Rate limit
OFF	100 calls/minute	1000 calls/day

- As in Scenario A, if a user calls the API 100 times in one minute, the 101st call within the same minute will be rejected, until that minute is up and the counter resets. These calls count toward the 1000 calls per day **rate limit** as well.
- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day **rate limit**, and the 1001st call will be accepted (since there is no hard limit). A message will be logged for each subsequent call until the time interval (one day) is up and the counter resets. During the remainder of the day, the **burst limit** will still be enforced, and calls will be rejected once the number of calls exceeds the 100 calls per minute within any given minute.
- Both burst limits and rate limits are applied per consumer.
Note: When Hard limit is unchecked, the **rate limit** is considered a "soft limit." With a soft limit, calls are not rejected after the **rate limit** is reached. Instead, a message is recorded in the log file. With a soft limit, the **burst limit** still rejects API calls after it is exceeded.

h. To include in the Plan all the APIs that were included in the Product in step 5, select Same as product in the Plan APIs section.
i. In the GraphQL Rate Limits section you can configure rate limits that will be applied to any GraphQL proxy APIs that are added to the Product.
The following rate limits are available:

graphql-field-cost
: Applies a limit to the total calculated field cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-design-request
: Applies a limit to the total number of calls of any of the following types made to the GraphQL proxy APIs in this Plan:
- Requests sent to the `graphql/cost` endpoint for retrieving the cost of a GraphQL query. For more information, see Enabling the cost endpoint for a GraphQL API.
- Standard introspection requests sent to the `/graphql` endpoint. For more information, see Supporting introspection for a GraphQL API.
- HTML web browser requests for a GraphiQL editor sent to the `/graphql` endpoint. For more information, see Enabling the GraphiQL editor for a GraphQL API.

graphql-input-type-cost
: Applies a limit to the total calculated input type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-type-cost
: Applies a limit to the total calculated type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

The calculated costs depend on weighting factors applied to the types and fields in the GraphQL schema. For details on the GraphQL proxy API, and configuring type and field weights, see Creating a GraphQL proxy API and Using the GraphQL schema editor.

j. To define one or more assembly burst limits or assembly count limits, click Add in the Assembly Burst Limits or Assembly Count Limits section as appropriate. For a burst limit you specify the maximum number of calls allowed in a specified time period, for a count limit you specify a maximum call limit. The name that you supply is for use in a Rate Limit policy in an API assembly, enabling the policy to define the burst or count limit that is to be applied; for more information, see Rate Limit.

k. To select the APIs that you want to include in the Plan, select Customize the plan API list in the Plan APIs section, then click Edit. The Edit plan APIs window opens. The APIs that are available for selection are those that were included in the Product in step 5. Use the check boxes to specify the required APIs, then click Save when done.

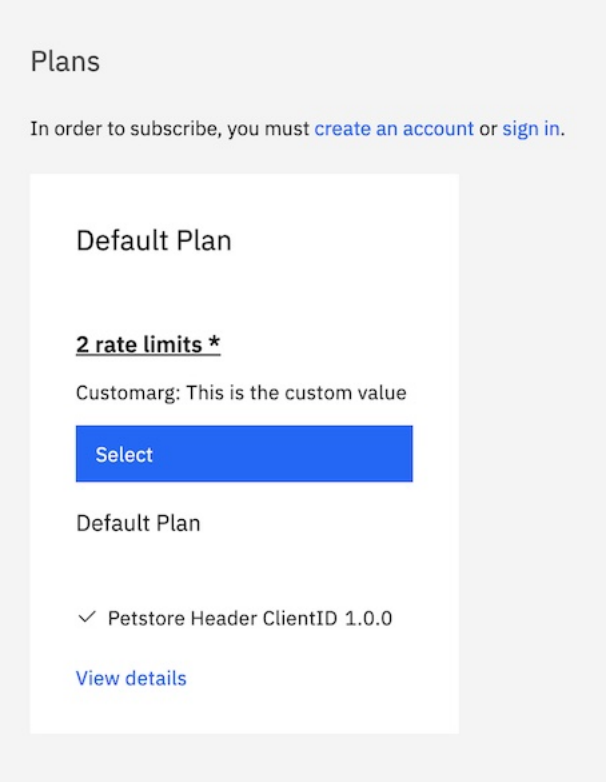
l. To select specific API operations to include in the Plan, click the options icon ⋮ alongside the required API , then click Edit operation list. The Select operations you want to include window opens. Use the check boxes to specify the required operations, then click Save when done.

m. To remove an API from the Plan, click the options icon ⋮ alongside the required API in the Plan APIs section, then click Remove.

n. For any GraphQL APIs in the Plan, if you want to prevent subscribers to this Plan from using certain types or fields, complete the following steps:

   i. Click the options icon ⋮ alongside the required GraphQL API in the Plan APIs section, then click Edit show/hide settings.
   ii. To prevent use of a GraphQL type, clear the check box selection alongside that type.
   iii. To prevent use a of a field in a type, expand the type then clear the check box selection alongside that field.
   iv. When done, click Next. A summary window opens. If the operation is permitted, any related elements that will also be hidden are listed; for example, if you hide a type, and that type is referenced as the data type of a field on another type, that field is also hidden. If the operation is not permitted, an explanation is displayed.
   v. If the operation is permitted, click Done to apply your changes. If the operation is not permitted, either click Cancel to close the window or click Back and amend your settings.

   You can use the Edit show/hide settings option to change existing settings; you can hide additional types or fields, and you can show types or fields that were previously hidden.



o. To define rate limits for specific API operations, select Override plan rate limits for individual operation in the Plan APIs section; for further details, see Defining rate limits for an API operation

p. Click Save to save your changes.

8. Optional: Specify Plan metadata to be displayed with the Plan in the Developer Portal :
   a. Click the Source tab to see the OpenAPI source for the Plan.
   b. Add the custom attribute **`x-name: value`** into the appropriate **`plan`** section. For example:

```
...
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    x-customarg: This is the custom value
    rate-limits:
      default:
        value: 100/1hour
        hard-limit: false
      minute:
        value: 20/1minute
        hard-limit: false
    apis:
      petstore-header-clientid1.0.0: {}
...
```

   Where ***`customarg`*** is the name of the custom metadata, and ***`This is the custom value`*** is the information content.
   c. Click Save.
   When the Plan is published in the Developer Portal , the custom metadata is displayed with the Plan. For example:

9. Optional: Click Categories, then define any categories that you want to organize your Product into. Click Save to save any updates.
   By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal . For more information, see tapic_apionprem_categories.html.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

- **Defining rate limits for an API operation**
  For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

Related tasks

- Creating a new version of your Product

Defining rate limits for an API operation

For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Procedure

1. Access the Product Setup page in one of the following ways:

- After completing the initial creation of the Product, click Edit Product.
- In the navigation pane, click Develop, then select the Products tab.
- Click the title of the Product that you want to edit.

2. Click Plans.
3. Click the options icon ⋮ alongside the required Plan, then click Edit.
4. Scroll down to the Plan APIs section, then select Override plan rate limits for individual operation.
   The Override Rate Limits section is displayed.
5. Click Add. The Override plan rate limits window opens.
6. Select the API, and the specific operation in that API, to which you want to apply rate limits.
   By default, calls to the operation are unlimited.
7. To apply one or more rate limits to the operation, select Rate Limits.
8. To define a rate limit, click Add.
9. Supply a name for the rate limit, and define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute. If you select HARD LIMIT and the limit is exceeded, subsequent calls are rejected, otherwise calls are still accepted and a message is logged.
10. Click Save when done.
    An entry for the operation is listed in the Override Rate Limits section.
11. To modify the rate limiting definition for an operation, click the options icon ⋮ alongside the required operation, then click Edit Operation; to delete it, click Remove.
12. Click Save to save your changes.

Staging a draft Product

Stage a draft Product to a Catalog to create a specific version of that Product before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.
Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

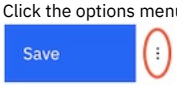
About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.
Staging is not available when you are working offline in API Designer.

A Catalog is a staging target, and behaves as a logical partition of the DataPower® Gateway, and the Developer Portal.

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it and the product can be published. For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests. For more information about publishing a Product, see Publishing a Product.

You cannot restage an existing Product version to a production Catalog. If you update an API, you must create a new version of that API. Then, create a new version of the Product so that it includes the newer version of the API. For more information on creating new versions of APIs and Products, see Creating a new version of an API definition and Creating a new version of your Product. If Spaces are enabled in a production Catalog, you cannot restage the same API or Product version to any Space in the Catalog. However, you can restage a Product version to the sandbox Catalog, or other non-production Catalog, for ease of iterative testing.
Note: When you restage a Product version to a non-production Catalog, the existing application subscriptions are deleted. The subscriptions are deleted to facilitate scripted deployment in a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts.
If Spaces are enabled in a non-production Catalog and you restage a Product version to a different Space to the one in which it was previously staged, it is removed from the previous Space and staged to the newly specified Space. If billing integration is enabled in a Product, you cannot re-stage the same Product version into a non-production, or production, Catalog. For more information about billing integration, see Monetizing your Products.
Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:



- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

To stage a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.

2. In the navigation pane, click Develop.
3. Select the Products tab.
4. You can stage a Product either from the Develop listing page, or from within the Product itself.
    a. To stage a Product from the Develop listing page, click the options menu icon alongside the required Product version, and then select Stage.
    b. To stage a Product from within the Product itself, complete the following steps:
        i. Click the Product version that you want to work with.
        ii. Click the options menu icon:
        

        iii. Select Stage.
5. Select the Catalog to which you want to stage the Product.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.

7. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. Click Next.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

What to do next

- Publish your Product for application developers to access it in the Developer Portal. For more information, see Publishing a Product.

Related information

- Managing your Products
- Removing a Product from a Catalog
- Working with Products in the API Manager

Publishing a draft Product

Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.
Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Manage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

You cannot re-publish a Product version to a production Catalog, you must create a new version of the Product for publication; see Creating a new version of your Product. If Spaces are enabled in a production Catalog, you cannot re-publish the same Product version to any Space in the Catalog, neither the same Space nor a different Space.

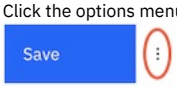
You can, however, re-publish a Product version to the Sandbox Catalog, or other non-production Catalog, for ease of iterative testing. When you re-publish a Product version to a non-production Catalog, you can choose whether or not to preserve any application subscriptions; deleting subscriptions can facilitate scripted deployment in

a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts.

If Spaces are enabled in a non-production Catalog and you re-publish a Product version to a different Space to the one in which it was previously published, it is removed from the previous Space and published to the newly specified Space.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.



Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

To publish a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
2. In the navigation pane, click  Develop.
3. Select the Products tab.
4. You can publish a Product either from the Develop listing page, or from within the Product itself.
   a. To publish a Product from the Develop listing page, click the options menu icon ⋮ alongside the required Product version, and then select Publish.
   If you are re-publishing a Product to non-production Catalog, and the Product has application subscriptions, the Publish option deletes them. To preserve application subscriptions, click Publish (Preserve Subscriptions) instead.
   Note: If there are any existing subscriptions to the Product, the Publish (Preserve Subscriptions) operation will fail if you remove any consumer organizations or consumer organization groups from the Product visibility or subscribability settings; you can, however, add further organizations or groups.
   For information on managing visibility and subscribability settings, see Editing a draft Product.

   For information on consumer organization groups, see Working with consumer organization groups.

   b. To publish a Product from within the Product itself, complete the following steps:
      i. Click the Product version that you want to work with.
      ii. Click the options menu icon:
      

      iii. Select Publish.
5. Select the Catalog to which you want to publish the Product. You must have a compatible gateway type associated with the catalog to proceed, as described in Creating and configuring Catalogs.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.

7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. The Visibility and Subscribability sections display the visibility and subscribability settings that have been configured for the draft Product, but you can modify these before publishing if required; proceed as follows:
   a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
   b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
   If you select Custom, use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
   Note:
   - If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
   - If custom visibility or subscribability has already been configured in the draft Product, the titles that are displayed in the table of selected organizations and groups are derived by taking the names that are defined in the draft Product and finding the corresponding titles in the Catalog that has been selected as the publish target.
9. Click Publish.

Results

Your Product is published to a Catalog. The state of the Product is shown as Published in the header of the Product itself, and you can click Published to see which Catalogs or Spaces the Product is published to.

You can also view the state of the product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click  Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

If your Product is DataPower® API Gateway compatible, the following states are available:

Staged - Success
: The product is successfully staged and ready for publishing. This phase prepares the product for availability in the Catalog.

Published-in-progress
: The product is published to the Catalog. Publishing to the Gateway(s) is in progress.

Published-success
: The product is successfully published to the Catalog and the Gateway(s).

Published-failed
: The product is published to the Catalog, but publishing to the Gateway(s) failed.
Note:
If the product is published to multiple Gateways, the operation might succeed on some and fail on others.

You can view the status for each Gateway by expanding the panel. APIs in this state cannot be invoked. Although subscriptions can still be created, they will not function as expected.

Deprecated - In Progress
: The product is being deprecated in the Catalog, and deprecation is in progress on the Gateway(s). During this phase, new subscriptions are restricted, and the product is prepared for retirement.

Deprecated-success
: The product is deprecated. Existing subscriptions remain active, but new subscriptions are blocked.

Deprecated - Failed
: The product is deprecated in the Catalog, but deprecation failed on Gateway(s). Because the Catalog status is Deprecated, new subscriptions are blocked. Existing subscriptions remain active.

Retired-in-progress
: The product is being retired from the Catalog, and retirement is in progress on the Gateway(s).

Retired - Success
: The product is retired. It is no longer available, and all subscriptions are terminated.

Retired - Failed
: The product is retired in the Catalog, but retirement failed on Gateway(s).
Note:
If the product is retired to multiple Gateways, the operation might succeed on some and fail on others.

You can view the status for each Gateway by expanding the panel. On Gateways where retirement fails, the product remains in the Published state, and all subscriptions continue to be active.

To know more about the status of a product, click the information  icon next to the product. A window with the product's state details opens. It shows the plan, subscription, and product status.
Note: The DataPower Gateway (v5 compatible) products do not have this feature.
If required, you can hide the product status feedback on the products page, see Disabling the status feedback on products page.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the publishing state; the Product is published in the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see Publishing a Product.
For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Creating a new version of your Product

You can have multiple versions of a Product in IBM® API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.

Before you begin

Create your Product and assign it a version. For more information, see Creating a draft Product.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create multiple versions of a Product, and these versions can be named according to your own preferences, and function as distinct Products when staged.

Procedure

To create a new version of a Product, complete the following steps:

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon, then click Save as a new version.
   The Save Product as a new version window opens.
4. Enter your new version number, then click Save.

Results

Your Product is saved as a new version.

Related information

- Managing your Products
- Working with Products in the API Manager

Specifying the gateway type for a Product

You can edit the Product configuration to specify a gateway type.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See Specifying the gateway type for an API definition.

When you create a new Product, or import a Product definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new Product

Gateway Service enablement in Sandbox Catalog	Default gateway type for new Product
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import a Product definition that already has a gateway type configured, that gateway type is retained.
For details of how to enable gateway services in a Catalog, see Creating and configuring Catalogs.

Procedure

To specify the gateway type for a Product, complete the following steps:

1. Ensure that you know the type of gateway that your APIs are configured to use.
2. In the navigation pane, click Develop, then select the Products tab.
3. Click the title of the Product you want to update.
4. On the Product Setup page, go to the Gateway Type section. Select the gateway type for your Product:
   - DataPower Gateway (v5 compatible)
   - DataPower API Gateway

   Note:
   You can only select the gateway type that satisfies the selected enforced APIs in your Product. To change the APIs included in your product, see Editing a draft Product.
5. Click Save to retain your changes.

Deleting a draft Product

You can delete draft Products that are no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Product-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Note:

- Deleting a draft Product does not remove it from any Catalogs to which it has been published. For details on how to remove a Product from a Catalog, see Removing a Product from a Catalog.
- You cannot directly delete a Product that was generated automatically from an API with the Activate API option; these Products have the title *api_title* auto product. To delete such Products, delete the API from which it was generated; the Product is deleted together with the API. For more information, see Deleting an API definition.

Procedure

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to delete, click the options icon and then click Delete.

Organizing your Products into categories

You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal , in their defined categories.

Before you begin

Your role must have the necessary permissions to stage and publish Products.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal .
Note: Organizing Products into a hierarchical view in the API Designer or API Manager UI is different to tagging in the Developer Portal.

Procedure

1. In the navigation pane, click Develop, then select the Products tab..
2. Click the title of the Product that you want to work with.
3. Click Categories.
4. In the Categories text box, enter the hierarchical taxonomy path that you want your Product to follow, in the following format:

   `top_level_element / next_level_element / x_level_element`

   For example:

   `Animals / Fluffy / Cat`

5. After you have completed entering the category specifications for the Product, click Save.

What to do next

- Publish the Product; see Publishing a draft Product.
- After publishing the Product, you can, in the Developer Portal , display Products in the categories that you have defined. For more information, see Displaying APIs and Products in categories.

Creating and validating API and Product definitions by using the CLI

The developer toolkit of IBM® API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.

The following topics explain how to use the command line interface to create an OpenAPI definition file, create a Product definition file, and validate a YAML or JSON definition.

- **Creating an OpenAPI definition file**
  APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the **create** command and then modify it by using an editor of your choice.
- **Specifying a gateway type for an API definition**
  An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify

which type of gateway the API uses.

- **Referring to an extension in an API definition**
  To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an `extensions` key under `x-ibm-configuration`.
- **Using $ref to reuse code fragments in your OpenAPI files**
  If you deploy an API to an IBM API Connect Management server by using the developer toolkit command line, you can use the `$ref` field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the `$ref` field is replaced with the contents of the target file.
- **Creating a Product definition file**
  You define a Product by creating a Product definition file.
- **Using x-ibm-languages to create multilingual API and Product documentation**
  Create multilingual API and Product documentation by using the `x-ibm-languages` extension in your API and Product OpenAPI definitions.
- **Using x-example to control the examples displayed in the Developer Portal**
  OpenAPI does not support the use of `example` attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use `x-example` in OpenAPI parameters.
- **Using x-embedded-doc to add additional documentation to products and APIs**
  You can use `x-embedded-doc` to add additional documentation to a product or an API as part of their definition.
- **Using x-pathalias to give consistent URLs for products and APIs**
  You can use `x-pathalias` to assign a URL to a product or an API.
- **Validating the YAML or JSON definition of an API or Product**
  You can validate a YAML or JSON definition by using the IBM API Connect developer toolkit.
- **Creating and using API and Product definitions templates**
  You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Related information

- API development and management commands

Creating an OpenAPI definition file

APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the **create** command and then modify it by using an editor of your choice.

You can stage or publish the API directly to a catalog in API Manager by referencing the API in a Product definition file, and then using the `apic products:publish` command to publish the Product. You can also create a draft API in API Manager by using the **apic draft-apis:create** command.

You can create an API in the CLI by running `apic create:api`, and supplying extra arguments on the command line.

Another option is to create an API interactively in the command line by running `apic create:api` and following the prompts.

You can see further details and available options for the `apic create:api` command by running:

```
apic create:api --help
```

IBM provides an extension to the OpenAPI specification; this extension is described in IBM extensions to the OpenAPI specification.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

Creating an API definition from a template

You can use a custom Handlebars template to create an API by using the following command:

```
apic create:api --template template_filename --title api_title
```

where *template_filename* is the name of the Handlebars template to use, and *api_title* is the title of your API.
An API template file must have a .hbs file name extension. You can create a template from scratch, or start with the example (default) API template that is provided in API and Product definition template examples.

You can create multilingual API and Product documentation by using an `x-ibm-languages` extension directly in the OpenAPI definition. For more information, see Using x-ibm-languages to create multilingual API and Product documentation.

- **IBM extensions to the OpenAPI specification**
  You use the `x-ibm-configuration` object in your OpenAPI definition file to add extensions that are specific to IBM API Connect.

Related information

- API development and management commands

IBM extensions to the OpenAPI specification

You use the **x-ibm-configuration** object in your OpenAPI definition file to add extensions that are specific to IBM® API Connect.

The x-ibm-configuration extension has the following structure:

```
x-ibm-configuration:
  enforced: enforced_boolean
  forceHttp500ForSoap11: forceHttp500ForSoap11_boolean
  compile-json-schemas: compile_json_schemas_boolean
  enforce-form-data-parameter: enforce_form_data_parameter_boolean
  phase: Phase
  testable: test_boolean
  cors:
    enabled: cors_boolean
  buffering: buffering_boolean
  activity-log:
      activity_logging_extension
  assembly:
    execute:
      - assembly_component
  gateway: gateway_type
  type: api_type
  properties:
      properties_extension
  catalogs:
      catalogs_extension
```

The following table lists the various extensions used by API Connect, whether they are required, a description of their use and behavior, and their type.

Table 1. IBM extensions

Extension	Required	Description	Type
phase	No	Use the phase extension to describe the maturity of the API. It can take the following values: • **identified**: the API is in the early conceptual phase and is neither fully designed nor implemented. • **specified**: the API has been fully designed and passed an internal milestone but has not yet been implemented. • **realized**: the API is in the implementation phase.	String
testable	No	Use the **testable** extension to specify whether the API can be tested using the test tool in the Developer Portal.	Boolean
enforced	No	Use the **enforced** extension to specify if the API Connect gateway is used to enforce the API. • **true** indicates that the API Connect gateway is used to enforce the API. • **false** indicates that the API Connect gateway is not used to enforce the API.	Boolean
cors	No	Use the **cors** extension to specify whether CORS access control is used for the API. The extension has an **enabled** field which is a Boolean.	Object (with a single Boolean field)
API Gateway only activity-log	No	Use the **activity-log** extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.	Object
assembly	No	Use the **assembly** extension to describe the application of policies and logic to an API. It contains an **execute** field that contains an array of policies that are applied in order. It can contain a **catch** field that contains an array of error cases to be caught. For information about use of the **execute** field, see execute. For information about use of the **catch** field, see catch.	Object
gateway	No	Use the **gateway** extension to specify which type of gateway you want to use. If you are using the DataPower® Gateway (v5 compatible) or DataPower API Gateway, it must be included and take one of the following values: • `datapower-gateway` (DataPower Gateway (v5 compatible)) • `datapower-api-gateway` (DataPower API Gateway) For information about types of gateways, see API Connect gateway types.	String
type	No	The **type** extension takes one of the following values: • **rest** • **wsdl**	
properties	No	Use the **properties** extension to define properties for use in an API.	Object (properties)
catalogs	No	Use the **catalogs** extension to define Catalog-specific values for properties defined in the **properties** extension.	Object (catalogs)
API Gateway only forceHttp500ForSoap11	No	Use the **forceHttp500ForSoap11** extension to force a 500 response code when an error occurs on a SOAP 1.1 API. This property works only with DataPower fix packs containing APAR IT46043.	Boolean
compile-json-schemas	No	Use this extension to enable precompilation of JSON schemas during configuration deployment. When set to true, JSON schemas are compiled and cached as the new configuration is applied, ensuring the compilation is ready and available when the first message is processed.	Boolean

Extension	Required	Description	Type
buffering	No	Use this extension to control whether to buffer API requests and responses before processing. It enables the DataPower **message-buffering** command • **true**: buffer API requests and responses before processing. API requests and responses are read as a binary large object (BLOB). • **false**: do not buffer API requests and responses before processing. API requests and responses are streamed. Only an asynchronous API call can read the streamed data. If the message processing requires parsing data at the payload level, then buffering is performed to capture the data. This setting is the default value.	Boolean
enforce-form-data-parameter	No	This command indicates whether to resolve and populate the form data parameter during API routing. • When enabled and the operation of the API path configures any form data, resolve the payload as BLOB data and populate the corresponding fields as context variables during routing. • When not enabled and no required form-data parameter is specified, processing does not resolve as a BLOB and populate the parameter.	Boolean

The following example shows the **x-ibm-extension** section of an API that is enforced by API Connect, is in the realized state, is testable through the test tool in the Developer Portal, has CORS access control enabled, and has a simple assembly that invokes a URL and then redacts a field from the request or response.

```
x-ibm-configuration:
  enforced: true
  phase: realized
  testable: true
  cors:
    enabled: true
  assembly:
    execute:
      - invoke:
          title: Example Invoke
          target-url: 'https://example.com/api'
          description: Example description
      - redact:
          actions:
            - action: redact
              from:
                - request
                - response
              path: //*[@name='secondaryAddress']/*[@name='streetAddress']
  properties:
    ID:
      value: 1234
      description: An ID to be used for validating.
      encoded: false
  catalogs:
    Sandbox:
      properties:
        ID: 5678
```

- **catch**
  Use the catch extension to catch errors that occur during an API call.
- **properties**
  Use the **properties** extension to define properties for referencing in an API.
- **catalogs**
  Use the **catalogs** extension to assign catalog-specific values to properties defined in the **properties** section.
- **activity-log**
  If you're using the DataPower API Gateway, you can use the **activity-log** extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.
- **finally**
  The finally extension specifies the final API rule to apply to the API call. This executes policies after the main assembly execution, catch extension, or both have been processed. It ensures that specific actions are performed before the API response is returned.

execute

The execute field of an assembly has the following structure:

```
execute:
 - Policy_1
 - Policy_2
```

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

- 

Indicates that the policy can be run on the DataPower Gateway (v5 compatible).
- 

Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see API Connect gateway types.

The following table describes the possible policies and logic constructs that can be included in an execute field.

Table 1. execute properties

Property	Required	Description	Data Type	DataPower Gateway	API Gateway
activity-log	No	Use the activity-log policy to log information that relates to the calling of API operations.	object (activity-log)	✓	✓ Functionality provided by the activity-log extension
client-security	No	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	object (client-security)	✗	✓
gatewayscript	No	Include a GatewayScript program.	object (gatewayscript)	✓	✓
graphql-cost-analysis	No	Use the graphql-cost-analysis policy to return a cost analysis of a target query.	object (graphql-cost-analysis)	✗	✓
graphql-execute	No	Use the graphql-execute policy to execute a GraphQL query by using sub-queries.	object (graphql-execute)	✗	✓
graphql-introspect	No	Use the graphql-introspect policy to introspect a GraphQL schema.	object (graphql-introspect)	✗	✓
if	No	Use the if policy to execute a section of the assembly only when a condition is fulfilled.	object (if)	✓	✓ Functionality provided by switch
invoke	No	Use the invoke policy to call an API. The last invoke in your policy might be replaced by a proxy automatically to improve performance. To disable this, see: API properties.	object (invoke)	✓	✓
json-to-xml	No	Convert payload from JSON to XML.	object (json-to-xml)	✓	✓
jwt-generate	No	Generate a JSON Web Token (JWT).	object (jwt-generate)	✓	✓
jwt-validate	No	Validate a JSON Web Token (JWT).	object (jwt-validate)	✓	✓
log	No	Use the log policy to customize or override the default activity logging configuration for an API.	object (log)	✗	✓
map	No	Use the map policy to transform variables.	object (map)	✓	✓
operation-switch	No	Use the operation-switch policy when you want to execute alternative policy assemblies, conditional on the operation that is being called.	object (operation-switch)	✓	✓
oauth	No	Use the oauth policy to policy to perform OAuth processing based on defined OAuth provider settings.	object (oauth)	✗	✓
parse	No	Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	object (parse)	✗	✓
proxy	No	Proxy a service.	object (proxy)	✓	✓ Functionality provided by invoke
ratelimit	No	Use the ratelimit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	object (ratelimit)	✗	✓
redact	No	Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	object (redact - DataPower API Gatewayredact - DataPower Gateway (v5 compatible))	✓	✓
set-variable	No	Use the set-variable policy to set a runtime variable to a string value, or to add or clear a runtime variable.	object (set-variable)	✓	✓
switch	No	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	object (switch)	✓	✓
throw	No	Use the throw policy to specify points at which an error should be thrown.	object (throw)	✓	✓
user-defined-policy	No	You can apply your own user-defined policies to your APIs.	object (User-defined policies)	✓	✓
user-security	No	Extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	object (user-security)	✗	✓
validate	No	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	object (validate - DataPower API Gateway, validate - DataPower Gateway (v5 compatible))	✓	✓
validate-usernametoken	No	Validate a WS-Security UsernameToken.	object (validate-usernametoken)	✓	✗
xml-to-json	No	Convert payload from XML to JSON.	object (xml-to-json)	✓	✓
xslt	No	Apply an XSLT transform to the payload.	object (xslt)	✓	✓

The following example shows an execute field for an assembly that invokes a URL and then redacts a field from the request or response.

```
execute:
 - invoke:
  title: Example Invoke
  target-url: 'https://example.com/api'
  description: Example description
 - redact:
```

```
  actions:
   - action: redact
     from:
      - request
      - response
    path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

activity-log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Activity Log.

Note: If you are using the DataPower API Gateway, you configure your logging preferences by using the activity-log extension.

About

The activity-log policy has the following format:

```
- activity-log:
  version: version
  title: title
  description: description
  content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

You can also apply an activity-log policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Activity Log in the built-in policies section.

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
buffering: true
```

Properties

The following table describes the policy properties:

Table 2. Activity Log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	A title for the policy.	string
description	No	A description of the policy.	string
content	Yes	Defines the type of content to be logged when the operation is successful. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **activity**.	string
error-content	No	Indicates what content to log if an error occurs. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **payload**.	string

Example 1

```
# use defaults

- activity-log:
  version: 1.0.0
  title: default activity logging
```

Example 2

```
- activity-log:
  version: 1.0.0
  title: no logging for successful calls
  content: none
  error-content: activity
```

client-security

The client-security policy can be used to extend client authentication access for your APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Client Security.

About

You use the client-security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
  - For all methods except **http**, use the id-name and the secret-name properties to specify the location that contains the ID and the location that contains the secret.
    - When **cookie**, specify which cookie.
    - When **context-var**, specify which runtime context variable.
    - When **form**, specify the form data.
    - When **header**, specify which header.
    - When **query**, specify which query parameter.
  - For the **http** method, use the http-type property to specify the format of the authorization header, which expects the **basic** form in the **basic base64_id:secret** format.
- Define the method to authenticate the extracted client credentials. The supported methods are **native** (this means by using IBM® API Connect), or by using a specified **third-party** user registry.
  - If **third-party**, use the user-registry property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The client-security policy has the following format:

```
- client-security:
    version: version
    title: title
    description: description
    stop-on-error: is_processing_stopped_on_client_security_failure
    secret-required: is_client_secret_required_in_request
    extract-credential-method: method_for_supplying_credentials
    id-name: parameter_that_specifies_client_id
    secret-name: parameter_that_specifies_client_secret
    http-type: authentication_type
    client-auth-method: method_for_client_authentication
    user-registry: user_registry_for_client_authentication
```

Table 2. client-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
stop-on-error	Yes	If set to **true**, assembly processing stops if client security fails, and an error is returned.	boolean

Property	Required	Description	Data type
secret-required	Yes	If set to **true**, the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID.	boolean
extract-credential-method	Yes	Specify one of the following values to define how the calling application authenticates: • **header**: client ID and client secret credentials must be supplied in the request header. • **query**: client ID and client secret credentials must be supplied as query parameters in the request URL. • **form**: client ID and client secret credentials must be supplied as form data sent in a POST request. • **cookie**: client ID and client secret credentials must be supplied in a header called **Cookie**. • **http**: the calling application must authenticate by using basic authentication. • **context-var**: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a gatewayscript policy for example. The names of these context variables are determined by the values that you supply in the id-name and secret-name properties of the client-security policy.	string
id-name	Yes, unless extract-credential-method is set to **http**	The name of the parameter whose value specifies the client ID. For all values of extract-credential-method other than **context-var** and **http**, the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For **context-var**, this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to **http**.	string
secret-name	Yes, if secret-required is set to **true** and extract-credential-method is other than **http**	The name of the parameter whose value specifies the client secret. For all values of extract-credential-method other than **context-var** and **http**, the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For **context-var**, this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to **http**.	string
http-type	Yes, if extract-credential-method is set to **http**	The authentication type. Currently, this must be set to **basic**.	string
client-auth-method	Yes	Specify one of the following values: • **native**: only client ID and client secret are used to authenticate the request. If extract-credential-method is set to **http** then the calling application must supply the client ID for the user name, and the client secret for the password. • **third-party**: a user registry is used to authenticate the client. If extract-credential-method is set to a value other than **http** then the calling application must supply the user name for the client ID, and the password for the client secret.	string
user-registry	Yes, if the client-auth-method is set to **third-party**	Specify the value of the **name** property of the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

client-security policy example

```
- client-security:
    version: 2.0.0
    title: client-security
    stop-on-error: true
    secret-required: true
    extract-credential-method: cookie
    id-name: my-client-id
    secret-name: my-client-secret
    client-auth-method: third-party
    user-registry: myauthurl
```

API Gateway only

extract

Use the extract policy to extract and transform data from fields in the API context.

Gateway support

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Extract.

About

The extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see Constructing JSONata expressions to extract and

transform data.

The input to the extract policy must be parsed data. One way to produce parsed data is to add a parse policy before the extract policy in your assembly.

The extract policy has the following format:

```
- extract:
    version: 2.0.0
    title: title
    root: data source
    extracts:
      - capture: path expression that identifies the field
        transform: expression that defines how to transform the content
                   .
                   .
                   .
    description: description
```

Apply this policy by adding an `assembly` extension with an `execute` field to your OpenAPI definition file.

Properties

Table 2. extract policy properties

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	Yes	The title of the policy. The default value is `extract`.	string
description	No	A description of the policy.	string
root	Yes	The data source that contains the content to transform. The default value is `message.body`.	string
capture	Yes	The path expression that identifies the field. The default setting is `$`, which indicates the entire input.	string
transform	Yes	The expression that defines how to transform the content.	string

Example

Transform the contents of the `account` field to include only the last 4 characters.

```
- extract:
    version: 2.0.0
    title: extract
    root: message.body
    extracts:
      - capture: $.members.policy.**.account
        transform: $substring($,-4)
    description: Include only the last 4 characters of the account field.
```

gatewayscript

Use the gatewayscript policy to execute a specified DataPower GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GatewayScript.

About

The gatewayscript policy has the following structure:

```
- gatewayscript:
   version: version
   title: Title
   desription: Description
   source: Script
```

Properties

The following table describes the policy properties:

Table 2. gatewayscript policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
source	Yes	The GatewayScript source code to execute.	string

Example

The following is an example of a simple gatewayscript policy:

```
- gatewayscript:
    version: 1.0.0
    title: Example_GatewayScript
    source: console.debug('Hello World!');
    description: A simple GatewayScript policy.
```

For more information about how to use a gatewayscript policy, see GatewayScript in the built-in policies section.

For more code examples, see GatewayScript code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- GatewayScript APIs for API management
- Accessing and manipulating a variable in the API context
- OAuth context variables

gemini-invoke

Use the Gemini invoke policy to invoke Gemini operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Gemini invoke.

About

The Gemini invoke policy provides access to six Gemini operations:

- `POST models/[model]:generateContent`
- `POST models/[model]:countTokens`
- `POST models/[model]:embedContent`
- `POST models/[model]:batchEmbedContents`
- `GET models/[model]`
- `GET models`

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Gemini invoke policy properties

Property name	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is Gemini invoke count tokens.	string

Property name	Required	Description	Data type
description	No	A description of the policy.	string
operation	Yes	The Gemini operation to invoke; must be one of the following operations: • **`POST models/[model]:generateContent`** An HTTP POST operation for **`generateContent`**. See Generating Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:countTokens`** An HTTP POST operation for **`/countTokens`**. See Counting tokens in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:embedContent`** An HTTP POST operation for **`embedContent`**. See Embed Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:batchEmbedContents`** An HTTP POST operation for **`batchEmbedContents`**. See Batch Embed Content in the Gemini API documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the Gemini API documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the Gemini API documentation for sample response examples.	string
api_key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Gemini requests.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the Gemini service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into theDataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the Gemini service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
path_params	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
query_params	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
output	No	The name of the DataPower API Gateway context message that receives the Gemini response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Example

```
gemini-invoke:
                    title: Gemini invoke count tokens
                    enable_cache: true
                    version: 2.0.0
                    api_key: $(gemini-apikey)
                    cache_ttl: 60
                    operation: POST models/[model]:countTokens
                    output: message
                    description: description goes here
                    cache_scope: cachescopevalue
```

graphql-cost-analysis

Use the graphql-cost-analysis policy to return a cost analysis of a target query.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GraphQL Cost Analysis.

Properties

Table 2. graphql-cost-analysis policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
input	No	A variable in the API context that contains the input to the GraphQL cost analysis. The content of the body field of the variable is the GraphQL cost query. By default, the variable name is **message**. The query should be in the format as specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.	string
output	No	A variable in the API context where the results of the GraphQL cost analysis are stored. The content of the body field of the variable is the result of GraphQL cost analysis. The default variable name is the same as that of the variable specified for the input field. Therefore, by default, the input of the GraphQL cost analysis is overwritten by the output.	string
target	No	A variable in the API context that contains the target for the GraphQL cost analysis. The content of the body field of the variable is the GraphQL context. By default, the variable name is **graphql_execute_args**. The target context specifies the query to analyze and, optionally, the result of the query execution.	string

graphql-execute

Use the graphql-execute policy to execute a GraphQL query by using sub-queries.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 (DataPower API Gateway Version 10.0.4.0 and later) 2.1.0 (DataPower API Gateway Version 10.5.2.0 and later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GraphQL Execute.

About

The graphql-execute policy executes a GraphQL query by using sub-queries. The policy splits up the original GraphQL query into different sub-queries that can then be processed in different ways. The graphql-execute policy supports the following four different sub-queries as targets:

1. **root**; contains the core GraphQL query that you want to invoke on the backend.
2. **__introspection**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend.
3. **__rateLimit**; contains the **__rateLimit** query that specifies the different rate limit data that you want to receive.
4. **__cost**; contains the **__cost** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.

The **root**, **__rateLimit**, and **__introspection** targets can be executed in any order, or at the same time. The **__cost** target can be executed at any time if no response data is expected. If response data is expected, then the **__cost** target is executed after the **root** target in order to accurately return correct response cost data. After all the targets are executed, the graphql-execute policy combines all of the responses together. To enable the responses of the individual targets to be correctly merged with each other into a final, single response, the graphql-execute policy must include all of the introspection types that are associated with each level of the response data.
The graphql-execute policy has the following format:

```
- graphql-execute:
    version: version
    title: title
    description: description
    targets:
      - execute: []
        catch:
        - execute: []
          otherwise: []
```

Properties

Table 2. graphql-execute policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
targets	No	The targets for the sub-queries. Valid values are: • `root`; contains the core GraphQL query that you want to invoke on the backend. • `__introspection`; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend. • `__rateLimit`; contains the `__rateLimit` query that specifies the different rate limit data that you want to receive. • `__cost`; contains the `__cost` query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: `__cost`.	string

Example

The following example shows a graphql-execute policy that includes all of the available targets.

```
- graphql-execute:
    title: GraphQL execute
    version: 2.1.0
    allowCostIntrospection: false
    targets:
      - target: root
        execute:
          - validate:
              input: message

```

graphql-introspect

Use the graphql-introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GraphQL Introspect.

Properties

Table 2. graphql-introspect policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
input	No	A variable in the API context that contains the input to introspect. The content of the `body` field of the variable is the input to introspect. By default, the variable name is `message`.	string
output	No	A variable in the API context where the results of the introspection are stored. The content of the `body` field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified for the `input` field. Therefore, by default, the input of the introspection is overwritten by the output.	string

Example

```
- graphql-introspect:
    version: 2.0.0
    title: introspect the accounts graphql schema
    input: message
```

API Gateway only

ibm-cloud-authentication

Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see IBM Cloud Authentication.

About

The ibm-cloud-authentication policy provides an API key to the IBM Access Manager and, if successfully authenticated, returns a Bearer token to be used by all subsequent watsonx.ai operation requests. The Bearer token is cached and will be valid for approximately 60 minutes. A new token is retrieved when a response for the API key was not cached. or expired.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. ibm-cloud-authentication policy properties

Property label	Required	Description	Data type

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is `ibm-cloud-authentication`. The title displays in the API assembly editor in the UI.	string
description	No	A description of the policy.	string
apikey	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate subsequent watsonx.ai requests.	string

Example

```
- ibm-cloud-authentication:
    version: 2.0.0
    title: ibm-cloud-authentication
    apikey: $(watsonx-ai-apikey)
```

if

Use the if construct when you want to execute a portion of your assembly only when a specific condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see if.

About

The if policy has the following format:

```
- if:
  version: version
  title: title
  description: description
  condition: 'condition_1
      execute:
        policy_assembly_1 ...
```

In the condition field, use the form `apim.getvariable('context.location.variable')` to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

The `execute:` section can define any policy assembly, including further if policies. For more information, see execute.

Properties

Table 2. if policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
condition	Yes	A script that returns `true` or `false`. Use GatewayScript for a DataPower Gateway implementation. For information about the context variables you can use and how to reference them in your script, see API Connect context variables.	string
execute	Yes	The policy assembly that you want to execute if the condition returns `true`. For more information, see execute.	string

Example

```
# carry out different redaction actions depending on the operation

- if:
  version: 1.0.0
  title: clear_region_and_set_body
  condition: 'apim.getvariable('request.body.secret') == true'
    execute:
      - redact:
          title: remove secret field
          actions:
            - action: remove
              from: all
              path: /document/user/secret
```

invoke

Use the invoke policy to call an API.

Gateway support

Restriction: It is not possible to cache a request that includes the Authorization request header.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.1 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Invoke.

About

The invoke policy has the following format:

```
- invoke:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  backend-type: how_payload_is_sent_to_backend
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
  password: password_if_authentication_required
  output: location_of_the_invoke_result
  cache-key: unique_identifier_of_the_document_cache_entry
  cache-response: cache_behavior
  cache-putpost-response: response_caching_behavior
  cache-ttl: cache_time_to_live
  inject-proxy-headers: are_proxy_headers_sent_to_target_url
  decode-request-params: are_request_parameters_decoded
  encode-plus-char: are_plus_characters_encoded
  keep-payload: is_payload_sent_on_delete
  use-http-10: are_transactions_restricted_to_http_1.0
  chunked-uploads: are_chunked_encoded_documents_sent_to_the_server
  persistent-connection: are_persistent_connections_enabled
  header-control:
        .
        .
        .
    headers_to_copy_to_target_url
        .
        .
        .
  parameter-control:
        .
        .
        .
    parameters_to_copy_to_target_url
        .
        .
        .
  follow-redirects: url_redirection_behavior
  stop-on-error: errors_that_stop_the_flow
```

Properties

The following table describes the properties of the invoke policy.

Table 2. Invoke policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

Property	Required	Description	Data type
target-url	Yes	The URL of the target API. Note: Do not manually append path or query parameters to the target-url field in the invoke policy. If these parameters are defined in the API operation, API Connect injects them into the target URL at run time. Avoid manually adding values such as **`$(request.search)`** or path segments, as doing so might result in duplication or malformed URLs. Use the **`parameter-control`** policy to manage query parameter inclusion.	string
API Gateway only backend-type	No	Specify one of the following values to determine how the payload is sent to the backend: • **`detect`**: detect the message type and send the payload to the backend accordingly. • **`xml`**: package the payload as XML and send. If the message type is not XML, the operation fails. • **`json`**: package the payload as JSON and send. If the message type is not JSON, the operation fails. • **`binary`**: package the payload as binary and send, regardless of the message type. • **`graphql`**: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. The default value is **`detect`**.	string
API Gateway only graphql-send-type(policy version 2.2.0 and later)	Yes, if backend-type is set to **`graphql`** or **`detect`**, and verb is set to **`POST`** or **`keep`**.	Specify one of the following values to determine how the GraphQL payload is sent to the back end: • **`detect`**: detect the message type and send the payload to the back end accordingly. • **`graphql`**: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. • **`json`**: package the payload as JSON and send. If the message type is not GraphQL, the operation fails. Note: graphql-send-type is supported only if backend-type is set to **`graphql`** or **`detect`**, and verb is set to **`POST`** or **`keep`**.	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data. Note: If you want to edit the API in the source view, make sure that the tls-profile value follows this format: name:version. For instance, it should look like nameofmytlsclientprofile:1.0.0.	string
verb	No	The operation method type. Valid values: • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **`GET`**. However, if the property is omitted from the source, the HTTP method from the incoming request is used.	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **`60`**.	integer
API Gateway only http-version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Valid values: • **`HTTP/1.0`** • **`HTTP/1.1`** • **`HTTP/2`**	string
API Gateway only http2-required (policy version 2.1.0 and later)	No	Set this property to **`true`** to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if http-version is set to **`HTTP/2`**.	boolean
compression	No	Specifies whether data is to be compressed by using compress before it is uploaded. The default value is **`false`**.	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
output	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable *message*. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as map. Note: If you want the response to be saved in *message*, leave the output property blank, do **not** supply the value `message`.	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
API Gateway only websocket-upgrade (policy version 2.1.0 and later)	No	Set this property to **`true`** to allow an HTTP or HTTPS connection to be upgraded to the WebSocket protocol if the request received by the corresponding HTTP or HTTPS handler on the DataPower API Gateway uses WebSocket (ws) or WebSocket Secure (wss). Note: • This property is available only for GraphQL APIs. • The **`websocket-upgrade`** property is deprecated. To allow WebSocket upgrade requests that can manage API processing data, define an assembly WebSocket upgrade policy. For more information, see websocket-upgrade.	boolean

Property	Required	Description	Data type
cache-response	No	The cache response type. Valid values: • **protocol**: The cache behavior is defined by the Cache-Control headers on the request and response. • **no-cache**: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. • **time-to-live**: Specifies that the response stays in the cache for the specified time. The default value is **protocol**.	string
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is **false**.	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to **time-to-live**. Enter a value in the range 5 - 31708800. The default value is **900**. Note: When users sign in by using the Toolkit login path (a URL that includes **?from=TOOLKIT**), the generated API key has a fixed time-to-live (TTL) of 5 minutes.	integer
API Gateway only inject-proxy-headers	No	When set to true, the **invoke** policy injects the **X-Forwarded-For**, **X-Forwarded-To**, **X-Forwarded-Host**, and **X-Forwarded-Proto** headers to the request that is sent to the t**target-url**. The default value is **false**.	boolean
API Gateway only decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the **target-url** of the invoke policy are URL-decoded. The default value is **false**.	boolean
API Gateway only encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the **target-url** are encoded to %2F. The default value is **false**.	boolean
API Gateway only keep-payload	No	When set to true, the invoke policy sends a payload on an **HTTP DELETE** method. The default value is **false**.	boolean
API Gateway only use-http-10 (policy version 2.0.0 only)	No	When set to true, HTTP transactions are restricted to version 1.0. The default value is **false**.	boolean
API Gateway only chunked-uploads	No	If you set this property to **true**, chunked-encoded documents are sent to the server. When the HTTP 1.1 protocol is used, the body of the document can be delimited by either **Content-Length** or chunked encoding. While all servers can interpret **Content-Length**, many applications fail to understand chunked-encoded documents. For this reason, **Content-Length** is the standard method. The use of **Content-Length** interferes with the ability of the DataPower Gateway to fully stream. If you must stream full documents to the target server, enable this property. When enabled, the server must be RFC 2616 compatible. Unlike all other HTTP 1.1 features that can be negotiated down at run time, you must know beforehand that the target server is RFC 2616 compatible. The default value is **true**. Note: Chunked encoding is not supported by the HTTP 1.0 protocol.	boolean
API Gateway only persistent-connection (policy version 2.3.0 and later)	No	Set this property to **true** to enable HTTP persistent connections, allowing connection re-use. The default value is **true**.	boolean
API Gateway only **header-control:** **type** **values**	No	Specifies the headers in **message.headers** that you want to copy to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the headers that you don't want to be copied. If the **values** property is empty then all headers are copied. If the **type** property is set to **allowlist**, the **values** property lists the headers that you want to be copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **header-control** property is **header-control:** **type: blocklist** **values: []** See header-control examples	object

Property	Required	Description	Data type

API Gateway only
`parameter-control:`
`type`
`values`
	No	Specifies the parameters in the incoming request that you want to be copied to the target URL.
		If the `type` property is set to `blocklist`, the `values` property lists the parameters that you don't want to be copied.
		
		If the `type` property is set to `allowlist`, the `values` property lists the parameters that you want to be copied. If the `values` property is empty then no parameters are copied.
		
		The items that are listed in the `values` property are in regular expression format. The values are not case-sensitive. The default value of the `parameter-control` property is
		
		`parameter-control:`
		`type: allowlist`
		`values: []`
		
		See parameter-control examples
			object

API Gateway only follow-redirect	No	Specifies the behavior if the back-end server returns the HTTP status code `301 Moved Permanently`. If this property is set to `true`, the `invoke` policy follows the URL redirection by making a further call to the URL specified in the `Location` header in the response. If this property is set to `false`, the `invoke` saves the `301` status code and the API call is considered to be complete. Note: The `follow-redirect` property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the `invoke` always follows the URL redirection; the `proxy` policy (not supported by the DataPower API Gateway) saves the `301` status code and completes the API call without following the URL redirection.	boolean
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a `catch` flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

Example

```
- invoke:
    version: 2.0.0
    title: get the account status
    target-url: https://example.com/accounts/{id}?status={status}
    cache-response: time-to-live
    cache-putpost-response: true
    tls-profile: MyTLSProfile:1.0.0
    verb: POST
    timeout: 60
    compression: false
    username: MyUser
    password: MyPassword
    stop-on-error:
      - ConnectionError
      - OperationError
```

API Gateway only `header-control` examples

```
# copy all headers to the target URL

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values:
        - ^X-Client-ID$
        - ^Content-Type$

# copy no headers

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values: []

# copy only the Content-Type header

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^Content-Type$
```

API Gateway only `parameter-control` examples

```
# copy no request parameters to the target URL

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values: []

# append the petid parameter to the target URL
# if the incoming request is http://apigw/org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values:
        - ^petid$

# The API definition includes a query parameter petid.
# Incoming request: https://apigw/org/sandbox/pets?petid=123
# API Connect will automatically forward petid to the target URL at runtime.

- invoke:
    target-url: https://myhost/pets
    parameter-control:
      type: allowlist
      values:
        - ^petid$
```

json-to-xml

Use the json-to-xml policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see JSON to XML.

About

The json-to-xml policy has the following structure:

```
- json-to-xml:
   version: version
   title: Title
   description: Description
```

Note: If you are using the DataPower API Gateway, the input to the json-to-xml policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a json-to-xml policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
API Gateway only input	No	The input message to convert. Specify the name of a variable in the API context. ***variableName*.body**, the message payload, represents the JSON input to convert. The default value of the variable is **message** and **message.body** is the default input.	string
API Gateway only output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***variableName*.body** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **message.body**. Otherwise, when the input message is the variable **my-message-variable**, for example, the default output is **my-message-variable.body**. The variable cannot be any read-only in the API context.	string
API Gateway only conversionType	No	The conversion type that determines the target format of the output. The following options are available: • None: No conversion of the output takes place. • badgerFish: BadgerFish convention is used to determine the target conversion format of the output.	string
root-element-name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the always-output-root-element property is set to **true**.	

Property	Required	Description	Data type
always-output-root-element	Yes	Select this property to **true** you always want the policy to output the root element, even if it is not required to make the XML document well formed.	boolean
unnamed-element-name	No	The XML element name to be used for JSON array elements.	string

Example

The following is an example of a json-to-xml policy:

```
- json-to-xml:
    version: 1.0.0
    title: JSON to XML transform
    description: Transforms JSON message body to XML format
```

jwt-generate

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.1.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Generate JWT.

Note:

- For algorithm types HS256, HS384, and HS512 the cryptographic objects referenced must be a Shared Secret Key.
- For algorithm types RS256, RS384, RS512, ES256, ES384, ES512, PS256, PS384, PS512 the cryptographic objects referenced must be a Crypto Key (private key).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to sign the JWT.

About

The jwt-generate policy has the following structure:

```
- jwt-generate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  jti-claim: jwt_id_claim
  iss-claim: issuer_claim
  exp-claim: validity_period
  sub-claim: subject_claim
  aud-claim: audience_claim
  jws-jwk: sign_jwk_variable_name
  jws-alg: cryptographic_algorithm
  jws-crypto: sign_crypto_object
  custom-kid-value-jws: jws.kid
  jwe-enc: encryption_algorithm
  jwe-jwk: encrypt_jwk_variable_name
  jwe-alg: key_encryption_algorithm
  jwe-crypto: encrypt_crypto_object
  custom-kid-value-jwe: jwe.kid
```

Properties

The following table describes the policy properties:

Table 2. Generate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
jwt	No	Runtime variable in which to place the JWT that is generated. The default value is: **generated.jwt**. However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
jti-claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to **true**, and a UUID is generated and set as the JTI claim value.	boolean
iss-claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: **iss.claim**	string
sub-claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string

Property	Required	Description	Data type
aud-claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
exp-claim	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is **3600**.	integer
private-claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
jws-jwk	No	Runtime variable that contains the JWK that is used to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-alg	No	The cryptographic algorithm to use. Valid values are: • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512	string
jws-crypto	No	The cryptographic object to use to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string
custom-kid-value-jws	No	The customized **kid** value for JWT signing.	string
jwe-enc	No	The encryption algorithm to use. Valid values are: • A128CBC-HS256 • A192CBC-HS384 • A256CBC-HS512	string
jwe-jwk	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string
jwe-alg	No	The key encryption algorithm to use. Valid values are: • RSA1_5 • RSA-OAEP • RSA-OAEP-256 • dir • A128KW • A192KW • A256KW	string
jwe-crypto	No	The cryptographic object to use to encrypt the claim.	string
custom-kid-value-jwe	No	The customized **kid** value for JWT encryption.	string

Example

The following is an example of a jwt-generate policy:

```
    - jwt-generate:
        version: 2.1.0
        title: jwt-generate
        description: New jwt-generate v2.1.0 policy.
        jwt: generated.jwt
        jti-claim: true
        iss-claim: iss.claim
        sub-claim: sub.claim
        aud-claim: aud.claim
        exp-claim: 3600
        private-claims: private.claims
        jws-jwk: jws.jwk
        jws-alg: HS256
        jws-crypto: jwsCryptoObjectName
        custom-kid-value-jws: jws.kid
        jwe-enc: A128CBC-HS256
        jwe-jwk: jwe.jwk
        jwe-alg: RSA1_5
        jwe-crypto: jweCryptoObjectName
        custom-kid-value-jwe: jwe.kid
```

For more information about how to use a jwt-generate security policy, see Generate JWT in the built-in policies section.

jwt-validate

Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate JWT.

Note:

- If the original message was signed with a Shared Secret Key, the cryptographic object that is specified must also be a Shared Secret Key.
- If the original message was signed with a Private Key, the cryptographic object that is specified must be a Crypto Certificate (public certificate).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If a JWK header parameter is included in the header of the JWT, the parameter must match the JWK or cryptographic object that is specified in the policy, or the JWT validation will fail.
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to decrypt or verify the JWT.
- The JWT validate action on the DataPower API Gateway can verify a JWT by using either a single JWK, or a JWK set.

About

The jwt-validate policy has the following structure:

```
- jwt-validate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  output-claims: output_full_set_of_jwt_claims
  iss-claim: issuer_claim
  aud-claim: audience_claim
  jwe-crypto: decrypt_crypto_object
  jwe-jwk: decrypt_crypto_jwk_variable_name
  jws-crypto: verify_crypto_object
  jws-jwk: verify_crypto_jwk_variable_name
```

Properties

The following table describes the policy properties:

Table 2. Validate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
jwt	Yes	Context or runtime variable that contains the JWT to be validated. The default value is: **request.headers.authorization**. However, if this property is not set, the policy looks for the JWT in the **request.headers.authorization** location by default. Note: The format of the authorization header must be: **"Authorization: Bearer *jwt-token*"** where *jwt-token* is the encoded JWT.	string
output-claims	Yes	Runtime variable to which the full set of claims that are contained in the JWT is assigned. The default value is: **decoded.claims**.	string
iss-claim	No	The Perl Compatible Regular Expressions (PCRE) to use to validate the Issuer (iss) claim.	string
aud-claim	No	The PCRE to use to validate the Audience (aud) claim.	string
jwe-crypto	No	The cryptographic object (a shared key or certificate) to use to decode the claim. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jwe-jwk	No	Runtime variable that contains the JWK to use to decrypt the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-crypto	No	The cryptographic object (a shared key or certificate) to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-jwk	No	Runtime variable that contains the JWK, or a JWK set, to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string

Example

The following is an example of a jwt-validate policy:

```
- jwt-validate:
    version: 1.0.0
```

```
    title: jwt-validate
    jwt: request.headers.authorization
    output-claims: decoded.claims
    iss-claim: "'^data.*'"
    aud-claim: "'^id.*'"
    jwe-crypto: jweCryptoObjectName
    jwe-jwk: jwe.jwk
    jws-crypto: jwsCryptoObjectName
    jws-jwk: jws.jwk
```

For more information about how to use a jwt-validate security policy, see Validate JWT in the built-in policies section.

log

Use the log policy to customize or override the default activity logging configuration for an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Log.

About

The log policy has the following format:

```
- log:
  version: version
  title: title
  description: description
  mode: activity_logging_actions
  log-level: type_of_content_to_log
```

Properties

The following table describes the properties of the log policy.

Table 2. log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

mode	Yes	Specify one of the following values:
		• **gather-only**: gather all analytics data and write it to the **log** context variable, which populates the API event record on completion of the API execution. For more information on the fields in the **log** context variable, and the consequent API event record, see API event record field reference.
		• **send-only**: perform the following actions:
		  ◦ Read the data from the **log** context variable.
		  ◦ Truncate all message payloads and convert to a textual representation.
		  ◦ Send the data to the analytics server.
		• **gather-and-send**; perform a **gather-only** operation, immediately followed by a **send-only** operation.
		If you use the Send-only or Gather-and-send option, data is buffered and sent to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information, see Configuring an analytics endpoint in the DataPower knowledge center.
		Note: If you are offloading to a third party analytics server, you can redact any aspect of the event data. If you are using API Connect analytics, you can redact only request and response payloads.
			string

log-level	No	The type of content to log. Specify one of the following values: • **none**: Indicates no logging. • **activity**; Logs the invocation only, which is only the resource URI. • **header**: Logs activity and header. • **payload**:Logs activity, header, and payload. • **default**; Use the log level setting defined in the API definition; for more information, see activity-log. This is the default value. • **$(value)**: An inline parameter in the format **$(value)** to retrieve a value from the API context.	string

Example

```
- log:
  version: 2.0.0
  title: Gather activity log data for processing
  mode: gather-only
```

map

Use the map policy to transform your assembly flow and specify relationships between variables.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.5.0.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Map.

About

For information about the use and structure of the map policy, see The Map policy structure. For more information about API properties that affect the map policy, see API properties.

The map policy has the following format:

```
- map
   version: version
   title: title
   description: description

   inputs:
      - input_1:
         variable: context_1
         $ref: '#/definitions/definition_1'
      - input_2
         variable: context_2
         type: type_2
         content: content_type

   outputs:
      - output_3
         variable: context_3
         type: type_3

   actions:
      - set: output_3.output_property_3
        from: input_1.input_property_1

      - set: output3.output_property_3
        from:
         - input1.input_property_1
         - input2.input_property_2
        value: 'script_A'
        default: 'default_A'

      - create: output3.output_property_3
        from: input1.input_property_1
        foreach: input1.input_property_1
        actions:
          - further_actions
   options:
         .
         .
         .
    advanced_XML_and_general_configuration_options
         .
         .
         .
```

Properties

Table 2.

Property	Required	Description	Data type	Belongs to
version	Yes	The policy version number	string	N/A
title	No	A title for the policy.	String	N/A
description	No	A policy description.	String	N/A
inputs	No	An array listing the inputs of the map policy.	Object	N/A
outputs	Yes	An array listing the outputs of the map policy.	Object	N/A
variable	Yes	A reference to the context variable that is the location of the input or output variable..	String	inputs or outputs

Property	Required	Description	Data type	Belongs to
$ref	Yes[1]	A reference to the definition of the type of the variable.	String	inputs or outputs
type	Yes[1]	The type of the variable.	String	inputs or outputs
content	No	The content type of the variable: `application/xml` or `application/json`. If None is selected, or the field is not included, then the type is treated as JSON.	String	inputs or outputs
actions	Yes	Lists actions to be performed by the map policy.	Object	N/A
set	Yes[2]	Specifies by name the output variable that is to be set to a value by the action.	String	actions
create	Yes[2]	Specifies by name the output variable that is to have a value appended to it by the action.	String	actions
from	No	Specifies by name any input variables used by the action.	String	actions
value	No	Contains a script that maps and transforms input variables into output variables.	String	actions
default	No	Contains a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see Inline references.	String	actions
foreach	No	Specifies by name an array for which further actions should be performed for each element.	String	actions
includeEmptyXMLElements	No	If set to **`true`**, empty XML elements are included in the output of the map policy. Set to **`false`** if you do not want empty XML elements to be included in the output of the map policy. The default value is **`true`**.	Boolean	options
namespaceInheritance	No	If set to **`true`**, XML namespaces are inherited from the parent element. Set to **`false`** if you want the map policy to use explicit namespaces. The default value is **`true`**.	Boolean	options
inlineNamespaces	No	If set to **`true`**, XML namespaces will be inserted into the document where they are first used. Set to **`false`** if you want namespaces to all be defined on the root element. The default value is **`true`**.	Boolean	options
API Gateway only mapResolveXMLInputDataType	No	If set to **`true`**, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Set to **`false`** if you want all XML element values to be returned as a string.	Boolean	options
API Gateway only mapParseXMLOutput	No	If set to **`true`**, the map policy will write XML output to **`message.body`** as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string. The default value is **`false`**.	Boolean	options
API Gateway only mapXMLEmptyElement	No	This property controls how the map policy handles the output of an empty XML element. Specify one of the following values: • **`string`** (the default option): An empty XML element is handled as an empty string. • **`null`**: An empty XML element is handled as a null value. • **`none`**: The data is ignored. • API Gateway only **`string-badgerfish`**: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. • API Gateway only **`null-badgerfish`**: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the **`mapNullValue`** property is set to **`true`**.	String	options
API Gateway only mapArrayFirstElementValue	No	If set to **`true`**, then if an array is encountered in the traversal of the input, only the first element is used. Set to **`false`** if you want the map policy to use all array elements. The default value is **`false`**.	Boolean	options
API Gateway only mapResolveApicVariables	No	If set to **`true`**, API Connect variable references found in the map properties are resolved. Set to **`false`** if you want the map policy to ignore API Connect variable references in the map policies. The default value is **`false`**.	Boolean	options
API Gateway only mapNullValue	No	If set to **`true`**, an input property value with a null value is mapped to the output document. Set to **`false`** if you want the map policy to ignore null input values. The default value is **`false`**.	Boolean	options
API Gateway only mapOptimizeSchemaDefinition	No	If set to **`true`**, complex schema types evaluation handles circular type references in an optimized manner. Set to **`false`** to evaluate these schema types in a standard manner. The default value is **`false`**.	Boolean	options

Property	Required	Description	Data type	Belongs to

API Gateway only
mapEmulateV4DefaultRequiredProps
	No	If set to **true**, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
		• An array consists of objects that contain one or more required properties.
		• An object which is optional has one or more child properties that are required.
		By default, these required properties are not present in the output. If you set this property to **true**, these required properties will be present in the output. If the output schema defines a **default** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:
		• String: empty string ("")
		• Number: 0
		• Boolean: false
		• Object: empty object
		• Array: empty array
		Example 1
		The input data has the following array of objects:
		`[{"a": "value1"}, {"a": "value2", "b": "value3"}]`
		The output schema defines the output object as having two properties, **a** and **b**, of which **b** is required. The map policy defines the following mappings:
		• `input.array.a` to `output.array.a`
		• `input.array.b` to `output.array.b`
		If this property is set to **true**, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:
		`[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]`
		Example 2
		The output schema defines the following structure:
		`{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }`
		Property **b** is optional but property **d** within **b** is required.
		The map policy defines a mapping to **output.a.b.c**.
		If this property is set to **true**, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:
		`{"a" : {"b" : {"c" : "value1", "d" : ""} } }`
		If this property is set to **false**, these required properties are **not** created in the output with their default values.
		The default value is **false**.
			Boolean	options

API Gateway only mapEnablePostProcessingJSON	No	If set to **true**, mapped JSON output is post processed. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set to **false** if you want no post processing of mapped JSON output. The default value is **false**.	Boolean	options
API Gateway only mapCreateEmptyArray	No	This property controls how the map policy handles the output of an empty array. Specify one of the following values: • **all**: Output all empty arrays, including empty children arrays. • **parent**: Output only the current property's empty array value. Children map actions of this property are not attempted. • **none**: Prevent any empty output array values from being produced. The default value is **all**.	String	options
API Gateway only mapReferenceLimit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String	options
messagesInputData	No	This property defines the severity level for log messages that relate to input data. Specify one of the following values: • **error** • **warn** • **info**	String	options

Property	Required	Description	Data type	Belongs to

API Gateway only
mapEmulateV4EmptyJSONObject
	No	If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set this property to **true** to create an empty object for the parent of the target mapping, emulating the behavior of IBM® API Management Version 4.0.
		
		Example
		The map policy defines a mapping to **output.a.b.c**.
		If input data is present, the output is as follows:
		`{ "a": { "b": { "c": "inputvalue" } } }`
		If there is no input data, and the mapEmulateV4EmptyJSONObject option is set to **true**, the output is as follows:
		`{ "a": { "b": { } } }`
		Properties **a** and **b** are created but the value of **b** is an empty object.
		The default value is **false**.
			Boolean	options

[1] There must be one of $ref or type in the description of a variable.

[2] There must be one of set or create in an actions field.

Example

```
    - map:
        version: 1.0.0
        title: Output mapping
        inputs:
          Monthly_cost:
            schema:
              type: double
            variable: loan_invoke.body.monthly_payment
            content: application/json
          Duration:
            schema:
              type: integer
            variable: request.parameters.duration
        outputs:
          Quote_Output:
            schema:
              $ref: '#/definitions/Quote_Output'
            variable: message.body
            content: application/json
        actions:
          - set: Quote_Output.monthly_repayment
            from: Monthly_cost
            value: ''
          - set: Quote_Output.total_cost
            from:
              - Duration
              - Monthly_cost
            value: '$(Duration)*$(Monthly_cost)'
        description: Maps and transforms contexts to the operation output.
        options:
          includeEmptyXMLElements: false
          namespaceInheritance: false
          inlineNamespaces: false
          API Gateway only mapResolveXMLInputDataType: true
          API Gateway only mapXMLEmptyElement: null
          API Gateway only mapArrayFirstElementValue: false
          API Gateway only mapResolveApicVariables: false
          API Gateway only mapNullValue: true
          API Gateway only mapOptimizeSchemaDefinition: true
          API Gateway only mapCreateEmptyArray: parent
          API Gateway only mapReferenceLimit: 5
          messagesInputData: warn
          mapEmulateV4EmptyJSONObject: true
```

operation-switch

Use the operation-switch construct when you want to execute alternative policy assemblies, conditional on the operation that is being called.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see operation-switch.

About

An operation can be described with a **verb**/**path** pair, or with an **operationId**. The **operationIds** are strings, or names, that are defined in the OpenAPI document.

The operation-switch policy has the following format:

```
- operation-switch:
  version: version
  title: title
  description: description
  case:
    - operations:
      - verb: operation_verb_1_1
        path: operation_path_1_1
      - verb: operation_verb_1_2
        path: operation_path_1_2
                      .
                      .
                      .
           further verb/path combinations
                      .
                      .
                      .
      execute:
        policy_assembly_1 ...
    - operations:
      - verb: operation_verb_2_1
        path: operation_path_2_1
      - verb: operation_verb_2_2
        path: operation_path_2_2
                      .
                      .
                      .
           further verb/path combinations
                      .
                      .
                      .
      execute:
        policy_assembly_2 ...
                    .
                    .
                    .
    - operations:
      - operationID_3_1
      - operationID_3_2
      - operationID_3_3

                      .
                      .
                      .
           further operationIDs
                      .
                      .
                      .
      execute:
        policy_assembly_3 ...
                    .
                    .
                    .
         further operations sections
                    .
                    .
                    .
```

For each **operations:** section, if the operation that is being called matches any of the **verb**/**path** combinations or **operationId** strings listed in that **operations:** section, then the policy assembly that is defined in the **execute:** section is executed. Therefore, each **operations:** section defines execution of a policy assembly conditional on the operation that is being called.

You can have as many **operations:** sections as you want, and each **operations:** section can have one or more **verb**/**path** combinations or **operationId** strings.

The **execute:** section can define any policy assembly, including further operation-switch policies.

Properties

Table 2. operation-switch policy properties

Property	Required	Description	Data type	Contained in
version	Yes	The policy version number	string	N/A
title	No	A title for the policy.	string	N/A
description	No	A policy description.	string	N/A
case	Yes	An array containing different cases, each entry contains an operations and execute field.	array (object)	N/A
operations	Yes	The operations to which a case applies.	object	case
verb	No	An operation verb. Valid values: • `GET` • `POST` • `PUT` • `DELETE` • `HEAD` • `PATCH` • `OPTIONS`	string	operations
path	No	A relative path to an individual endpoint. For example, `/account_status`.	string	operations
operationID	No	The operation is defined in OpenAPI. The policy operation refers to the OpenAPI operation.	string	operations
execute	Yes	The policy assembly that you want to execute if the operation that is being called matches any one of the verb/path combinations. For more information, see execute.	string	case

Example

Example that defines match operations with `verb/path` combinations:

```
# carry out different redaction actions depending on the operation

- operation-switch:
  version: 1.0.0
  title: clear_region_and_set_body
  case:
    - operations:
      - verb: GET
        path: /account_details
      execute:
        - redact:
            title: remove secret field
            actions:
              - action: remove
                from: all
                path: /document/user/secret
    - operations:
      - verb: GET
        path: /account_status
      execute:
        - redact:
            title: redact address
            actions:
              - action: redact
                from: response
                path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

Example that defines match operation with `operationIDs`:

```
# match on operationIDs

- operation-switch:
  title: customer_actions
  case:
    - operations:
      - getCustomerByName
      - deleteCustomer
      - addACustomer
      execute:
           .
           .
           .
```

oauth

Use the oauth policy to policy to perform OAuth processing based on defined OAuth provider settings.

Gateway support

Table 1. Table showing which gateways support this policy, and the

corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see OAuth.

About

The oauth policy has the following format:

```
- oauth:
  version: version
  title: title
  description: description
  oauth-provider-settings-ref:
            .
            .
            .
    references_to_oauth_settings
            .
            .
            .
  supported-oauth-components:
    - oauth_component_1
    - oauth_component_2
            .
            .
            .
```

Note: You add an oauth policy to the OpenAPI source in a native OAuth provider. For more information, see the following topics:

- Editing the native OAuth provider configuration using the API Editor (Cloud Manager UI)
- Editing the native OAuth provider configuration using the API Editor (API Manager UI)

Properties

Table 2. oauth policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A description of the policy.	string
`oauth-provider-settings-ref: default`	Yes	The name of an existing OAuth provider that defines the required settings.	string
`oauth-provider-settings-ref: url`	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings. URL reference takes precedence over any existing literal configuration or object reference.	string
`oauth-provider-settings-ref: literal`	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings. Literal configuration takes precedence over any existing object reference.	string
`supported-oauth-components: - oauth_component_1 - oauth_component_2 . . .`	Yes	Specify the OAuth components that are supported by this policy, as follows: - OAuthValidateRequest Validates the authorization request from the client. - OAuthGenerateAZCode Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource. - OAuthVerifyAZCode Verifies the authorization code from the client. - OAuthVerifyRefreshToken Verifies the refresh token that is presented by the client. - OAuthCollectMetadata Collects metadata about a client for later user interaction - OAuthGenerateAccessToken Generates the access token to the client when the authorization code or refresh token is verified. - OAuthIntrospectToken Introspects the token to determine its state and, when active, its metadata.	string

Overriding default OAuth provider settings

You can use either the `literal` property or the `url` property to dynamically override any OAuth provider configuration settings to dynamically override any OAuth provider configuration settings defined by the `default` property.

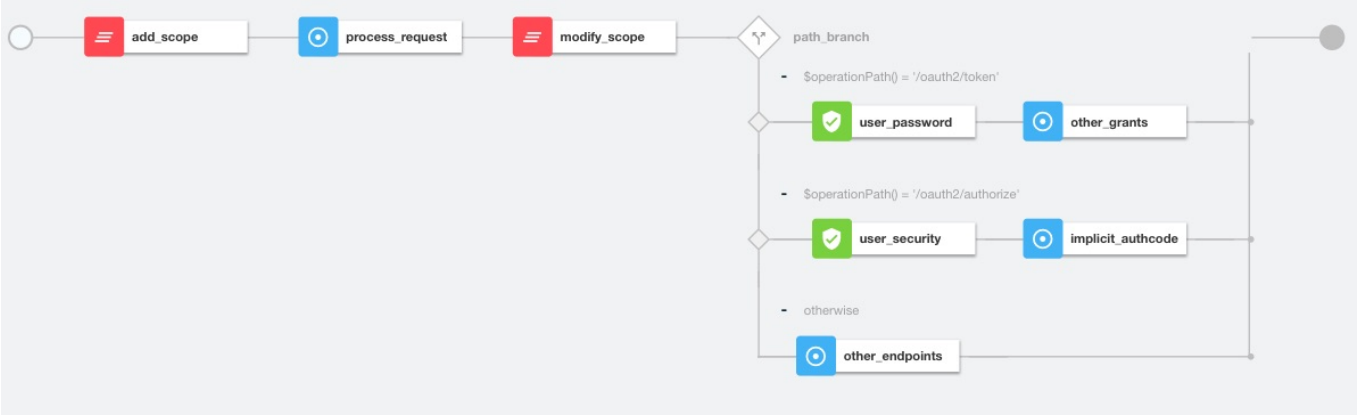
For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the `OAuthProviderSettings` management schema, defined in the xml-mgmt.xsd file located in the store: directory on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

oauth policy example



```
- oauth:
    version: 2.0.0
    title: my-oauth-policy
    oauth-provider-settings-ref:
      default: my-oauth
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthIntrospectToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
```

Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of **gatewayscript** policies that use OAuth context variables to manipulate the OAuth flow. For details on creating a native OAuth provider, see Configuring a native OAuth provider.

It has the following assembly flow:

The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download multiple_oauth_policies.txt.

Sample policy to add a custom scope

The **add_scope** policy is a **gatewayscript** policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: add_scope
    source: |-
      // Add another custom scope to the request
      let scope = context.get("request.parameters.scope.values[0]");
      if (scope)
        context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first **process_request** policy is an **oauth** policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the oauth.processing context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: process_request
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect protocol steps
      that are needed for OAuth Validation by default. The inputs and
      outputs of each of the steps are driven by documented context
      variables. Add or remove the Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthValidateRequest
```

Sample policy to modify the scope

The **modify_scope** policy is a **gatewayscript** policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: modify_scope
    source: |-
      let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

      // Check application and modify the scope
      let app = context.get("oauth.processing.client_id");
      let scope = context.get("oauth.processing.scope");
      if (app === admin_id) {
        context.set("oauth.processing.scope", scope + " admin");
      } else {
        context.set("oauth.processing.scope", scope + " customer");
      }
```

Branch conditionally according to the OAuth path

The **path_branch** policy is a **switch** policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
    version: 2.0.0
    title: path_branch
    case:
      - condition: ($operationPath() = '/oauth2/token')
        execute:
            .
            .
            .
          definition of the user_security and other_grants policies
            .
            .
            .
      - condition: ($operationPath() = '/oauth2/authorize')
        execute:
            .
            .
            .
          definition of the user_password and implicit_authcode policies
            .
            .
            .
      - otherwise:
            .
            .
            .
          definition of the other_endpoints policy
            .
            .
            .
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The **user_password** policy for password grant type processes the user name and password from the **x-www-form-urlencoded** body. The authentication method is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **other_grants** policy is an **oauth** policy that enables the **OAuthGenerateAccessToken**, **OAuthVerifyAZCode**, **OAuthVerifyRefreshToken**, and **OAuthCollectMetadata** components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_password
    version: 2.0.0
    description: ''
    factor-id: default
    extract-identity-method: context-var
    user-context-var: request.parameters.username.values
    pass-context-var: request.parameters.password.values
    ei-stop-on-error: false
    user-auth-method: auth-url
    au-stop-on-error: false
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
- oauth:
    title: other_grants
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for token path by default.
```

```
      The inputs and outputs of each of the steps are driven by
      documented context variables. Add or remove the Supported
      OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAccessToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
      - OAuthCollectMetadata
```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The **user_security** policy configuration is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **implicit_authcode** policy is an **oauth** policy that enables the **OAuthGenerateAZCode**, **OAuthGenerateAccessToken**, and **OAuthCollectMetadata** components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_security
    version: 2.0.0
    description: >-
      This user security policy performs EI(basic) and AU(auth
      url) check for oauth assembly. Change the security check
      method as required
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: auth-url
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
- oauth:
    title: implicit_authcode
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for az code path by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthCollectMetadata
```

Process all other endpoints

The **otherwise** condition catches all other endpoints such as the introspect and revoke endpoints. The **other_endpoints** policy in the **otherwise** condition is an **oauth** policy that enables the **OAuthIntrospectToken**, and **OAuthRevokeTokencomponents** components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: other_endpoints
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for all other paths by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthIntrospectToken
      - OAuthRevokeToken
```

API Gateway only

openai-invoke

Use the OpenAI invoke policy to invoke OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see openai invoke.

About

The OpenAI invoke policy provides access to four OpenAI operations:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OpenAI invoke policy properties

Property name	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is `OpenAI` invoke chat completions.	string
description	No	A description of the policy.	string
operation	Yes	The OpenAI operation to invoke; must be one of the following operations: • `POST /chat/completions` An HTTP POST operation for `/chat/completions`. See Create chat completion in the OpenAI documentation for sample request and response examples. • `POST embeddings` An HTTP POST operation for `/embeddings`. See Create embeddings in the OpenAI documentation for sample request and response examples. • `GET models` An HTTP GET operation for `/models`. See List Models in the OpenAI documentation for sample response examples. • `GET models/[model]` An HTTP GET operation for `/models/[model]`. See Retrieve model in the OpenAI documentation for sample response examples.	string
api_key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate OpenAI requests.	string
organization_id	No	An optional property where you can specify the organization identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy request specifying this property will count as usage by the organization specified.	string
project_id	No	An optional property where you can specify the project identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy request specifying this property will count as usage by the project specified.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into theDataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean

Property name	Required	Description	Data type
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
path_params	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation `GET models/[model]`, the path parameter property would be specified as `model:somename`. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
query_params	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
output	No	The name of the DataPower API Gateway context message that receives the OpenAI response. By default, this property uses `message` as the value, which enables the response to be accessible by subsequent API policies in `message.body` and `message.headers`.	string

Example

```
openai-invoke:
                    title: OpenAI invoke chat completions
                    enable_cache: true
                    version: 2.0.0
                    api_key: $(openai-apikey)
                    cache_ttl: 60
                    operation: POST chat/completions
                    output: message
                    description: description goes here
                    project_id: openai project id
                    cache_scope: cachescopevalue
                    organization_id: openai organization id
```

API Gateway only

Azure openai-invoke

Use the Azure OpenAI invoke policy to invoke Azure OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Azure openai invoke.

About

The Azure OpenAI invoke policy provides access to four Azure OpenAI operations:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Azure OpenAI invoke policy properties

Property name	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is Azure OpenAI invoke chat completions.	string
description	No	A description of the policy.	string

Property name	Required	Description	Data type
operation	Yes	The Azure OpenAI operation to invoke; must be one of the following operations: • **`POST /chat/completions`** An HTTP POST operation for **`/chat/completions`**. See Create chat completion in the Azure OpenAI documentation for sample request and response examples. • **`POST embeddings`** An HTTP POST operation for **`/embeddings`**. See Create embeddings in the Azure OpenAI documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the OpenAI documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the Azure OpenAI documentation for sample response examples.	string
api_key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Azure OpenAI requests.	string
deployment_id	Yes	Name of project/deployment in Azure where model is deployed.	string
resource_id	Yes	Serves as part of endpoint of URL that points to your provisioned resources.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into theDataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
op-version	No	The operation version specifies the version of the OpenAI operation (such as completions, chat/completions, embeddings) that the policy applies to. It is defined using YYYY-MM-DD format.	
path_params	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
query_params	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
output	No	The name of the DataPower API Gateway context message that receives the OpenAI response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Example

```
azure-openai-invoke:
          title: Azure-OpenAI invoke policy
          description: Azure-OpenAI invoke policy desc
          api_key: keyvalue
          deployment_id: $(dep-id)
          resource_id: $(res-id)
          operation: POST chat/completions
          op-version: $(azure-op-version)
          path_params:
          enable_cache: true
          cache_ttl: 60
          cache_scope: azureScope
          output: request
          version: 2.0.0
```

parse

Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the

corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later) 2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Parse.

About parse

The parse policy has the following format:

```
- parse:
  version: version
  title: title
  description: description
  use-content-type: request_header_usage_setting
  parse-settings-reference:
            .
            .
            .
    references_to_parse_settings
            .
            .
            .
  input: input_message
  output: output_message
```

Properties

Table 2. parse policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
use-content-type	No	If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the **Content-Type** specified in the request headers. If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the **Content-Type** specified in the request headers and fails if the **Content-Type** in the request headers does not match the parse setting. Enabling this setting is applicable only when the expected **Content-Type** is either JSON or XML. If this setting is not enabled, the parse operation uses either the document type specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type. The default value is **false**.	boolean
parse-settings-reference: default	No	An existing valid object from which to retrieve default property values for the dynamic object.	string

Property	Required	Description	Data type

document_type	No	The type of document to parse. Specify one of the following values:
		
		• **detect**: the document type is detected and the payload is parsed accordingly. This type is the default option.
		• **JSON**: the payload is parsed as JSON.
		• **XML**: the payload is parsed as XML.
		• **graphql**: parsing is performed in one of the following ways:
		  ◦ As GraphQL in the body of a POST request. The GraphQL is in the following format:
		
		`{ me { name } }`
		
		  ◦ As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format:
		
		`{ "query": "query MyData ($idVar: Int!) { user (id: $idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} }`
		
		  ◦ Through the URL query of a GET request. The URL is in the following format:
		
		`https://myapi/graphql?query={me{name}}`
		
		The following example includes the **variables** and **operationName** properties, with URL encoding:
		
		`https://hostname/basepath/graphql?query=query%20fetchAccounts%20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}}&variables={"limit":100}&operationName=fetchAccounts`
		
		Query variables in a GET request can be sent as a JSON string in a query parameter called **variables**. If the query contains several named operations, an **operationName** query parameter is required to determine which operation is to be executed.
			string

max_doc_size	No	Optionally, the maximum document size in bytes that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. This setting is applicable to JSON, XML, or GraphQL input documents. The default value is 4194304.	integer
max_nesting_depth	No	Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message. • When XML, it is the maximum level of element depth. • When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. • When GraphQL, it is the maximum level of nested selection sets. Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth. The default value is 512.	integer
max_width	No	Optionally, the maximum width of the payload that the parse operation accepts. • When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. • When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. • When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document. The default value is 4096.	integer
max_name_length	No	Optionally, the maximum name length in bytes in a document that the parse operation accepts. • For XML, it is the length of the name portion of a tag. • For JSON, it is the length of the label portion of the JSON label-value pair. • For GraphQL, it is the maximum length of the identifiers, including field names and directive names. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document. The default value is 256.	integer

Property	Required	Description	Data type
max_value_length	No	Optionally, the maximum value length in bytes in a document that the parse operation accepts. • For XML, it is the length of an attribute or the length of a text value. • For JSON and GraphQL, it is the length of a string value. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document. The default value is 8192.	integer
max_unique_names	No	Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts. • For XML, it is the number of unique XML local names. • For JSON, it is the number of unique JSON labels. Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document. The default value is 1024.	integer
max_unique_prefixes	No	Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document. The default value is 1024.	integer
max_unique_namespaces	No	Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document. The default value is 1024.	integer
max_number_length	No	Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document. The default value is 128.	integer
strict-utf8-encoding	No	For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document. • When **`on`**, the entire document is checked for valid UTF-8 encoding. • When **`off`**, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. The default value is **`off`**.	boolean
`parse-settings-reference: literal`	No	A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.	string
`parse-settings-reference: url`	No	A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.	string
input	No	The name of a variable in the API context. The content of the **`body`** field of the variable is the input to the policy. The default variable name is **`message`**.	string
output	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

parse policy example

```
- parse:
    version: 2.0.0
    title: my-parse-policy
    use-content-type: true
    parse-settings-reference:
      default: my-parse
    input: input-message
    output: output-message
```

parse-settings-reference: literal example

In XML:

```
- parse:
    version: 2.0.0
```

```
    title: parse
    parse-settings-reference:
    default: apic-default-parsesettings
    literal: <ParseSettings><DocumentType>xml</DocumentType></ParseSettings>
```

In JSON:

```
- parse:
    version: 2.0.0
    title: parse
    parse-settings-reference:
    default: apic-default-parsesettings
    literal: { \"ParseSettings\" : { \"propertyName\" : propertyValue } }
```

proxy

Apply the proxy policy to proxy another API within your operation, particularly if you need to call a large payload.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Proxy.

About

Keep the following considerations in mind regarding the proxy policy.

- Only one proxy policy is permitted to be called per assembly.
- More than one proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.
- You can use the proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, proxy must be the final policy in the assembly, otherwise the response that is received is manipulated causing the multipart form data to be lost.
- The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the invoke policy rather than the proxy policy.
- The Proxy policy does not currently attempt to rewrite a Location header that is returned from the back end.

The proxy policy has the following structure:

```
- proxy:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  http-version: HTTP_version
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
  password: password_if_authentication_required
  output: location_of_the_proxy_result
  cache-key: unique_identifier_of_the_document_cache_entry
  cache-response: cache_behavior
  cache-putpost-response: response_caching_behavior
  cache-ttl: cache_time_to_live
  stop-on-error: errors_that_stop_the_flow
```

Properties

The table describes the properties of the proxy policy.

Table 2. Proxy policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
target-url	Yes	The URL of the target API.	string
tls-profile	No	The TLS profile to be used.	string

Property	Required	Description	Data type
verb	No	The operation method type. Valid values: • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **`Keep`**.	string
http-version	No	The HTTP version. The default value is **`1.1`**.	string
timeout	No	The timeout value in seconds. The default value is **`60`**.	integer
compression	No	Specifies whether data is to be compressed by using gzip before it is uploaded. The default value is **`false`**.	boolean
username	No	The user name, if authentication is required.	string
password	No	The password, if authentication is required.	string
output	No	Specifies the location of the proxy result. By default, the proxy result, that is the body, headers, statusCode and statusMessage, is saved in the variable **`context.message`**. The assembly developers can specify an additional location to store the proxy result with the output property.	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
cache-response	No	The cache response type. Valid values: • protocol: The cache behavior is defined by the Cache-Control headers on the request and response. • no-cache: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. • time-to-live: Specifies that the response stays in the cache for the specified time. The default value is **`protocol`**.	string
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is **`false`**.	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to **`time-to-live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**. Note: When users sign in by using the Toolkit login path (a URL that includes **`?from=TOOLKIT`**), the generated API key has a fixed time-to-live (TTL) of 5 minutes.	integer
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a **`catch`** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

API Gateway only

ratelimit

Use the ratelimit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.5.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Rate Limit.

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a ratelimit policy is placed before an invoke policy, and the call made by the invoke policy exceeds the limits defined by the ratelimit policy, the API call itself fails.

The ratelimit policy has the following format:

```
- ratelimit:
    version: version
```

```
    title: title
    description: description
    source: rate_and_burst_limit_location
    rate-limit: rate_limits_to_apply
    burst-limit: burst_limits_to_apply
```

Properties

The following table describes the properties of the ratelimit policy.

Table 2. ratelimit policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Specify one of the following values: • **`catalog-named`**: the rate or burst limits to be applied are defined in the appropriate **`api-collection`** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the **`api-collection`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • **`plan-named`**: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a **`plan-named`** rate limit policy: ◦ Every Plan that contains the API that is being limited must have the named rate limit applied. ◦ A **`plan-named`** rate limit policy cannot be used with automatically generated Products. • **`gateway-named`**: the limits to be applied are defined in the **`apigw`** object, named **`apiconnect`**, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the **`apigw`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • **`plan-default`**: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies.	string
rate-limit	Yes[1]	If the **`source`** property is set to **`catalog-named`**, a list of rate limit names as defined in the DataPower API Gateway configuration, [1]You must provide at least one rate, burst, or count limit.	string
burst-limit	Yes[2]	If the **`source`** property is set to **`catalog-named`**, a list of a burst limit names as defined in the DataPower API Gateway configuration. If **`source`** is set to **`plan-named`**, a list of names of assembly burst limits defined in a Plan. [2]You must provide at least one rate, burst, or count limit.	string
count-limit	Yes[3]	If **`source`** property is set to **`catalog-named`**, a list of count limit names as defined in the DataPower API Gateway configuration. If **`source`** is set to **`plan-named`**, a list of names of assembly count limits defined in a Plan. [3]You must provide at least one rate, burst, or count limit..	string

Property	Required	Description	Data type
operation	No	For a rate limit, specify one of the following values: • **consume**: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified by the **rate-limit** property. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. • **replenish**: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified by the **rate-limit** property. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55. Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1. The default value is **consume**. For a count limit, specify one of the following values: • **inc**: the current count is incremented by the value that results from the weight expression defined in the count limit specified by the **count-limit** property. • **dec**: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the **count-limit** field. By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway. The default value is **inc**. For a burst limit, the only possible value is **consume**, meaning that the limit applied is that defined in the burst limit specified by the **burst-limit** field.	string

Example

```
- ratelimit:
    version: 2.0.0
    title: Apply rate and burst limits
    source: catalog-named
    rate-limit:
      - 30perMinute
      - 2000per3Hours
    burst-limit:
      - 5per10Seconds
```

API Gateway only

ratelimitinfo

Use the ratelimitinfo policy to return information about rate limits, burst limits, and count limits. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Rate Limit Info.

About

The Rate Limit Info policy returns information about the rate limits, burst limits, and count limits that are applied to the API.

The ratelimitinfo policy has the following format:

```
- ratelimitinfo:
    version: version
    title: title
    description: description
    input: input_context
    output: output_location
```

Properties

The following table describes the properties of the ratelimitinfo policy.

Table 2. ratelimitinfo policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
input	No	The input context that specifies what rate limit information is requested.	string
output	No	The destination of rate limit information.	string

API Gateway

redact - DataPower API Gateway

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see redact - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Redaction - DataPower API Gateway.

About

The redact policy has the following format:

```
- redact:
    version: version
    title: title
    description: description
    redactions:
      - action: remove_or_redact
        path: JSONata_expression_for_field_to_remove_or_redact
                .
                .
                .
    root: content_source
```

Note: With the DataPower API Gateway, the input to the redact policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a redact policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the properties of the redact policy.

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

Property	Required	Description	Data type
root	No	Specifies the data source that contains the content to which the redact or remove action applies. If the root property is omitted, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of `message.body`. The actual content to which the action is applied then depends on the positioning of the redact policy in the overall assembly flow; for example: • If positioned at the beginning, the action is applied to the client request. • If positioned after an invoke policy, the action is applied to the response from the back end. • If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the redact policy is used after a log policy that specifies **`gather-only`** for the mode property, specify a root value of **`log.request_body`** for the logged request payload, or **`log.response_body`** for the logged response payload.	string
path	Yes	Specifies a JSONata path expression that identifies the fields to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
action	Yes	Specifies whether you want to remove or redact the content. Supply one of the following values: • **`remove`**: Completely removes the specified fields. • **`redact`**: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is **`redact`**. Note: If a numerical value is being redacted, the redacted value is depicted as **`******`** and the type is changed to **`string`**.	string

Example

```
# Specify separate remove and redact actions

- redact:
    version: 2.0.0
    title: remove price, redact author
    redactions:
      - action: remove
        path: xpath($, ''//price'')"
      - action: redact
        path: $.**.author"
    root: message.body
```

DataPower Gateway (v5 compatible)

redact - DataPower Gateway (v5 compatible)

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see redact - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Redaction - DataPower Gateway (v5 compatible).

About

The redaction policy has the following format:

```
- redact:
  version: version
  title: title
  description: description
  actions:
    - action: remove_or_redact
      from:
        - where_the_redaction_is_to_be_applied
      path: XPath_expression_for_field_to_remove_or_redact
```

```
                    .
                    .
                    .
          further action/from/path combinations
                    .
                    .
                    .
```

You can specify as many **action**/**from**/**path** combinations as you want.

Properties

The following table describes the policy properties:

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
action	No	Specifies whether you want to remove or redact the fields. Valid values: • **remove**: Completely removes the specified fields. • **redact**: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is **redact**. Note: If a numerical value is being redacted, the redacted value is depicted as ****** and the type is changed to **string**.	string
from	No	Determines where the redaction is to be applied. Valid values: • **all**: Apply the redaction to the request body, the response body, and the activity logs. • **request**: Apply the redaction to the request body only. • **response**: Apply the redaction to the response body only. • **logs**: Apply the redaction to the activity logs only. You can supply one or more values. The default value is **all**.	string
path	Yes	Specifies an XPath expression that defines the fields to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields.	string

Example

```
# Specify separate remove and redact actions

- redact:
  version: 1.0.0
  title: remove secret field, redact address
  actions:
    - action: remove
      from:
        - all
      path: /document/user/secret
    - action: redact
      from:
        - request
        - response
      path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

set-variable

Use the set-variable policy to set the value of a runtime variable, or to add or clear a runtime variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Set Variable.

About

The set-variable policy has the following format:

```
- set-variable:
  version: version
  title: title
  description: description
  actions:
    - action_type: variable_name
      value: value
      type: data_type
```

Properties

Table 2. set-variable policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
actions	Yes	Lists the actions to be performed by the set-variable policy.	array
set	Yes[1]	For setting a variable. specifies the name of the variable that you want to set. [1]One of the properties set, add, or clear is required.	string
add	Yes[2]	For adding a variable. specifies the name of the variable that you want to add. [2]One of the properties set, add, or clear is required.	string
clear	Yes[3]	For clearing a variable. specifies the name of the variable that you want to clear. [3]One of the properties set, add, or clear is required.	string
value	Yes[4]	Allocates this value to the specified variable. Can be a literal value, or another variable. [4]value is required only when **set** or **add** is specified as the action.	string
API Gateway only type	Yes	Specifies the data type of the variable. Valid values: • **any** • **string** • **number** • **boolean** For all values other than **any**, the value is validated against the specified data type. If the data type is specified as **boolean**, the value property must be set to **true** or **false**.	string

Example 1

```
# clear a variable

set-variable:
  version: 1.0.0
  title: clear_region
  actions:
    - clear: message.headers.region
```

Example 2

```
# set a variable to the value of an API Gateway context variable

set-variable:
  version: 2.0.0
  title: set content type
  actions:
    - set: message.headers.contenttype
      value: $(message.headers.content-type)
      type: string
```

Example 3

```
# add a variable

assembly:
    execute:
      - set-variable:
          version: 2.0.0
          title: set-variable
          actions:
            - value: testing add
              add: message.headers.jja
              type: string
```

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see switch.

About

The switch policy has the following format:

```
- switch:
  version: version
  title: switch
  description: 'Description'
  case:
    - condition: Script_1
      execute:
      Assembly_Section_1
    - condition: Script_2
      execute:
      Assembly_Section_2
    - otherwise:
      Assembly_Section_3
```

The **execute:** section can define any policy assembly, including further switch policies. For more information, see execute.

Properties

Table 2. switch policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
case	Yes	Contains the condition and execute pairs of the switch policy.	string
condition	Yes (one or more)	A script that returns **true** or **false**. API Gateway Use the JSONata expression language to define your condition. See Writing switch condition scripts - DataPower API Gateway DataPower Gateway (v5 compatible) Use GatewayScript to define your condition. See Writing switch condition scripts - DataPower Gateway (v5 compatible).	string
execute	Yes (one per condition)	The policy assembly that you want to execute if the condition returns **true**. For more information, see execute.	string
otherwise	No	The case you want to execute if no other cases are fulfilled. It functions in the same manner as an execute property. For more information, see execute.	string

For examples, see one or other of the following topics, depending on which gateway type you are using:

- Writing switch condition scripts - DataPower API Gateway
- Writing switch condition scripts - DataPower Gateway (v5 compatible)

API Gateway only

Writing switch condition scripts - DataPower API Gateway

You write condition scripts for the switch policy in the DataPower® API Gateway by using the JSONata expression language.

The payload of the message must be parsed before you can use JSONata in a switch policy condition. Therefore, a parse policy must precede the switch policy. You can then use a JSONata condition on the parsed content that is stored in the **body** field of the output variable. The default variable is **message**. For example, if the output variable is **message**, you can use the JSONata condition **$exists(message.body.username)** on the parsed content.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - **$eval()**

    - `$sift()`
    - `$each()`
    - `$error()`
    - `$assert()`
- `$fromMillis()` is supported with the following restrictions:
    - The `$fromMillis()` parameter supports numbers in the range -5364662400000 - 2903299199000.
        - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
        - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- `$now()` is supported with the following restrictions:
    - The following component specifiers are not supported:
        - `W` = Week in year
        - `w` = Week in month
        - `X` = ISO week-numbering year
        - `x` = ISO week-numbering month
    - Representing numbers as words are not supported, so the following presentation modifiers are not supported:
        - `W` = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
        - `w` = Lowercase word (for example: [Yw] => two thousand and twenty-four)
        - `Ww` = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
    - Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description

`$apiCtx()`	Generic access to an API context	The `$apiCtx()` extension gives generic access to an API context.
		• Sample transform field in an extract action:
		`"$apiCtx().request.uri"`
		• Sample condition of a case in a switch action:
		`"$apiCtx().request.path = '/simple/apictx-function'"`

`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation
`$queryParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keyword is `query`. • `request.parameters.`*`name`*`.values`	Searches for the index of `query` in `request.parameters.`*`name`*`.locations` and returns `request.parameters.`*`name`*`.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*`variable`*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

`$urlParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keywords are `path` and `query`
	• `request.parameters.`*`name`*`.values`
		Searches for the index of `path` and `query` in `request.parameters.`*`name`*`.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.`*`name`*`.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values.
		`http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese`
		The `$urlParameter('breed')` URL returns the following array of values.
		`[cats, adopt, Sphynx, Siamese]`
		In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.

`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.

Extension	Variable	Description
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- *`operationName`*
  For an anonymous operation, *`operationName`* can be empty.

- *`~fragmentSpreadName`*
- *`on~typeCondition`*
- *`~~fragmentDefinitionName`*

Simple condition statements

The following examples show conditions that use a single function.

This example uses the `$httpVerb()` extension to specify the HTTP method of the request.

```
$httpVerb()="GET"
```

This example uses the `$operationPath()` extension to specify the path of the operation.

```
$operationPath()="/base/path-2"
```

This example uses the `$operationID()` extension to specify the operation ID.

```
$operationID()="test-gatewayscript-GET"
```

This example uses the `$statusCode()` extension to specify the message status code.

```
$statusCode()=200
```

This example uses the `$header(name)` extension to specify the content type of the message header.

```
$header("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use `and` and `or` operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to `test-gatewayscript-GET`.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a `POST` or `PUT` request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to `test-gatewayscript_POST` and a message status code equal to `200`, or an API operation ID equal to `test-gatewayscript-GET` and a message status code equal to `500`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and $statusCode()=500)
```

This example specifies an API operation ID equal to `test-gatewayscript-POST` and a message status code equal to `200` with an API operation path equal to `/base/path-2`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to `text/plain` and a message header length equal to `300`, or a message status code equal to `200`.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

Note: When users sign in by using the Toolkit login path (a URL that includes `?from=TOOLKIT`), the generated API key has a fixed time-to-live (TTL) of 5 minutes.

Example switch policy

```
- switch:
  version: 2.0.0
  title: switch
  case:
    - condition: ($statusCode() = 200)
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/1'
    - condition: ($statusCode() != 200 and ($httpVerb() = 'GET' or $httpVerb() = 'PUT'))
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/2'
    - otherwise:
      - set-variable:
        title: set-variable
        actions:
          - set: message.body
            value: Default result
            description: 'Set the default result for the otherwise case'
```

DataPower Gateway (v5 compatible) only

Writing switch condition scripts - DataPower Gateway (v5 compatible)

You write condition scripts for the `switch` policy in the DataPower® Gateway (v5 compatible) by using GatewayScript.

To reference variables in your `switch` conditions, use the form `apim.getvariable('context.location.variable')`, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

to define a `switch` condition based on the operation called, use one of the following forms:

```
- condition: "((request.verb==='GET')&&(api.operation.path==='/path-1'))"
```

```
- condition: "((api.operation.id=='Operation_ID'))"
```

where the context variables `request.verb` and `api.operation.path` retrieve the HTTP verb and the path segment of the API and operation that you want your case to apply to, while `api.operation.id` retrieves the operation ID of your operation, if one has been specified.
For information about the context variables you can use and how to reference them in your script, see API Connect context variables.

Example switch policy

```
- switch:
  version: 1.0.0
  title: switch
  case:
    - condition: message.status.code===200
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/1'
    - condition: ((request.verb==='GET')&&(api.operation.path==='/path-2'))||((request.verb==='GET')&&
(api.operation.path==='/path-1'))
      execute:
        - invoke:
```

```
        title: invoke
        timeout: 60
        verb: GET
        cache-response: protocol
        cache-ttl: 900
        target-url: 'https://example.com/2'
    - otherwise:
      - set-variable:
        title: set-variable
        actions:
          - set: message.body
            value: Default result
            description: Set the default result for the otherwise case
```

throw

Use the throw construct to throw an error when it is reached during an assembly flow, usually as a result of a condition being reached.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see throw.

About

The throw policy has the following format:

```
- throw:
   title: title
   name: 'error_name'
   error-status-code: http_status_code_for_error
   error-status-reason: http_reason_phrase_for_error
   message: error_message
```

When the throw policy is encountered, the specified error and error message is returned. If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

Properties

Table 2. throw policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
name	Yes	The name of the error to be thrown.	string
API Gateway only error-status-code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the `$(variable)` format to reference the `message.status.code` API context variable.	integer
API Gateway only error-status-reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the `$(variable)` format to reference the `message.status.reason` API context variable.	string
message	No	The message to accompany the error.	string

Example

```
      - throw:
          version: 1.0.0
          title: throw
          name: '404'
          message: Not found
```

API Gateway only

token-mediation

The token-mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.

Table 1. Gateway support

Gateway	Policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

Note: The token-mediation policy will only work for the DataPower API Gateway. The DataPower firmware version that the API Gateway is running on must be **LTS 10.6.0.0 (or later) or CD firmware release 10.6.3 (or later).**
This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see Token Mediation.

Prerequisites

Before using the token-mediation policy, ensure that distributed variable settings are enabled. Distributed variables allow you to read from or write to DataPower® facilities across transactions or domains. They serve as an alternative to system variables and must be enabled for the registration process to function end-to-end (E2E). For more details, see Configuring settings to manage distributed variables.

About

The token-mediation policy (token-mediation_2.0.0) serves as a mediator for OAuth tokens by caching the token received from an OAuth Token Endpoint and exchanging it for a session cookie, which is sent to the Client Application via a `Set-Cookie` header. Depending on the policy configuration, this session token can be used to (A) retrieve the original token from the cache or (B) instruct the policy to set the HTTP Authorization header for seamless access to resources on the Resource Server.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. token-mediation policy properties

Property label	Required	Description	Data type
`title`	No	The title of the policy.	string
`description`	No	A description of the policy.	string
`cookie- name`	Yes	The name of session cookie returned to the client application.	string
`token-url`	Yes	The URL of the OAuth provider's Token Endpoint.	string
`token-url-tls`	No	The TLS profile used for connecting to the `token-url`. Note: The `token-url-tls` property is optional for this policy but may be required by the Token Endpoint, and it is the responsibility of the policy user to determine its necessity. The policy must match the exact DataPower object name. For TLS profiles created by API Connect, the DataPower object follows this naming convention: `<provider-org>_<catalog>_<tls-profile-name>V<tls-profile-version>`. **Example:** `myorg_mycatalog_my-tls-profile1.0.0`.	string
`auth-url`	Yes	The URL of the OAuth provider's Authorization Endpoint.	string
`output`	No	The output context that receives the Authorization header. Note: The `output` parameter plays a key role in policy behavior. When specified, the policy retrieves the Access Token Response from the cache, extracts the access token (if available), and sets the Authorization header in the designated output message context. If the `output` parameter is not specified, the policy writes the Access Token Response to the `message` context and sets the `Content-Type` header to `application/json`.	string

User-defined policies

You can apply your own user-defined policies to your APIs.

The policy configuration that you add to the OpenAPI definition file must conform to the schema that you defined in the YAML file that describes the policy, and will have the following general format:

```
policy_name:
  property1: value1
  property2: value2
      .
      .
      .
```

For details on user-defined policies, and how to describe and implement them, see Authoring policies.

user-security

Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see User Security.

About

The user-security policy has the following format:

```
- user-security:
  version: version
  title: title
  description: description
  factor-id: factor ID
  extract-identity-method: method_used_to_extract_credentials
        .
        .
        .
     properties_specific_to_the specified_identity_extraction_method
        .
        .
        .
  user-auth-method: authentication_method
        .
        .
        .
     properties_specific_to_the specified_authentication_method
        .
        .
        .
  user-az-method: authorization_method
        .
        .
        .
     properties_specific_to_the specified_authorization_method
        .
        .
        .
```

Properties

Table 2. user-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
factor-id	No	The identity that identifies the results of factor-authentication in the API context.	string
