extract-identity-method	Yes	Select the method that is used to extract the user credentials. The following options are available: basic Use basic authentication; no additional configuration is required. context-var The credentials are provided by API Connect context variables; specify the following properties: • user-context-var: the context variable that is used to obtain the user name. • pass-context-var: the context variable that is used to obtain the password. html-form Use forms based identity-extraction. You can use the default form or a custom form. To use the default form, specify **`ei-default-form: true`**. To use a custom form, specify **`ei-default-form: false`** and supply the following properties: • ei-custom-form: the location of the form. • ei-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. Use the ei-form-time-limit property to specify the time allowed to submit the form. redirect Use a redirect for identity-extraction; specify the following properties: • redirect-url: the URL fragment to which to redirect the request to obtain user credentials. • redirect-time-limit: the time allowed for the transaction to complete. disabled Identity-extraction is disabled; this aspect of processing is skipped. Specify **`ei-stop-on-error: true`** to halt assembly processing in the event of identity-extraction failure. This field is required if identity extraction is not disabled.	string

Property	Required	Description	Data type
user-auth-method	Yes	Select the authentication method. The following options are available: auth-url The credentials are authenticated by an external endpoint; specify the following properties: • auth-url: the URL of the authentication endpoint. • auth-tls-client-profile: the TLS client profile that is used to secure the connection to the authentication endpoint. • auth-response-headers-pattern: the pattern that is used to select which response headers to add to the API context. • auth-response-header-credential: the response header that contains the authenticated user credentials. ldap The credentials are authenticated by an LDAP user registry; use the ldap-registry property to specify the required registry. disabled Authentication is disabled; this aspect of processing is skipped. Specify **`au-stop-on-error: true`** to halt assembly processing in the event of user authentication failure. This field is required if authentication is not disabled.	string
user-az-method	Yes	Select the authorization method. The following options are available: authenticated Implicitly accept any previously authenticated users; no additional configuration is required. html-form The user provides authorization through an HTML form. You can use the default form or a custom form. To use the default form, specify **`az-default-form: true`**. To use a custom form, specify **`az-default-form: false`**. Supply the following properties: • az-table-dynamic-entries: the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form. • az-form-time-limit: the time allowed to submit the form. For a custom form, supply the following properties: • az-custom-form: the location of the form. • az-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. disabled Authorization is disabled; this aspect of processing is skipped. Specify **`az-stop-on-error: true`** to halt assembly processing in the event of user authorization failure. This field is required if authorization is not disabled.	string

Example

```
# basic authentication with LDAP registry

- user-security:
    version: 2.0.0
    title: user-security
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: ldap
    ldap-registry: corporate-ldap
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
```

validate - DataPower API Gateway

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see validate - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.4.0 (DataPower API Gateway Version 10.0.4.0 or later) 2.5.0 (DataPower API Gateway Version 10.5.0.0 or later) 2.6.0 (DataPower API Gateway Version 10.5.0.2 or later 2.7.0 (DataPower API Gateway Version 10.5.0.3 or later

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate - DataPower API Gateway.

About

The validate policy has the following format:

```
- validate:
    version: version
    title: title
    description: description
    validate-against: validation_mechanism
          .
          .
          .
       properties_specific_to_the specified_validation_mechanism
          .
          .
          .
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Note: With the DataPower API Gateway, the input to the validate policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
input	No	Identifies a variable in the API context. The content of the **body** field of the variable, which is represented by ***variable_name*.body**, is the input data to validate. By default, the variable name is **message**.	string
output	No	Specifies the name of a variable in the API context. • If the validation passes, the body field of the output variable, which is represented by ***variable_name*.body**, stores the output of the assembly validate action. • If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. • If the validation fails, no output is stored. • If an output variable is not specified, the results of the assembly validate action are not saved.	string

Property	Required	Description	Data type
validate-against	Yes	Specifies the schema to be used for validating the payload. Valid values: • **`definition`**: A previously defined schema will be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. In addition, supply a **`definition`** property to specify the required schema. • **`url`**: the schema is identified by a URL location. In addition, supply the following properties: ◦ **`json-schema`** field: the URL of the JSON schema to be used for validating a JSON payload. ◦ **`xml-validation-mode`**, specify one of the following values to define how an XML payload is validated: ▪ **`xsd`**: use an XML schema; in addition, supply an **`xml-schema`** property that specifies the URL of the XML schema. ▪ **`wsdl`**: use a WSDL schema; in addition, supply an **`xml-schema`** property that specifies the URL of the WSDL schema to be used for validating a SOAP payload.. ▪ **`soap-body`**: validate the body of a SOAP message against the XML schema only. Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported. ▪ Maximum of 6,500 lines. Each key and each item in an array count as a line. ▪ Maximum recursion depth of 250. ▪ Maximum of 3,000 items in **`enum`** lists. • **`wsdl`**: (use with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. • **`body-param`**: validate the request input against the schema definition that is specified in the **`schema`** property for the request parameter for this operation. • **`response-param`**: validate the response to be returned to the client application, against the schema definition that is specified in the **`schema`** property for the response parameter for this operation. • **`graphql`**: (use with a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables. .	string
xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
wsi-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property	Required	Description	Data type
wsdl-validate-body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
wildcards-ignore-xsi-type	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
allow-xop-include	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

You can also apply a validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Validate - DataPower API Gateway in the built-in policies section.

Example 1

```
- validate:
    version: 2.0.0
    title: 'validate, response parameter schema'
    validate-against: response-param
```

Example 2

```
- validate:
    version: 2.0.0
    title: 'validate, predefined schema'
    validate-against: definition
    definition: '#/definitions/RouteOutput'
```

Example 3

```
- validate:
    version: 2.0.0
    title: 'validate, JSON and XML schema URLs'
    validate-against: url
    json-schema: 'https://my.json.schema'
    xml-validation-mode: xsd
    xml-schema: 'https://my.xml.schema'
```

DataPower Gateway (v5 compatible)

validate - DataPower Gateway (v5 compatible)

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see validate - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate - DataPower Gateway (v5 compatible).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the `message.body` variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then `message.body` is not set, and validate is not able to act.
- If you use the `multipleOf` keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
  - The value must not be less than `0.00000099999999999999848869`.
  - If the value is greater than 1, the amount before the decimal point must not be greater than `99999999999999934463`.

About

The validate policy has the following format:

```
- validate:
  version: version
  title: title
  description: description
  definition: swagger_schema_definition_to_be_used
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

Property	Required	Description	Data type
definition	Yes	The schema to be used to validate the payload. Valid values: • **request**: Select this value to validate the request input against the schema definition that is specified in the Type field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. • **response**: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the Schema field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. • The name of a schema definition, in the following format: `#/definitions/schema_name` The schema must be defined in the **definitions:** section of your OpenAPI file.	string

You can also apply an validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Validate - DataPower Gateway (v5 compatible) in the built-in policies section.

Example 1

```
validate:
  version: 1.0.0
  title: validate the response
  definition: #/definitions/RouteOutput
```

validate-usernametoken

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate Username Token.

About

The validate-usernametoken policy has the following format:

```
- validate-usernametoken:
    version: version
    title: title
    description: description
    auth-type: Authentication URL_or_LDAP Registry (policy version 1.0.0 only)
    auth-url: authentication_url_to_use (policy version 1.0.0 only)
    tls-profile: tls_profile_to_use (policy version 1.0.0 only)
    ldap-registry: name_of_the_ldap_user_registry (policy version 1.0.0 only)
    registry: name_of_the_ldap_or_authurl_user_registry (policy version 1.1.0 and later)
    ldap-search-attribute: name_of_the_ldap_user_password_attribute
```

Properties

The following table describes the policy properties:

Table 2. Validate Username Token policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
auth-type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: • **Authentication URL**: Specify this value to validate the user credentials against an authentication URL. • **LDAP registry**: Specify this value to validate the user credentials against an LDAP user registry. The default value is: **Authentication URL**.	string

Property	Required	Description	Data type
auth-url (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to `Authentication URL`.	string
tls-profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to `Authentication URL`.	string
ldap-registry (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to `LDAP registry`.	string
registry (policy version 1.1.0 and later)	Yes	The name of the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
ldap-search-attribute	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "LDAP Registry"
    ldap-registry: "wstest"
    ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "Authentication URL"
    auth-url: "https://www.google.com"
    tls-profile: "default-ssl-profile"
```

For more information about how to use a validate-usernametoken security policy, see Validate Username Token in the built-in policies section.

API Gateway only

watsonx-ai-invoke

Use the watsonx.ai invoke policy to invoke watsonx.ai operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see watsonx.ai invoke.

About

The watsonx.ai invoke policy provides access to three watsonx.ai operations:

- `POST /text-generate`
- `POST /tokenize`
- `GET /deployment-models`

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. watsonx.ai invoke policy properties

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is `watsonx-ai-invoke text generation`.	string
description	No	A description of the policy.	string

Property label	Required	Description	Data type
operation	Yes	The watsonx.ai operation to invoke; must be one of the following operations: • **`POST text-generate`** An HTTP POST operation for **`/text-generate`**. See Infer text in the watsonx.ai documentation for sample request and response examples. • **`POST tokenize`** An HTTP POST operation for **`/tokenize`**. See Text tokenization in the watsonx.ai documentation for sample request and response examples. • **`GET deployment-models`** An HTTP GET operation for **`/deployment-models`**. See List the available foundation models in the watsonx.ai documentation for sample response examples. If the request payload contains a **`project_id`** property, it is ignored and the policy's own **`project_id`** property is used.	string
op-version	Yes	The watsonx.ai API operation version, using the format **`yyyy-mm-dd`**. To see the available version dates, refer to Active Version Dates in the watsonx.ai API documentation. For information on API versioning in watsonx.ai, see Versioning in the same documentation.	string
project_id	Yes	The ID of the watsonx.ai project used for resolving API requests.	string
region	Yes	The IBM Cloud region where watsonx.ai requests are sent.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the watsonx.ai service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the watsonx.ai service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
output	No	The name of the DataPower API Gateway context message that receives the watsonx.ai response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`**.	string

Example

```
- watsonx-ai-invoke:
    version: 2.0.0
    title: watsonx-ai-invoke text generation
    description: get an AI response to the provided prompt
    region: us-south
    operation: POST text-generate
    op-version: '2024-03-14'
    enable_cache: true
    cache_ttl: 60
    project_id: $(watsonx-ai-projectid)
    output: watsonxaiResponse
    cache_scope: somesaltkey
```

websocket-upgrade

Use the websocket-upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Websocket Upgrade.

The websocket-upgrade policy has the following format:

```
- websocket-upgrade:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
```

```
timeout: timeout_value_in_seconds
follow-redirects: redirect_behavior_on_301_error
username: username_if_authentication_required
password: password_if_authentication_required
inject-proxy-headers: are_proxy_headers_sent_to_target_url
decode-request-params: are_request_parameters_decoded
encode-plus-char: are_plus_characters_encoded
header-control:
      .
      .
      .
  headers_to_copy_to_target_url
      .
      .
      .
parameter-control:
      .
      .
      .
  parameters_to_copy_to_target_url
      .
      .
      .
```

Properties

Table 2. websocket-upgrade policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
target-url	Yes	Specify the URL to be invoked.	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
follow-redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **301 Moved Permanently**. If this property is set to **true**, the **invoke** policy follows the URL redirection by making a further call to the URL specified in the **Location** header in the response. If this property is set to **false**, the **invoke** saves the **301** status code and the API call is considered to be complete. Note: The **follow-redirect** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **invoke** always follows the URL redirection; the **proxy** policy (not supported by the DataPower API Gateway) saves the **301** status code and completes the API call without following the URL redirection.	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
inject-proxy-headers	No	When set to true, the **invoke** policy injects the **X-Forwarded-For**, **X-Forwarded-To**, **X-Forwarded-Host**, and **X-Forwarded-Proto** headers to the request that is sent to the t**target-url**. The default value is **false**.	boolean
decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the **target-url** of the invoke policy are URL-decoded. The default value is **false**.	boolean
encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the **target-url** are encoded to %2F. The default value is **false**.	boolean
header-control: **type** **values**	No	Specifies the headers in **message.headers** that you want to copy to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the headers that you don't want to be copied. If the **values** property is empty then all headers are copied. If the **type** property is set to **allowlist**, the **values** property lists the headers that you want to be copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **header-control** property is **header-control:** **type: blocklist** **values: []** See header-control examples	object
parameter-control: **type** **values**	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the parameters that you don't want to be copied. If the **type** property is set to **allowlist**, the **values** property lists the parameters that you want to be copied. If the **values** property is empty then no parameters are copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **parameter-control** property is **parameter-control:** **type: allowlist** **values: []** See parameter-control examples	object

Property	Required	Description	Data type

`request-assembly:`
`  execute`
`  .`
`  .`
`  .`
`  policy assembly`
`  .`
`  .`
`  .`
	No	The request processing assembly. For details on configuring an assembly in the **execute** section, see execute.	object

`response-assembly:`
`  execute`
`  .`
`  .`
`  .`
`  policy assembly`
`  .`
`  .`
`  .`
	No	The response processing assembly. For details on configuring an assembly in the **execute** section, see execute.	object

Example

```
- websocket-upgrade:
  version: 2.0.0
  title: websocket-upgrade
  timeout: 60
  target-url: 'https://my.websocket.upgrade.com'
  secure-gateway: false
  follow-redirects: true
  inject-proxy-headers: true
  decode-request-params: false
  encode-plus-char: true
  response-assembly:
    execute:
      - parse:
          version: 2.0.0
          title: parse
          parse-settings-reference:
            default: apic-default-parsesettings
          description: Parse the response from the backend server
```

`header-control` examples

```
# copy all headers to the target URL

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^X-Client-ID$
        - ^Content-Type$

# copy no headers

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values: []

# copy only the Content-Type header

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^Content-Type$
```

`parameter-control` examples

```
# copy no request parameters to the target URL

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values: []
```

```
# append the petid parameter to the target URL
# if the incoming request is http://apigw/org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values:
        - ^petid$
```

xml-to-json

Use the xml-to-json policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see XML to JSON.

About

The xml-to-json policy has the following structure:

```
- xml-to-json:
   version: version
   title: Title
   description: Description
```

Note: If you are using the DataPower API Gateway, the input to the xml-to-json policy must be parsed data. One way to produce parsed data is to use a **parse** policy before an xml-to-json policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
API Gateway only input	No	The input message to convert. Specify the name of a variable in the API context. ***variableName*.body**, the message payload, represents the JSON input to convert. The default value of the variable is **message** and **message.body** is the default input.	string
API Gateway only output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***variableName*.body** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **message.body**. Otherwise, when the input message is the variable **my-message-variable**, for example, the default output is **my-message-variable.body**. The variable cannot be any read-only in the API context.	string
API Gateway only conversionType	No	The conversion type that determines the target format of the output. The following options are available: • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. • apicv5: apicv5 convention is used to determine the target conversion format of the output.	string

Example

The following is an example of a xml-to-json policy:

```
- xml-to-json:
   version: 1.0.0
   title: XML to JSON transform
   description: Transforms XML message body to JSON format
```

xslt

Use the xslt policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see XSLT.

About

The xslt policy has the following structure:

```
- xslt:
    version: version
    title: Title
    description: Description
    input: Input_True_False
    source: Transform
```

Note: If you are using the DataPower API Gateway, the input to the xslt policy must be parsed data. One way to produce parsed data is to use a **parse** policy before an xslt policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. xslt policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The default value is **false**.	boolean
API Gateway only serialize-output	No	If set to **true**, the output tree that is generated by the XSLT policy is serialized. The content of **message.body** is updated with the serialized binary data rather than the XML tree. The default value is **false**.	boolean
source	Yes	The XSLT transform source to execute.	string
API Gateway only xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
API Gateway only strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
API Gateway only profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
API Gateway only debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
API Gateway only stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
API Gateway only try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
API Gateway only minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
API Gateway only stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
API Gateway only wsi-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property	Required	Description	Data type
API Gateway only wsdl-validate-body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-validate-headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
API Gateway only allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
API Gateway only validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
API Gateway only wildcards-ignore-xsi-type	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
API Gateway only wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
API Gateway only xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
API Gateway only allow-xop-include	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

You can also apply an xslt policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see XSLT in the built-in policies section.

For examples of the OpenAPI definitions of xslt policies, see XSLT policy examples in the built-in policies section.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

catch

Use the catch extension to catch errors that occur during an API call.

The catch extension takes the following form:

```
catch:
   - errors:
      - Error_1
      - Error_2
   - execute:
      assembly_1
   - errors:
      - Error_3
   - execute:
      assembly_2
   - default:
      assembly_3
```

The following table shows the properties of the **catch** extension:

Table 1. The properties of the catch extension

Property	Required	Description	Type
errors	Yes	The errors for which the catch will activate. For a list of errors, see Error cases supported by assembly catches.	Array (String)
execute	Yes	The section of the assembly that will execute when the catch is activated.	Array (Object)
default	No	The section of the assembly that will execute when an error does not trigger other catches. It behaves in the same manner and has the same structure as **execute**	Array (Object)

The following is an example of a **catch** extension:

```
    catch:
      - errors:
          - ConnectionError
          - JavaScriptError
        execute:
          - activity-log:
              title: activity-log
              content: activity
              error-content: payload
      - default:
          - activity-log:
              title: activity-log
              content: activity
              error-content: payload
```

properties

Use the **properties** extension to define properties for referencing in an API.

The **properties** extension has the following structure:

```
properties:
   property_1:
      value: default_value_1
      description: description_1
      encoded: encoded_boolean_1
   property_2
      value: default_value_2
      description: description_2
      encoded: encoded_boolean_2
```

The following table lists the fields found in the **properties** extension:

Table 1. The properties extension

Property	Required	Description	Data type
property	Yes	The name of the property. It is used when referencing the property. Note that this is the field name, not the contents of the field.	Object
value	No	The default value that the property takes. It can be empty.	String
description	No	The description of the property. It can be empty.	String

Property	Required	Description	Data type
`encoded`	No	Specifies whether to encode the value of this property.	Boolean

The following example shows a sample `properties` field:

```
properties:
  ID:
    value: 1234
    description: An ID to be used for validating.
    encoded: false
```

catalogs

Use the `catalogs` extension to assign catalog-specific values to properties defined in the `properties` section.

The `catalogs` section has the following structure:

```
catalogs:
   catalog_name_1:
      properties:
         property_name_1: value_1
         property_name_2: value_2
   catalog_name_2:
      properties:
         property_name_1: value_3
```

The following table lists the fields found in the `catalogs` extension:

Table 1. Catalogs properties

Property	Required	Description	Data type
`catalog_name`	Yes	The name of the catalog. It must match a catalog in API Manager. Note that this is the field name, not the contents of the field.	Object
`properties`	Yes	This field contains any properties that are to be set.	Object
`property_name`	Yes	The field name is the property to be set and must match a property defined in the `properties` extension. It contains the value of the property for the catalog to which the field belongs. If, in the `properties` extension, it has been specified as encoded, this will be encoded when saved or staged by IBM® API Connect.	String

The following is an example of a `catalogs` extension:

```
catalogs:
  Sandbox:
    properties:
      ID: 5678
```

API Gateway only

activity-log

If you're using the DataPower® API Gateway, you can use the `activity-log` extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is `activity` for when API execution completes successfully, and `payload` for when API execution completes with an error code. When you compose your API definition, you can change the type of content to log in these API event records. For more information about API event records, see API event record field reference.

Note that if you're using the DataPower Gateway (v5 compatible), you can configure your logging preferences by using an `activity-log` policy in your API assembly. For more information, see activity-log.

The `activity-log` extension takes the following form:

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
```

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
buffering: true
```

The following table shows the properties of the `activity-log` extension:

Table 1. The properties of the activity-log extension

Property	Required	Description	Type

Property	Required	Description	Type
`success-content`	No	Defines the type of content to be logged when the operation is successful. Valid values: • `none`: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • `activity`: Logs invocation only (only the resource URI is recorded). • `header`: Logs activity and header. • `payload`: Logs activity, header, and payload (the original request, if any, and the final response). The default value is `activity`.	String
`error-content`	No	Indicates what content to log when an error occurs. Valid values: • `none`: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • `activity`: Logs invocation only (only the resource URI is recorded). • `header`: Logs activity and header. • `payload`: Logs activity, header, and payload (the original request, if any, and the final response). The default value is `payload`.	String
`enabled`	No	Indicates whether activity logging is enabled or disabled.	Boolean

Example 1

Override the default activity logging settings:

```
activity-log:
    success-content: none
    error-content: header
    enabled: true
```

Example 2

Turn off activity logging:

```
activity-log:
    enabled: false
```

finally

The finally extension specifies the final API rule to apply to the API call. This executes policies after the main assembly execution, catch extension, or both have been processed. It ensures that specific actions are performed before the API response is returned.

The finally extension takes the following form:

```
finally:
   - Policy_1
   - Policy_2
```

The following is an example of a `finally` extension:

```
assembly:
    execute:
      - set-variable:
          version: ...
    catch:
      - errors:
          - ConnectionError
        execute:
          - set-variable:
              version: ...
      - default:
          - set-variable:
              version: ...
    finally:
      - Policy_1
      - Policy_2
```

Specifying a gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify which type of gateway the API uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see execute.

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see invoke.

Procedure

1. Edit the API definition YAML file and add the gateway type. For example:
   - DataPower Gateway (v5 compatible):

     ```
     gateway: datapower-gateway
     ```

   - DataPower API Gateway

     ```
     gateway: datapower-api-gateway
     ```

   Note: If your API YAML file includes the `gateway:` property, the `enforced:` property must be set to `true`
2. Ensure that the policies, including policy versions, in your APIs are supported by the gateway type. Review the list of policies on the execute page. If necessary, review the individual policy pages to determine the supported version number.
3. Ensure that any Product that uses this API is configured to use the same gateway type. See Specifying a gateway type for your Product.

Related information

- DataPower API Gateway porting notes

Referring to an extension in an API definition

To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an `extensions` key under `x-ibm-configuration`.

Before you begin

Add the OpenAPI extension to any Catalogs that the API is to be published to, by importing its definition file; for details, see Working with OpenAPI extensions. If the target Catalog does not contain the OpenAPI extension then attempts to publish the API to it will fail.

About this task

The following example shows an extension definition file that defines a bank branch, in YAML format:

```
extension: '1.0.0'

info:
   title: Banking services
   name: banking
   version: 1.0.0
   description: Banking extensions
   contact:
     name: IBM API Connect
     url: https://apiconnect.ibm.com/
     email: myname@ibm.com

properties:
  title: "Branch"
  type: "object"
  properties:
    Branch type:
      type: "string"
      enum:
        - "ATM"
        - "Walk in"
    location:
      type: "object"
      title: "Location"
      properties:
        city:
          type: "string"
          default: "San Francisco"
        state:
```

```
        type: "string"
        default: "CA"
      citystate:
        type: "string"
        description: "This is generated automatically from the previous two fields"
        template: "{{city}}, {{state}}"
        watch:
          city: "location.city"
          state: "location.state"
required:
  - Branch type
```

The following table provides more information on the available fields when creating an API extension.

Table 1. Description of the fields

Field	Description	Required	Default value	Example
`version`	Version number of the extension Note: The `version` field must follow the `version.release.modification` version numbering scheme.	Yes		`1.0.0`
`title`	Title of the extension Note: The `title` and `name` fields must be kept short so that they can be displayed in the API Manager user interface.	Yes		Banking service
`name`	Short name for the extension Note: The `name` field must be a single word and contain only alphanumeric characters, dash, and underscore characters.	Yes		banking
`description`	Short description of the extension	No		Banking extensions
`termsofservice`	Terms of service for the extension	No		Terms_of_Service
`license.name`	Name of the license	No		IBM API Connect
`license.URL`	URL to the license	No		https://apiconnect.ibm.com/
`contact.name`	Name of the contact	No		myname@ibm.com
`contact.URL`	URL for contacting the organization	No		https://www.example.com/support
`contact.email`	Email for contacting the organization	No		support@example.com
`portal`	Whether the extension is visible in the developer portal	No	`true`	`true` or `false`
`gateways`	List of gateways the extension can be used with Note: The `gateways` field is optional, but if included, it must list the types of gateways the extension can be used with.	No		• `datapower-api-gateway` • `datapower-gateway`

`properties`	The custom properties to be included in the OpenAPI extension.	No		The `properties` field can be customized to include any valid OpenAPI properties.
				`properties:`
				`  title: "Branch"`
				`  type: "object"`
				`  properties:`
				`  Branch type:`
				`  type: "string"`
				`  enum:`
				`  - "ATM"`
				`  - "Walk in"`

Procedure

To enable the use of custom extensions in an API definition, complete the following steps:

1. Edit the API definition YAML file and add the reference. For example:

```
x-ibm-configuration:
      .
      .
      .
  extensions:
    banking: 1.0.0
```

2. In your API definition file, add a property whose name must begin with `x-` and references the name of the extension you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file.
   The following example uses the banking extension:

```
      .
      .
      .
x-banking:
  Branch type: ATM
  location:
    city: San Francisco
    state: CA
    citystate: 'San Francisco, CA'
```

Using $ref to reuse code fragments in your OpenAPI files

If you deploy an API to an IBM® API Connect Management server by using the developer toolkit command line, you can use the **$ref** field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the **$ref** field is replaced with the contents of the target file.

Use the following syntax in your source YAML file:

```
$ref: path_to_file_containing_code_fragment
```

Use the following syntax in your source JSON file:

```
{
$ref: path_to_file_containing_code_fragment
}
```

For example:

```
$ref: code_fragments/my_fragment.yaml
```

```
{
  "$ref": "code_fragments/my_fragment.json"
}
```

The replacement of the **$ref** field with the target code fragment occurs when you perform any of the following actions on the API defined by the source API definition file:

- Stage or publish an API to an API Connect Management server by using the **apic publish** command. For more information, see Publishing APIs and applications.
- Validate the API definition YAML file by using the **apic validate** command. For more information, see Validating the YAML or JSON definition of an API or Product.

Important: You cannot insert a $ref field at the root level of your OpenAPI file.

Example 1

A source YAML file contains the following OpenAPI code:

```
swagger: '2.0'
info:
  version: 1.0.0
  title: Branches
  x-ibm-name: Branches
  description: Provides operations relating to BankA branch information.
basePath: /branches
paths:
  /details:
    get:
      responses:
        - $ref: code_fragments/paths.yaml#/details/get/responses
        .
        .
        .
```

The file paths.yaml contains the following OpenAPI code fragment:

```
details:
  get:
    responses:
      '200':
        description: 200 OK defined in $ref file
        schema:
          $ref: '#/definitions/branch'
    summary: Branch details
    description: Retrieve details of the current branches of BankA.
```

When API Connect processes the source YAML file, the **$ref** field is replaced with the target code fragment, yielding the following OpenAPI code:

```
swagger: '2.0'
info:
  version: 1.0.0
  title: Branches
  x-ibm-name: Branches
  description: Provides operations relating to BankA branch information.
basePath: /branches
paths:
  /details:
    get:
      responses:
        '200':
          description: 200 OK
          schema:
            $ref: '#/definitions/branch'
      summary: Branch details
      description: Retrieve details of the current branches of BankA.
        .
        .
        .
```

Example 2

Example of a reference to an external file that contains just the parameter details:

```
openapi: 3.0.0

info:
  version: 3.0.1
```

```
  title: BeamUp API
  x-ibm-name: BeamUpAPI
servers:
  - url: /
paths:
  /customers:
    get:
      parameters:
        - $ref: tests/fixtures/api/referenceFile.yaml
      responses:
        200:
          description: An array of customers
          content:
            application/json:
              schema:
                type: object
                properties:
                  customerID:
                    type: string
                  customerName:
                    type: string
.
.
.
```

The file referenceFile.yaml contains the following OpenAPI code fragment:

```
name: page
in: query
description: page of results to return
required: true
schema:
  type: integer
```

Example of a reference to an external file that contains the parameters inside a path code fragment:

```
openapi: 3.0.0

info:
  version: 3.0.1
  title: BeamUp API
  x-ibm-name: BeamUpAPI
servers:
  - url: /
paths:
  /customers:
    get:
      parameters:
        - $ref: tests/fixtures/api/referenceFileWithPath.yaml#/customers/get/parameters
      responses:
        200:
          description: An array of customers
          content:
            application/json:
              schema:
                type: object
                properties:
                  customerID:
                    type: string
                  customerName:
                    type: string
```

The file referenceFileWithPath.yaml contains the following OpenAPI code fragment:

```
customers:
  get:
    parameters:
      name: page
      in: query
      description: page of results to return
      required: true
      schema:
        type: integer
```

Creating a Product definition file

You define a Product by creating a Product definition file.

About this task

You can create a Product definition file in either of the following ways:

- Create the file in an editor of your choice.
- Create a Product definition file by using the `apic create:product` command and then modify it. You can base your Product definition file on the default Product template or on your own custom template.

This topic describes the syntax that is needed for both options and also the structure needed when the file is created in the editor. For details on what you can include in the product definition file, see Product definition schema.

You can create a Product in the CLI by running **apic create:product** and supplying additional arguments on the command line. For example, you can enter the following text in a single command:

```
apic create:product --name product_name --title product_title --filename product_file_name.yaml
--apis "filename_of_api1.yaml filename_of_api2.yaml"
```

where:

- *product_name* is the name for your new Product.
- *product_title* is the title of your new Product.
- *product_file_name.yaml* is the name of the yaml file that is created for your new Product.
- *filename_of_api1.yaml* is the file name of one of the APIs that is used within the new Product.
- *filename_of_api2.yaml* is the file name of one of the APIs that is used within the new Product.

Another option is to create a Product interactively in the command line by running **apic create:product** and following the prompts.
You can see further details and available options for the **apic create:product** command by entering the command:

```
apic create:product --help
```

You can also create a Product from a custom Handlebars template by using the following command:

```
apic create:product --template template_filename --title product_title
```

where *template_filename* is the name of the Handlebars template to use, and *product_title* is the title of your Product. A Product template file must have a .hbs file name extension. You can create a template from scratch, or start with the example (default) Product template provided in API and Product definition template examples.
A Product definition file contains the following sections:

- The specification version
- An information section
- A visibility section
- An APIs section
- A Plans section

In this topic, YAML is used, but the instructions can be adapted to use JSON. Both .yaml and .yml file extensions are supported, but the use of the .yaml file extension is recommended by yaml.org.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Procedure

Structure your Product definition file by completing the following steps:

1. Set the specification version by adding the following line to the beginning of the file: `product: 1.0.0`.
   This line specifies the template version, and is always **product: 1.0.0**.
   Note: The specification version is distinct from your Product version. The specification version refers to this YAML file, while the Product version is by your discretion.
2. Include an information section with details about the Product, as described in Completing the information section of your Product description.
3. Include a visibility section that specifies who can view and subscribe to the Product, as described in Specifying the visibility of your Product.
4. Include an APIs section that references the APIs to be included in the Product, as described in Referencing the APIs for your Product.
5. Include a Plans section that described the Plans you want include in your Product, as described in Describing Plans in your Product.

Results

You have completed a YAML representation of your Product. A complete example with full indentation can be found in An example YAML representation of a Product.

You can create multilingual API and Product documentation by using an **x-ibm-languages** extension directly in the OpenAPI definition. For more information, see Using x-ibm-languages to create multilingual API and Product documentation.

- **Product definition schema**
  The product definition schema defines the properties (and their data types) that you can include in a product definition file.
- **Converting a Product YAML file to use DataPower API Gateway**
  IBM API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

          }
        }
      }
    }
}
```

Completing the information section of your Product description

Provide users with information about your Product.

About this task

The information section of a YAML representation of a Product contains the Product's name and version. It can also include contact and license details.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
An example information section for a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To complete the information section of your Product description, complete the following steps.

1. Begin the section and provide a name, title, description, and version number; use the following syntax:

   ```
   info:
     version: Product_Version
     title: Product_Title
     name: Short_Name
     summary: Product_Description
   ```

   where:
   - *version* is the version number of the policy.
     Tip: The **version.release.modification** version numbering scheme is recommended, for example `1.0.0`.
   - *Product_Title* is the title of the Product. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - *Short_Name* is the short name for the policy. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface of IBM API Connect.
   - *Product_Description* is a short description of the policy. Any string can be used.
2. Optional: Under info, supply contact information; use the following syntax:

   ```
     contact:
       name: Contact_Name
   ```

```
    url: 'Contact_URL'
    email: Contact_email
```

where:

- *Contact_Name* is the name of the contact for this Product.
- *Contact_URL* is the URL for contact your organization.
- *Contact_email* is an email for contacting your organization.

3. Optional: Under info, add license information for your Product; use the following syntax:

```
  license:
    name: License_Name
    url: 'License_URL'
```

where:

- *License_Name* is the name of the license that applied to your Product.
- *License_URL* is the URL at which information about the license can be accessed.

4. Optional: Under info, add your terms of service; use the following syntax:

```
 termsOfService: Terms
```

where *Terms* is a string that details the terms of service for using your Product.

Results

You have completed the information section of your Product's YAML representation. It should have the following form:

```
info:
  version: Product_Version
  title: Product_Title
  name: Short_Name
  description: Product_Description
  contact:
    name: Contact_Name
    url: 'Contact_URL'
    email: Contact_email
  license:
    name: License_Name
    url: 'License_URL'
  termsOfService: Service_Terms
```

where all variables are as described in previously in this topic. The indentation must be as in the example.

Specifying a gateway type for your Product

Product definitions must specify which type of gateway the Product uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See Specifying a gateway type for an API definition.

Procedure

1. Determine the gateway type that is configured for the APIs in your Product. The Product gateway type must match the APIs gateway type.
   To review the APIs for your Product, see Referencing the APIs for your Product.

2. Edit the Product definition file (YAML source) to add the gateway type you want to use:
   - DataPower Gateway (v5 compatible):

     ```
     gateways:
                 datapower-gateway
     ```

   - DataPower API Gateway

     ```
     gateways:
                 datapower-api-gateway
     ```

3. Ensure that the policies, including policy versions, in the APIs in your Product are supported by the gateway type. Review the list of policies on the execute page. If necessary, review the individual policy pages to determine the supported version number.

Related information

- DataPower API Gateway porting notes

Converting a Product YAML file to use DataPower API Gateway

IBM® API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

Before you begin

IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

Product definitions can specify only one type of gateway. The type of gateway must match the gateway type that is used by the APIs that are included in the product. If you want to take advantage of the capabilities of DataPower API Gateway, you can easily modify your existing Product definitions to specify it as the gateway type.

Procedure

1. Verify that the APIs in the product specify DataPower API Gateway as the gateway type, and that the APIs have been converted for use with the DataPower API Gateway.
2. Open the Product YAML file for editing.
   For example:

```
product: '1.0.0'          .

info:
  name: testprod
  title: testprod
  version: 1.0.0
           .
           .
           .
```

3. Add a `gateways:` setting, and specify `datapower-api-gateway`.
   For example:

```
product: '1.0.0'          .

info:
  name: testprod
  title: testprod
  version: 1.0.0
gateways:
  - datapower-api-gateway
              .
              .
              .
```

4. Save the modified YAML file.

Specifying the visibility of your Product

How to set the availability of your Product by specifying its visibility and subscribability levels.

About this task

The visibility section of your Product's YAML representation determines who can view and subscribe to your Product in IBM® API Connect.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
An example visibility section of a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To complete the visibility section of your Product description, complete the following steps:

1. Title the section by adding `visibility:`
2. Under `visibility:`, specify who can `view` the Product; use the following syntax:

```
   view:
      enabled: View_Toggle
```

```
      type: View_Audience
      tags: View_Tag
      orgs: View_Organizations
```

where

- *View_Toggle* determines whether the Product is visible to anybody or not. It must be **true** or **false**. If **false**, the Product will not be visible in the Developer Portal.
- *View_Audience* must be **public**, in which case the Product is visible to anybody who uses the Developer Portal, **authenticated**, in which case the Product is visible to anybody registered through the Developer Portal, or **custom**, in which case the Product is visible to a specified group of users. You can specify these custom users as one or more consumer organizations in the **orgs:** section, and as one or more consumer organization groups in the **tags:** section.
- The *View_Tag* specifies the consumer organization groups that can view the Product if *View_Audience* is set to **custom**. If *View_Audience* is not set to **custom**, do not include **tags:**. If *View_Audience* is **custom**, you can specify groups in the following manner:

  ```
      tags:
         - Organization group 1
         - Organization group 2
  ```

  where the *Organization group* variables are the names of the groups that are to be allowed to view the Product. Note that when a Product is published, the **tags:** property name becomes **group_urls:**, and the content is changed to URL strings.
- *View_Organizations* specifies the consumer organizations that can view the Product if *View_Audience* is set to **custom**. If *View_Audience* is not set to **custom**, do not include **orgs:**. If *View_Audience* is **custom**, you can specify organizations in the following manner:

  ```
      orgs:
         - Organization 1
         - Organization 2
  ```

  where the *Organization* variables are the names of the organizations that are to be allowed to view the Product. Note that when a Product is published, the **orgs:** property name becomes **org_urls:**, and the content is changed to URL strings.

3. Under **visibility:**, specify who can **subscribe** to your Product's Plans; use the following syntax:

```
   subscribe:
      enabled: Subscribe_Toggle
      type: Subscribe_Audience
      tags: Subscribe_Tag
      orgs: Subscribe_Organizations
```

where:

- *Subscribe_Toggle* must be **true** or **false**. If **false**, no developers will be able to subscribe to the Product.
- *Subscribe_Audience* must be **authenticated**, in which case the Product's Plans can be subscribed to by anybody who is registered through the Developer Portal, or **custom**, in which case the Product's Plans can be subscribed to by a specified group of users.
- The *Subscribe_Tag* specifies the consumer organization groups that can subscribe to the Product's Plans if *Subscribe_Audience* is set to **custom**. If *Subscribe_Audience* is not set to **custom**, omit it or set as **[]**. If *Subscribe_Audience* is **custom**, you can specify groups in the following manner:

  ```
      tags:
         - Organization group 1
         - Organization group 2
  ```

  where the *Organization group* variables are the names of the groups that are to be allowed to subscribe to the Product. Note that when a Product is published, the **tags:** property name becomes **group_urls:**, and the content is changed to URL strings.
- *Subscribe_Organizations* specifies the organizations that can subscribe to the Product's Plans if *Subscribe_Audience* is set to **custom**. If *Subscribe_Audience* is not set to **custom**, omit it or set as **[]**. If *Subscribe_Audience* is **custom**, you can specify organizations in the following manner:

  ```
      orgs:
         - Organization 1
         - Organization 2
  ```

  where the *Organization* variables are the names of the organizations that are to be allowed to subscribe to the Product. Note that when a Product is published, the **orgs:** property name becomes **org_urls:**, and the content is changed to URL strings.
  Note: If a Product is to be available for subscription, it must already be visible. As a result, for the subscription audience to be **authenticated**, the view audience cannot be **custom**.

Results

You have completed the visibility section of your Product's YAML representation. It should have the following form:

```
visibility:
   view:
      enabled: View_Toggle
      type: View_Audience
      tags:
         - View_Tag_1
         - View_Tag_2
      orgs:
         - Organization_1
         - Organization_2

   subscribe:
      enabled: Subscribe_Toggle
      type: Subscribe_Audience
      tags:
         - Subscribe_Tag_1
         - Subscribe_Tag_2
      orgs:
         - Organization_1
         - Organization_2
```

where all variables are as described previously in this topic. The indentation must be as in the example.

What to do next

You can also define Product visibility at a Catalog or Space level. For more information, see Configuring Product visibility at a Catalog or Space level.

- Configuring Product visibility at a Catalog or Space level

Referencing the APIs for your Product

Detail the file paths for the APIs you want to include in your Product in IBM® API Connect.

About this task

Before an API can be included in a Plan, it must first be referenced in the APIs section of your Product description.

Procedure

Begin the APIs section and reference the APIs you want to include in your Product. The syntax that you use depends on which user interface you are using, as follows:

- API Designer:

```
apis:
  API_1_NameAPI_1_Version
    $ref: API_1_File_Path
  API_2_NameAPI_2_Version
    $ref: API_2_File_Path
```

- API Manager:

```
apis:
  API_1_NameAPI_1_Version
    name: 'API_1_Name:API_1_Version'
  API_2_NameAPI_2_Version
    name: 'API_2_Name:API_2_Version'
```

  where
  - the *API_n_Name* variables are the case-sensitive names of your APIs.
  - the *API_n_Version* variables are the versions of your APIs.
  - the *API_n_File_Path* variables are the file paths for the YAML files containing OpenAPI representations of your APIs.

The following example shows a complete sample APIs section:

```
apis:
  api11.0.0:
    name: 'api1:1.0.0'
  api21.0.0:
    name: 'api2:1.0.0'
  api31.0.0:
    name: 'api3:1.0.0'
```

For more information about creating OpenAPI definitions, see Creating an OpenAPI definition file.

The indentation must be as in the examples and the APIs must have been created before they can be referenced.

Results

You have referenced the APIs that are to be included in your Product. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Describing Plans in your Product

Describe the Plans that you want to include in your IBM® API Connect Product and which APIs they will contain, as well as any rate limits that apply.

About this task

A Plan contains APIs and their operations. It can be used to implement rate limits and tailor visibility.

Note: If you are using more than one DataPower® server in a Gateway service, then to properly calculate API calls for rate limits the servers must be able to communicate with each other by using SLM peer groups, using either SLM unicast peering or SLM multicast peering depending on your network configuration. For more information, see SLM peering.
In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Two example Plan descriptions from a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To describe your Plans, include APIs in them, and set rate limits for Plans or specific operations, complete the following instructions:

1. Begin the Plans section with `plans:`
2. Under Plans, begin the description of your first Plan by providing a name, description, and specifying whether approval is required for subscription requests; use the following syntax:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
```

   where:
   - *Plan_Name* is the name of the Plan. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface.
   - *Plan_Title* is the title of the Plan.Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - *Plan_Description* is a description of your Plan.
   - *Approval_Toggle* must be either `true`, in which case approval is needed for subscription requests, or `false`, in which case subscriptions are automatically approved.
3. Optional: Under your Plan, add multiple burst and rate limits that will be shared across all the operations in the Plan; use the following syntax:
   Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

```
    rate-limits:
      Name:
        value: Rate_Limit
        hard-limit: Limit_Toggle
      Name:
        value: Rate_Limit
        hard-limit: Limit_Toggle
    burst-limits:
      Name:
        value: Burst_Limit
```

   where:
   - *Name* is the name of the limit.
   - *Rate_Limit* is your rate limit. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: **`1/2minute`**. If the time unit is singular, then it is not necessary to precede it with a number, for example, **`1/minute`**. If you do not want to apply a rate limit, set *Rate_Limit* as `unlimited`.
   - *Limit_Toggle* must be `true` or `false`. If *true*, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Rate_Limit* to `unlimited`.
   - *Burst_Limit* is your burst limit. It can be for multiples of seconds or minutes, written as `second` or `minute`; do not use the plural forms of the words.

   Note:
   - Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
   - The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see Working with Catalogs
4. Under your Plan, specify which APIs are to be included.
   Reference APIs by name and version, as follows:

```
    apis:
      API_1_nameAPI_1_version: {}
      API_2_nameAPI_2_version: {}
```

   where
   - the *API_n_name* variables are the case-sensitive names of your APIs.
   - the *API_n_version* variables are the versions of your APIs.
5. Optional: If you want to include only a subset of an API's operations, list the operations that are to be included; use the following syntax:

```
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_1_Verb
            path: Operation_1_Path
          - operation: Operation_2_Verb
            path: Operation_2_Path
```

   where
   - the *Operation_n_Path* variables are the paths of operations that is to be included. The dash is required for each new operation.
   - the *Operation_n_Verb* variables are the appropriate REST verbs for the operations.
6. Optional: If you want to specify multiple rate limits for a single operation; use the following syntax:

```
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_Verb
            path: Operation_Path
            rate-limits:
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
```

where:

- *Operation_Limit* is the rate limit that you want to apply to your operation. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: **`1/2minute`**. If the time unit is singular, then it is not necessary to precede it with a number, for example, **`1/minute`**. If you do not want to apply a rate limit, set *Operation_Limit* as `unlimited`.
- *Operation_Limit_Toggle* must be `true` or `false`. If *true*, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Operation_Limit* to `unlimited`.

Results

You have described the Plans that are to be included in your Product. Your Plans section should be similar to the following scenarios.

If you have enforced a rate limit for your Plan and not specified individual operations, your Plans section should have the following form:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
    rate-limits:
      Name:
        value: Limit
        hard-limit: Limit_Toggle
    apis:
      API_1_nameAPI_1_version: {}
      API_2_nameAPI_2_version: {}
```

If you have enforced rate limits at the Plan level and want to include two operations, with a separate rate limit one for one of the operations, your Plans section should have the following form:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
    rate-limits:
      Name:
        value: API_Limit
        hard-limit: API_Limit_Toggle
    burst-limits:
      Name:
        value: Burst_limit
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_1_Verb
            path: Operation_1_Path
            rate-limits:
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
          - operation: Operation_2_Verb
            path: Operation_2_Path
```

In both examples, variables are as in the previous steps and the indentation must be as presented.

The following example shows a complete sample Plans section:

```
plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  my-plan:
    title: my_plan
    rate-limits:
      Default rate-limit:
        value: 50/1hour
        hard-limit: false
    burst-limits:
      Default burst-limit:
        value: 10/1second
    apis:
      api21.0.0:
        operations:
          - operation: get
            path: /path2
      api31.0.0:
        operations:
          - operation: get
            path: /path3
            rate-limits:
              limit3:
                value: 10/1second
                hard-limit: true
              limit4:
                value: 100/1hour
                hard-limit: true
      api11.0.0: {}
```

An example YAML representation of a Product

Products in IBM® API Connect can be represented by using a YAML file in a similar fashion to how APIs can be represented by using OpenAPI.

The following code describes a complete Product, with sample values.

```
info:
  version: 1.0.0
  title: SampleProduct
  name: SampleProduct
  summary: This is a sample product
gateways:
  - datapower-gateway
product: 1.0.0
visibility:
  view:
    enabled: true
    type: public
    tags: []
    orgs: []
  subscribe:
    enabled: true
    type: authenticated
    tags: []
    orgs: []
plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  newplan:
    title: NewPlan
    rate-limits:
      low:
        value: 10/1hour
        hard-limit: true
    burst-limits:
      Default burst-limit:
        value: 10/1second
apis:
  SampleAPI:
    name: 'Sampleapi:1.0.0'
```

Using `x-ibm-languages` to create multilingual API and Product documentation

Create multilingual API and Product documentation by using the **`x-ibm-languages`** extension in your API and Product OpenAPI definitions.

You can scale your API initiatives to a global user base, while still maintaining a single API definition. Translations are custom configured and controlled, so that they can be tailored to both your API documentation and the API consumer. The extensions that are used in API Connect are added directly to the YAML file as **`x-ibm-languages`**. These extensions are then used in the Developer Portal, so that whatever language the Developer Portal is set to reflects the translations that are contained in the API and Product definitions.

Add the following syntax into your API or Product YAML file at every point that you require some translated text:

```
x-ibm-languages:
  item_name:
    language_code: translated_text
```

Where:

- ***`item_name`*** is the name of the item that you want to translate, for example **`summary`**.
- ***`language_code`*** is the ISO code for the translation language. Supported languages with their ISO codes are listed in the following table.

Table 1. List of supported language codes

Language	Code
Chinese, simplified	**`zh_cn`**
Chinese, traditional	**`zh_tw`**
Dutch	**`nl`**
English	**`en`**
French	**`fr`**
German	**`de`**
Italian	**`it`**
Japanese	**`ja`**
Korean	**`ko`**
Portuguese	**`pt`**
Spanish	**`es`**
Turkish	**`tr`**

- *translated_text* is the translated text that you want to be displayed for the item in the Developer Portal.

Note: The Developer Portal automatically assumes that the default language in the OpenAPI definition is English. If you want to use a different default language in the definition, you must provide both the English translation and the default language text in the **x-ibm-languages** extension sections of your OpenAPI definition, by using the following syntax:

```
x-ibm-languages:
  item_name:
    en: English_translated_text
    default_language_code: default_language_text
```

For an example of how to write an OpenAPI YAML file with French as the default language, see the Examples section.

Examples

An example API OpenAPI YAML file that contains the **fr** language extension, where English is the default language:

```
swagger: '2.0'
info:
  x-ibm-name: climbing-weather-api
  title: Climbing Weather API
  version: 1.0.0
  x-ibm-languages:
    title:
      fr: Climat d'escalade
schemes:
  - https
host: $(catalog.host)
consumes:
  - application/json
produces:
  - application/json
x-ibm-configuration:
  assembly:
    execute:
      - invoke:
          target-url: 'https://1234.com'
          title: 3 day forecast invocation
          cache-response: time-to-live
          cache-key: $(request.search)
  gateway: datapower-gateway
  enforced: true
  testable: true
  phase: realized
  cors:
    enabled: true
paths:
  /weather/forecast:
    get:
      summary: Retrieve the 3 day forecast for a location
      description: Retrieve the locations weather forecast descriptions for the next 3 days and nights
      operationId: getWeather
      x-ibm-languages:
        summary:
          fr: Récupérer la prévision de 3 jours pour un emplacement
        description:
          fr: Récupérer les descriptions des prévisions météo pour les 3 prochains jours et les nuits
      tags:
        - Weather
      parameters:
        - name: zip
          type: string

        fr: "25 appels par jour"
      description:
        fr: "Vous voulez donc encore plus d'appels?"
    rate-limits:
      25 calls per day:
        hard-limit: true
        value: 25/1day
  100-calls-per-day:
    title: 100 Calls every day
    description: 'You get 100 calls each and every day!'
    x-ibm-languages:
      title:
        fr: "100 appels par jour"
      description:
        fr: "Vous recevez 100 appels chaque jour"
    apis: {}
    rate-limits:
      100 Calls per day:
        hard-limit: true
        value: 100/1day
```

An example of how to write an OpenAPI YAML file with French as the default language:

```
info:
  name: climat-d-escalade
  title: Climat d'escalade
  version: 1.0.0
  x-ibm-languages:
    title:
      en: Climbing Weather API
      fr: Climat d'escalade
...
```

This example shows that both the default French language, and the English language translation, must be provided in the **`x-ibm-languages`** section.

Using `x-example` to control the examples displayed in the Developer Portal

OpenAPI does not support the use of **`example`** attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use **`x-example`** in OpenAPI parameters.

In this example, you cannot use **`example`** as it isn't supported by the OpenAPI spec, but you can use **`x-example`**.

```
- name: city
  in: query
  required: false
  type: string
  maxLength: 50
  description: "Location"
  x-example: "New York"
```

An **`example`** attribute is honored where set and allowed by the spec. If **`example`** is not found, **`default`** is honored where set and allowed by the spec. An **`x-example`** attribute is honored if found, if not found, a random example to match the schema is generated.

If the spec allows you to use **example**, then you should use it in preference to **x-example**.

Using x-embedded-doc to add additional documentation to products and APIs

You can use **x-embedded-doc** to add additional documentation to a product or an API as part of their definition.

You can embed additional documentation pages within the api swagger documentation. These pages can be base64 encoded strings or markdown strings of the html content of the page. These pages show up in the navigation, on the left side, underneath the overview for that product or API, and above the paths. Any styling that is needed to theme the documentation can be included in the Developer Portal custom theme.

Embedded docs for products and APIs

You can embed documentation for individual products and APIs by specifying an additional **x-embedded-doc** object in the product or API specification.

Field name	Type	Description
name	string	Required, the name of the embedded document
title	string	Required, The display title of the embedded document
format	string	Optional, the format of the embedded document content value. Values are **b64html** or **md**. Default value is **md**.
content	string	The base64 encoded html of page, or, the markdown string.
docs	x-embedded-doc	Additional embedded documentation. If no content is specified for parent, then the first child is the content that is shown.

Hierarchies of documents are supported by nesting of further doc properties. Language support is available by using **x-ibm-languages**.

Examples

Documentation can be added to an api, by using the following JSON:

```
"x-embedded-doc": [
   {
     "name": "introduction",
     "title": "Introduction",
     "format": "md",
     "content": "# some markdown"
   },
   {
     "name": "concepts",
     "title": "Concepts",
     "format": "md",
     "content": "## more markdown"
   },
   {
       "name": "authentication",
       "title": "Authentication",
       "docs": [{
             "name": "auth_clientid_secret",
             "title": "Obtaining a Client ID and Secret",
             "format": "md",
             "content": "### even more markdown"
             },
             {
               "name": "auth_bearertoken",
               "title": "Getting and Using a Bearer Token",
               "format": "md",
               "content": "#### yet more markdown"
             }
             ]
   }
 ]
```

Alternatively, by using base 64 encoded HTML:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImludHJvZHVjdGlvbiIgY2xhc3M...."
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImNvbmNlcHRzIiBjbGFzcz0icGFnZSI....."
  },
  {
    "name": "authentication",
    "title": "Authentication",
    "docs": [{
            "name": "auth_clientid_secret",
            "title": "Obtaining a Client ID and Secret",
            "format": "b64html",
            "content": "PGFydGljbGUgaWQ9ImNsaWVudC1pZC1zZWNyZX....."
            },
            {
            "name": "auth_bearertoken",
            "title": "Getting and Using a Bearer Token",
```

```
            "format": "b64html",
            "content": "ICA8YXJ0aWNsZSBpZD0iYmVhcmVyLXRva2VuIiBjbGFz....."
            }
          ]
      }
]
```

Or mixed formats:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImludHJvZHVjdGlvbiIgY2xhc3M...."
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "md",
    "content": "# some markdown"
  }
]
```

An example of some `x-embedded-doc` code and how it might render:

```
x-embedded-doc:
  - name: document
    title: Interesting
    format: b64html
    content: >-
      PGFydGljbGUgaWQ9ImNsaWVudC1pZ...=
securityDefinitions:
  api_key:
    type: apiKey
    in: header
    name: api_key
```

```
x-embedded-doc:
  - name: introduction
    title: Introduction
    format: md
```

```
    content: >-
      ## Overview

      ### Philosophy

      Markdown is intended to be as easy-to-read and easy-to-write as is
      feasible. Compellingly facilitate 2.0 intellectual capital for
      cross-platform networks.  Dynamically incubate ethical sources after
      optimal technologies. Phosfluorescently restore global users via excellent
      niche markets. Credibly impact cross-media mindshare through strategic
      best practices. Synergistically impact interdependent web services rather
      than unique interfaces.

      Continually reintermediate enabled sources rather than professional
      architectures. Appropriately embrace viral collaboration and idea-sharing
      whereas granular solutions. Energistically revolutionize competitive
      paradigms vis-a-vis highly efficient models. Objectively incentivize
      enterprise customer service through compelling e-markets. Competently grow
      multifunctional e-markets with business methods of empowerment.

      Dramatically iterate equity invested scenarios and focused data.
      Compellingly reconceptualize next-generation deliverables rather than
      out-of-the-box architectures. Competently foster cross-unit web services
      with interactive innovation. Quickly revolutionize enabled communities and
      alternative content. Globally administrate resource maximizing
      deliverables whereas corporate e-business.

      Progressively develop maintainable leadership.

- Using x-ibm-languages to create multilingual API and Product documentation

Using `x-pathalias` to give consistent URLs for products and APIs

You can use **x-pathalias** to assign a URL to a product or an API.

The information section of a YAML representation of a Product or API can include **x-pathalias**. This option can be useful as it allows the same URL to be used on different revisions of your product. It also allows the use of a vanity URL, which might better represent the branding of your site, or make the URL easier to pronounce.

In this example, you set an API called `Climbing weather API` in product `Weather watch` to have a URL of ***portalURL*/product/weather/api/climbing**.

Product information:

```
info:
  version: 1.0.0
  title: Weather watch
  name: weather-watch
  x-pathalias: weather
```

API information:

```
info:
  title: Climbing Weather API
  x-ibm-name: climbing-weather-api
  version: 1.0.0
  x-pathalias: climbing
```

Validating the YAML or JSON definition of an API or Product

You can validate a YAML or JSON definition by using the IBM® API Connect developer toolkit.

Before you begin

To complete the steps that are described in this topic, you must have installed the developer toolkit. For more information, see Installing the toolkit.

Procedure

To perform validation by using the developer toolkit, enter the following command:

```
apic validate filename
```

where *filename* is the file name of the API definition file you want to validate.

- Include `--product-only` to validate only a Product definition and not any APIs that it references.
- Include `--no-extensions` to validate only the default OpenAPI section of the API and none of its extensions.

Note:

- If the OpenAPI file that defines your API uses a **$ref** field to reference a fragment of OpenAPI code that is defined in a separate file, the **$ref** field is replaced with the contents of the target file before the draft API is created with the **apic drafts:validate** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "**(?**" cannot be validated or published. An error message is returned. For example:

  ```
  Product has not been published!
  The multipart 'openapi' field contains an OpenAPI definition with validation errors.
      definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,
  col: 0)
  400
  ```

Related concepts

- Creating an OpenAPI definition file

Creating and using API and Product definitions templates

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form **{{variable-name}}** that are substituted with values when you create the API or Product definition.

Before you begin

To complete the steps that are described in this topic, you must have installed the IBM® API Connect developer toolkit. For more information, see Installing the toolkit.

Procedure

1. Create a Product or API definition template, either from scratch, or by copying one of the examples provided in API and Product definition template examples. The template file must have `.hbs` filename extension, and may contain any of the handlebars variables described in Template variables for API and Product definitions.
2. To create a Product or API definition from a template, enter the following command:

   ```
   apic create:[api | product] --template template_file --title [api_title | product_title] options
   ```

   where *template_file* is the template `.hbs` file to use, *api_title* or *product_title* is the title of the API or Product to create, and *options* is any additional command-line options. The path to the template file can be either an absolute path or relative to the location where the command is executed.

   When the Product or API definition is created, the value of each command-line option is substituted for the corresponding handlebars template variable. For example, the value of the required `--title` option is substituted for the `info.title` field in the template file. The command creates an API or Product definition YAML file with the name specified in the `--name` option. If you don't supply the `--name` option, the command derives the name of the API or Product YAML file from the specified title by down-casing the title and replacing spaces with dashes.

Working with global policies

Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can upload global policies into each of the gateway services in your catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.

Note: Global policies are not the same as global-scoped policies, which you define with gateway extensions as documented on Authoring policies for the DataPower® API Gateway.

Prerequisites

IBM® DataPower Gateway version that is compatible with your deployed version of API Connect.

To complete the global policy management tasks described in this topic, you must be the owner of the provider organization, or be assigned a role that has the `Settings:Manage` permission. The pre-supplied Administrator role has this permission by default; if you are assigned a custom role that it must have this permission. For more information, see Creating custom roles.

Overview

For each of the gateway services in a catalog, a global policy that you want to be called before any API assembly is called is designated as a *pre-request* global policy, and a global policy that you want to be called after any API assembly is called is designated as a *post-response* global policy. A policy that you want to be called when an error is thrown is called an *error* global policy. You can upload as many global policies into a gateway service as you want, but you can designate at most one global policy to be pre-request, one to be post-response, and one to be an error, at any one time.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
Note:

- If you are using the DataPower Gateway (v5 compatible), there can be only one `proxy` policy across the combined pre-request, API, and post-response assembly flows.
- Catalog properties, as described in Creating and configuring Catalogs, and API properties, as described in Setting API properties, are not supported by global policies. Therefore, if you use such properties in a global policy, they are **not** replaced with the values that are specified in the API or catalog property definitions.

A global policy is defined in a .yaml file. The global policy file specifies the policy assembly that you want to call. A global policy file has the following structure:

```
global-policy: 1.0.0

info:
    name: global_policy_name
    title: global_policy_title
    version: global_policy_version

gateways:
    - gateway_type

assembly:
    - policy_assembly_to_be_called
```

where *gateway_type* has the value `datapower-gateway` if you want to use the global policy in a DataPower Gateway (v5 compatible), and `datapower-api-gateway` if you want to use the global policy in a DataPower API Gateway. For more information on the different types of gateway, see API Connect gateway types.
Note: Error global policies are supported only by the DataPower API Gateway, not by the DataPower Gateway (v5 compatible).
The `assembly` section for a pre-request or post-response global policy can contain any valid API assembly flow. For more information, see the execute section.

The **assembly** section for an error global policy can only contain a **catch** extension in the assembly, an **execute** section is not valid. For details of the **catch** extension, see catch.

Sample global policy .yaml file for pre-request or post-reponse

```
global-policy: 1.0.0

info:
  name: sample-policy
  title: Sample Policy
  version: 2.0.0

gateways:
  - datapower-api-gateway

assembly:
  execute:
    - invoke:
        target-url: http://myhost.com/mytarget
        version: 2.0.0

  catch:
    - errors:
        - ConnectionError
      execute:
        - activity-log:
            title: activity-log
            content: activity
            error-content: payload
            version: 2.0.0
```

Sample error global policy .yaml file

Note: An error global policy .yaml file can contain only a **catch** extension in the assembly.

```
global-policy: 1.0.0

info:
  name: sample-error-policy
  title: Sample Error Policy
  version: 2.0.0

gateways:
  - datapower-api-gateway

assembly:
  catch:
    - errors:
        - ConnectionError
      execute:
        - activity-log:
            title: activity-log
            content: activity
            error-content: payload
            version: 2.0.0
    - errors:
        - SOAPError
      execute:
        - xslt:
            version: 2.0.0
            title: xslt
            input: true
            source: |-
              <!-- Placeholder -->
              <xsl:stylesheet xmlns:xsl=''/>
```

Logging in to the Management server

You work with global policies by using developer toolkit CLI commands. Before you can run the commands, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

Uploading a global policy to a gateway service

You upload a global policy to a gateway service by using the **apic global-policies:create** command. The command has the following format:

```
apic global-policies:create --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] filename
```

where:

- *catalog_name* is the value of the **name** property of the catalog that contains the gateway service to which you want to upload the global policy.
- *gateway_service_name* is the value of the **name** property of the gateway service.
- *organization_name* is the value of the **name** property of the provider organization that contains the catalog.
- *mgmt_endpoint_url* is the platform API endpoint URL.
- *scope* has one of the following values:
  - **catalog** if the catalog does not have Spaces enabled.
  - **space** if the catalog has Spaces enabled. If you specify **space** for the **--scope** parameter you must also supply the **--space** parameter to specify the Space that contains the gateway service.
- **Optional**: *space* is the name of the Space that contains the gateway service. The **--space** parameter is required if the catalog has Spaces enabled, in which case you must also include **--scope space** in the command.
- *filename* is the name of the global policy .yaml file that you want to upload.

Note: If Spaces are enabled in a catalog, a global policy that you apply to one Space is applied to **all** Spaces; you cannot apply a global policy to an individual Space in the catalog. Any subsequent updates are also applied to all Spaces.
You can confirm the global policies that have been uploaded by using the **apic global-policies:list-all** command, which has the following format:

```
apic global-policies:list-all --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space]
```

For reference details of the **apic global-policies** commands, see the toolkit CLI reference documentation.

Designating the pre-request global policy

To designate the pre-request policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

   ```
   apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
   ```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy **.yaml** file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string **url** with **global_policy_url**. The resulting file has the following format:

   ```
   global_policy_url: >-
     https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-policies/policy_id
   ```

3. Designate the global policy to be the pre-request policy by using the following command:

   ```
   apic global-policy-prehooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
   ```

To replace the designated pre-request global policy with another policy, repeat the steps 1 and 2, then use the **apic global-policy-prehooks:update** command. To remove the pre-request global policy designation, use the **apic global-policy-prehooks:delete** command.
For reference details of the **apic global-policy-prehooks** commands, see the toolkit CLI reference documentation.

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a pre-request global policy that you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization. For more information, see Customizing the preflow policies.

Designating the post-response global policy

To designate the post-response policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

   ```
   apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
   ```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy **.yaml** file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string **url** with **global_policy_url**. The resulting file has the following format:

   ```
   global_policy_url: >-
     https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-policies/policy_id
   ```

3. Designate the global policy to be the post-response policy by using the following command:

```
apic global-policy-posthooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated post-response global policy with another policy, repeat the steps 1 and 2, then use the **apic global-policy-posthooks:update** command. To remove the post-response global policy designation, use the **apic global-policy-posthooks:delete** command.
For reference details of the **apic global-policy-posthooks** commands, see the toolkit CLI reference documentation.

Designating the error global policy

The error global policy is applied to an error caught in the API pre-request, assembly, and post-response stages unless any of those stages has its own error rule that is defined for the same error, in which case that error rule takes priority.

To designate the error global policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

```
apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
--server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
```

where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy **.yaml** file that was originally uploaded to the gateway service.
The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string **url** with **global_policy_url**. The resulting file has the following format:

```
global_policy_url: >-
  https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
policies/policy_id
```

3. Designate the global policy to be the error policy by using the following command:

```
apic global-policy-errors:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated error global policy with another policy, repeat the steps 1 and 2, then use the **apic global-policy-errors:update** command. To remove the error global policy designation, use the **apic global-policy-errors:delete** command.

For reference details of the **apic global-policy-errors** commands, see the toolkit CLI reference documentation.

Customizing the preflow policies

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a global policy that you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization.

Before you begin

- For details on how to configure and deploy a global policy, see Working with global policies.
- For details on how to avoid authentication errors on a WSDL action, see the IBM troubleshooting technote, API Connect HTTP GET ?WSDL retrieval returns "401 - Unauthorized Invalid client id or secret".

Default preflow policies

The following preflow policies are invoked by default:

- **cors**: handles cross-origin resource sharing (CORS) requests for the API; invoked if CORS is enabled in the API definition settings.
- **wsdl**: handles WSDL requests.
- **html-page**: for a GraphQL API, if the GraphQL editor option is enabled, returns the GraphQL HTML page.
- **client-identification**: examines the API key credentials that are carried in the API request and matches the API Plan through which the target API is made available to the client.
- **ratelimit**: enforces the rate limit scheme that is configured for the matching API Plan. When the rate limit is reached, the request is rejected.
- **security**: performs the authentication and authorization checks that are required by the target API and operation. if the security requirement is not fulfilled, the request is rejected.

Configuring a global policy to customize the preflow policies

To customize the preflow policies, complete the following steps:

1. Add the following property to the **info:** section of your global policy .yaml file:

```
mode: mode_type
```

Where ***mode_type*** is one of the following options:
   - **after-builtin** - this means that your preflow policies are applied after the default preflow policies.
   - **before-builtin** - this means that your preflow policies are applied before the default preflow policies.
   - **full-custom** - this means that you must explicitly add the preflow policies to the assembly of your global policy. However, you can remove, reposition, or replace any of the preflow policies as required.
2. Configure the policies in your global policy assembly as required.

An `after-builtin` global policy example:

```
global-policy: 1.0.0
info:
  name: foo-example
  title: foo-example
  version: 2.0.0
  mode: after-builtin
gateways:
  - datapower-api-gateway
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-Flexible-Preflow
            value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed after all default builtins'
            type: string
```

A `before-builtin` global policy example:

```
global-policy: 1.0.0
info:
  name: foo-example
  title: foo-example
  version: 2.0.0
  mode: before-builtin
gateways:
  - datapower-api-gateway
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-Flexible-Preflow
            value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed before all default builtin
policies'
            type: string
```

A `full-custom` global policy example:

```
global-policy: 1.0.0
info:
  name: preflow-4-actions
  title: preflow-4-actions
  version: 2.0.0
  mode: full-custom
gateways:
  - datapower-api-gateway
assembly:
  execute:
    - cors:
        version: 2.0.0
        title: cors-in-preflow
    - wsdl:
        title: default-wsdl
    - html-page:
        title: html-page-in-preflow
        output: message
        version: 2.0.0
    - helloworld:
        version: 1.0.0
        title: helloworld
    - client-identification:
        version: 2.0.0
        title: ci-in-preflow
    - ratelimit:
        version: 2.0.0
        title: assembly-rt-in-preflow
        source: plan-default
    - security:
        version: 2.0.0
        title: sec-in-preflow
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-Flexible-Preflow
            value: 'Hello reboot with 4 actions'
            type: string
```

3. Deploy your global policy as a pre-request global policy.

Reference

Reference information for developing your APIs in API Connect, including context variables, and template variables.

Note: For product-wide reference material, including command-line tool and REST APIs documentation, see Reference information for IBM® API Connect.

- **API Connect context variables**
  List of IBM API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext()` function when defining a policy.
- **OAuth context variables**
  You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.
- **Error cases supported by assembly catches**
  Several error cases that can be returned by the assembly are available to the catch function.
- **API and Product definition template examples**
  You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by `apic` to create Products and APIs as examples you can use to copy and customize for your own use.
- **Template variables for API and Product definitions**
  You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Related information

- IBM API Connect overview

API Connect context variables

List of IBM® API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext()` function when defining a policy.

The following tables are presented:

- General context variables.
- OAuth context variables - DataPower Gateway (v5 compatible).
- Application certificate context variables.
- API activity logging context variables.
- GraphQL context variables.

For more information about implementing an assembly component, see Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly, and for information about how to reference context variables in API Connect see Variable references in API Connect and Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For more information about creating a user-defined policy, see Authoring policies.

General context variables

Note:

- For plan variables (such as `plan.name` or `plan.version`), plan information is available only when the requested operation requires identification and the client passes the authentication check.
- If you deploy your API to the DataPower® Gateway (v5 compatible) then, with the exception of client ID and client secret, the passing of form input as a parameter into an API is not supported. This restriction does not apply if you deploy your API to the DataPower API Gateway.

Table 1. API Connect context variables

Name	Description	Permission
API Gateway only `api.catalog.id`	The ID of the Catalog in which the API is published.	Read/write
API Gateway only `api.catalog.name`	The name of the Catalog in which the API is published.	Read/write
API Gateway only `api.catalog.path`	The path segment that represents this Catalog.	Read/write
`api.endpoint.address`	The address of the API Gateway endpoint.	Read/write
`api.endpoint.hostname`	The host name of the API Gateway endpoint, as requested by the application.	Read/write
API Gateway only `api.id`	The identifier of the API.	Read/write
`api.name`	The name of the API; this corresponds to the `x-ibm-name` field in the OpenAPI definition for the API.	Read/write
`api.operation.id`	The ID of the operation.	Read/write
`api.operation.path`	The path of the operation.	Read/write
`api.org.id`	The organization ID of the API provider.	Read/write
`api.org.name`	The organization short name of the API provider.	Read/write
`api.properties.`*`propertyname`*	The name of a custom API property. Property values are Catalog specific. Note: • You have write permission to a custom property **only** from the user interface, **not** from GatewayScript.	Read/write
`api.root`	The API base path.	Read/write
`api.type`	The API type; REST or SOAP.	Read/write
`api.version`	The version string of the API.	Read/write

Name	Description	Permission
`client.app.id`	The client ID or application key that is received on the request.	Read/write
API Gateway only `client.app.'lifecycle-state'`	The lifecycle status of the calling client application. The possible values are as follows: • `DEVELOPMENT` • `PRODUCTION` (default)	Read/write

API Gateway only
`client.app.metadata.`*`key`*
	The string value of an application metadata key, where *key* is the name of the key.
	You can add metadata keys to an application by using either the **apic apps:create** or the **apic apps:update** command; you include the metadata keys in the configuration file parameter that is passed to the command.
	
	For example:
	
	`apic apps:create myapp.yaml --server myserver.com --org myorg --catalog mycatalog --consumer-org mycorg`
	
	where myapp.yaml contains the following:
	
	`name: myapp`
	`title: My test application`
	`metadata:`
	`  key1: value1`
	`  key2: value2`
	`  key3: value3`
	`  key4: value4`
	`  key5: value5`
	
	You can then retrieve the value of a metadata key in an API assembly policy by using a context variable such as the following:
	
	`client.app.metadata.key3`
	
	Note that adding application metadata might impact gateway trans performance.
		Read/write

`client.app.name`	The name of the application that is identified as having issued the request.	Read/write
`client.app.secret`	The client secret that is received in the request.	Read/write
`client.app.type`	The type of the client application that issued the request.	Read/write
`client.org.id`	The unique identification key of the organization that owns this application.	Read/write
`client.org.name`	The name of the organization that owns this application.	Read/write
API Gateway only `client.result`	The result of the client security policy, which is `SUCCESS` or `FAILURE`.	Read/write
API Gateway only `client.third_party.type`	The type of user registry used for third-party authentication of the extracted client credentials. The possible values are `LDAP` and `auth-url`.	Read/write
API Gateway only `client.third_party.headers`	The array of headers added to the request that was sent to that API authentication URL during third-party authentication.	Read/write
API Gateway only `client.third_party.response.authenticated`	The third-party authentication results. The possible values are as follows: • `true`: the authentication was successful. • `false`: the authentication failed.	Read/write
API Gateway only `client.third_party.response.user`	The user for third-party authentication.	Read/write
API Gateway only `client.title`	The title for the credentials that are received in the request.	Read/write
DataPower Gateway (v5 compatible) only `env.name`	The name of the Catalog in which the API is published.	Read/write
DataPower Gateway (v5 compatible) only `env.path`	The path segment that represents this Catalog.	Read/write
API Gateway only `error.message`	The message text for the error.	Read/write
API Gateway only `error.name`	The name of the error.	Read-only
API Gateway only `log`	The transaction data gathered in an assembly log action.	Read/write
`message.attachments`	The array of attachments in a multipart message.	Read/write
`message.attachments[].body`	The attachment payloads in a multipart message.	Read/write
`message.attachments[].headers`	The attachment headers in a multipart message.	Read/write
`message.body`	The payload of the request or response message. Note: The `message.body` context variable is not supported with `getContext()` function. Use the `getvariable()` function instead.	Read/write
`message.headers.`*`name`*	The value of the current named header of the message or of the current named header of the root part of a multipart message. The *name* segment is case-insensitive.	Read/write
API Gateway only `message.original.headers.`*`name`*	The value of the original named header of the HTTP message. When the assembly contains an invoke action, the value is automatically populated by the original named header of the response message from the invoked URL. The *name* segment is case-insensitive.	Read-only

Name	Description	Permission
API Gateway only **message.package.headers.*name***	The value of the current named header of the multipart message. The *name* segment is case-insensitive.	Read/write
message.status.code	The HTTP status code of the response.	Read/write
message.status.reason	The HTTP reason phrase of the response.	Read/write
API Gateway only **message.variables.*name***	The value of a property in the message. For example, when **myvar** is the property in the message, you can retrieve the value of the **myvar** property by reading **message.variables.myvar**.	Read/write
plan.name	The name of the plan.	Read/write
plan.id	The unique identifier of the plan.	Read/write
plan.rate-limit	The rate limit of the plan, which is the number of API calls per time interval.	Read/write
API Gateway only **plan.rate-limit[index].hard-limit**	The hard limit setting for the rate limit scheme that is identified by **[index]**.	Read/write
API Gateway only **plan.rate-limit[index].value**	The value of the rate limit scheme that is identified by **[index]**. The syntax is **rate/interval**.	Read/write
plan.spaceId	The unique identifier of the space that the plan is contained within.	Read/write
plan.spaceName	The name of the space that the plan is contained within.	Read/write
plan.version	The version number of the plan.	Read/write
request.authorization	The parsed HTTP **authorization** header.	Read-only
request.body	The payload from the incoming request.	Read-only
request.content-type	Normalized content-type value.	Read-only
request.date	A date object that represents approximately when the request was received by the Gateway.	Read-only
request.headers.*name*	The value of the original named header of the HTTP request, or the value of the current named header of the root part of a multipart request. The *name* segment is case-insensitive. The request header can be modified only in preflow policies. For more information, see Customizing the preflow policies.	Read/write
API Gateway only **request.original.headers.*name***	The value of the original named header of the HTTP request. This variable is created only when the request header is modified. The *name* segment is case-insensitive.	Read-only
API Gateway only **request.package.headers.*name***	The value of the named header of the multipart request. The *name* segment is case-insensitive.	Read-only
API Gateway only **request.parameters**	You can obtain your incoming parameters from path and query parameters.	
API Gateway only **request.parameters.*name*.locations**	An array of strings that specify the parameter types associated with the parameter specified in name. The supported keywords for parameter types are as follows. **formData** The parameter is in the body as form data **header** The parameter is in the request header **path** The parameter is in the path **query** The parameter is in the query	Read-only
API Gateway only **request.parameters.*name*.values**	An array containing values of the parameter types associated with the parameter specified in name. For example, when the first value is **path** in **request.parameters.myparam.locations[]**, the first value in **request.parameters.myparam.values[]** is the array of path values associated with **myparam**. Request parameters can be modified only in preflow policies. For more information, see Customizing the preflow policies.	Read/write
API Gateway only **request.original.parameters.*name*.values**	An array containing the original values of the parameter types associated with the parameter specified in *name*. This variable is created only when a request parameter value is modified.	Read-only
request.path	The path section of the **request.uri** that starts with the base path of the API, including the '/' character that begins the base path.	Read-only
API Gateway only **request.protocol**	The protocol that is used to receive the request: **http** or **https**.	Read-only
request.querystring	The request query string without the leading question mark.	Read-only
request.search	The request query string with the leading question mark.	Read-only
request.uri	The full HTTP request URI from the application.	Read-only
request.verb	The HTTP verb of this request.	Read-only
API Gateway only **session.apiGateway**	The gateway that receives the request.	Read-only
API Gateway only **session.apiGatewayName**	The name of the API gateway as defined in the API Manager.	Read-only

Name	Description	Permission
API Gateway only `session.clientAddress`	The address of the client that sent the request.	Read-only
API Gateway only `session.domainName`	The name of the domain that the gateway belongs to.	Read-only
API Gateway only `session.globalTransactionID`	The global transaction ID in the logs.	Read-only
API Gateway only `session.localAddress`	The address of the gateway on the DataPower® Gateway.	Read-only
API Gateway only `session.timeStarted`	The time that the gateway started to process the request.	Read-only
API Gateway only `session.transactionID`	The transaction ID of the gateway request.	Read-only
`system.datetime`	Returns a string that represents the current date and time in the system time zone of the gateway.	Read-only
`system.time`	Returns a string that represents the current time in the system time zone of the gateway.	Read-only
`system.time.hour`	Returns a number 0 - 23 inclusive, representing the hour of the current time in the system time zone of the gateway.	Read-only
`system.time.minute`	Returns a number 0 - 59 inclusive representing the minute of the current time in the system time zone of the gateway.	Read-only
`system.time.seconds`	Returns a number 0 - 59 inclusive representing the seconds of the current time in the system time zone of the gateway.	Read-only
`system.date`	Returns a string that represents the current date in the system time zone of the gateway.	Read-only
`system.date.day-of-week`	Returns a number 1 - 7 (Monday to Sunday) inclusive representing the day of the week in the system time zone of the gateway.	Read-only
`system.date.day-of-month`	Returns a number 1 - 31 representing the day of the month in the system time zone of the gateway.	Read-only
`system.date.month`	Returns a number 1 - 12 representing the month in the system time zone of the gateway.	Read-only
`system.date.year`	Returns a four-digit number that represents the year in the system time zone of the gateway.	Read-only
`system.timezone`	Returns a system time zone ISO 8601 identifier for the gateway, which might include a sign, a two-digit hour, and minutes. For example, `-04:00`.	Read-only

OAuth context variables - DataPower Gateway (v5 compatible)

The OAuth context variables described in this section apply only to the DataPower Gateway (v5 compatible). For details of the OAuth context variables that apply to the DataPower API Gateway, see OAuth context variables.

Table 2. OAuth context variables (DataPower Gateway (v5 compatible)).
Note: Most OAuth context variables are available only when IBM API Connect is acting as the OAuth resource server. However, the `oauth.introspect` variables are also available when integrating with third party providers.

Name	Description
`oauth.access-token`	If the request is authenticated with OAuth, this variable contains the access token string.
`oauth.miscinfo`	This variable contains information explicitly included in the Authentication URL and Metadata URL headers. For more information, see Authenticate URL.
`oauth.not-after`	If the request is authenticated with OAuth, this variable contains the date when the token expires.
`oauth.not-before`	If the request is authenticated with OAuth, this variable contains the date when the token was issued.
`oauth.resource-owner`	If the request is authenticated with OAuth, this variable contains the name of the resource owner.
`oauth.scope`	If the request is authenticated with OAuth, this variable contains the scope of this access token.
`oauth.introspect.active`	Always available to introspection. Boolean value.
`oauth.introspect.response`	Always available to introspection. Shows the complete current response payload. Example payload value: `{"active":true, "client_id", "xxx-xxx", "token_type", "bearer", "scope":"neon"}`

Other variables might be available from the third party, in the form of: `oauth.introspect.<variable>`	Decoding the previous example payload, the following variables are made available for further processing.
	
	`oauth.introspect.client_id: xxx-xxx`
	`oauth.introspect.token_type: bearer`
	`oauth.introspect.scope: neon`

Application certificate context variables

The following table describes context variables that are available when a certificate is used to verify access to an API, although these will vary depending on the signature mechanism that is being used; for more information, see the Internet X.509 Public Key Infrastructure Certificate and CRL Profile specification.

Table 3. Application certificate context variables

Name	Description
`application.certificate.Base64`	Base64 format.
`application.certificate.fingerprint`	Fingerprint
`application.certificate.Version`	Version
`application.certificate.SerialNumber`	Serial number
`application.certificate.SignatureAlgorithm`	Signing algorithm
`application.certificate.Issuer`	The issuer of the certificate
`application.certificate.Subject`	Subject
`application.certificate.NotBefore`	Not valid before this date
`application.certificate.NotAfter`	Not valid after this date

Name	Description
`application.certificate.SubjectPublicKeyAlgorithm`	Algorithm for the subject public key
`application.certificate.SubjectPublicKeyBitLength`	Length for the subject public key
`application.certificate.KeyValue.type`	Various context variables that depend on the algorithm and key. The following are possible context variables: • `application.certificate.KeyValue.RSAKeyValue.Modulus` • `application.certificate.KeyValue.RSAKeyValue.Exponent`

API activity logging context variables

If activity logging is enabled for an API, a `log` context variable is created; the `log` context variable contains the data relating to an API execution event. On completion of API execution, the `log` context variable is written to an API event record that is stored for subsequent access by API analytics. For details of the fields contained in the `log` context variable, see API event record fields.

The way in which you enable and configure activity logging depends on the type of gateway you are using, as follows:

- If you are using the DataPower API Gateway, you configure activity logging in the API configuration settings; see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).
- If you are using the DataPower Gateway (v5 compatible), you configure activity logging by adding an Activity Log policy to the API assembly.

The activity logging configuration defines the default content of the `log` context variable, but you can modify it in an API assembly; for example:

- Add your own data values by using a Set Variable policy.
- Remove or redact data values by using a Redaction policy; see Redaction - DataPower API Gateway or Redaction - DataPower Gateway (v5 compatible).
- API Gateway only Modify or replace the `log` context variable by using a Log policy.

GraphQL context variables

The GraphQL query and response variables generated from API processing and assembly actions are stored in the API context in the `message.attributes.graphql` context variables.

Table 4. GraphQL context variables

Name	Description
`message.attributes.graphql`	The query and response attributes of the GraphQL message.
`message.attributes.graphql.query`	The attributes of a GraphQL query, including the query string, operation name, and variables.
`message.attributes.graphql.query.query`	The GraphQL query string.
`message.attributes.graphql.query.variables`	The map of GraphQL variables.
`message.attributes.graphql.query.operationName`	The name of the operation to execute.
`message.attributes.graphql.query.operationType`	The type of the operation to execute.
`message.attributes.graphql.request`	The attributes of the GraphQL request.
`message.attributes.graphql.request.fieldCost`	The weighted sum of the cost of all fields accessed in the query. The cost of each field access is configured in the schema. This count includes fields whose field costs are not set to 0.0.
`message.attributes.graphql.request.fieldCounts`	The maximum number of times that each field can be retrieved by the given query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. This count includes fields whose field costs are not set to 0.0.
`message.attributes.graphql.request.typeCost`	The weighted sum of the cost of all types retrieved in the query. The cost of each type is configured in the schema. This count includes types whose type costs are not set to 0.0.
`message.attributes.graphql.request.typeCounts`	The maximum number of times that a value of each type can be retrieved by the given query. This count includes types whose type costs are not set to 0.0.
`message.attributes.graphql.response.fieldCost`	The weighted sum of the cost of all fields in the response to the query. The cost of each field access is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the field cost is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.fieldCounts`	The number of times that each field was retrieved in the response to the query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. If this sum cannot be calculated based on the analysis configuration in the request, the field count is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.typeCost`	The weighted sum of the cost of all types in the response to the query. The cost of each type is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the type cost is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.typeCounts`	The number of times that a value of each type was contained in the response to the query. If this sum cannot be calculated based on the analysis configuration in the request, the type count is expressed as the maximum integer value that can be assigned.

Name	Description
`message.attributes.parse.GraphQLIntrospection`	The introspection type of the assembly GraphQL introspect action. When a GraphQL query is parsed, this context variable is populated with one of the following values: • `not-introspection` • `custom-introspection` • `default-introspection`

Related concepts

- Variable references in API Connect

API Gateway only

OAuth context variables

You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.

Note: The OAuth context variables described here apply only to the DataPower® API Gateway. For details of the OAuth context variables that apply to the DataPower Gateway (v5 compatible), see OAuth context variables - DataPower Gateway (v5 compatible).
There are two main types of OAuth context variables:

- Information variables, outputs of an OAuth policy.
- Processing variables, processed during the execution of an OAuth policy.

Information variables

These context variables are outputs of an OAuth policy. They are not used in the processing of the OAuth action.

`oauth.result`
: The result of the latest action; returns `SUCCESS` or `FAILURE`.

`oauth.settings.variable_name`
: Basic settings from the OAuth provider. The following context variables are available:

```
oauth.settings.allowed_scopes
oauth.settings.access_token_ttl
oauth.settings.authorization_code_ttl
oauth.settings.refresh_token_ttl
oauth.settings.refresh_token_limit
oauth.settings.maximum_consent_ttl
```

`oauth.executed_components[0].variable_name`
: The components that have executed in this transaction, with their result. If a failure occurs then the error and error description will be added. The following context variables are available:

```
oauth.executed_components[0].result
oauth.executed_components[0].type
oauth.executed_components[0].error_description
oauth.executed_components[0].error
```

The possible values for the `type` variable are as follows:

```
ValidateRequestComponent
GenerateAZCodeComponent
VerifyAZCodeComponent
VerifyRefreshTokenComponent
GenerateAccessTokenComponent
IntrospectTokenComponent
RevokeTokenComponent
CollectMetaDataComponent
```

The following example shows a corresponding JSON extract from the OAuth context:

```
"executed_components": [
  {
    "type": "ValidateRequestComponent",
    "result": "SUCCESS"
  },
  {
    "type": "GenerateAccessTokenComponent",
    "result": "SUCCESS"
  }
]
```

`oauth.verified_access_token.variable_name`
: The token that was verified in the security requirement for a native OAuth provider. The following context variables are available:

```
oauth.verified_access_token.access_token

oauth.verified_access_token.client_id
oauth.verified_access_token.consented_on
oauth.verified_access_token.consented_on_text
```

`oauth.verified_access_token.grant_type`
`oauth.verified_access_token.misc_info`
`oauth.verified_access_token.not_after`
`oauth.verified_access_token.not_after_text`
`oauth.verified_access_token.not_before`
`oauth.verified_access_token.not_before_text`
`oauth.verified_access_token.one_time_use`
`oauth.verified_access_token.resource_owner`
`oauth.verified_access_token.scope`

`oauth.third_party.variable_name`
The token that was verified in the security requirement for a third party OAuth provider. Provides the following information:

- The response headers from the external, third-party OAuth provider.
- The body of response from the external, third-party OAuth provider.
- Whether the response is cached. When cached, the value is `true`. When not cached, the value is `false`.

The following context variables are available:

`oauth.third_party.headers`
`oauth.third_party.response`
`oauth.third_party.cached`

`oauth.code.variable_name`
The code that was generated during the execution of a component of type `GenerateAZCodeComponent`. The following context variables are available:

`oauth.code.client_id`
`oauth.code.code`
`oauth.code.redirect_uri`
`oauth.code.resource_owner`
`oauth.code.scope`

`oauth.token.variable_name`
The token that was generated during the execution of a component of type `GenerateAccessTokenComponent`. The following context variables are available:

`oauth.token.token_type`
`oauth.token.access_token`
`oauth.token.scope`
`oauth.token.expires_in`
`oauth.token.consented_on`
`oauth.token.redirect_uri`
`oauth.token.resource_owner`
`oauth.token.client_id`
`oauth.token.refresh_token`
`oauth.token.refresh_token_expires_in`
`oauth.token.refresh_token_count`

`oauth.introspect.variable_name`
The token that was introspected during execution of a component of type `IntrospectTokenComponent`. The following context variables are available:

`oauth.introspect.active`
`oauth.introspect.scope`
`oauth.introspect.client_id`
`oauth.introspect.resource_owner`
`oauth.introspect.token_type`
`oauth.introspect.grant_type`
`oauth.introspect.ttl`
`oauth.introspect.expires`
`oauth.introspect.expires_text`
`oauth.introspect.iat`
`oauth.introspect.not_before`
`oauth.introspect.not_before_text`
`oauth.introspect.consented_on`
`oauth.introspect.consented_on_text`
`oauth.introspect.one_time_use`

`oauth.external_manager.variable_name`
Token management when using an external token manager. Provides the following information:

- The response headers from the external management server.
- The response JSON body from the external management server.
- When caching is enabled, whether the response is found in the cache or set in the cache. When caching is not enabled, that the response is not set in the cache.

The following context variables are available:

`oauth.external_manager.headers`
`oauth.external_manager.response`
`oauth.external_manager.cached`

Processing variables

These context variables are processed during the execution of an OAuth policy in your API assembly. If they are set prior to any OAuth policy then the value overrides what was sent in the request. They can also be modified between OAuth policies to manipulate the next component that executes. The following context variables are available:

`oauth.processing.assertion`
`oauth.processing.client_id`
`oauth.processing.client_secret`
`oauth.processing.grant_type`
`oauth.processing.redirect_uri`
`oauth.processing.scope`
`oauth.processing.response_type`
`oauth.processing.state`

```
oauth.processing.resource_owner
oauth.processing.refresh_token
oauth.processing.code
oauth.processing.token
oauth.processing.token_type_hint
oauth.processing.nonce
oauth.processing.max_age
oauth.processing.oidc_values_requested
oauth.processing.id_token_requested
oauth.processing.oidc_signing_algorithm
oauth.processing.code_challenge
oauth.processing.code_challenge_method
oauth.processing.code_verifier

oauth.processing.metadata.access_token
oauth.processing.metadata.payload
oauth.processing.metadata.azcode_miscinfo

oauth.processing.verified_code.client_id
oauth.processing.verified_code.resource_owner
oauth.processing.verified_code.misc_info
oauth.processing.verified_code.scope
oauth.processing.verified_code.is_verified
oauth.processing.verified_code.nonce

oauth.processing.verified_refresh_token.client_id
oauth.processing.verified_refresh_token.resource_owner
oauth.processing.verified_refresh_token.misc_info
oauth.processing.verified_refresh_token.scope
oauth.processing.verified_refresh_token.refresh_token_count
oauth.processing.verified_refresh_token.is_verified
oauth.processing.verified_refresh_token.one_time_use
oauth.processing.verified_refresh_token.grant_type
```

The following example shows the OpenAPI source code for a `gateway-script` policy that executes before an OAuth policy in your API assembly and adds a custom scope to the request:

```
// Add another custom scope to the request
let scope = context.get("request.parameters.scope.values[0]");
if (scope)
  context.set("oauth.processing.scope", scope + " custom");
```

The following example shows the OpenAPI source code for a `gateway-script` policy that between OAuth policies in your assembly and modifies the scope depending on the resource owner:

```
// Check resource owner and modify the scope
let owner = context.get("oauth.processing.resource_owner");
let scope = context.get("oauth.processing.scope");

if (owner === 'admin') {
    context.set("oauth.processing.scope", scope + " admin");
} else {
    context.set("oauth.processing.scope", scope + " customer");
}
```

Advanced scope context variables

The following context variables are used in OAuth advanced scope checking. They are populated by the values entered in the Endpoint and TLS Client Profile fields for the Application scope check and Owner scope check in the native OAuth provider configuration. Do not change these values as this might result in incorrect advanced scope operation.

For information on scope configuration, see Configuring scopes for a native OAuth provider. For information on advanced scope checking, see Scope.

```
oauth.advscope.app.url
oauth.advscope.app.tls-profile
oauth.advscope.own.url
oauth.advscope.own.tls-profile
```

Custom error context variables

These context variables are used to stop OAuth processing and specify the respective error details. They can be used before OAuth processing takes place.

```
oauth.custom_error.status.code
oauth.custom_error.status.reason
oauth.custom_error.message
oauth.custom_error.description
```

- Example - using multiple OAuth policies in an OAuth provider assembly

Error cases supported by assembly catches

Several error cases that can be returned by the assembly are available to the catch function.

ConnectionError

An error occurred while establishing a connection to another URL.

JavaScriptError
: An error occurred while executing JavaScript or GatewayScript in a policy.

PropertyError
: An error occurred due to an incorrect property during an invoke call or during the execution of a set-variable policy when an action was not set, add, or clear.

RedactionError
: An error occurred during the redaction of a field as part of a redact policy.

TransformError
: An error occurred during a transformation policy.

RuntimeError
: An otherwise unspecified error occurred.

BadRequestError
: An error occurred while trying to access the request. This is not supported by the default catch; to catch this condition, specify it in your catch definition.

SOAPError
: A SOAP Fault response was received as the result of a web service invoke request.

OperationError
: An invoke request received a response with an unsuccessful HTTP status code.

ValidateError
: An error occurred while trying to schema validate a message payload.

AssemblyRateLimitError
: The request exceeds the transaction count threshold specified in the API's Plan.

UnauthorizedError
: The API cannot be invoked based on the client ID and/or client secret provided, or id/secret were specified in the wrong location. This is not supported by the default catch; to catch this condition, specify it in your catch definition.

ForbiddenError
: The application making the API request has been disabled or is not active. This is not supported by the default catch; to catch this condition, specify it in your catch definition.

API and Product definition template examples

You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form **`{{variable-name}}`** that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by **`apic`** to create Products and APIs as examples you can use to copy and customize for your own use.

Default API definition template (OpenAPI 2.0)

The following example template, which is for an OpenAPI 2.0 API definition, is the default template that developer toolkit uses when you create an API definition. Copy this example template into your own template file (which must have the **`.hbs`** extension), then edit it for your purposes. Template variables are enclosed by double curly braces, for example **`{{name}}`**. For information on template variables, see Template variables for API and Product definitions. For more information on Handlebars, see https://handlebarsjs.com/.

    produces:
      - application/json
    summary: Request Access Tokens
```

```
    description: |
      This endpoint allows requesting an access token following one of the flows below:
      - Authorization Code (exchange code for access token)
      - Client Credentials (2-legged, there isnt resource owner information)
      - Resource Owner Password Credentials (2-legged, client provides resource owner name and password)
      - Refresh Token (exchange refresh token for a new access code)

      The table below indicates the required parameters for each specific grant_type options.
      Empty cells indicate a parameter is ignored for that specific grant type.

      Client authentication:
      - Confidential clients should authenticate using HTTP Basic Authentication. Alternatively, they may post
        their client_id and client_secret information as a formData parameter.
      - Public clients should send their client_id as formData parameter.

      | grant_type           | code       | client_credentials | password    | refresh_token |
      |----------------------|------------|--------------------|-------------|---------------|
      | client_id            | required*  | required*          | required*   | required*     |
      | client_secret        | required*  | required*          | required*   | required*     |
      | code                 | required   |                    |             |               |
      | redirect_uri         | required   |                    |             |               |
      | username             |            |                    | required    |               |
      | password             |            |                    | required    |               |
      | scope                |            | optional           | optional    |               |
      | refresh_token        |            |                    |             | required      |

      The implicit grant requests, see /oauth2/authorize.

Product definition template

The following example template is the default template that developer toolkit uses when you create a Product definition. Copy this example template into your own template file (which must have the **.hbs** extension), then edit it for your purposes. Template variables are enclosed by double curly braces, for example **{{name}}**. For information on template variables, see Template variables for API and Product definitions. For more information on Handlebars, see https://handlebarsjs.com/.

Template variables for API and Product definitions

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form **{{variable-name}}** that are substituted with values when you create the API or Product definition.

Product definition variables

The following table describes the Handlebars template variables that can be used in a product definition file. For more information on Handlebars, see https://handlebarsjs.com/. Product definition template files must have a **.hbs** filename extension.

Table 1. Product definition Handlebars template variables

Variable	Type	Description

{{apis}}	Array of string	The APIs to which the product definition refers. After substitution, the array values become the values of **apis.routes[*n*].$ref** fields, for example:
		`apis:`
		`  'routes':`
		`  $ref: apidef.yaml`
		`  ...`

{{name}}	String	Value of **info.x-ibm-name** field.
{{title}}	String	Value of **info.title** field.
{{version}}	String	Value of **info.version** field.

API definition variables

The following table describes the Handlebars template variables that can be used in an API definition file. For more information on Handlebars, see https://handlebarsjs.com/. API definition template files must have a **.hbs** filename extension.

Table 2. API definition Handlebars template variables

Variable	Type	Description
{{basepath}}	String	Base path on which the API is served, which is relative to the **host**.
{{definitions}}	OpenAPI definitions objectconverted to a YAML string ("stringified").	API contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{definitionsObj}}	OpenAPI definitions objectconverted to a YAML string ("stringified").	API contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{hostname}}	String	Value of the **host** field.
{{name}}	String	Value of **info.x-ibm-name** field.
{{paths}}	OpenAPI paths object	API contains the relative paths to the individual endpoints. The path is appended to **{{basePath}}** to construct the full URL.
{{pathsObj}}	OpenAPI paths object	API contains the relative paths to the individual endpoints. The path is appended to **{{basePath}}** to construct the full URL.
{{schemes}}	Array of string	Transfer protocol of the API. Values must be one of: **"http"**,**"https"**, **"ws"**, or **"wss"**.
{{targeturl}}	String	Value of **x-ibm-configuration.assembly.execute[invoke]**. Default is **$(runtime-url)$(request.path)**.
{{title}}	String	Value of **info.title** field.
{{version}}	String	Value of **info.version** field.

Learn to manage your APIs

Manage your APIs by using the API Manager user interface of IBM® API Connect. You can also analyze your API usage by using the analytics that are provided and socialize your APIs in a Developer Portal.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Why use APIs?

Whether you are a business user, an IT user, or an application developer, APIs are increasingly important to your business. You can use an API to publicize your company. Also, you can provide the assets, data, or services of your company to the external application developers to expand your enterprise and open new markets.

API Manager provides a solution for companies to manage APIs for private internal APIs, and public external APIs. By using this on-premises offering, you can externalize and manage your services as REST or SOAP APIs.

What do you need to know?

Depending on your role, you can complete different tasks to manage your API catalogs. Each task is covered in this document in the order that they are run.

Each task introduces new features of API Manager as they become relevant to the catalog that you are building.

For security reasons, your session times out after a period of inactivity.

Before you start, check that the browser you are using is supported and meets the required minimum levels. For more information, in the Detailed system requirements for a specific product document, search for the IBM API Connect product, and then select the required version.

The following topics explain the different ways that you can manage your APIs.

- **API management checklist**
  A summary, with links, of the key tasks for managing APIs in IBM API Connect.
- **Activating your API Manager user account**
  Activate the user account that your Cloud Manager administrator invited you to join before you access IBM API Connect API Manager application.
- **Accessing the API Manager user interface**
  The IBM API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.
- **Searching for items in API Manager**
  Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- **Using Engagement to automate notification tasks**
  You can create complex workflows that automate tasks based on the specified criteria and enhances the overall API management experience by using the Engagement feature in the API Manager helps .
- **Working with Catalogs**
  Products must be staged and published to a Catalog to be accessible to application developers through their consumer organizations.
- **[Technology preview] Using Governance enforcement for validation**
  Governance enforcement in IBM API Connect is used for enforced validation of API Products before they are published to catalogs.
- **Managing the application lifecycle**
  By using the application lifecycle capability in IBM API Connect, the applications that are created in the associated Developer Portal initially has Development status, and can make API calls through the development endpoints. When application testing is complete, the application developer can request to upgrade the application to Production status. After the request is approved, the application is upgraded can make API calls through Production endpoints.
- **Using syndication in API Connect**
  With the API Connect syndication feature, you can partition your catalogs into *Spaces*. Each space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that space, enabling each team to manage their APIs independently.
- **Working with products**
  In IBM API Connect, plans and APIs are grouped in products.
- **Working with APIs**
  For a specific Product, you can work with the APIs that are contained in the Plans in that Product.
- **Working with Plans**
  After a Product is published to a Catalog, you can work with the Plans in that Product.
- **Working with consumer organizations**
  Manage the consumer organizations that access your APIs and Plans when their users sign up to use the IBM API Connect Developer Portal .
- **Working with developer applications**
  You can work with the applications that have been registered in the Developer Portal associated with a Catalog.
- **Working with application subscriptions**
  You can work with the subscriptions to the Plans in all the Products in a specific Catalog. Plan subscriptions are created by application developers in the Developer Portal.
- **Security and authentication**
  In API Manager, you can use TLS profiles to secure the transmission of data between the management server and other API Connect subsystems and external services, and also configure user registries to securely authenticate your catalogs and APIs.
- **API Analytics**
  You can use API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.
- **Configuring governance in the API Manager**
  How to add custom governance rulesets to your API development process to validate and enforce organizational governance policies and best practices in your provider organization.
- **Administering user access**
  If you have permission to administer users in IBM API Connect, you can add and delete users. After users are removed from an organization through deletion, the user account remains in API Manager.
- **Changing your API Manager password**
  You can change your API Manager password in IBM API Connect.

- **Resolving login problems by increasing HTTP header size**
  You can resolve login problems for the API Manager UI by increasing the maximum HTTP client header size.
- **Reviewing processing status and downloading gateway logs**
  View and download the processing status information for the Gateway services that are enabled in your API Connect Catalogs and Spaces.
- **Reference**
  Reference information for the API Manager component in IBM API Connect.
- **API Manager tutorials**
  Tutorials for using the API Manager user interface in IBM API Connect.
- **Using Config Sync to replicate catalog data**
  Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

API management checklist

A summary, with links, of the key tasks for managing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	To connect to a Management server that uses the API Manager user interface, you must be an owner or a member of a provider organization.
Log in to the API Manager user interface	After you have activated your account, you can log in to your Management server from the API Manager user interface.
Configure your Catalogs	APIs are published to a catalog to make them available to application developers. The URLs for API calls, and for the Developer Portal, are specific to a particular catalog. By default, a *sandbox* catalog is provided for API testing, but you can create your own catalogs; for example, a production catalog for hosting APIs that are ready for full use.
Manage the membership of your Catalogs	You can add users to your catalogs, and assign roles and permissions to control their level of access.
Configure API security	You can configure user registries of various types for authenticating API access, TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Manage your Products	Move your Products through their lifecycle, from initially staging a Product to a catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. You can also display analytics information, and control who can see or subscribe to your Products.
Analyze your API usage	You can use IBM API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.
Manage user access to your provider organization	You can add users to your provider organization, remove users, and assign roles and permissions.
Partition your Catalogs into Spaces for syndication	With the syndication feature, you can partition your catalogs into *Spaces*. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

Activating your API Manager user account

Activate the user account that your Cloud Manager administrator invited you to join before you access IBM® API Connect API Manager application.

Before you begin

The Cloud Manager administrator has invited you to join API Connect.

Procedure

1. To create your API Manager account, complete the following steps.

   If the Identity Provider uses LDAP
   : An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If the Identity Provider uses a local registry
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign-up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:
     - Uppercase letters
     - Lowercase letters

- Numbers
- Special characters (for example, ! # $ %)

Note:

- The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
- If you previously had an account that the administrator removed, and they are inviting you again, you must reactivate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; \re-registration attempt fails.

If the Identity Provider uses an authentication URL

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your API Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for API Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.

2. To open the API Manager login page, click Sign up to complete your registration, then click Sign in .

Results

You have created your API Connect account.

What to do next

Log in to the API Manager user interface and, depending on your role, start to work with Catalogs, consumer organizations, APIs and Products.
To access the API Manager login page in the future, use the following URL:

`https://host/manager`

where *host* is the fully qualified host name or IP address of the Management server.

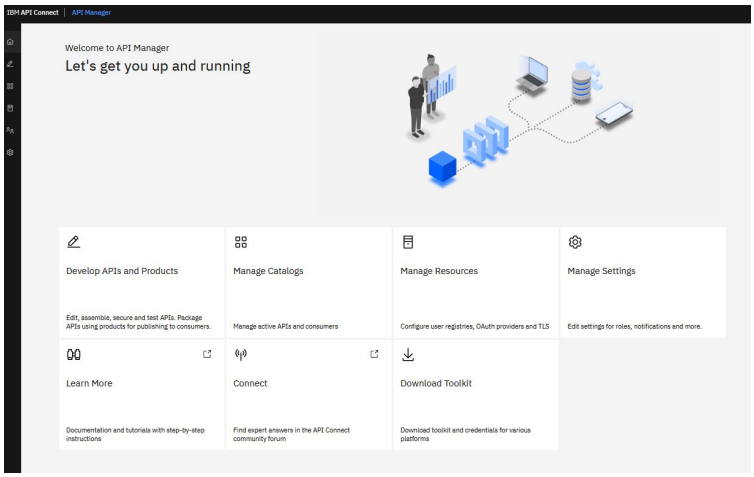
Accessing the API Manager user interface



The IBM® API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.

To log in to the API Manager user interface, complete the following steps:

1. In a web browser, enter the following URL:

   `https://host/manager`

   where *host* is the fully qualified host name or IP address of the Management server.
2. If your cloud contains multiple user registries, then select the user registry that contains the login credentials for your API Manager account. You might need to ask your administrator which user registry is appropriate for your account.
   For information on configuring user registries and making them available for API Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.
3. Enter your user name and password, then click Sign in.
   The API Manager user interface opens:

Depending on your role, you can now start to work with Catalogs, consumer organizations, APIs and Products.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager.

1. To start searching, type a string into the Search field.
2. Press Enter.
   - Whenever you press Enter in the Search field, the Search page displays with results and additional options.
   - If you press Enter in an empty Search field, or click Search in the navigation list, then the Search page displays a list all items.
   - If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose that you searched for "Crafted". The page displays with items that don't match the search string exactly, but includes the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the three dots (Actions menu) next to the item's Modified column to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view additional types. If you select a type from the More menu, it replaces a type in the list.

To refine the search further,

1. Click Options and then select Select Catalogs to Search.
2. Select the required catalogs to search.
   You can select up to 5 catalogs for a limited search.
3. Click the Filter selected catalogs tab.

Using Engagement to automate notification tasks

You can create complex workflows that automate tasks based on the specified criteria and enhances the overall API management experience by using the Engagement feature in the API Manager helps .

Engagement allows external HTTP(S) endpoints to be triggered when specific criteria are met within the IBM® API Connect. This helps the user to create multiple complex workflows that automate tasks. The Engagement resources are provisioned within a specific provider organization or catalog, enabling targeted access and management.

To use Engagement, click on the API Manager and specify the criteria as required.

Note: You can use Engagement only if there is at least one active analytics service and storage is enabled.
You can specify the criteria as required, and a guided workflow facilitates the creation of rules. Each rule can have multiple triggers, which can be configured to run multiple actions that target specific destinations. When you configure rules and triggers, make sure to fulfill the following criteria:

- Each rule can have up to 7 filter criteria and 5 triggers
- Each trigger can have up to 3 actions

For more information on creating a notification task, see Creating a notification task.

You can use Engagement on your API Manager to receive notifications for various purposes. The API consumers receive notifications based on the data source option that they select while configuring rules for the notification tasks. For more information, see Engagement datasource.

- **Creating a notification task**
  You can use Engagement on your API Manager to receive notifications based on the defined criteria.
- **Engagement datasource**
  Utilize Engagement on the API Manager to receive notifications for various purposes.

Creating a notification task

You can use Engagement on your API Manager to receive notifications based on the defined criteria.

Before you begin

You must have at least one active Analytics service to use Engagement in the API Manager. When you create your notification task, you must fulfill the following criteria:

- Each rule can have only up to 7 filter criteria and 5 triggers.
- Each trigger can have only up to 3 actions.

About this task

The Engagement feature in the API Manager helps the user to create complex workflows that automate tasks and enhance the overall API management experience. Based on the criteria defined while creating notification tasks, each user receives notifications.

Create a notification task

To use Engagement, click  on the API Manager and specify the criteria as required.

You can create a notification task by configuring a destination, rules, triggers, and actions.

1. Configure a **`destination`**, which is the definition of the HTTP(S) endpoint that will receive the notification tasks. For more information, see Creating a destination.
2. Configure a **`rule`**, which is the job that runs on a defined schedule and send queries to the data source. For more information, see Creating a rule.
3. Configure a **`trigger`**, which define the conditions that generate events. For more information, see Add triggers.
4. Configure an **`action`**, which defines what happens after a notification task is triggered. For more information, see Add actions.

Creating a destination

1. Click the Create destinations tab.
   Note: The API Manager sends emails by using the SMTP settings that you configure in the Cloud Manager. The **`Email`** destination is available out of the box, so you do not need to create a new destination. The system automatically creates an email destination for each provider organization and catalog. Each email destination has a unique ID specific to its provider organization and catalog. Ensure that you use the correct email destination ID for your configuration.
2. Click Destination.
3. Click Create and provide the following details:
   a. In the Title, provide a title for the destination.
   b. In the Description box, provide a description.
   c. To configure Webhook, complete the following steps:
      i. Select Webhook as the **`type`**.
      ii. Select an option from the **`Method`** list to specify the HTTP method for the destination. The available options are **`POST`**, **`PUT`**, and **`PATCH`**.
      iii. In the **`Webhook URL`** field, enter the target HTTP(S) endpoint.
      iv. **Optional:** Click Add + to include extra HTTP headers.
   d. To configure PagerDuty, complete the following steps:
      i. Select PagerDuty as the type.
      ii. Enter your `pagerduty integration routing key` in **`Routing key`** field. For more information about **`pagerduty integration`**, see Services and Integrations.
      Note: When integrating with PagerDuty, select `Events API v2` as the integration type.
   e. To configure Slack, complete the following steps:
      i. Select Slack as the type.
      ii. In the **`Token`** field, enter the Slack API token.
      iii. In the **`Channel ID`** field, enter your `Channel ID`. For more information about **`Token and Channel ID`**, see How to quickly get and use a Slack API bot token.
      Note: Use the Channel ID, not the channel's name. For example: **`C1234567890`**.
   f. To configure Amazon Simple Notification Service, complete the following steps:
   Note: To enable Amazon SNS for Engagement, you must create the AWS client secret and reference the secret in the analytics custom resource YAML file. For more information, see Enable Amazon SNS.
      i. Select Amazon SNS as the type.
      ii. In the Topic ARN field, enter the Amazon SNS topic's ARN.
      iii. In the Role ARN field, enter the Amazon SNS role's ARN.
   g. To configure Kafka HTTP Bridge, complete the following steps:
      i. Select Webhook as the **`type`**.
      ii. Select an option from the **`Method`** list to specify the HTTP method for the destination. The available options are **`POST`**, **`PUT`**, and **`PATCH`**.
      iii. In the **`Webhook URL`** field, enter the target HTTP(S) endpoint.

      `http://<route-name>.apps.<cluster-name>.<namespace>.com/topics/<topic-name>`

      For more information about **`Kafka HTTP Bridge`** configuration, see Connecting over HTTP with Kafka Bridge.

iv. Click Add + to add an HTTP header.
v. In the **Name** filed, enter `content-type`.
vi. In the **Value** field, enter `application/vnd.kafka.json.v2+json`.
vii. Define the JSON payload to be sent to the Kafka topic in the trigger action of your rule.
Note: Check your Kafka setup and adjust the payload format if needed. The following example shows a JSON message format required by some Kafka implementations:

```
{
     "records": [
        {
            "key": "my-key",
            "value": "my-value"
        }
    ]
}
```

h. To configure IBM MQ, complete the following steps:
i. Select Webhook as the **type**.
ii. Select an option from the **Method** list to specify the HTTP method for the destination. The available options are **POST**, **PUT**, and **PATCH**.
iii. In the **Webhook URL** field, enter the target HTTP(S) endpoint.

```
https://<host>:<port>/ibmmq/rest/v3/messaging/qmgr/<your_qm_name>/queue/<your_queue_name>/message
```

For more information about **IBM MQ messaging REST API**, see IBM MQ messaging REST API.
iv. Click Add + to add an HTTP header.
v. In the **Name** filed, enter `content-type`.
vi. In the **Value** field, enter the value of the content type you are using, for example: **text/plain;charset=utf-8**.
vii. Click Add + to add a second HTTP header.
viii. In the **Name** filed, enter `authorization`.
ix. In the **Value** field, enter `Basic <base64encodedstring>`.
Where:

- **base64encodedstring** is the **username:password** base 64 encoded.

x. Click Add + to add a third HTTP header.
xi. In the **Name** filed, enter `ibm-mq-rest-csrf-token`.
xii. You can leave the value field blank.
Note: Ensure that this header is included, even if the value field is blank, as the IBM MQ Queue Manager rejects the payload without it.
i. To configure IBM Cloud Event Notification Service, complete the following steps:
Note: The destinations in IBM Cloud Event Notification Service are not linked to the destinations in API Connect. You must configure the destination in IBM Cloud Event Notification Service before configuring Engagement in API Connect.
i. Select Webhook as the **type**.
ii. Select **POST** from the **Method** list to specify the HTTP method for the destination.
iii. In the **Webhook URL** field, enter the target HTTP(S) endpoint.

```
{base_url}/v1/instances/{instance_id}/notifications
```

Where:

base_url
Enter the base URL path

instance_id
Enter the identifier corresponding to the instance

For more information about **IBM Cloud Event Notification Service**, see Event notifications API.
iv. Click Add + to add an HTTP header.
v. In the **Name** filed, enter `content-type`.
vi. In the **Value** field, enter `application/json`.
vii. Click Add + to add a second HTTP header.
viii. In the **Name** filed, enter `Authorization`.
ix. In the **Value** field, enter your IAM token.
x. Define the JSON payload that you want to send to the notification service in the trigger action of your rule. For more information, see Event notifications API.

4. Click Create.

Creating a rule

1. Click Rules.
2. Click Create and provide the following details:
a. In the Title field, provide a `Title` for the rule.
b. In the Schedule section, specify a schedule to run this rule. You can specify a schedule either by defining a time interval or a cron string.
c. Click Next to select data and define query.
d. In the Select data section, select an option from the Data source list based on the data against which you want to run the rule.
e. In the Query section, define the aggregation metric that you want to use for the query. The default is a count of matching records. You can also use mathematical aggregations for numerical fields, such as the maximum value or the average over a time period.
f. In the Data time range for the last fields, enter the time range based on how far back in the past you want to run the search for matching data items.
g. Click Add filter + to select up to 7 data filters to based on the data you want to include while running the query. You can use any of the analytics event record fields.
h. Click Add group by + to select a group based on how you want to group the selected data and streamline the target criteria. For example, a rule that matches 10 API events with a status code of 500 within a 24-hour period can use **Group by** on **api_name** to call for 10 matching events for an individual API as opposed to a total across all events for all APIs.
i. Click Next to configure triggers.

Add triggers +:

a. Click Add trigger +. You can add up to 5 triggers.
b. In the Trigger details section, provide a `Title` for the trigger and then, select the severity level and trigger condition from the corresponding lists.
c. From the Severity drop down list, select an option.
d. In the Trigger condition section, set a condition as needed.
Define the numerical target, which allows a single rule to have multiple triggers with different severity and trigger conditions. When the specified criteria are met, each trigger can trigger up to 3 actions, which then invokes different endpoints or with different payloads.

Add actions:

a. Click Add action + to configure the action that happens when the trigger criteria are met.
b. In the Trigger action section, provide a `title` for the action,
c. From the Destination list, select the destination to be invoked when the criteria are met.
d. Enable Throttling and define the throttling window to prevent invoking multiple triggers for the same rule in the same time period.
e. In the Payload section, provide a message subject and a payload value. You can add context variables in the Payload field based on the task payload information you want to display in the destination.
Note: The message subject is not sent to the HTTP endpoint. The payload value acts as the HTTP body of the notification task that is sent to the destination endpoint

3. Click Save.
4. Click Finish.

What you did in this task

On your API Manager, you used Engagement to automate notification tasks based on the specified criteria. The Task status tab displays the latest notification tasks for each trigger.

Engagement datasource

Utilize Engagement on the API Manager to receive notifications for various purposes.

The API consumers receive notifications based on the datasource option they select while configuring rules for the notification tasks. The available datasource options are:

- **API events**
  Reference table and example use cases for API event based engagement rules.
- **Audit events**
  Reference table and example use cases for audit event based engagement rules.
- **API summary**
  Reference table and example use cases for API summary based engagement rules.
- **Config sync**
  Reference table and example use cases to monitor the use of config sync based engagement rules for artifact replication.

API events

Reference table and example use cases for API event based engagement rules.

The following are some of the example use cases for API event based engagement rules:

- An API Provider can use Engagement to get notified:
  - If there are more than 3 HTTP 500 errors on any single API in any 24 hr period.
  - When the average response time for an API goes beyond a certain threshold.
- A corporate security officer can use engagement to receive an email if someone accesses their banking APIs from an embargoed country.
- An AI API Provider can use engagement to get notified if the total of the AI Tokens used within an hour goes beyond a certain threshold.

The following table shows the list of fields available for an API event record. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. API event record fields

Field name	Type	Description
ai_cache_hit	Boolean	Indicates whether the AI response was served from cache.
ai_model	String	The name or identifier of the AI model that is used.
ai_request_tokens	Number	The number of tokens in the input prompt to the AI model.
ai_response_tokens	Number	The number of tokens that are generated in the AI response.
ai_total_tokens	Number	The total number of tokens that are used in the AI interaction that includes both request and response.
alert_action	String	The action that is taken in response to an alert.
alert_description	String	The description or message that is associated with the alert.
alert_source	String	The source system or module that generated the alert.
alert_type	String	The type or category of the alert.
api_id	String	The API identifier.
api_name	String	The name of the API.
api_resource_id	String	Field format is: **`api_name:api_version:method:path`**. Only available on API Gateway v10.5.3 or higher.

Field name	Type	Description
api_version	String	The version number of the API.
api_type	String	The type of API. For example, REST, GraphQL, SOAP.
app_id	String	The identifier for the registered application.
app_lifecycle_state	String	The lifecycle state of the application.
app_name	String	The name of the registered application. Note: The property is set to **`undefined`** when a client ID is not used or is invalid on the API. The gateway needs a client ID to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app was invoked, because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
app_type	String	The application type, with a value of **`Production`** or **`Development`**.
backend_method	String	The HTTP method that is used in the backend request.
backend_request_body	String	The body content of the backend request.
backend_request_headers	Object	The headers that are sent in the backend request.
backend_response_body	String	The body content of the backend response.
backend_response_headers	Object	The headers that are received in the backend response.
backend_status_code	String	The HTTP status code returned by the backend.
backend_time_to_serve_request	Number	Time in milliseconds taken by the backend to serve the request.
backend_url	String	The URL of the backend service invoked.
bytes_received	Number	The number of bytes received from the consumer in the request.
bytes_sent	Number	The number of bytes sent to the consumer in the response.
cached_response	Boolean	Indicates whether the response was served from a cache.
callback_request	Boolean	Indicates whether the request was a callback.
catalog_id	String	The Identifier of the API catalog.
catalog_name	String	The name of the API catalog.
client_geoip.area_code	Number	The public switched telephone network (PSTN) area code of the client, as identified from its IP address.
client_geoip.city_name	String	The city name of the client, as identified from its IP address.
client_geoip.continent_code	String	The two-letter continent code of the client, as identified from its IP address.
client_geoip.country_code2	String	The two-letter country code of the client, as identified from its IP address.
client_geoip.country_code3	String	The three-letter country code of the client, as identified from its IP address.
client_geoip.country_name	String	The country name of the client, as identified from its IP address.
client_geoip.dma_code	Number	The Designated Market Area (DMA) code of the client, as identified from its IP address.
client_geoip.ip	String	The IP address of the client.
client_geoip.latitude	Number	The latitude of the client location, as identified from its IP address.
client_geoip.location	String	The longitude and latitude of the client location (separated by a comma), as identified from its IP address.
client_geoip.longitude	Number	The longitude of the client location, as identified from its IP address.
client_geoip.postal_code	String	The postal code of the client, as identified from its IP address.
client_geoip.region_code	String	The region code based on client IP.
client_geoip.region_name	String	The abbreviated form of the region that corresponds to the IP address of the client.
client_geoip.timezone	String	The time zone of the client, as identified from its IP address.
client_id	String	The unique ID of the client that is attached to the API request.
client_ip	String	The IP address of the client.
consumer_organization_id	String	The Identifier of the consumers organization.
consumer_organization_name	String	The name of the consumers organization
consumer_organization_title	String	The title or display name of the consumer organization.

Field name	Type	Description
custom_data	Array map	Custom data can be added to this field.
datetime	Date	A timestamp that records when the API was invoked. The timestamp is always shown in Coordinated Universal Time.
developer_org_id	String	The identifier for the consumer organization that owns the application.
developer_org_name	String	The name of the consumer organization that owns the application.
endpoint_url	String	When the request failed, **`endpoint_url`** identifies the proxy or invoke target URL on which the request failed. It is not included with a successful request. On V5 compatible gateway, this field is only populated when the backend server URL that was invoked returns an HTTP 404 code.
error_description	String	A detailed description of any error encountered.
error_message	String	A brief message describing the error.
event_type	String	The type of event.
filter_name	String	The name of the filter that is applied during the request.
gateway_geoip.area_code	Number	The public switched telephone network (PSTN) area code of the gateway, as identified from its IP address.
gateway_geoip.city_name	String	The city name of the gateway, as identified from its IP address.
gateway_geoip.continent_code	String	The two-letter continent code of the gateway, as identified from its IP address.
gateway_geoip.country_code2	String	The two-letter country code of the gateway, as identified from its IP address.
gateway_geoip.country_code3	String	The three-letter country code of the gateway, as identified from its IP address.
gateway_geoip.country_name	String	The country name of the gateway, as identified from its IP address.
gateway_geoip.dma_code	Number	The Designated Market Area (DMA) code of the gateway, as identified from its IP address.
gateway_geoip.ip	String	The IP address of the gateway.
gateway_geoip.latitude	Number	The latitude of the gateway location, as identified from its IP address.
gateway_geoip.location	String	The longitude and latitude of the gateway location (separated by a comma), as identified from its IP address.
gateway_geoip.longitude	Number	The longitude of the gateway location, as identified from its IP address.
gateway_geoip.postal_code	String	The postal code of the gateway, as identified from its IP address.
gateway_geoip.region_name	String	The abbreviated form of the region that corresponds to the IP address of the gateway.
gateway_geoip.timezone	String	The time zone of the gateway, as identified from its IP address.
gateway_host_name	String	The hostname of the API gateway.
gateway_ip	String	The IP address of the gateway.
gateway_port	Number	The port number used by the API gateway.
gateway_service_name	String	The name of the DataPower API gateway service. Configured by the cloud admin user when registering the gateway service. Only available on DataPower API Gateway v10.5.3 or higher.
gateway_time_to_serve_request	Number	Time in milliseconds taken by the gateway to serve the request.
gateway_type	String	The type and version of the gateway that processed the call, in format: **`type`**/**`version`**. Set by all gateway types except for v5c, and only available on v10.0.8.0 or higher.
global_transaction_id	String	The DataPower global transaction ID. See https://www.ibm.com/docs/en/datapower-gateway/latest?topic=variables-varserviceglobal-transaction-id-servicevarsglobaltransactionid.
graphql_document_hash	String	The hash value of the GraphQL query document.
graphql_error_count	Number	The number of errors encountered in the GraphQL query execution.
graphql_operation_name	String	The name of the GraphQL operation.
graphql_operation_type	String	The type of the GraphQL operation.
graphql_request_field_cost	Number	GraphQL APIs only. The maximum cost of all fields accessed in the query. The cost of each field access is configured in the schema.
graphql_request_max_nesting	Number	GraphQL APIs only. The maximum nesting depth found in the query by the assembly validate action. The schema configuration is used to determine which types are nested, so this value might be less than the nesting depth found by the assembly parse action.
graphql_request_top_field_counts	Object	GraphQL APIs only. The maximum number of times that a query can retrieve each field. This number is equal to the number of times that the resolver is required to run. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.

Field name	Type	Description
graphql_request_top_type_counts	Object	GraphQL APIs only. The maximum number of times that a query can retrieve an object of each type. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_request_type_cost	Number	GraphQL APIs only. The maximum cost of all types retrieved in the query. The cost of each type is configured in the schema.
graphql_response_field_cost	Number	GraphQL APIs only. The cost of all fields accessed in the query. The cost of each field access is configured in the schema.
graphql_response_max_nesting	Number	GraphQL APIs only. The nesting depth found in the query by the assembly validate action. The schema configuration is used to determine which types are considered nested, so this value might be less than the nesting depth found by the assembly parse action.
graphql_response_top_field_counts	Object	GraphQL APIs only. The number of times that each field was retrieved by the query. This number is equal to the number of times that the resolver is required to run. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_response_top_type_counts	Object	GraphQL APIs only. The number of times that an object of each type was retrieved by the query. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_response_type_cost	Number	GraphQL APIs only. The cost of all types that were retrieved in the query. The cost of each type is configured in the schema.
headers.*field_name*	String	Internal information that is related to analytics ingestion. headers.*field_name* is not related to the API call or its response, see **`request_http_headers`** for that information.
host	String	The hostname or IP address of the ingestion node that received the API event.
http_user_agent	String	The value of the User Agent header on the inbound request.
immediate_client_ip	String	The client IP address that is directly in front of the gateway. Usually **`immediate_client_ip`** is the IP of a load balancer.
latency_info.started	Number	The time delay (in milliseconds) between when the request was received and when the gateway started the corresponding task. Starting a task comprises multiple steps to prepare for executing an API; for example, completing the TCP/TLS handshake, verifying an app's client ID and secret, and matching the request URI to a catalog, API, and Plan. When the gateway receives a request, the "Start" duration is set to 0. The duration of each step within the Start task is then added up, and the total represents the duration of the Start task.
latency_info.task	String	The API transaction that was processed.
log_policy	String	The defined logging policy. Values include none, event, headers, and payload.
method	String	The HTTP method used in the request. For example, GET, POST.
monitor_attribute	String	The custom attribute that is used for API monitoring.
opentracing_info	Object	The distributed tracing data for the request.
operation_path	String	The specific operation path within the API.
org_id	String	The identifier for the provider organization that owns the API and associated Products.
org_name	String	The name of the provider organization that owns the API and associated Products.
path	String	The full path of the API request.
path_id	String	The Identifier for the API path that is accessed.
plan_id	String	The Plan identifier.
plan_name	String	The name of the Plan. Note: The property is set to **`undefined`** when a client ID is not used or is invalid on the API. The gateway needs a client id to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app was invoked because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
plan_version	String	The version number of the Plan.
product_id	String	The Identifier of the product that is associated with the API.
product_name	String	The Product name. Note: The property is set to **`undefined`** when a client ID is not used or is invalid on the API. The gateway needs a client ID to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app wasinvoked because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
product_title	String	The title of the Product.
product_version	String	The version number of the Product.
query_string	String	The URL query string value on the inbound request.
rate_limit	String	The maximum number of requests an application is allowed to make to the API during a specified time window.
rate_limit.count	Number	The number of API calls remaining in the specified rate limit time window.
rate_limit.interval	Number	The total time window during which a certain number of API calls are allowed.
rate_limit.limit	Number	The maximum number of requests an application is allowed to make to the API during a specified time window.
rate_limit.period	Number	The time window that is used to set a rate limit for API calls.
rate_limit.reject	String	An indication of whether calls that exceed the specified rate limit are rejected. If true, the API call is rejected with a 429 status code. If false, a record is created in the Activity log.

Field name	Type	Description
rate_limit.shared	String	An indication of whether the rate limit is shared at a Plan level by all operations, or whether a rate limit is specified on indivIDual operations.
rate_limit.unit	Number	The time unit used for calculating the rate limit. Note: Allowed values are second, minute, hour, day, and week
request_body	String	The body of the inbound request.
request_http_headers.*field_name*	String	A component of the HTTP header section of the inbound request; for example, the acceptable encodings, the identification string for the user agent, or the proxies through which the request was sent. Note: The following types of headers are considered sensitive and do not show in analytics data for security reasons: • Any secret key configured in the API security • Any header that contains `secret` • Any header that contains `Authorization`
request_method	String	The method of the inbound request.
request_protocol	String	The protocol of the inbound request.
resource	String	The name of the operation.
resource_id	String	The operation identifier.
resource_path	String	The operation path.
response_body	String	The body of the outbound response.
response_http_headers.*field_name*	String	A component of the HTTP header section of the outbound response; for example, the MIME type of the content or the data and time when the message was sent.
rule_name	String	The name of the rule that is applied to the request.
scope	String	Not used for DataPower® API Gateway or DataPower Gateway.
space_id	String	The Identifier of the space under which the API call was made.
space_name	String	The name of the space.
status_code	String	The status code set on the outbound response.
time_to_serve_request	Number	The time elapsed (in milliseconds) from when the gateway received the request to when it sent a response.
transaction_id	String	The identifier for the API transaction. See https://www.ibm.com/docs/en/datapower-gateway/latest?topic=variables-varservicetransaction-id-servicevarstransactionid.
uri_path	String	The URI path on the inbound request.
user_agent	Object	The parsed contents of the `http_user_agent` field, which contains information about the user that made the API call.
user_agent.device	String	Device name.
user_agent.major	String	User agent major version number.
user_agent.minor	String	User agent minor version number.
user_agent.name	String	User agent name.
user_agent.os_full	String	Detected operating system full name.
user_agent.os_major	String	Detected operating system major version number.
user_agent.os_minor	String	Detected operating system minor version number.
user_agent.os_name	String	Detected operating system name.
user_agent.os_patch	String	Detected operating system patch version.
user_agent.os_version	String	Detected operating system version.
user_agent.patch	String	User agent patch version.
user_agent.version	String	Detected user agent version.
websocket_message_type	String	The type of WebSocket message.
websocket_origin	String	The origin header of the WebSocket connection.

Audit events

Reference table and example use cases for audit event based engagement rules.

The following are some of the example use cases for audit event based engagement rules:

An API Provider can use Engagement to get notified:

- When catalogs are created, updated, or deleted.
- When Catalog or Cloud configuration settings are modified.
- On user login, logout, and failed login.

The following table shows the list of fields available for an audit event record. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. Audit event record fields

Field name	Type	Description
action	String	The type of action performed.
attachments.component	String	The name of the system or module where the event originated.
attachments.scope	String	The contextual boundary or scope of the event. For example, org, catalog, cloud.
attachments.method	String	The HTTP method or action method involved in the operation. For example, POST, GET
attachments.summary	String	A brief description or summary of the event or action.
attachments.operation	String	The specific operation or function executed.
attachments.resource	String	The type or name of the resource that is affected.
attachments.user.url	String	The URL involved in the action.
attachments.user.context	String	The context from which the user initiated the action.
attachments.user.idp_name	String	The name of the Identity Provider.
attachments.user.name	String	The display name of the user who initiated the action.
attachments.registration.url	String	The registration URL.
attachments.registration.type	String	The type of registration.
catalogId	String	The identifier for the catalog associated with the action.
initiator.host	String	The hostname of the initiator system.
initiator.host.address	String	The network address of the initiating system (for example, an IP address). It can be enriched with GeoIP data to provide geographic and location details. For more information, see #reference_j2j_s4x_32c1__table_bdt_v3v_1h.
initiator.host.agent	String	The software agent or process running on the initiator system.
initiator.id	String	The unique identifier that initiated the action.
initiator.name	String	The name of the initiator of the action.
initiator.typeURI	String	The URI indicating the type or classification of the initiator.
outcome	String	The result or outcome of the action.
reason.reasonCode	String	The code representing the reason for the action or outcome.
reason.reasonType	String	The category or type of the reason provided.
spaceId	String	The Identifier for the space where the action occurred.
target.id	String	The Identifier of the target resource affected by the action.
target.typeURI	String	The URI indicating the type of the target resource.
typeURI	String	The URI representing the type of the event .

API summary

Reference table and example use cases for API summary based engagement rules.

The following are some example use cases for API summary based engagement rules:

- An API Provider can use Engagement to get notified:
  - If the calls for a particular API decrease quarter to quarter.
  - If there is an increase in the time to serve requests for the current month when compared to the previous month.

Note: The API summary data is retained for longer periods and the rules created for API summary data can be used to perform long-term trend analysis over months or quarters.
The following table shows the list of fields available for the API summary datasource. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. API summary data

Field	Type	Description
api_ref	string	API reference (api_name:api_version).
product_ref	string	Product reference (product_name:product_version).

Field	Type	Description
app_name	string	The name of the registered application.
catalog_name	string	The name of the catalog.
space_name	string	The name of the space, if spaces are enabled.
gateway_service_name	string	The name of the DataPower API gateway service that is configured by the Cloud Admin user when registering the gateway service. Only available on DataPower API Gateway v10.5.3 or higher.
plan_id	string	The plan identifier.
status_code	string	The status code set on the outbound response.
bytes_received	number	The number of bytes received from the consumer in the request.
bytes_sent	number	The number of bytes sent to the consumer in the response.
time_to_serve_request	number	The time elapsed (in milliseconds) between the gateway received the request and sent a response.

Config sync

Reference table and example use cases to monitor the use of config sync based engagement rules for artifact replication.

- An API Provider can use Engagement to get notified:
  - If the number of config sync records in a given period was less than expected, indicating that the sync failed to execute correctly.
  - If the number of config sync records in a given period was more than expected, indicating that the customers on call based licensing would be charged more.

The following table shows the list of fields available for the config sync datasource. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. Config sync data

Field	Type	Description
apis	integer	The number of apis
catalog_name	string	The name of the catalog.
catalog_id	string	The catalog ID.
consumer_orgs	number	The number of consumer organizations synchronized.
members	number	The number of members synchronized.
users	number	The number of users synchronized.
applications	number	The number of applications synchronized.
credentials	number	The number of credentials synchronized.
subscriptions	number	The number of subscriptions synchronized.
total items	number	The total number of items synchronized.
products	integer	The number of products

Working with Catalogs

Products must be staged and published to a Catalog to be accessible to application developers through their consumer organizations.

When you create a provider organization, API Connect creates a sandbox catalog by default. The characteristics of the sandbox catalog are:

- The sandbox catalog is designed for API development and testing.
- The sandbox catalog cannot be deleted and does not have production mode or Spaces options under catalog settings.
- A sandbox catalog includes a default application and a consumer organization.

In API Connect, you can create multiple Catalogs. Catalogs are useful for separating products and APIs for testing before you make them available to consumer organizations. The syndication feature in API Connect means that you can also publish a product to a Space in a Catalog.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
A Catalog is a staging target, and behaves as a logical partition of the gateway and the Developer Portal. The URL for API calls and the Developer Portal are specific to a particular Catalog. In a typical configuration, an API provider organization uses a development Catalog for testing APIs under development and a production Catalog for hosting APIs that are ready for full use. A common approach is to have a development cloud with a development Catalog, a few test Catalogs and a production cloud that might have its own test Catalog.

You can use a *Space* to partition a Catalog so multiple teams can manage products and APIs independently in a single Catalog. A Space is conceptually like a sub-catalog, except that products and APIs in all Spaces in a given Catalog are published to the same Developer Portal . For more information about Spaces, see Using syndication in API Connect.

Note:
Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. A user account cannot be created with the same email address as the Admin or Catalog owner account. Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **`A user already exists with this email address`**.

For more information about using the Developer Portal, see Developer Portal: Socialize your APIs.

- **Creating and configuring catalogs**
  How to create and configure catalogs in IBM API Connect.
- **Configuring Product visibility at a Catalog or Space level**
  How to set a limit on the visibility for all Products that are published to a Catalog or Space.
- **Configuring sub paths for Developer Portal sites**
  You can increase the specificity of a IBM API Connect Developer Portal site URL by using sub paths.
- **Consumer Catalog and Developer Portal considerations**
  A customer can have a Developer Portal, Consumer Catalog, or both to test and subscribe to the APIs published in the Catalog.
- **Managing Catalog membership**
  Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.
- **Importing a user-defined policy into a Catalog**
  You can make your user-defined policy available to API developers by importing it into an IBM API Connect Catalog, or a Space in a Catalog.
- **Importing an OpenAPI extension into a Catalog**
  You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.
- **Retaining Version 5 vanity endpoint behavior in a Catalog**
  The behavior of vanity endpoints in a Catalog is changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.
- **Protecting catalog properties**

Creating and configuring catalogs

How to create and configure catalogs in IBM® API Connect.

Before you begin

You must have catalog create permissions to complete this task. For more information about permissions, see API Connect user roles.

- As the user who creates the catalog, you are automatically the catalog owner and have all catalog permissions.
- If you configure a new user registry for authenticating users to the Developer Portal , you must also complete the onboarding section in the catalog, to make the registry available to Developer Portal users. See Step 10 for details.
- Every account in the Developer Portal , including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the catalog owner. It is not possible to create a user account (and associated consumer organization) with the same email address as the Admin account (or that of the catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address.`

Procedure

To create and configure your catalog, complete the following steps:

1. Log in to API Manager and click Manage.
2. Create the catalog.
   You can create the catalog in either of the following ways:
   Specify the owner, then configure the catalog as described below.
   a. Click Add > Create catalog.
   b. In the Catalog Owner field, select the owner of the catalog.
   By default, you are the owner. However, you can specify any user who is a member of the provider organization.
   c. Continue from step 3 to configure the catalog.
   Send an invitation email, with an activation link, to the intended catalog owner:
   a. Click Add > Invite catalog owner.
   b. Enter the email address of the catalog owner, then click Invite.
   c. On receipt of the email, the catalog owner must activate the catalog and configure it:
   i. Open the activation link, complete the sign-up form, and sign in to the API Manager UI.
   ii. Click Manage Catalogs, click the catalog name that was provided on the sign-up form, then click the Catalog settings tab.
   iii. Continue from step 6 to configure the catalog.
3. Enter the catalog Title. A Name is entered automatically and cannot be changed.
   Note: The value in the Name field is a single string that is used to identify the catalog in developer toolkit CLI commands. The Title is used for display; you can change the title but the name does not change.
   To view the CLI commands to manage catalogs, see the toolkit CLI reference documentation.
4. Click Create.
   Your new catalog is displayed on the Manage page.
5. To continue to configure your catalog, select the catalog on the Manage page, then click the Catalog settings tab.
6. To configure the general settings for the catalog, click Overview, then proceed with the following steps.
   a. To use the catalog in production, set the Production Mode slider control to the On position, then click Confirm.
   By default, the new catalog is a development catalog.

   In a development catalog, all publish operations are forced, and any conflicts are resolved automatically. If you republish a previously published product version it is overwritten without warning, allowing you, for example, to repeatedly republish the same product version during testing. If spaces are enabled in a development catalog and you republish a previously published product version to a different space, it is removed from the previous space.

   However, if the catalog has been configured to require approvals, a development catalog behaves the same as any other catalog regarding requiring approval for staging and publishing actions.

Note: In a production catalog, the following conditions apply:
- You cannot publish a product to the catalog if there is already a product in the catalog with the same name and version. Instead, you must create a new version of the product for publication; see Creating a new version of your product . If spaces are enabled in a production catalog, you cannot publish a product with the same name and version to more than one space in the catalog.
- If this new product contains one or more modified APIs, you must create new versions of the APIs for inclusion in the product; see Creating a new version of an API definition. If the product contains a modified API and there is already a published API of the same name and version, the changes are not published.

b. To enable the partition of this catalog into spaces, set the Spaces slider control to the On position, then click Confirm.
For more information, see Using syndication in IBM API Connect.

c. If the catalog is the default staging catalog, move the Default slider control to the On position, then click Confirm. Then, calls to APIs that are published to the catalog can use a shorter URL that does not include the catalog name.
Note: You can enable Default for only one catalog. If another catalog is already set as the default catalog, you are unable to enable the setting on this catalog without first disabling the setting on the other catalog.

d. To enable application lifecycle for applications that are created in the Developer Portal that is associated with this catalog, set Application Lifecycle to On, then click Confirm.
When application lifecycle is enabled, any application that an application developer creates in the Developer Portal has Development status by default. When application testing is complete, the application developer can request to upgrade the application to production status. For more information, see Managing the application lifecycle.

7. To configure the gateway service settings for the catalog, click Gateway services, then proceed with the following steps.
Note: If spaces are enabled in the catalog, then you configure the gateway settings for the spaces, not for the catalog as a whole.

a. Click Edit.

b. Select the gateway services that you want to use with this catalog.
Cloud Manager UI configures the Gateway services. For more information, see Registering a gateway service. If any catalog default gateway services have been configured, they are selected when you create a new catalog; see Configuring default gateway services for catalogs.
The TYPE column indicates the gateway type for each gateway service listed, DataPower® Gateway (v5 compatible), DataPower API Gateway, or Event Gateway Service. For more information, see API Connect gateway types.

c. Click Save to save your changes.
The UI for creating or importing AsynchAPIs from Event Endpoint Management is disabled for catalogs that do not have the Event Gateway service available. If you want to work with AsynchAPIs in the catalog, you must add an Event Gateway service to the catalog.

You publish APIs by adding them to a product and then publishing the product to a catalog. To be able to publish products to a catalog, the catalog must be assigned to at least one gateway service so that the APIs in the product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a catalog, and they can be of mixed types, DataPower API Gateway and DataPower Gateway (v5 compatible).

A product is gateway type specific, either DataPower API Gateway or DataPower Gateway (v5 compatible). By default, when you publish a product to a catalog, it is published to all the assigned gateway services of the same gateway type as the product, but you can choose to publish the product only to selected gateway services, of that type, at publish time; see Publishing a draft product for more information. The APIs in the product are available to be called at all the specified gateway service endpoints.

If you select two or more Gateway services, you select or more Gateway services then, for analytics data to be available in the Developer Portal for this catalog, the Gateway services must all be associated with the same analytics service. If the set of associated analytics services for the selected gateway services includes two or more different analytics services, then the Developer Portal does not display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see Associating an analytics service with a gateway service.
Note: You can also configure the gateway service settings for the catalog by using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

8. To specify the product lifecycle state changes for which you want to enforce approval, complete the following steps:

a. Click Lifecycle approvals in the catalog settings navigation pane, then click Edit.

b. Select the required state changes, then click Save when done.
For example, if you select Publish and leave the other check boxes cleared, approval is required when anyone attempts to publish a product, but no approval is required for any of the other lifecycle state changes.
Note: Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.

c. To allow the originator of a product lifecycle change to approve it themselves, move the Task self-approval slider control to the On position, then click Confirm.
Note: In a development catalog, the originator of a product lifecycle change can always approve it themselves. In a production catalog, the originator of a product lifecycle change can approve it themselves only if the catalog setting Task self-approval is enabled.

d. Click Save.

9. To configure the permissions that each role in API Manager has, complete the following steps.

a. Click Roles in the catalog settings navigation pane.
To see the current permissions for a role, expand the role.

b. Click the options icon ⋮ alongside the role that you want to work with, then click Edit.

c. Select or clear the permissions check boxes as required.
To ensure that a role can manage user-defined policies, select Manage for the Settings permission.

To grant a role the permission to approve a specific lifecycle state change, select the state change in the Product-Approval section.

Note: You cannot remove a permission that has been assigned to the role at the provider organization level. However, you can add permissions that haven't been assigned at the provider organization level.

d. To map the roles to groups, under External Role mapping, select the Enable external group mapping checkbox and then enter the required information in each field.

e. Click Save.

10. To manage the onboarding of API consumers into this catalog, complete the following steps:

a. Click Onboarding in the catalog settings navigation pane.

b. To select the registries that are used to authenticate users of the Developer Portal associated with this catalog, click Edit in the Catalog user registries section, select the required registries, then click Save.
For more information about how to configure a user registry, see Authenticating by using your enterprise user registry.
Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

c. To set a default registry, locate the required registry and click ⋮ Set default.
When an API consumer signs up to the Developer Portal , the specified registry is used by default, with the option to select another registry.

d. To allow API consumers to complete their own sign-up process to the Developer Portal , set Self service onboarding to On.
If this option is disabled, an API consumer cannot sign up without an invitation from a consumer organization owner.

e. To require approval for all new self service onboarding to the Developer Portal , set Self service onboarding approval to On.
If this option is enabled, then any attempt by an API consumer to sign up to the Developer Portal results in an approval request being sent. This request is displayed in the Tasks tab in the catalog for the associated Developer Portal , from where the request can be approved or declined.
The Self service onboarding approval is honored whenever a consumer organization is created. So, even if an API consumer has already been approved to access a Developer Portal with a specific consumer organization, if they then try to create another consumer organization in the same Developer Portal , their request will still go through the approval process.

Note: To enable self-service onboarding approval, you must also complete the following tasks:
- Configure the user registry to require the user's email address.
- Configure the OIDC apps to send the user's email address for approval.

f. To edit the timeout period for the self service onboarding task, click Edit in the Self service onboarding task timeout section, specify the timeout period required, and click Save. The timeout period for this task covers both the email activation link and, if Self service onboarding approval is enabled, the approval process. The default timeout period for the self service onboarding task is 72 hours.
Expired self service onboarding tasks are cleared only once per day in the Developer Portal . Therefore, any API consumers with expired onboarding tasks must wait until these tasks are cleared before attempting to sign up again.

g. To configure the ability for API consumers to invite collaborators and assign them to roles, click Edit in the Consumer invitation and roles section, select the options required, and click Save.

h. To configure the timeout for activation links that are sent in email invitations to application developers, click Edit in the Invitation Timeout section, specify the timeout length, then click Save. The default timeout period for the invitation link is 48 hours.

i. To override the timeouts set by consumer organization invitations, set Override consumer organization's invitation timeout with catalog invitation timeout to On.
The catalog's own timeout setting is used instead.

Note: The onboarding catalog settings apply to both the Consumer Catalog and Developer Portal.

11. To specify the user registries that are used to secure access to APIs in this catalog, and to add the user registry to the sandbox catalog, complete the following steps:
    a. Click the Catalog settings tab, and then select API user registries.
    b. Click Edit and select the user registries you want to use.
    For more information about how to configure a user registry, see Authenticating by using your enterprise user registry.
    c. Click Save when done.

    Note:
    - Only LDAP and Authentication URL registries can be used to secure access to APIs. Therefore, only registries of these types are listed and available for selection.
    - If spaces are enabled in the catalog, then you specify the user registries for the spaces, not for the catalog as a whole. If you specify a user registry in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
    For more information about enabling and managing spaces, see Using syndication in API Connect

    .

12. To specify the OAuth Providers that can be used to secure access to APIs in this catalog, complete the following steps.
    Note:
    - If you want to specify an OAuth provider for a catalog, ensure that the Sandbox catalog is configured to use the same OAuth provider
    - Any resources that the OAuth provider references, such as API user registries or TLS client profiles, must also be enabled in the catalog
    - If spaces are enabled in the catalog, then you specify the OAuth providers for the spaces, **not** for the catalog as a whole. If you specify an OAuth provider in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
    For more information about enabling and managing spaces, see Using syndication in API Connect.

    a. Click OAuth providers in the catalog settings navigation pane.
    b. Click Edit, then select the OAuth providers that you want to use.
    To configure an OAuth provider, see either Configuring a native OAuth provider using Cloud Manager or Configuring a native OAuth provider using API Manager.

    c. Click Save when done.

13. To configure the TLS client profiles that are used with this catalog, complete the following steps:
    Note: If spaces are enabled in the catalog, then you configure the TLS client profiles for the spaces, not for the catalog as a whole. If you configure a TLS client profile in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
    For more information about enabling and managing spaces, see Using syndication in API Connect.

    a. Click TLS client profiles in the catalog settings navigation pane.
    b. Click Edit, then select the TLS client profiles that you want to use with this catalog.
    For more information about how to create a TLS client profile, see Creating a TLS client profile.
    c. Click Save when done.

14. You have two options for sharing your APIs with the application developers. Use the default Consumer Catalog for a lightweight consumer experience; no customization, basic functionality, and ideal for small API catalogs, and internal users. You do not need Portal service to configure the Consumer Catalog. For more details on choosing between Developer Portal and Consumer Catalog, see Consumer Catalog and Developer Portal considerations.
    To enable the Consumer Catalog, complete the following steps:
    a. Click Portal in the catalog settings navigation pane, then set Consumer Catalog to On. The Consumer Catalog URL is displayed.
    By default, the Consumer Catalog is set to On.
    b. Click the URL to access the Consumer Catalog.

    If you require a complete content management system for your catalog, create a Developer Portal; fully customizable, full functionality, and ideal for large API catalogs and business users. You need a Portal service to configure the Developer Portal. To configure the Developer Portal, complete the following steps:
    a. Click Portal in the catalog settings navigation pane, then click Create.
    b. Select the portal service that you want to use with this catalog.
    Portal services are configured by using the Cloud Manager UI. For details, see Registering a portal service.
    c. Optionally, override the default generated portal URL.
    The URL must have the following format:

`https://host_name.portal.com`

where *host_name.portal.com* must resolve to the IP address of the Developer Portal machine.
For example:

`https://myhost.mydomain.com`

Important:
- The URL must be unique across all catalogs.
- Mixed-case names are supported for resource names; however, portal endpoint URLs can support only lower-case. If a provider organization is created with a mixed-case name, you must edit the default-generated portal URL to make the provider organization name lower-case in the URL.

To use sub paths in your site URL, see Sub paths for Developer Portal sites.

d. Click Create to save your changes.
For more information on using the Developer Portal, see Developer Portal: Socialize your APIs.

If you want to edit the portal service or URL, return to this portal settings page and click Edit. To delete the portal site, click the options icon ⋮, and click Delete.
Note: The account profile for the owner of the catalog must have an email address specified to receive the creation notification, otherwise the Developer Portal creation operation will fail. To check whether your account profile has an email address, and specify a value, complete the following steps:

a. Click the User icon, and then select My Account.
b. Check the contents of the Email field, and specify a value if necessary, then click Save.

15. To define catalog properties, complete the following steps:
    a. Click Catalog properties in the catalog settings navigation pane, then click Create.
    b. Enter the property Name and Value.
    c. Select the Protected checkbox to redact the property.
    Note: After the property is created as protected, it remains redacted and the value is depicted as `******`. If you want to make the value visible, delete the property and create it again without selecting the Protected option.
    d. Click Create.

    The properties that you define can be referenced in any of the API definitions in this catalog. It is also possible to define properties that are specific to an API definition; see Setting API properties. For information on how to reference a property in an API definition, see Variable references in API Connect.
    Note:
    - If you define a catalog property of the same name as an API property, the API property takes precedence over the catalog property.
    - If you change the value of a catalog property, any API that references that property must be republished for it use the new value.
16. Optional: To configure the visibility of products that are published to a catalog or a space, see Configuring Product visibility at a Catalog or Space level.

What to do next

Additional catalog options

You can also configure the following settings for your catalog:

- Transfer ownership - To transfer ownership of the Catalog to a different user.
- Publish validations - Configure the publish validations that are performed when a Product is published.
- Configure vanity API endpoints - Configure vanity API endpoints, so that you can publish endpoints that are different to these gateway endpoints. A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API. If you do not configure vanity endpoints, these two endpoints are the same, and point to the gateway endpoint at which an API is invoked.

Import policies

Import your own policies into the Catalog. For details, see Importing a user-defined policy into a Catalog.

Note: When you import a policy, its implementation is imported into all Gateway devices associated with the Gateway service that hosts the Catalog. Additionally, API Connect modifies some object names and file locations to mark them with the appropriate Catalog name and policy version.
For more information about how to create and manage user-defined policies, see User defined policies.

- **Additional catalog options**
  The additional configuration options for your Catalog.

Additional catalog options

The additional configuration options for your Catalog.

Transferring the catalog ownership

To transfer ownership of the Catalog to a different user, complete the following steps:

1. Click Catalog settings and select Overview.
2. Click Edit.
3. From Select owner user, select the user who becomes the new owner.
4. If Spaces are enabled in the Catalog, then to also have the ownership of all Spaces in the Catalog transferred to the new Catalog owner, select the Also transfer ownership of owned Spaces checkbox.
5. Click Save to save the changes.

Note:

- To have permission to change the Catalog owner, you must be either the Catalog owner, or the owner of the provider organization that contains the Catalog.
- When the ownership changes, the new owner is assigned administration privileges for the Catalog, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Managing Catalog membership.
- The ownership can be transferred only to a user who is already a member of the Catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the Catalog, as described in Managing Catalog membership.

Configuring the publish validations

To configure the published validations that are performed when a product is published, complete the following steps:

1. Click Catalog settings and select Publish validations.
2. Click Edit, and select or clear the validation check boxes as required.
   Note: You can select the following validation options.
   - Publishing APIs with empty paths is not allowed.
   - Validate custom policy schema in assembly.
   - Validate the references inside the API and perform additional OpenAPI validations.
   - Publishing APIs with duplicate base paths is not allowed.
3. Click Save to save the changes.

Configuring the vanity API endpoints

For any API, there are two possible endpoints to consider:

- The gateway endpoint at which the API is started.
- The endpoint that is visible to the consumer in the Developer Portal.

If you do not configure vanity endpoints, these two endpoints are the same, and point to the gateway endpoint at which an API is started.
To have an endpoint visible to the consumer that is different from the gateway endpoint, you configure a vanity endpoint. A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to start the API. How the gateway endpoints for an API are determined depends on the OpenAPI version of the API, as described below.

(OpenAPI 2.0): For any enforced API in API Connect, the gateway endpoint formats for the API are as follows:

- If the OpenAPI definition has no **`host`** field, the API endpoint has the following format:

  `https://`*`gateway_service_host`*`/`*`provider_organization`*`/catalog/`*`basepath`

- If the OpenAPI definition has a **`host`** field (for example, **`petstore.com`**), the host is appended to the path after the *provider_organization*/*catalog* segments, and the API endpoint has the following format:

  `https://`*`gateway_service_host`*`/`*`provider_organization`*`/catalog/`*`host_field_value`*`/`*`basepath`

  Note: This is a change in behavior from IBM® API Connect Version 5.0, where the **`host`** field is not included in the API endpoint.

In these endpoint URLs, the variables are as follows:

- *gateway_service_host* is the hostname of the gateway service on which the API is running.
- *provider_organization* is the value of the **`name`** field of the provider organization that contains the Catalog in which the API is published.
- *catalog* is the value of the **`name`** field of the Catalog in which the API is published.
- *basepath* is the value of the **`basepath`** field in the OpenAPI definition for the API.
- *host_field_value* is the value of the host field in the OpenAPI definition for the API.

For more information about configuring the host server URL, see Specifying the host for an API.

API Gateway only **(OpenAPI 3.0):** The DataPower® API Gateway actively enforces API's security and access controls, the value of the first **`URL`** entry in the OpenAPI definition's **`servers`** array determines the API endpoint's **`basepath`** element, as follows:

1. If a relative URL is specified for the server URL, that value is used as-is for the **`basepath`**, and the API endpoint has the following format:

   `https://`*`gateway_service_host`*`/`*`provider_organization`*`/catalog/`*`basepath`

2. If a full URL is specified for the server URL, the DataPower API Gateway ignores the scheme (**`http://`** or **`https://`**), and the remaining hostname and **`basepath`** are used to form the API endpoint as follows:

   `https://`*`gateway_service_host`*`/`*`provider_organization`*`/catalog/`*`host_name`*`/`*`basepath`

In these endpoint URLs, the variables are as follows:

- *gateway_service_host* is the hostname of the gateway service on which the API is running.
- *provider_organization* is the value of the **`name`** field of the provider organization that contains the Catalog in which the API is published.
- *catalog* is the value of the **`name`** field of the Catalog in which the API is published.
- *host_name* is the value of the hostname in the server URL.
- *basepath* is the value of the **`basepath`** derived from the server URL.

For details on configuring the server URL in an OpenAPI 3.0 API definition, see Defining servers for an API, Defining servers for a Path, and Defining servers for an operation.
Note: You can change your Catalog settings to use the IBM API Connect Version 5.0 endpoint behavior, including support for a feature known as *host to catalog mapping*, whereby an API can be started without having to include the provider organization or Catalog in the URL path; see Retaining Version 5 vanity endpoint behavior in a Catalog.
To configure vanity API endpoints, so that you can publish endpoints that are different from these gateway endpoints, complete the following steps:

1. Click API endpoints in the Catalog settings navigation page. The Vanity API endpoint page opens.
2. Click Edit.
3. To display the current API base endpoint settings, select Display vanity endpoint.
4. Select the required Preference setting. Choose one of the following settings:
   - Catalog priority: Any host defined in the OpenAPI definition of the API is ignored and all API endpoints point to the endpoints that you define here. For example, suppose that you define a vanity API endpoint, with Catalog priority preference, to be **`https://prod.acme.com/`**. Then, the API endpoint is **`https://prod.acme.com/`*`basepath`**.
     The way in which the **`basepath`** is determined depends on the OpenAPI version of the API, as follows:
     - **(OpenAPI 2.0):** The **`basepath`** is taken from the **`basepath`** field in the OpenAPI definition.

- API Gateway only **(OpenAPI 3.0):** The `basepath` is taken from the first `url` entry in the `servers` array in the OpenAPI definition, ignoring any scheme (`http://` or `https://`) and host name.

- API priority: The host defined in the OpenAPI definition for the API takes precedence. For example, suppose you define a vanity API endpoint, with API priority preference, to be `https://api.acme.com/`. Then, the following rules determine the endpoint that is used when an API is called:
  - If the OpenAPI definition has a host defined, `test.acme.com` for example, then that value is used to determine the API endpoint. For example,`https://test.acme.com/basepath`.
  - If the OpenAPI definition has no host defined, the API endpoint is `https://api.acme.com/basepath`, as determined by the vanity API endpoint setting.

  The way in which any defined host is determined depends on the OpenAPI version of the API, as follows:
  - **(OpenAPI 2.0):** The host is taken from the `host` field in the OpenAPI definition.
  - API Gateway only **(OpenAPI 3.0):** The host is determined by the host name of the first `URL` entry in the OpenAPI definition's servers array.

5. Supply one or more endpoints, as follows:
   - If you selected Catalog priority, click Add to enter one or more endpoints URLs, and an optional summary for each. Any of the endpoint URLs can be used to start an API.
   - If you selected API priority, enter the endpoint URL, and an optional summary.

Note: After configuring your Catalog to support your vanity URL, you must configure your external network to map the vanity endpoints to the corresponding gateway endpoints. This configuration includes the following:

- A DNS mapping to ensure that the vanity host resolves to the gateway.
- Additional URL routing for the API as required.

For example, if your gateway has a default domain name of `apigw.dc.zone.mycompany.com` and an IP address of `29.12.141.150`, then the generic DNS configuration might look like:

```
api.acme.com. CNAME apigw.dc.zone.mycompany.com.
```

or

```
api.acme.com. A 29.12.141.150
```

Consult your network administrator and the DNS provider's documentation to do this configuration.

Configuring Product visibility at a Catalog or Space level

How to set a limit on the visibility for all Products that are published to a Catalog or Space.

Before you begin

To configure Product visibility at the Catalog or Space level, you must be assigned to a role that has the Settings > Manage permission for that Catalog or Space. For more information on assigning Catalog permissions to a role, see Creating and configuring catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

About this task

The availability of a Product to users is determined by both the visibility setting (that covers which users can view the Product), and the subscribability setting (that covers which users can subscribe to the Product). When you create a draft Product, you typically define the visibility and subscribability in the Product document; see Specifying the visibility of your Product, and Creating a draft Product for details.
Note: After a Product is published, its visibility and subscribability can be changed in the Catalog in the API Manager UI. For more information, see Changing the availability of a Product.
You can define a Catalog or Space setting to control the visibility of all the Products that are published to that Catalog or Space, as described in the following instructions. When this Catalog or Space setting is enabled, it can be used for the following two purposes:

- The setting can ensure that any Product published to that Catalog or Space, cannot have a visibility setting that exceeds the visibility limit set at the Catalog or Space level.
- The setting can also be used as the default visibility setting for all Products that are published to that Catalog or Space.

When you're publishing a Product, the visibility setting can come from the following four places:

1. Product override; set during the API Manager UI sequence to publish a Product. If this setting is used, it supersedes any visibility setting in the draft Product.
2. Product document; set in the draft Product.
3. Catalog or Space setting. If Product visibility is enabled in the Catalog or Space, and the visibility is not set by a Product override or in the Product document, then the Catalog or Space visibility setting is used as the default setting. This setting can also be used as a limiter to ensure that any Product that is published cannot exceed the Catalog or Space visibility setting.
4. Default setting. If there are no other visibility settings, then the following default visibility and subscribability settings are used:

```
visibility: {
    view: {
        enabled: true,
        type: 'public',
        orgs: []
    },
    subscribe: {
        enabled: true,
        type: 'authenticated',
        orgs: []
    }
}
```

The following table shows which Product level visibility settings are allowed, if the Catalog level visibility setting is enabled.

Table 1. Relationship between the Catalog level visibility settings, and the Product level visibility settings.

Catalog level visibility setting	Product level visibility setting
Public.	Public, Authenticated, or Custom.
Authenticated.	Authenticated, or Custom.
Custom.	Custom. The Product level visibility organization and group URLs are limited by the Catalog level organization and group URLs.

Note:

- Even if you restrict the product visibility to a smaller audience, the product still appears under Forums in the Developer Portal.
- If you want to disable a Forum module in the Developer Portal, click Extend > Disable module. For more information, see Turning off forums in the Developer Portal.

The following table shows that how the Product subscribe setting is limited by the Product visibility level. The basic premise to remember, is that if a Product is to be available for subscription, it must be visible. For example, if you want the subscription audience to be `authenticated`, the visibility audience cannot be `custom`.

Table 2. Relationship between the Product visibility settings, and the Product subscribe settings.

Product visibility level	Products subscribe setting
Public.	Authenticated, or Custom.
Authenticated.	Authenticated, or Custom.
Custom.	Custom. The Product subscribe organization and group URLs are limited by the Product visibility organization and group URLs.

Note:

- Changes to the Catalog visibility setting affect only future Product publishes. There is no change to Products that are already published.
- Any updates to the visibility of a Product are always verified against the Catalog visibility setting, as the Catalog visibility setting sets the maximum visibility level that is allowed. Therefore, if Product visibility is enabled in a Catalog, and the visibility setting of a Product is less restrictive than is set in the Catalog, then the Product publish to that Catalog will fail. For example, if the Catalog visibility setting is **`authenticated`**, then any Products that are published to that Catalog cannot have a visibility setting of **`public`**.
- You can also modify the Catalog visibility settings by using the API Connect REST APIs; see the API Connect REST API documentation.

Procedure

- To modify the Catalog or Space visibility settings by using the API Manager UI, complete the following steps.
  1. Open the Catalog that you want to work with.
  2. Click the Catalog settings tab.
  3. Click Product visibilty in the side navigation bar.
  4. Set the Enable product visibility toggle to On and then click Confirm.
  5. Select the organization or groups that you want the Products in the Catalog to be visible to.
     You can select from the following options:
     - Public - Products are visible to all users.
     - Authenticated - Products are visible only to users who have successfully authenticated.
     - Custom - Products are visible only to the consumer organizations and groups that you specify.
  6. Click Save.
- To modify the Catalog or Space visibility settings by using the developer toolkit CLI, complete the following steps.
  1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

     ```
     apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
     ```

     Where:
     - *mgmt_endpoint_url* is the platform API endpoint URL.
     - *user_id* is the user ID that you want to log in with. The user ID must be a member of a provider organization. This is an ID that you might also use to log in to the API Manager user interface.
     - *password* is the password that is associated with the supplied user ID.
     - *identity_provider* is the identity provider that is used to authenticate the supplied user ID.

     For example:

     ```
     apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
     ```

     You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

     ```
     apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
     ```

     For example,

     ```
     apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
     total_results: 2
     results:
       - title: API Manager User Registry
         realm: provider/default-idp-2
       - title: Corporate LDAP user registry
         realm: provider/corporate-ldap
     ```

     The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **`default-idp-2`**.
     For full details on how to log in to your management server from the CLI, see Logging in to the management server.

  2. Define your visibility settings by creating a YAML file with the following structure:

     ```
     allowed_product_visibility: {
         view: {
             enabled: true_or_false,
             type: 'visibility_type',
             org_urls: [],
             group_urls: []
     ```

```
    },
    subscribe: {
        enabled: false,
        type: 'authenticated'
    }
}
```

Where, in the `view` section of the `allowed_product_visibility` property:

- `enabled` - can be set to `true` or `false`. The default setting is `false`.
  If set to `true`, then any Product that is published to that Catalog or Space can have only a visibility that is the same or more restrictive than is configured in the `type` setting. If no visibility is set in the Product document, then the Catalog or Space setting is used as the default for the publish. If you want to always use the Catalog or Space setting as the default, then you must ensure that a Product visibility is not set.
  Note: If you are creating draft Products, and no visibility is set, then the value from the `allowed_product_visibility` field in the Sandbox Catalog is used as the default.
  If set to `false`, the feature is disabled, and the Product visibility settings that are defined in the Product document are used.
- `type` - if `enabled` is set to `true`, then this property specifies the maximum visibility of the Products that are published to this Catalog or Space. Valid settings are:
  - `public` - Products are visible to all users.
  - `authenticated` - Products are visible only to users who have successfully authenticated.
  - `custom` - Products are visible only to the consumer organizations and groups that are specified in `org_urls` and `group_urls`.
- `org_urls` - if `type` is set to `custom`, then this property specifies the URLs of the consumer organizations that you want the Products to be visible to. Otherwise, leave empty.
- `group_urls` - if `type` is set to `custom`, then this property specifies the URLs of the consumer organization groups that you want the Products to be visible to. Otherwise, leave empty.

The `subscribe` section cannot be edited at the Catalog or Space level. Subscribability is defined in the Product document `subscribe` section, and must be at least as restrictive as `authenticated`. For more information, see Specifying the visibility of your Product.

3. Modify your Catalog settings by using the following command:

   ```
   apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename
   ```

   Where *`filename`* is the name of the YAML file that you created in step 2.

   Note: If Spaces are enabled for the Catalog, then the visibility settings must be set at the Space level by using the `--space` option.
4. Confirm your updated Catalog settings by using the following command:

   ```
   apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -
   ```

- Creating and configuring catalogs

Configuring sub paths for Developer Portal sites

You can increase the specificity of a IBM® API Connect Developer Portal site URL by using sub paths.

By adding extra text to the URL of a Developer Portal site, you can create more site permutations for an organization. Developer Portal site URLs must be unique across all Catalogs.

Important:

- Sub paths are case-sensitive.
- The Developer Portal hostname must contain only lowercase characters.

You can create a Developer Portal in the following format:

`https://host_name.portal.com/sub_path_1/sub_path_2/.../sub_path_n`

Where *sub_path* can be any text that you want to implement to specify your site URL. There is no limit to the number of sub paths that you can have for the first site that you want to create.
However, you must not create overlaps in the naming of your URLs. A URL of one site must not be able to be confused with pages belonging to another site. For example, if you create the following site URL:

`https://host_name.portal.com/bank/safe/dollar`

Then, you cannot have the following site URL permutations:

`https://host_name.portal.com/bank/safe`

or

`https://host_name.portal.com/bank/safe/dollar/cent`

However, you can lengthen or shorten a site URL if you change a single sub path value, or the *host_name.portal.com* value. For example, if you created the following site URL:

`https://host_name.portal.com/bank/safe/dollar`

Then, you can create the following site URL permutations:

`https://host_name.portal.com/bank/euro`

and

`https://host_name.portal.com/bank/euro/vault/cent`

Important: If you already have a site URL that ends in *sub_path* texts, you cannot create a new site URL with the sub path text at the start.
For example, if you create the following site URL:

`https://host_name.portal.com/bank`

then, you cannot create the following site URL:

`https://bank.host_name.portal.com`

Consumer Catalog and Developer Portal considerations

A customer can have a Developer Portal, Consumer Catalog, or both to test and subscribe to the APIs published in the Catalog.

Consumer Catalog

The Consumer Catalog is a noncustomizable, web-based site for application developers to test and subscribe to the API published in your Catalog. The site uses less resources when compared to the Developer Portal and offers quick and basic credential access. The Consumer Catalog is ideal for small API catalogs and internal users, who are looking for a lightweight consumer experience with basic functionality.

You can enable or disable the Consumer Catalog in the API Manager under Catalog settings. By default, the Consumer Catalog is enabled. For more information, see Configuring Consumer Catalogs on API Manager.

The Consumer Catalog site supports the following key features:

- Create consumer accounts
- Delete consumer accounts
- Create new applications
- View analytics for an application
- View the available API products
- Local user registry, OIDC user registry, or LDAP registry
- Test the API
- Subscribe to the API

Attention:
It is not possible to modify the Consumer Catalog settings except for the options provided in the Catalog settings. For example, the self-service feature of the Consumer Catalog depends on your catalog settings. If the Self service onboarding option is not enabled for your catalog, the user cannot sign up to the Consumer Catalog. If you want to control the user experience, configure a Developer Portal for your site.

Known limitations

If your catalog has more than one user registry, the default user registry is used. Furthermore, the Consumer Catalog does not support the following options:

- Twitter OIDC user registries
- Content or documentation update after the API or Product publish
- Consumer organization management:
  - Changing the consumer organization ownership
  - Viewing users
  - Editing users
  - Adding users
  - Removing users
- Custom consumer catalog URL
- Branding
- Customization
- Configuration options
- Monetization

Note: If you have any suggestions to enhance the Consumer Catalog in future releases, you can raise your ideas in the IBM Ideas portal.

Developer Portal

The Developer Portal is a fully customizable, web-based portal site for application developers to explore, discover, test, and subscribe to the APIs published in your Catalog. The portal also provides extra features, such as application and consumer organization analytics, forums, blogs, and ratings, for socialization and collaboration. The default configuration supports consumer organization management, content management, user registry management, and other options. The Developer Portal is ideal for larger API catalogs and external users, who are looking for complete developer experience.

You can create the Developer Portal in the API Manager under Catalog settings. For more information, see Creating Developer Portal.

Important: Each portal site created, even if unused, uses resources in the portal service that's associated with the catalog, and more infrastructure might be required. If you do not want to modify your portal site, you can consider configuring a Consumer Catalog.

Managing Catalog membership

Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.

Before you begin

To manage Catalog members in the API Manager, you must be assigned to a role that has the Member > Manage permission for that Catalog. For more information on assigning Catalog permissions to a role, see Creating and configuring catalogs.

About this task

The Catalog owner can invite members of the provider organization work with the Catalog in the API Manager. The invited users are called "Catalog members" and are different from consumer users who are members of consumer organizations.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Members tab.
3. To add an existing user, click Add > Add member. To add a new user, click Add > Invite member.
   If you are using the Add member option, you can add any user who is already a member of another Catalog, or of a Space, in the provider organization, and is not currently a member of this Catalog, or the Catalog owner.
4. Enter the email address of a new user, or search for, and select, an existing user.
5. Select the roles that you want to assign to the user.
   For details of the roles and the default permissions that are assigned to them, see API Connect user roles. For details on how to create your own roles, see Creating custom roles.

   If Spaces are enabled in the Catalog, any role that you assign to the user at the Catalog level is assigned automatically to the user in all Spaces in that Catalog. Furthermore, if a user had originally been assigned a role only in a specific Space in a Catalog and you after assign the user that role at the Catalog level, the Space specific role assignment is lost and the user now has that role in all Spaces in the catalog.
   Note: You can subsequently change the roles that are assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members tab. If a user was originally added to the provider organization, rather than to the Catalog itself, the following conditions apply:
   - Any role assigned to the user at the provider organization level is assigned automatically to the user in all Catalogs, and cannot be removed at the Catalog level.
     For details on adding a user to a provider organization, see Adding provider organization users and assigning roles.
   - In the Catalog, the user has the permissions that are configured for the role at the Catalog level.
   - Any role that is not assigned to the user at the provider organization level can be assigned to the user at the Catalog level.
6. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Importing a user-defined policy into a Catalog

You can make your user-defined policy available to API developers by importing it into an IBM® API Connect Catalog, or a Space in a Catalog.

About this task

For instructions, see Defining, packaging, and publishing a catalog-scoped policy for the API Gateway.

Importing an OpenAPI extension into a Catalog

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.

Before you begin

You must have Catalog edit permissions to complete this task.

About this task

This task describes how to import an OpenAPI extension into a Catalog by using the browser-based API Manager user interface. Alternatively, you can use the developer toolkit CLI; see Working with OpenAPI extensions.

For an example of an extension schema file, see Referring to an extension in an API definition.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
3. Click the Catalog settings tab if you are working in a Catalog, or the Space settings tab if you are working in a Space.
4. Click Gateway services.
5. Alongside the Gateway service that you want to work with, click the options icon ⋮, and then click View extensions.
6. Click Upload then upload the extension file as indicated, either by dragging and dropping the file, or by browsing and selecting it. The extension schema file is either a JSON or YAML file.
7. Click Upload when done.

Results

The user-defined extension is now imported into a Catalog or Space, and can it be used when developing an API by using the API editor in either the API Designer or the API Manager user interface.

What to do next

Add the OpenAPI extension to your APIs as required; see Adding an OpenAPI extension to an API.

Retaining Version 5 vanity endpoint behavior in a Catalog

The behavior of vanity endpoints in a Catalog is changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.

About this task

A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to start the API.

You can modify your Catalog settings to define vanity endpoints that retain the API Connect Version 5 behavior.

Note: Vanity endpoints for APIs function as expected. Vanity URLs for OAuth providers in Version 10 support the same functions as in Version 5 when legacy vanity behavior is enabled for a catalog. This behavior supports flat hostname URLs (for example, https://www.myvanityhostname.com/) but does not extend to full URLs with a URI path (for example, https://www.myvanityhostname.com/mypath).
You can modify the Catalog settings in either of the following ways:

- Use the API Manager user interface.
- Use the developer toolkit CLI.

You can also use the API Connect REST APIs; see the API Connect REST API documentation.

Procedure

- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the API Manager user interface, complete the following steps:
  1. Click API Endpoints in the Catalog settings navigation pane. The Vanity API Endpoint page opens.
  2. Click Edit, then select v5 legacy behavior.
  3. To use the API Connect URLs, select Use gateway URLs. To configure a vanity endpoint, select Display vanity endpoint then provide the following information:
     - Endpoint: The URL of your vanity endpoint.
     - Gateway URI: The URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint; select from the list provided.
     - Summary: An optional description of the vanity endpoint.
- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the developer toolkit CLI, complete the following steps:
  1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

     ```
     apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
     ```

     where:
     - *mgmt_endpoint_url* is the platform API endpoint URL.
     - *user_id* is the user ID that you want to log in with. The user ID must be a member of a provider organization. This *user_id* is an ID that you might also use to log in to the API Manager user interface.
     - *password* is the password that is associated with the supplied user ID.
     - *identity_provider* is the identity provider that is used to authenticate the supplied user ID.

     For example:

     ```
     apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
     ```

     You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

     ```
     apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
     ```

     For example,

     ```
     apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
     total_results: 2
     results:
       - title: API Manager User Registry
         realm: provider/default-idp-2
       - title: Corporate LDAP user registry
         realm: provider/corporate-ldap
     ```

     The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
     For full details on how to log in to your management server from the CLI, see Logging in to the management server.

  2. Create a YAML file with the following structure to define the configuration for your vanity endpoint:

     ```
     legacy_endpoint_behavior: enabled
     v5_endpoint_substitution_behavior:
       base_endpoints:
     ```

```
    - endpoint: vanity_endpoint_url
      description: description
      gateway_service_url: gateway_service_url
  unenforced_api_base_endpoint: unenforced_api_base_endpoint
```

Where:

- The `legacy_endpoint_behavior: enabled` setting specifies that the Catalog retains API Connect Version 5 behavior. A Catalog can support either Version 5 behavior or Version 10 behavior but not both.
- *vanity_endpoint_url* is the URL of your vanity endpoint.
  Note: API Connect Version 5 supports only the hostname in a vanity endpoint URL; a URL of the form `https://host_name/path` is not supported. Therefore, the vanity endpoint URL that you supply here must contain only a hostname; for example, `https://vanity.com`.
- *description* (optional) is a description of your vanity endpoint.
- *gateway_service_url* is the URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint.
  Note: You can determine the gateway service URL by using the following command:

  ```
  apic configured-gateway-services:list --scope catalog --catalog catalog_name --server mgmt_endpoint_url --org organization_name
  ```

  Where:
  - *gateway_service_name* is the name of the gateway service.
  - *catalog_name* is the name of the Catalog.
  - *organization_name* is the name of the provider organization that contains the Catalog.

  The command output lists all the gateway services that are enabled in the Catalog, together with their gateway service URLs.

- *unenforced_api_base_endpoint* (optional) is a custom API URL that specifies the URL for APIs that are deployed to a third-party gateway.

Note: `base_endpoints:` is an array. You can configure multiple vanity endpoints by defining multiple `endpoint:` entries.

3. Modify your Catalog settings by using the following command:

   ```
   apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename
   ```

   Where *filename* is the name of the YAML file that you created in step 2.

4. Confirm your updated Catalog settings by using the following command:

   ```
   apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -
   ```

Protecting catalog properties

You can protect a catalog property so that its data is returned as redacted in the response to an API call.

Catalog administrator access is required to protect a property. When a property is marked as protected, you cannot unprotect it. However, you can delete the property and then create it newly as an unprotected property.

You can update the value in a protected property; the property remains protected. The protection feature applies only to catalog-level properties and does not affect spaces or API properties.

The API invoke call returns the property in clear text, all other calls returns the property as redacted and display only asterisks as in: ******.

To protect a catalog property, complete the following action:

1. Log in to IBM® API Connect as the catalog administrator and navigate to the catalog.
2. Create or edit a property.
   a. To create a protected property, complete the following action:
      i. Click Create.
      ii. Provide the name and value for the new property.
      iii. Click Protect.
      Note: When you protect a property, its value is displayed as *****.
   b. To edit a property, complete the following action:
      i. Select a property and click Edit.
      ii. Update the property's value.
      Note: The value for a protected property displays as ***** but you can replace the value.
      iii. If the property is not already protected, click Protect.
      Note: When you protect the property, its value displays as *****.
      iv. Click Save to update the property.

To unprotect a catalog property, complete the following action:

1. Log in to IBM API Connect as the catalog administrator and navigate to the catalog.
2. Delete the protected property.
3. Add the property again and do not mark it as protected.
4. Save your changes.

[Technology preview] Using Governance enforcement for validation

Governance enforcement in IBM® API Connect is used for enforced validation of API Products before they are published to catalogs.

Note: This feature is provided as a Technology Preview. As such, the feature might not be fully functional in your environment and support is limited. In addition, the feature's appearance, functions, and name are subject to change both in this release and in later releases of API Connect.

Governance enforcement is valid for API Connect version 10.0.10.0. Use governance enforcement in IBM API Connect to validate Products and the APIs within the Products before publishing them to a catalog with API and Product rulesets. The governance enforcement rules improve the quality, security, and consistency of the APIs and Products, which can ensure that they meet specific standards, policies, and requirements before they are published to the catalog. For more information about configuring governance enforcement rules, see [Technology preview] Configuring rulesets and enforcement type.

The APIs and Products are validated based on the enforcement type that you define. You can select any of the following three enforcement types to validate APIs and Products:

- Soft
- Approval
- Strict

When a product is published to the catalog, a governance validation task is automatically created depending on the enforcement type that you define.
Note: You must have the Catalog Administrator permission to define the enforcement type.
For more information about defining the enforcement type, see [Technology preview] Configuring rulesets and enforcement type.

- **[Technology preview] Configuring rulesets and enforcement type**
  Select the API and Product rulesets and the enforcement type that you want to use as part of product validation.
- **[Technology preview] Enabling governance enforcement to validate APIs and Products before publishing to a Catalog**
  Enable governance enforcement in your Catalog to validate APIs and Products with rulesets.

[Technology preview] Configuring rulesets and enforcement type

Select the API and Product rulesets and the enforcement type that you want to use as part of product validation.

Before you begin

To define the governance enforcement type, you must have the Catalog Administrator permission.

About this task

When a product is published to the catalog, a governance validation task is automatically created depending on the enforcement type that you selected. After you add the API and Product rulesets that you want to use as part of enforcement, you can select the governance enforcement type policy. You can select one of the three types of enforcement policies:

Soft
: In soft enforcement, APIs and Products are published even if it fails validation due to errors detected by the applied rulesets. A governance validation task is created under Tasks in Governance enforcement tasks tab of the Catalog. To view the enforcement results, select the corresponding task from the list. The soft enforcement type allows for a more flexible validation process, where errors are acknowledged but not necessarily addressed before publication.

Approval
: In approval enforcement, the APIs and Products are not published if it fails validation due to errors detected by the applied rulesets. Instead, an approval request is sent to the administrator for review. The administrator must approve or reject the publication. A governance validation approval task is created under Tasks in Governance enforcement tasks tab of the Catalog. The administrator can view the enforcement results by selecting the corresponding task from the list. Only the organization members with the following permissions can view the governance approval tasks:

  - `governance-enforcement-approval: view`
  - `governance-enforcement-approval: manage`

  The product remains in a staged state until the administrator approves or rejects the task. If the task is approved, the product is published. If the task is rejected, you must review and address the validation errors before the APIs and Products can be published again.

Strict
: In strict enforcement, APIs and Products are not published if it fails validation due to errors detected by the applied rulesets. A governance validation task is created under Tasks in Governance enforcement tasks tab of the Catalog. To view the enforcement results, select the corresponding task from the list. If there are no validation errors, the API or Product is published.

Procedure

1. Log in to API Manager.
2. Click Manage and select the catalog to which you want to publish the API Product.
3. On the Governance tab, click Enforcement.
4. Click Add to add one or more enforcement rulesets.
5. On the Select rulesets page, click one of the following tabs based on how you want to apply rulesets:
   - Click API rulesets to apply rulesets to an API file. API rulesets allow the validation of the API files with the rules of an API ruleset applied to an API file. By default, the API rulesets tab is selected.
   - Click Product rulesets if you want to apply rulesets to a Product file. Product rulesets allow the validation of the specification of the Product file to ensure the accuracy of the Product file. The rules of a Product ruleset are applied to the Product file.

   For more information about rulesets, see Configuring governance in the Cloud Manager.
6. Select one or more rulesets from the list by selecting the corresponding check boxes.
7. Click Next to set the enforcement policy.
8. On the Select Enforcement rule page, select the enforcement type that you want to apply to the rulesets. For more information, see Enforcement types.
   Note: The enforcement rule that you select is applied to all the selected rulesets by default.
9. Click Save.
   Follow the same steps to configure the governance enforcement rules when the spaces are enabled.

What to do next

Enable governance enforcement in the Catalog settings. For more information, see [Technology preview] Enabling governance enforcement to validate APIs and Products before publishing to a Catalog.

[Technology preview] Enabling governance enforcement to validate APIs and Products before publishing to a Catalog

Enable governance enforcement in your Catalog to validate APIs and Products with rulesets.

Before you begin

To enable governance enforcement, you must have the Catalog Administrator permission.

About this task

Enable governance enforcement settings to add enforced validation for your APIs and Products before you publish it to the Catalog. The rulesets that you selected when you configured enforcement rules are used for the validation of Products and APIs within the Product. For more information, see [Technology preview] Configuring rulesets and enforcement type.

Procedure

1. Log in to API Manager.
2. Click Manage.
3. Select the catalog to which you want to publish the API products.
4. Click the Catalog settings tab and select Publish validations.
5. Click Edit.
6. On the Edit publish validations page, select Enable governance enforcement to validate APIs and products with rulesets.
7. Click Save to apply the selected publish validation.

What to do next

When a product is published to the catalog, a governance validation task is automatically created, depending on the enforcement type that you selected. For more information, see [Technology preview] Configuring rulesets and enforcement type. A governance enforcement task is created for each validation. To access the newly created tasks, in the catalog for the API or product, click Governance enforcement tasks and then click the Tasks tab.

Managing the application lifecycle

By using the application lifecycle capability in IBM® API Connect, the applications that are created in the associated Developer Portal initially has Development status, and can make API calls through the development endpoints. When application testing is complete, the application developer can request to upgrade the application to Production status. After the request is approved, the application is upgraded can make API calls through Production endpoints.

Note: The development and production endpoints must be configured in the API by using the *Switch* policy.

Configuring API Connect to use the application lifecycle

To configure API Connect to use the application lifecycle capability, you must enable Application Lifecycle in the Catalog settings. For more information, see step 6.d in Creating and configuring catalogs.

Using the application lifecycle in the Developer Portal

If the application lifecycle is enabled for the Catalog, any application that an application developer registers in the associated Developer Portal initially has the Development status, and when you subscribe the application to use an API, it can make API calls only to development endpoints.

When you have completed your application testing, you can request to upgrade your application to Production status; For more information, see Upgrading a Development application to Production status. After the application upgrade request has been approved, the application can make calls to Production endpoints.

Creating an API that uses switch policy for different endpoints

You can configure the *switch* policy to create an API that starts a different endpoint depending on whether your application is set to Development or Production status. The following example shows how you can create a conditional API that uses the *switch* policy:

```
assembly:
           execute:
             - switch:
                 version: 2.1.0
                 title: switch
                 case:
                   - condition: $apiCtx().client.app.lifecycle-state = 'PRODUCTION'
                     execute:
                       - invoke:
```

```
                    version: 2.0.0
                    title: invoke
                    backend-type: detect
                    header-control:
                      type: blocklist
                      values: []
                    parameter-control:
                      type: allowlist
                      values: []
                    timeout: 60
                    verb: GET
                    chunked-uploads: true
                    persistent-connection: true
                    cache-response: protocol
                    cache-ttl: 900
                    target-url: https://backend.server.example.com/v1/stores/{id}
                - condition: $apiCtx().client.app.lifecycle-state = 'DEVELOPMENT'
                  execute:
                   - message-template:
                      version: 2.0.0
                      title: message-template
                      template: |-
                        {
                           "id": "12345",
                           "status": "closed"
                         }
```

For more information about configuring the *switch* policy to create an API, see Built - in policies.

Approving an application upgrade request

A request to upgrade a Development application to the Production status is approved or declined in the API Manager UI. For more information, see Approving application upgrade requests.
Note: To place the upgrade request, the API must be configured to use two different endpoints depending on the application lifecycle state.

Related information

- Registering a gateway service
- Applications in the Developer Portal
- Exploring APIs and Products in the Developer Portal

Approving application upgrade requests

To approve or decline requests by application developers to upgrade a Development application to Production status, use the Approvals tab in the Catalog that is associated with the IBM® API Connect Developer Portal from which the application upgrade request was submitted.

Before you begin

To approve application upgrade requests in a Catalog, you must either be the owner of the associated API provider organization, or you must be assigned a user role that has Subscription and Application Approvals > Manage permission in the Catalog. For information on configuring permissions for a Catalog, see Creating and configuring catalogs. For information on assigning user roles, see Managing Catalog membership.

About this task

If application lifecycle is enabled for a Catalog, any application that an application developer registers in the associated Developer Portal initially has Development status. When application testing is complete, the application developer can request to upgrade the application to Production status.

Procedure

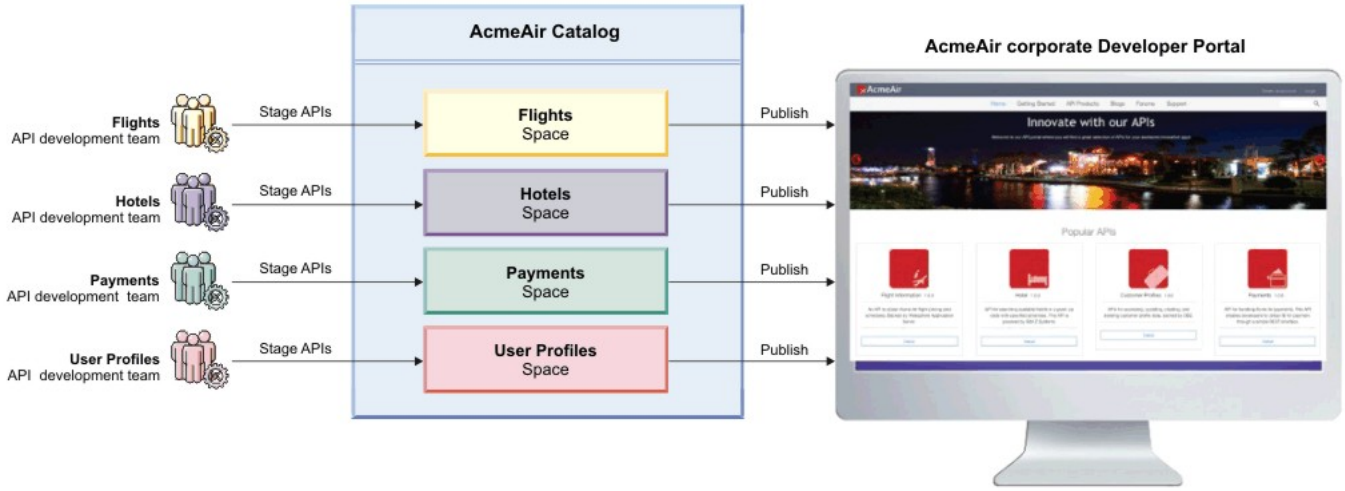
To approve application upgrade requests, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. Click the Tasks tab, The Approval tasks page opens. You can find the application upgrade requests here. Locate the application upgrade request that you want to deal with.
   An application upgrade request has an Application Lifecycle label.
3. Click Approve or Decline as required. If you decline the request, a Reason for declining window is displayed, giving you the option to supply the reason why you declined the request. Click Decline and send when done.
   A notification email is sent to the originator of the request.

Using syndication in API Connect

With the API Connect syndication feature, you can partition your catalogs into *Spaces*. Each space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that space, enabling each team to manage their APIs independently.

When you stage or publish an API to a catalog that has spaces enabled, you specify the space within that catalog that you want to stage or publish to. However, application developers that access the Developer Portal for the catalog are unaware of the space partitioning of the catalog and see the APIs as a coordinated offering.



Each space has its own product lifecycle management, subscription approvals, and analytics data. You use space-specific access control to restrict user access to each space; for example, a developer in the Flights team is able to stage APIs only to the Flights space.

Example

A travel company, AcmeAir, has separate API provider development teams for each of the following areas of their business:

- Flights
- Hotels
- Payments
- User Profiles

They have an AcmeAir corporate catalog, with its associated corporate Developer Portal. They partition their catalog into separate spaces, one for each development team.

Spaces are described in detail in the following sections:

- **Enabling Spaces in a Catalog**
  To use the syndication feature in IBM API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.
- **Creating, modifying, and deleting Spaces**
  You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.
- **Working with Spaces**
  If Spaces are enabled in an IBM API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Enabling Spaces in a Catalog

To use the syndication feature in IBM® API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.

Before you begin

If Spaces are enabled for a Catalog, Products (and their associated APIs) can be published only to a Space within that Catalog. For information about publishing, see Staging a Product for publishing by using the API Designer, and see Publishing APIs for publishing by using the developer toolkit.

Note: You cannot enable Spaces in a Catalog to which one or more Products have already been staged or published. If the Catalog does contain staged or published Products, first complete the following steps for each Product in the Catalog:

1. Remove all staged Products.
2. Retire, then remove, all published Products.

After enabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

About this task

By default, Spaces are disabled in a Catalog. You enable Spaces by modifying the Catalog settings. After Spaces are enabled for a Catalog, a default Space is automatically created that inherits all of the configuration settings from the Catalog.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

Procedure

To enable Spaces in a Catalog, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.

2. Click the Catalog settings tab.
3. Set the Spaces slider control to the On position.
4. In the Toggle spaces pop-up window, click Confirm.

Results

Spaces are enabled for your Catalog, and a default Space is created that automatically inherits all of the configuration settings from the Catalog. The Catalog owner is also the owner of the default Space.

What to do next

You can modify Space settings, and create more Spaces; see Creating, modifying, and deleting Spaces and Working with Spaces for more information.

Creating, modifying, and deleting Spaces

You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.

Before you begin

Navigate to the Spaces page of the Catalog containing the Space you want to work with, by completing the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

Procedure

- To create a new Space, complete the following steps:
  1. Click Add > Create space.
  2. From the Select user drop-down menu, choose a user.
  3. In the Create space window, enter the Title of the Space and, optionally, a descriptive summary. A Name is entered automatically.
     Note: The value in the Name field is a single string that is used to identify the Space in developer toolkit CLI commands. The Title is used for display.
     To view the CLI commands to manage Spaces, see the toolkit CLI reference documentation.
  4. Click Create to create the Space.

  Note:
  - As the user who creates the Space, you are automatically the Space owner and have all Space permissions.
  - When you create a new Space, it does not automatically inherit all of the configuration settings from the Catalog. So you should check and modify the settings as necessary.
- To modify the details of a Space, complete the following steps:
  1. On the Spaces page, select the Space that you want to modify.
  2. Click the Space settings tab.
  3. Use the options in the navigation pane to modify the details as required.
     The following types of resource can be enabled in a Space:
     - Gateway services
     - API user registries
     - OAuth providers
     - TLS client profiles

     Note:
     - If you enable a resource of any of the following types in one Space in a Catalog, it is deployed to the gateway services across all Spaces in that Catalog:
       - API user registries
       - OAuth providers
       - TLS client profiles
     - If you deploy any of the following types of resource to a gateway in a Space, it is actually deployed to the gateway at Catalog scope:
       - Custom policy
       - Global policy
       - Global policy pre-hook
       - Global policy post-hook
       - Gateway extension
- To change the owner of a Space, complete the following steps:
  1. On the Spaces page, select the Space that you want to modify.
  2. Click the Space settings tab to open the Space details page, then click Edit.
  3. From the Select owner user drop-down menu, select the user who will become the new owner.
  4. Click Save.

  Note:
  - To have permission to change the Space owner, you must be either the Catalog owner, the Space owner, or the owner of the provider organization that contains the Space.
  - When the ownership changes, the new owner is assigned administration privileges for the Space, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Managing Space membership.
  - The ownership can be transferred only to a user who is already a member of the Space or Catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the Space, as described in Managing Space membership, or to the Catalog, as described in Managing Catalog membership.
- To delete a Space, complete the following steps:
  1. On the Spaces page, select the Space that you want to delete.

2. On the selected Space, click Options > Delete.
3. On the pop-up window, click Delete.

Note:

- You cannot delete a Space to which one or more Products have been staged or published.
- If there is only one Space in a Catalog, you cannot delete it, but you can disable Spaces for the Catalog.
  However, you cannot disable Spaces in a Catalog to which one or more Products have already been staged or published. If any of the Spaces in the Catalog do contain staged or published Products, first complete the following steps for the Products in each of the Spaces:
  1. Remove all staged Products.
  2. Retire, then remove, all published Products.

  Then, to disable Spaces for the Catalog, complete the following steps:
  1. Click the Catalog settings tab in the Catalog.
  2. Set the Spaces slider control to the Off position.

  After disabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

Working with Spaces

If Spaces are enabled in an IBM® API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Procedure

To work with a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.

What to do next

For details of the Space management tasks, see the following subtopics:

- **Managing Products in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.
- **Managing subscription requests in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.
- **Managing application subscriptions in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.
- **Managing Space membership**
  If Spaces are enabled in an IBM API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.
- **Managing user access in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.
- **Managing Gateways in a Space**
  If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM API Connect Catalog.

Managing Products in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.

Before you begin

To manage Products in a Space in the API Manager UI, a user must be assigned a role that has the Products > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

To manage the Products that are staged or published to a specific Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.

What to do next

For details of the management tasks that you can perform on the Products in the Space, see Working with products.

Managing subscription requests in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.

Before you begin

To manage Space subscription requests in the API Manager UI, a user must be assigned a role that has the Subscriptions > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

To manage the subscription requests in a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Tasks tab.
   The Tasks page lists only the subscription requests for the selected Space.

What to do next

For details on how to manage approvals, see Approving Product lifecycle and subscription requests.

Managing application subscriptions in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.

Before you begin

To manage application subscriptions in the API Manager UI, a user must be assigned a role that has the Subscriptions > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. In the navigation pane of the API Manager UI, click the Applications tab.
   All applications that have been registered in the Developer Portal associated with this Space are listed.
5. Click the options icon ⋮ alongside the application you want to work with, then click View Subscriptions.

What to do next

For details of the management tasks that you can perform on application subscriptions in a Space, see Working with application subscriptions.

Managing Space membership

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.

Before you begin

To manage Space members in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For more information on assigning Space permissions to a role, see Managing user access in a Space.

About this task

Note: You can add the same user to two or more Spaces and assign different roles in each, allowing a user to have differing levels of access in different Spaces.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.

4. Click the Members tab.
5. To add an existing user, click Add > Add member. To add a new user, click Add > Invite member.
   If you are using the Add member option, you can add any user who is already a member of another Space, or of a Catalog, in the provider organization, and is neither currently a member of this Space, nor the Space owner.
6. Enter the email address of a new user, or search for, and select, an existing user.
7. Select the roles that you want to assign to the user.
   For details of the roles and the default permissions assigned to them, see API Connect user roles. For details on how to create your own roles, see Creating custom roles.

   If a user was originally added either to the provider organization, or to the Catalog that contains the Space, rather than to the Space itself, the following conditions apply:
   - Any role assigned to the user at the provider organization or Catalog level is assigned automatically to the user in all Spaces, and cannot be removed at the Space level.
     For details on adding a user to a provider organization, see Adding provider organization users and assigning roles.

     For details on adding a user to a Catalog, see Managing Catalog membership.
   - In the Space, the user has the permissions that are configured for the role at the Space level.
     For details on configuring role permissions for a Space, see Managing user access in a Space.
   - Any role that hasn't been assigned to the user at the provider organization or Catalog level can be assigned at the Space level

   Note: You can subsequently change the roles assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members page.
8. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Managing user access in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.

Before you begin

To manage Space permissions in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see Managing Space membership.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Space settings tab.
5. Click Roles, click the Menu icon alongside the role whose permissions you want to modify, then click Edit.
6. Select the required permissions, then click Save.

Related tasks

- Creating custom roles

Related information

- API Connect user roles

Managing Gateways in a Space

If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM® API Connect Catalog.

Before you begin

To manage Space Gateway settings in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see Managing Space membership.

About this task

Note: If Spaces are enabled in a Catalog then you configure the Gateway settings for each Space separately, **not** for the Catalog as a whole.

Procedure

To manage the Gateway settings for a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.

2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Space settings tab.
5. Click Gateway services.
   The Gateway services that are currently enabled for the Space are listed.
6. To change the Gateway service configuration for the Space, click Edit, then select which Gateway services you want the Space to use.
7. Click Save to save your changes.

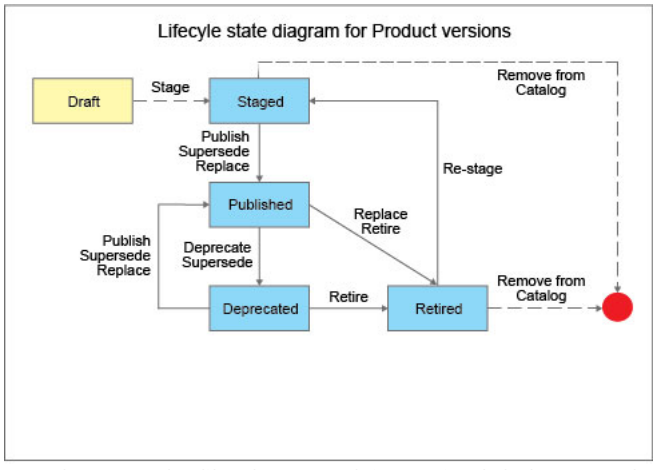
Related information

- Configuring the initial Gateway service

Working with products

In IBM API Connect, plans and APIs are grouped in products.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
Information about managing products in the API Manager UI can be found in the following topics.



- **The product lifecycle**
  When you manage your product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.
- **Monetizing your products**
  In addition to offering no cost plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM API Connect.
- **Managing your Products**
  You can manage your products in API Manager by using the Products page of the associated catalog. In this view, you can move the products through their lifecycle, display analytics information, and control who can see or subscribe to the products. The syndication feature in IBM API Connect means that products can also be managed by using the Products tab of the associated space.

The product lifecycle

When you manage your product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM® API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.

Product lifecycle state diagram

The following diagram shows the possible lifecycle states for a Product version, and the Product management operations that move a Product version from one lifecycle state to another. For example, the retired operation moves a Product version from the Published to the retired state.

Note: The same Product lifecycle states apply irrespective of whether your Product is managed within a Catalog, or within a Space in a Catalog. For more information about the syndication feature, see Using syndication in API Connect.
If approval is required for a Product management operation, an approval request is sent and the Product version moves to the pending state. When the request is approved, the operation is completed and the Product version moves to the next lifecycle state. If approval is not required, the operation is completed immediately.
Note: Approval is not required for the following lifecycle state transitions:

- Retired to staged.
- Deprecated to published.

For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.
Note:

- Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- To view the subscription tasks history, complete the following steps:
  - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
  - Click Tasks tab.
  - Click Approvals history from the navigation pane.
- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

The following sections describe the various lifecycle states for a Product version.
Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise.

Draft

The draft state for a Product or API is when a Product or API definition is not deployed and is not associated with any Catalog.

Staged

When you stage a Product, a copy of the Product version is deployed to the target Catalog. Staged is the initial state when you publish a Product. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. For more information about staging a Product, see Staging a Product.

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it and the product can be published. For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests. For more information about publishing a Product, see Publishing a Product.

Published

When you publish a Product, a fixed copy of the Product version is deployed to the target Catalog. The Product version is visible to, and subscribable by, the targeted developers or communities. When a Product is published in a Catalog, the visibility and subscription settings can be changed for the published version of that Product. Any further changes require a new version of the Product to be staged and published before they take effect.

If you replace a Published Product with a Staged or Deprecated Product, the replacement Product is published, and the replaced Product is retired.

If you supersede a Published Product with a Staged or Deprecated Product, the superseding Product is published, and the superseded Product is deprecated.

For more information about publishing a Product, see Publishing a Product.

Note: If you want to update a Product, you must republish it. The `products:update` command only updates a Product's metadata.

Deprecated

When you deprecate a Product, the Product version is visible only to developers whose applications 're subscribed. No new subscriptions to the plans in the Product are possible. For more information about deprecating products, see Deprecating a Product.

A Product is also deprecated if you supersede it with another Product. For more information, see Superseding a Product with another Product.

Retired

When you retire a Product, the Product version cannot be viewed and cannot its plans be subscribed to, and all of the associated APIs are taken offline. For more information about retiring products, see Retiring a Product.

A Product is also retired if you replace it with another Product. For more information, see Replacing a Product with another Product.

Replace product

Use the replace product option when you want to replace product A with product B and migrate all subscriptions. This action retires the source product and publishes the destination product. For more information, see Replacing a Product with another Product.

Migrate Subscriptions

Use Migrate Subscriptions to perform the same function as Replace Product, except it does not retire the source product, and the destination product must already be published.

You can also use Migrate Subscriptions to migrate individual subscriptions between different products or between plans within the same product. For more information, see Migrating application subscriptions to another Product and Migrating application subscribers to new Product versions.

Supersede product

Use Supersede Product to replace product A with product B and migrate all subscriptions at a later time. This option deprecates the source product and publishes the destination product.

When a product is deprecated, new subscriptions are not allowed, but existing subscriptions continue to function until they are migrated. Consumers can migrate all subscriptions or individual subscriptions at a time that suits them. For more information, see Superseding a Product with another Product.

Set migration target

Use Set Migration Target option to perform the same function as the Supersede option. It prepares subscriptions for migration to the destination product but does not deprecate the source product. The destination product must already be published. For more information, see Migrating application subscribers to new Product versions.
Note:
Both Supersede Product and Set Migration Target assume that the source product will no longer be used after all subscriptions are migrated and that it will not be used as a migration target in the future.

These options are typically used when a new version of product A supersedes an older version of the same product. The source and destination products are labeled with the attributes **`superseded_by`** and **`supersedes`**, respectively.

Execute Migration Target

Use Execute Migration Target to force the migration of all subscriptions from a superseded product before retiring it. For more information, see Migrating application subscribers to new Product versions.
Note:
Supersede Product and Set Migration Target prevent setting the migration target to an older product version to avoid circular dependencies, where two products point to each other as migration targets.

To reset the migration target to an older version, first clear the **`superseded_by`** and **`supersedes`** settings created by Supersede Product or Set Migration Target. Then, run Execute Migration Target to migrate all subscriptions to the destination product.

After all subscriptions are migrated, retire the source product. To reuse it, restage and republish it before using Set Migration Target with the older version.

Monetizing your products

In addition to offering no cost plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM® API Connect.

API Connect includes a subscription billing feature that allows API providers to define pricing Plans in their API Products, and monetize their API offerings. If a Product contains a pricing Plan, API consumers must enter their payment information into the Developer Portal before they can subscribe to that Plan.

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information and their subscription history. To generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

You can define both no-cost plans and paid plans within the same product. To charge your customers more for greater access to your APIs, you can create multiple Plans with different tiers of prices and rate-limits. For example, an introductory Plan might have a low monthly price and restrictive rate-limiting, while a higher tier Plan might couple a higher monthly price with less restrictive rate limiting controls. Your customers can then select the Plan that is appropriate for their usage rates. As your customers have different needs for the use of your Products, so you can offer different levels of service. For example, a smaller customer might need a rate of only 5 API calls per hour, whereas a larger company might need a rate of 1000 API calls per hour. You can create the Plans that are appropriate for your customers, and they can subscribe to the service and pricing Plan that is appropriate for them.

Restriction: The following limitations apply to the subscription billing feature:

- Billing and monetization requirements vary by country, where IBM and the independent cloud billing provider, Stripe, cannot guarantee every country requirement is supported. Country requirements change, and are out of scope for this document. Some limitations on storing and passing fields to the Stripe billing provider might exist, when fields are unique to a subset of countries. For example, the passing of a billing address from API Connect to Stripe, which is required by some EU countries due to GDPR and taxation laws, is not currently supported.
- Two data centers disaster recovery configurations including the optional billing microservice are not supported currently.
- After a configured billing resource is in use by a Catalog, it might not be possible to remove it. Do not add your Stripe test keys to production Catalogs. If you want to prototype with your nonproduction Stripe keys, create a separate temporary Catalog.
- If an API consumer's payment method fails, for example, deletion, expiration or insufficient credit, there is no automatic alert or suspension of API access. Provider organizations can monitor their Stripe dashboards for nonpayment events and, if necessary, notify the consumer, suspend the application for that subscription, or cancel the API Connect subscription manually. The URL of the API Connect subscription is saved in the metadata of the Stripe subscription object to assist in reverse lookups.
- Suspending an application does not automatically pause the billing cycles of the subscriptions for that application.
- You can republish a Product that includes billing only when the Catalog Production mode is set to On.

The procedure for setting up paid and no-cost plans is similar, but paid plans require extra steps. For more information, see the following topics:

1. First, you must configure a billing integration resource for your provider organization; see Adding a billing integration resource.
2. Before you can publish a Product Plan with pricing to a Catalog, you must add your billing integration resource to that Catalog; see Adding a billing integration resource to a Catalog.

3. Also, before you can publish to a Catalog, an administrator must enable the Stripe payment method module in the Developer Portal for that Catalog; see Configuring Stripe in the Developer Portal.
4. After the Catalog and Developer Portal are configured, you can create Products that include pricing Plans; see Defining a Product with billing integration.

Note:

- Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. For more information, see Configuring monetization on Kubernetes.
- You can also create and manage billing integration resources by using the developer toolkit CLI. For more information, see toolkit CLI reference documentation.

Adding a billing integration resource

To enable the monetization of your Product Plans, you must add a billing integration resource in your IBM® API Connect provider organization that defines the configuration data needed to synchronize with an external subscription billing system.

Before you begin

To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes for more information about this requirement.

Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on Kubernetes for more information.

You must either be the provider organization owner, or have `Settings: Manage` permissions, to complete this task.

You must have an account with Stripe to be able to complete this task. If you do not already have a Stripe account, you can set one up at: www.stripe.com.

About this task

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, you must first specify your Stripe account information by creating a billing integration resource. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that you provide as the API provider.

Important: Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To create a billing integration resource, complete the following steps:

1. In the API Manager, click  Resources.
2. Ensure that you are in the provider organization to which you want to add the billing integration.
3. Select Billing, and then click Add.
   The Add billing integration page for Stripe integration is displayed.
4. Enter a Title for your billing integration.
5. The Name is auto-generated based on the Title that you enter, and is a single string that can be used in developer toolkit CLI commands.
6. Enter the Publishable key and Secret key for your Stripe account.
   Refer to your Stripe dashboard to get your publishable key and secret key; see https://dashboard.stripe.com/apikeys.
7. Click Add to create your billing integration resource.

Results

Your new billing integration resource is listed in the table on the Billing dashboard. The table also displays the state of the job queue for the billing integration. Any issues with the job queue are displayed in this table. See Billing integration resource job queues for more information.

What to do next

To be able to publish monetized Product Plans, you must add the billing integration resource to your Catalog, and to the Sandbox Catalog. See Adding a billing integration resource to a Catalog for details.

Billing integration resource job queues

Billing integration resources use job queues to manage the bulk product lifecycle operations in IBM® API Connect.

Subscription billing systems such as stripe, typically provide APIs that support updating a single resource at a time. However, IBM API Connect has Product lifecycle operations that can modify many resources in a single transaction, such as migrating a set of subscriptions from one Product to another Product. To bridge the mismatch between these two APIs, API Connect adds a job queue to each billing integration resource in your provider organization. Jobs on this queue are responsible for mapping bulk operations to a series of API calls against the subscription billing system. Jobs run one at a time, in the order that they were created. When a job completes it's deleted from the queue, and the next job runs. When all of the jobs in the queue complete running and the queue is empty, the data model of the subscription billing system should be up to date with the changes made in API Connect.

There are potential issues when moving this type of synchronization to background jobs. Network connectivity, outages at the billing provider, or rolling of the API keys of the billing system, might all cause the job queue to be blocked if the root issue does not resolve by itself in the span of an hour. If a job encounters an error, such as a network connectivity error, the job is retried up to five times over the course of 70 minutes before changing the state of the job from Running to either Blocked or Failed. Only when the state of the head job is blocked or failed, the Retry Blocked Jobs action appear in the options menu. So if an error is shown but the job is still attempting to run, you need to wait up to 70 minutes before the Retry Blocked Jobs action appears.

The job queue status can be viewed in the table on the Billing dashboard. The table lists any blocked jobs, and the error that is blocking them. If the error indicates that your API keys are no longer valid, you must update your billing resource to contain the correct values. After the root cause is resolved, you can click the ⋮ options menu on the row of the billing integration resource, and click Retry Blocked Jobs. This action retries the jobs on the job queue. After a few minutes, the number of jobs should go down. You can click the Refresh icon ↻ to refresh the results from the server.

Adding a billing integration resource to a Catalog

To be able to publish monetized Product Plans, you must add a billing integration resource to your Catalogs.

Before you begin

You must have created a billing integration resource. See Adding a billing integration resource for details.

You must either be the provider organization owner, or have `Settings: Manage` permissions, to complete this task.

About this task

Before you can publish any Products that include pricing Plans, you must add the billing integration resource to the Catalog where you will create the monetized Products. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, after you have specified your Stripe account in a billing integration resource, you must then apply that resource to your Catalogs. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that is provided in the billing integration resource.

Note:

- Before you can publish a monetized Product Plan to a Catalog, the Stripe payment method module in the Developer Portal must also be enabled; see Configuring Stripe in the Developer Portal.
- Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To add a billing integration resource to a Catalog, complete the following steps:

1. In the API Manager, click Manage.
2. Select the Catalog tile on the Manage page that you want to update, then click the Catalog settings tab.
3. Select Billing, and then click Edit.
4. Select the billing integration resource that you want to apply to the Catalog, and click Save. You should apply only one billing integration resource to each production Catalog.

The billing integration resource is now listed in the Billing section.
Note: More than one billing resource can be applied to the Sandbox Catalog.

Results

The billing integration resource is added to the Catalog.

What to do next

The Stripe payment method module must be enabled in the Developer Portal for that Catalog; see Configuring Stripe in the Developer Portal for details.

After both the Catalog and the Developer Portal are configured, you can create Products with pricing Plans. See Defining a Product with billing integration for more information.

- Troubleshooting your billing configuration

Defining a Product with billing integration

To monetize your APIs, you must create Product Plans with pricing information that allow API consumers to subscribe to your Plans with integrated billing.

Before you begin

You must have a billing integration resource, and this resource must be added to the Catalog that you want to publish your Product to, as well as to the Sandbox Catalog. See Adding a billing integration resource, and Adding a billing integration resource to a Catalog for details.

Also, the Stripe payment method module must be enabled in the Developer Portal for the Catalog; see Configuring Stripe in the Developer Portal for details.

About this task

When you decide to charge customers to use your API Products, your customers have different requirements for the number of API calls that they are willing to pay for. You can solve this issue by defining Plans at different levels of service, and at different costs.

Within your Product, you can define free Plans as well as Plans that contain billing integration. The following instructions guide you through defining a Plan with pricing information. For more detailed information about creating Products, see Creating a draft Product and Editing a draft Product.

Important: Products that contain a billing integration cannot be re-staged into non-production Catalogs. To experiment with billing on the Sandbox Catalog, or any other non-production Catalogs, you must publish new versions of your monetized Product. This practice aligns with how you have to work with production Catalogs currently, as they also don't support the re-staging of existing versions of the same Product.

Procedure

To add pricing information to a Product Plan, complete the following steps:

1. In the API Manager, click  Develop.
2. Select the Products tab.
3. Select the Product that you want to add billing integration to, or create a new draft Product by clicking Add > Product and following the wizard.
4. With the Product open and the Design tab selected, select Billings in the navigation menu.
5. In the Billing integration section, select the billing integration resource that you want to apply to the Product.
   In the Plans section, you can then either edit the Default Plan to add pricing information, or create a new Plan with pricing information.
6. If this is a new Plan, enter a Title, and if you require approval for someone to subscribe to this Plan also select the Approval check box.
7. In the Plan pricing section, complete the following steps to add the pricing information:
   a. Change the toggle to On for Plan pricing.
      The Plan pricing definition section is displayed.
   b. Optional: If you want to include any free trial days in your Plan, select Include free trial days, and then enter the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.
   c. Select the Currency for the billing process use.
   d. Enter the Price per month to bill the subscriber for.
      If the selected currency supports fractional units, enter the price including any fractional units, such as cents.
8. Optional: In the Plan rate limits section, set the rate limits by entering the number of calls that are allowed per unit of time.
   Remember that this rate limit applies only to this Plan. You can set multiple rate limits, at second, minute, hour, day, and week time intervals. You can override this Plan rate limit for specific endpoints if you prefer, adding a different rate limit or enabling unlimited calls to it. You can also create more Plans with different rate limits. For more information about rate limits, see Understanding rate limits for APIs and Plans.

9. Optional: Select the Hard limit checkbox if you want the gateway to reject any calls beyond the specified rate, rather than adding them to a queue to be resolved when the limits reset.
10. Optional: Add more burst limits, GraphQL limits, and assembly limits, as appropriate for your APIs.
11. Complete the Plan APIs section if you want to customize the APIs and operations that are available in this Plan.
12. If you want to add more Plans to the Product, repeat the process from Step 6.
13. Click Save to save the Product.

Results

Your Product with billing integration and a pricing Plan is listed in the Products dashboard of the Develop area. If your Product doesn't appear, click the Refresh icon to refresh the results from the server.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

Managing your Products

You can manage your products in API Manager by using the Products page of the associated catalog. In this view, you can move the products through their lifecycle, display analytics information, and control who can see or subscribe to the products. The syndication feature in IBM® API Connect means that products can also be managed by using the Products tab of the associated space.

Before you begin

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

For more information about the product lifecycle, see The product lifecycle.
For more information about the syndication feature, see Using syndication in API Connect.

For information on viewing analytics that can provide insight into product and API usage and performance, see capim_analytics_apianalytics.html.

For information about product billing, see capim_product_billing.html.

Procedure

To manage your product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Expand a product to see details of the APIs and plans in that product.

   Manage options are also available, depending on the state of the product. To view the manage options, click the options icon and select the options that you require.
4. To manage the lifecycle of a version of a product, click the options icon alongside the product version, and select the required lifecycle action.
5. To set the migration target of a version of a product, click the options icon alongside the product version, and select Set migration target. In the Set migration target window, select the product that you want to set as the migration target, and select Next. Then map the migration source plans to the migration target plans, and click OK.
   Restriction: If the plan is part of a product that is contained within a space in the catalog, and the migration action is being made at the space level, the plan that you are migrating subscriptions from must be located in the same space as the plan you are migrating to. If the migration action is being made at the catalog level, subscriptions can be migrated across spaces. For more information about the Space feature, see Using syndication in API Connect.

- **Considerations when changing a product lifecycle with billing integration**
  There are special considerations for lifecycle operations for products that contain a billing integration in IBM API Connect.
- **Publishing a Product**
  APIs become accessible when a Product is published and made visible on the IBM API Connect Developer Portal for use by application developers. A Product can be published to selected communities of application developer organizations, and the Plans within the Product can be used to tailor access and visibility further.
- **Migrating application subscriptions to another Product**
  By using the Products view within a Catalog in API Manager, you can migrate application subscriptions between Products. The syndication feature in IBM API Connect means that you can also use the Products view within a Space in a Catalog to migrate application subscriptions. Use the Migrate Subscriptions option to perform the same function as Replace Product, except it does not retire the source product. The destination product must already be published. You can also use Migrate Subscriptions to migrate individual subscriptions between different products or between plans within the same product.
- **Migrating application subscribers to new Product versions**
  When new versions of Products are created in IBM API Connect, there are a number of ways that subscribers can be moved to the Plans of the new Product.
- **Changing the availability of a Product**
  You can change the availability of a Product and the associated Plans by using the Products view within a Catalog or Space in API Manager. The availability of a Product covers both the visibility of that Product to users, and which users can subscribe to it.
- **Deprecating a Product**
  You can deprecate a published Product by using the Manage Products page within a Catalog in API Manager. When you deprecate a Product, application developers that are already subscribed to the Product can continue to use it, but no new developers can subscribe to the Product. The syndication feature in IBM API Connect means that you can also use the Manage Products page within a Space in a Catalog to deprecate a published Product.
- **Retiring a Product**
  You can retire a published or deprecated Product by using the Manage Products page within a Catalog in API Manager. When a Product is retired, all associated APIs are taken offline, and any subscriptions are deleted. The syndication feature in IBM API Connect means that you can also use the Manage Products page within a Space in a Catalog to retire a Product.
- **Restaging a Product**
  If a Product in a Catalog is retired, you can restage the Product so that it can reenter the Product lifecycle. A restaged Product moves to the Staged state, from where it can be published. The syndication feature in IBM API Connect means that you can also restage a Product within a Space in a Catalog.
- **Working with the subscriptions in a Product**
  You can work with the subscriptions to the Plans in a specific Product. Plan subscriptions are created by application developers in the Developer Portal.
- **Updating the gateway services for a Product**
  When you stage or publish a draft Product to a Catalog, you specify the gateway services at which the APIs in the Product are to be made available. However, you can later update the selected gateway services after a Product has been stage or published.
- **Removing a Product from a Catalog**
  You can remove a Product from a specific Catalog by using the Products view within a Catalog in API Manager. The syndication feature in IBM API Connect means that you can also use the Products view within a Space to remove a Product from a Catalog.
- **Approving Product lifecycle and subscription requests**
  To approve or decline requests to change the lifecycle state of a Product, and requests by application developers to subscribe to a Plan, use the Tasks page in the Catalog that contains the associated Product in API Manager. The syndication feature in IBM API Connect means that you can also use the Tasks page within a Space in a Catalog to approve or decline requests.

Considerations when changing a product lifecycle with billing integration

There are special considerations for lifecycle operations for products that contain a billing integration in IBM® API Connect.

For example, if you release new versions of your product that contain pricing changes, you need to define the upgrade pathways for your existing subscribers. The following scenarios detail the special considerations for Product lifecycle changes:

Deprecating
: Preparing an existing Product to be removed from production. You can define a replacement Product by using the Set Migration Target option in the Catalog. API consumers can see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid plan, they must enter a payment method before upgrading. Upgrades by API consumers from no cost plan to a paid plan are supported. For more information about deprecating products, see Deprecating a Product.

Migrating
: Moving subscriptions from one Product to a different Product, and from a no plan to a paid Plan, is not supported. Instead, see the superseding scenario.

Replacing
: Replacing a Product with a newer version of the same Product, and automatically upgrading all existing subscribers to the new Product. You must map which Plans from your new Product correspond to which Plans in your old Product. You cannot map a no cost plan to a paid plan in the replaced operation. For more information about replacing Products, see Replacing a Product with another Product.

Retiring
: Removing a product or plan from production, and canceling the existing subscriptions and their billing cycles. For more information about retiring Products, see Retiring a Product.

Superseding
: Deprecating the old Product, and at the same time defining its migration target to a newer version of itself. Retaining the existing Product and Plan for subscribers who would like to keep it, but offering a different Product and Plan for the updated version of a product. API consumers can see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a no cost plan to a paid plan are supported. For more information about superseding Products, see Superseding a Product with another Product.

Note: You can use the Set Migration Target option in the Catalog on a Product that isn't being deprecated. For example, if you wanted to give customers the option to move to a different Product without affecting the original Product.
While these follow the same basic procedures that are described in Managing your Products for Products and Plans without billing, there are some considerations that only apply to Products that contain paid Plans.

You cannot migrate a customer directly from a no-cost plan to a plan with billing

Customers who subscribe to Plans with billing must set up their billing information in the Developer Portal. If they subscribe only to no cost plans, they don't have billing accounts.

There are two ways to migrate customers from a no-cost Plan to a paid Plan:

- Supersede the no-cost Product Plan and provide a migration target to a paid Product Plan. This deprecates the no cost Product Plan so no new users can subscribe to it, and gives the customer a Migrate this subscription message in the Developer Portal to move to the new Product Plan.
- Set a migration target to a paid Product Plan. In this case the no cost Product Plan is not deprecated, but it still gives the customer the Migrate this subscription message in the Developer Portal for moving to the new product plan. With this method, new customers can still subscribe to the no cost product plan.

Both of these methods require action from the customer before they move from the no cost Product Plan to the paid Product Plan.
Note: No cost trial days do not apply to customers when they migrate. They are available only for new customers.

You must map the existing Plans to the new Plans when you supersede or replace a Product

When you replace or supersede a plan with billing with another plan, you must map the plans from the product that is being removed to the plans that are in the new product. It is convenient if there are the same number of Plans for each, but you can map more than one Plan from the existing Product to one Plan in the new Product.

Billing charges are prorated when subscriptions are migrated

When customers change their subscriptions to a Plan that has a different price, their next monthly invoice contains prorated charges, depending on how long they spent on different billing Plans. For more information about how stripe handles proration, see https://stripe.com/docs/billing/subscriptions/prorations.

- Troubleshooting your billing configuration

Publishing a Product

APIs become accessible when a Product is published and made visible on the IBM® API Connect Developer Portal for use by application developers. A Product can be published to selected communities of application developer organizations, and the Plans within the Product can be used to tailor access and visibility further.

Before you begin

You must stage a Product before it can be published. For more information about staging Products, see Staging a Product.
Note:
If you want to publish a project, you must publish both the APIs (by publishing the Products that contain the APIs) and the associated applications so the project can be run. For more information about publishing applications, see Publishing APIs and applications.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

A community is a collection of consumer organizations, used to control which organizations have access to Products and Plans without having to assign access on an individual basis. A Product can be published to selected communities, which means that only application developers within those organizations contained within the community can see the Product on the Developer Portal and obtain application keys to access it. A Product can alternatively be published to all communities. Communities are used to restrict the visibility and accessibility of APIs, for example to particular business partners, internal organizations, or other groups of application developers.

Note: If you want to update a Product, you must republish it. The `products:update` command only updates a Product's metadata.

Procedure

You can publish a product in any of the following ways:

- Publish a new Product.
- Replace a Product with another Product.
- Supersede a Product with another Product
  For details of the ways in which you can publish a Product, see the following subtopics:

- **Publishing a new Product**
  Publish a Product from within its containing Catalog in API Manager. The syndication feature in IBM API Connect means that you can also publish a Product from within its containing Space in a Catalog.
- **Replacing a Product with another Product**
  You can replace a published Product in IBM API Connect with another Product, and migrate all subscriptions at the same time, by using the API Manager. This action retires the source product and publishes the destination product.
- **Superseding a Product with another Product**
  You can use the supersede option to supersede product A with product B and migrate all subscriptions at a later time. This action deprecates the source product and publishes the destination product, by using the API Manager. A deprecated product does not allow new subscriptions, but existing subscriptions continue to function until they are migrated. Consumers can migrate all subscriptions at once or individually, at a time that suits them.

Publishing a new Product

Publish a Product from within its containing Catalog in API Manager. The syndication feature in IBM® API Connect means that you can also publish a Product from within its containing Space in a Catalog.

Before you begin

The Product that you are publishing must be in the Staged or Deprecated state.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

If you publish a Product to a non-development Catalog, the Product that is published is an independent and fixed copy of the version of the Product that you chose to stage. Editing the Product through the Products page will not affect the published Product. For this reason, it is recommended that when you stage a Product, you then create a new version of the Product to edit in future, so as to avoid confusion regarding the properties of the published Product. For more information on creating new versions of your Product, see Creating a new version of your Product.

An exception is that if you publish a Product to a development Catalog, editing it through the Products page will enable you to re-stage and publish the same version of the Product. For information on how to create a development Catalog, see Creating and configuring Catalogs.

Although you can publish to a development Catalog, the development Catalog must be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

Procedure

To publish a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click Publish.
   The Confirm Visibility Settings page opens.
4. Specify the following options:
   - The users that the Product is visible to
     You can choose Public users, Authenticated users, or Custom.
     - Custom - You can use the Type to add... field to search for organizations or communities that you want your Product to be visible to.
   - Who can subscribe to the Product
     You can add or remove one or more consumer organizations or communities.
     - Custom - You can use the Type to add... field to search for organizations or communities that you want to allow to subscribe to your Product.
5. Click Next, then click Confirm to proceed with the publish operation.
   If approval is required to publish Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is published when the request is approved. If approval is not required, the Product version is published immediately, and moves to the Published state. For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Published state.

Your Product is published to your Catalog and available to your specified organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Replacing a Product with another Product

You can replace a published Product in IBM® API Connect with another Product, and migrate all subscriptions at the same time, by using the API Manager. This action retires the source product and publishes the destination product.

Before you begin

The Product to be replaced must be in the Published state, and the replacement Product must be in the Staged, Published, or Deprecated state.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you replace a Product with another Product, the following actions are taken:

- The replacement Product is published.
- If the visibility and subscribability settings in the replacement Product are such that access is the same as, or less restrictive than, the original Product, the settings in the replacement Product are used. If the settings in the replacement Product are more restrictive, meaning that fewer consumer organizations can see or subscribe to the Product, the replace operation fails. For more information on visibility and subscribability settings, see Changing the availability of a Product.
- The subscribers to the original Product are migrated to the replacement Product.
  Note: Customers cannot be migrated automatically from a free Plan to a paid Plan. To move your customers from a free Plan to a paid Plan, you can supersede the product with a new product and set a migration target to the paid Plan. The customers then select a button to migrate and must enter their credit card information before the process is complete. For more information, see Considerations when changing a product lifecycle with billing integration.
- The original Product is moved to the Retired state. Products in the Retired state are removed from the Developer Portal; they are no longer visible to the application developers, and any subscriptions to them are canceled. However, the Product can be staged again later if required.

Although you can publish to a development Catalog, the development Catalog must be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise.

Procedure

To replace a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to replace, click the options icon, then click Replace.
   The Replace window opens.
4. Select the replacement Product, then click Next.
5. From the drop-down list, select which Plans from your new Product correspond to Plans in your old Product.
6. Click Replace.
   If approval is required to replace Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is replaced when the request is approved. If approval is not required, the Product is replaced immediately. For information on configuring product lifecycle approvals for a catalog, see Creating and configuring catalogs. For information on approving requests, see Approving product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:

- In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
- Click Tasks tab.
- Click Approvals history from the navigation pane.

- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

Results

Your new Product is in the Published state, and the original Product is in the Retired state.

Your new Product is published to your preferred organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Superseding a Product with another Product

You can use the supersede option to supersede product A with product B and migrate all subscriptions at a later time. This action deprecates the source product and publishes the destination product, by using the API Manager. A deprecated product does not allow new subscriptions, but existing subscriptions continue to function until they are migrated. Consumers can migrate all subscriptions at once or individually, at a time that suits them.

Before you begin

The Product to be superseded must be in the Published state. The superseding Product must be in the Staged, Published, or Deprecated state.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you supersede a Product with another Product, the following actions are taken:

- The superseding Product is published.
- If the visibility and subscribability settings in the superseding Product are such that access is the same as, or less restrictive than, the original Product, the settings in the superseding Product are used.
- If the settings in the superseding Product are such that access is more restrictive, meaning that fewer consumer organizations can see or subscribe to the Product, the superseded operation fails. For more information on visibility and subscribability settings, see Changing the availability of a Product.
- The original Product is moved to the Deprecated state.
- The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product. In the Developer Portal, the application developers see a Migrate this subscription message, which they can click to upgrade their subscription to the migration target.
- The deprecated product can be published again if required.

Although you can publish to a development Catalog, the development Catalog must be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise.

Procedure

To supersede a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to supersede, click the options icon ⋮, and then click Supersede.
4. Select the superseding Product and then click Next.
5. From the drop-down, select which Plans from your new Product correspond to Plans in your old Product.

6. Click Supersede.
   If approval is required to supersede Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is superseded when the request is approved. If approval is not required, the Product is superseded immediately. For information on configuring product lifecycle approvals for a catalog, see Creating and configuring catalogs. For information on approving requests, see Approving product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

Results

Your superseding Product is in the Published state.

The Product that was superseded is in the Deprecated state.

Your superseding Product is published to your preferred organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product. The original Product is deprecated.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Existing customers remain subscribed to the deprecated product, and any billing cycles for subscriptions to paid plans continue uninterrupted. For more information, see Considerations when changing a product lifecycle with billing integration.

Migrating application subscriptions to another Product

By using the Products view within a Catalog in API Manager, you can migrate application subscriptions between Products. The syndication feature in IBM® API Connect means that you can also use the Products view within a Space in a Catalog to migrate application subscriptions. Use the Migrate Subscriptions option to perform the same function as Replace Product, except it does not retire the source product. The destination product must already be published. You can also use Migrate Subscriptions to migrate individual subscriptions between different products or between plans within the same product.

Before you begin

Your Product that you are migrating subscriptions from must be in one of the following states:

- Published
- Deprecated

To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for Products in the Catalog that contains the Product. If you have View permission for Products in this Catalog, you will have read-only access to the Product management page. For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

Application developers initially subscribe their applications to one or more Plans in Products by using the Developer Portal. For more information, see Exploring APIs and Products in the Developer Portal. However, by using API Manager, for a chosen Product you can migrate one or more of its application subscriptions from one Plan to a Plan in another Product.

Procedure

To migrate Product subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.

The Products page of the space opens, and all of the products available in that space are displayed.

3. Alongside the Product version that you want to work with, click the options icon ⋮ and then click Migrate Subscriptions.
4. Select the Plan from which you want to migrate subscriptions, then click Next.
5. Select the subscriptions that you want to migrate, then click Next.
6. Select the Product that you want to migrate the subscriptions to, then click Next.
7. Select the Plan that you want to migrate the application subscriptions to, and then click Migrate.

Results

The target Product has the migrated subscriptions, and those subscriptions are removed from the Product from which they were migrated.

Migrating application subscribers to new Product versions

When new versions of Products are created in IBM® API Connect, there are a number of ways that subscribers can be moved to the Plans of the new Product.

About this task

You can move users to the new Plans in different ways, depending on your Product strategy, by using the options icon ⋮ alongside the Product in the associated Catalog in the API Manager UI.

Procedure

To automatically migrate all existing subscribers to a new Product, for example, when you are applying fixes to a Product:

- You should Replace the original version of the Product with a new version of the Product.
  - The replacement Product is Published.
  - The original Product is Retired.
  - The subscribers to the original Product are automatically migrated to the replacement Product.
    Note: Customers cannot be migrated automatically from a free Plan to a paid Plan. To move your customers from a free Plan to a paid Plan, you can supersede the product with a new product and set a migration target to the paid Plan. The customers then select a button to migrate and must enter their credit card information before the process is complete. For more information, see Considerations when changing a product lifecycle with billing integration.

  For more information about replacing Products, see Replacing a Product with another Product.

To encourage subscribers to move to a new Product, and stop new users from subscribing to the original Product, for example, if an enhancement or new feature is added:

- You should Supersede the original version of the Product with a new version of the Product.
  - The superseding Product is Published.
  - The original Product is Deprecated.
  - The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product. In the Developer Portal the subscribers will see a Migrate this subscription message, which they can click to upgrade their subscription to the migration target.
  - If the migration target is a paid Plan, subscribers must enter a payment method before they can upgrade. Upgrades by subscribers from a free Plan to a paid Plan are supported.

  For more information about superseding Products, see Superseding a Product with another Product.

To prepare a Product to be removed from production, but leave the existing subscriptions as they are:

- You should Deprecate the original Product.
  - The Product is Deprecated.
  - The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product.
  - You can define a replacement Product by using the Set Migration Target option in the Catalog. Application developers will then see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a free Plan to a paid Plan are supported.
  - Use Set Migration Target option to perform the same function as the Supersede option. It prepares subscriptions for migration to the destination product but does not deprecate the source product. The destination product must already be published.
    Note:
    Both Supersede Product and Set Migration Target assume that the source product will no longer be used after all subscriptions are migrated and that it will not be used as a migration target in the future.

    These options are typically used when a new version of product A supersedes an older version of the same product. The source and destination products are labeled with the attributes **`superseded_by`** and **`supersedes`**, respectively.

  - Use Execute Migration Target to force the migration of all subscriptions from a superseded product before retiring it.
    Note:
    Supersede Product and Set Migration Target prevent setting the migration target to an older product version to avoid circular dependencies, where two products point to each other as migration targets.

    To reset the migration target to an older version, first clear the **`superseded_by`** and **`supersedes`** settings created by Supersede Product or Set Migration Target. Then, run Execute Migration Target to migrate all subscriptions to the destination product.

After all subscriptions are migrated, retire the source product. To reuse it, restage and republish it before using Set Migration Target with the older version.

For more information about deprecating Products, see Deprecating a Product.

Changing the availability of a Product

You can change the availability of a Product and the associated Plans by using the Products view within a Catalog or Space in API Manager. The availability of a Product covers both the visibility of that Product to users, and which users can subscribe to it.

Before you begin

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

Procedure

To change the availability of a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Edit visibility.
   The Visibility page opens.
4. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization groups, see Working with consumer organizations.

   Use the Temporarily disable visibility check box to toggle whether the Product is or is not visible, without having to change other visibility settings.

5. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Working with consumer organizations.

   Use the Temporarily disable subscribability check box to toggle whether the Product can or cannot be subscribed to, without having to change other subscription settings.

6. Click Save when done.
   The Product version is configured with the modified availability settings.
   Note:
   - Changing who can view or subscribe to a Product does not affect the settings of the draft Product. The change applies only in the Catalog that was selected in Step 1.
   - Changing who can view or subscribe to a Product does not affect existing subscriptions.
   - Any updates to the visibility of a Product are always verified against the Catalog visibility setting, as the Catalog visibility setting sets the maximum visibility level that is allowed. Therefore, if Product visibility is enabled in a Catalog, and the visibility setting of a Product is less restrictive than is set in the Catalog, then the Product publish to that Catalog will fail. For example, if the Catalog visibility setting is `authenticated`, then any Products that are published to that Catalog cannot have a visibility setting of `public`.

Results

Your Product remains in the same lifecycle state, but now with new availability settings.

What to do next

You can also set Product visibility at the Catalog or Space level. For more information, see Configuring Product visibility at a Catalog or Space level.

Related tasks

- Working with Spaces
- Configuring Product visibility at a Catalog or Space level

Deprecating a Product

You can deprecate a published Product by using the Manage Products page within a Catalog in API Manager. When you deprecate a Product, application developers that are already subscribed to the Product can continue to use it, but no new developers can subscribe to the Product. The syndication feature in IBM® API Connect means that you can also use the Manage Products page within a Space in a Catalog to deprecate a published Product.

Before you begin

The Product that you are deprecating must be in the Published state.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To deprecate a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Deprecate.
   The Deprecate Product window opens.
4. Click Confirm to deprecate the Product.
   If approval is required to deprecate Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is deprecated when the request is approved. If approval is not required, the Product is deprecated immediately. For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Deprecated state.

Retiring a Product

You can retire a published or deprecated Product by using the Manage Products page within a Catalog in API Manager. When a Product is retired, all associated APIs are taken offline, and any subscriptions are deleted. The syndication feature in IBM® API Connect means that you can also use the Manage Products page within a Space in a Catalog to retire a Product.

Before you begin

The Product that you are retiring must be in the Published or Deprecated state.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To retire a Product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon , and then click Retire. The Retire Product window opens.
4. Click Confirm.
   If approval is required to retire Products in this Catalog, an approval request is sent, and the Product moves to the Pending state. The Product is retired when the request is approved. If approval is not required, the Product is retired immediately. For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Retired state. It is also removed from the Developer Portal , is no longer visible to the application developers, and any subscriptions to it are deleted. You can stage the Product again later if required; for details, see Staging a Product.
If the Product has any monetized Plans, the billing cycles for any subscriptions are canceled as well. For more information, see capim_mon_change_plan.html.

Restaging a Product

If a Product in a Catalog is retired, you can restage the Product so that it can reenter the Product lifecycle. A restaged Product moves to the Staged state, from where it can be published. The syndication feature in IBM® API Connect means that you can also restage a Product within a Space in a Catalog.

Before you begin

The Product that you are restaging must be in the Retired state.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it and the product can be published. For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests. For more information about publishing a Product, see Publishing a Product.

Procedure

To restage a Product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, and then click Re-stage. The Restage Product window opens.
4. Click Confirm.
   If approval is required to stage Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is restaged when the request is approved. If approval is not required, the Product is restaged immediately. For more information about configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For more information about approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Staged state, from where it can be published; see Publishing a new Product.

Working with the subscriptions in a Product

You can work with the subscriptions to the Plans in a specific Product. Plan subscriptions are created by application developers in the Developer Portal.

Procedure

To work with the Plan subscriptions in a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Alongside the Product version that you want to work with, click the options icon and then click View Subscriptions.
   A window opens listing all subscriptions to the Plans in the selected Product.
4. Alongside the subscription that you want to work with, click the options icon.
   You can then select from the following options:
   - View Consumer Organization: a window opens listing the consumer organization that the subscribing application belongs to. If required, you can click the options icon to work with the consumer organization For details of the available options, see Working with consumer organizations.
   - View Application: a window opens listing the subscribing application. If required, you can click the options icon to work with the application. For details of the available options, see Working with developer applications.
   - View Plan: a window opens listing the Plan that the application is subscribed to. If required, you can click the options icon to work with the Plan. For details of the available options, see Working with Plans.
   - View Product: a window opens listing the Product that contains the Plan that the application is subscribed to. If required, you can click the options icon to work with the Product. For details of the available options, see Managing your Products.
5. To display the Client ID's for a particular Product subscription, click the information icon in the Application column for the subscription that you require.

Updating the gateway services for a Product

When you stage or publish a draft Product to a Catalog, you specify the gateway services at which the APIs in the Product are to be made available. However, you can later update the selected gateway services after a Product has been stage or published.

Before you begin

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you stage or publish a draft Product to a Catalog, you can either choose to make the APIs in the Product available at all the gateway services that match the gateway service type of the Product, either DataPower® API Gateway or DataPower Gateway (v5 compatible), or can you select specific gateway services of that type. The APIs in the Product can then be called at those gateway service endpoints.

However, after a Product has been staged or published you can later update the gateway services to change the selections.

For more information on staging and publishing a Product, see Staging a draft Product and Publishing a draft Product.

For more information on the gateway service types, see API Connect gateway types.

Procedure

To update the gateway services for a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Update gateway services.
   The Select Gateway Services window opens.
4. Select the required gateway services, then click Save.

Removing a Product from a Catalog

You can remove a Product from a specific Catalog by using the Products view within a Catalog in API Manager. The syndication feature in IBM® API Connect means that you can also use the Products view within a Space to remove a Product from a Catalog.

Before you begin

The Product that you are removing from the Catalog must be in the Staged or Retired state. For more information, see Staging a Product or Retiring a Product.

To complete the product management tasks that are described, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To remove a Product from a Catalog, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Delete.
   The Delete Product window opens.
4. Click Confirm to delete the Product.

Results

Your Product is removed from the Catalog. If required, you can stage the Product again. For more information, see Staging a Product.
If your Product is contained within a Space in a Catalog, your Product is removed from both the Space and the Catalog.

Approving Product lifecycle and subscription requests

To approve or decline requests to change the lifecycle state of a Product, and requests by application developers to subscribe to a Plan, use the Tasks page in the Catalog that contains the associated Product in API Manager. The syndication feature in IBM® API Connect means that you can also use the Tasks page within a Space in a Catalog to approve or decline requests.

Before you begin

To see lifecycle change requests for a Product, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or manage Products in the Catalog that contains the Product. For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

The syndication feature in API Connect means that Products can be contained within a Space in a Catalog. In this case, to see lifecycle change requests for a Product, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or manage Products in the Space that contains the Product. For information on configuring Product management permissions for a Space, see Managing user access in Space.

About this task

If approvals for Product lifecycle changes are enabled for a Catalog, then an attempt to change the lifecycle state of a Product results in an approval request being sent. This request is displayed in the Tasks page in the Catalog, from where the request can be approved or declined. The authority to approve Product lifecycle state changes is restricted to users in specified roles. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs.
Note:

- Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- To view the subscription tasks history, complete the following steps:
  - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
  - Click Tasks tab.
  - Click Approvals history from the navigation pane.
- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

If a Product is set to require approval for subscription by application developers, then an attempt by an application developer to subscribe to the Product results in an approval request being sent. This request is displayed in the Approvals tab in the Catalog that contains the associated Product in API Manager, from where the request can be approved or declined.

Procedure

To work with a Product lifecycle change request, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Click the Tasks tab, then locate the Product lifecycle change request that you want to deal with.
4. Click the Approve or Decline as required.
   Note: You can approve or decline lifecycle change requests only if you have a user role that has permission to approve Product publish requests in the Catalog in which the changes will take place.
   For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

To work with a subscription request, complete the following steps.

5. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
6. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.

The Products page of the space opens, and all of the products available in that space are displayed.

7. Click the Tasks tab, then locate the subscription requests that you want to deal with.
   Note: To see subscription approvals, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or approve subscription requests. For information on creating and assigning user roles, see Administering user access.
8. Click the Approve or Decline as required.
   Note: The options to approve or decline a subscription request are available only if you are assigned a user role that has permission to approve subscription requests. For information on configuring permissions for a Catalog, see Creating and configuring catalogs For information on assigning user roles, see Managing Catalog membership.

Results

For a subscription request, an email is sent confirming whether you approved or declined the request. For a request to change the lifecycle state of a Product, no email is sent.

Working with APIs

For a specific Product, you can work with the APIs that are contained in the Plans in that Product.

Procedure

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
To work with the APIs in a Product, complete the following steps:

1. List the Plans in the Product:
   a. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   b. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
      i. Click the Spaces tab.
      ii. Select the space that you want to work with.
   c. If the Products page is not already displayed, click the Products tab.
   d. Alongside the Product version that you want to work with, click the options icon, then click View Plans.
      A window opens listing the Plans in the Product.
2. Alongside the required Plan, click View APIs.
   A window opens listing the APIs in the Plan.
3. Alongside the required API, click the options icon.
   You can then select from the following options:
   - Take Offline: if you take an API offline, the API is no longer available to be called. When required, you can make the API available again by selecting Online.
   - View Products: a window opens listing all the Products that contain the API. If required, you can click the options icon alongside a Product to work with that Product. For details of the available options, see Managing your Products.
   - View Plans: a window opens listing all Plans, across all Products, that contain the API. If required, you can click the options icon alongside a Plan to work with that Plan. For details of the available options, see Working with Plans.

Working with Plans

After a Product is published to a Catalog, you can work with the Plans in that Product.

Before you begin

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
For details on configuring a Plan in a Product, see Editing a draft Product.

For details on Publishing a Product to a Catalog, see Publishing a Product.

To complete the tasks, you must either be the owner of the API provider organization, or you must be assigned a role that has either the Product > Manage or the Product > View permission for the Catalog. For more information, see Adding provider organization users and assigning roles and Managing Catalog membership. For information

on configuring Product management permissions for a Catalog, see Creating and configuring Catalogs.

Procedure

To work with Plans in a Catalog, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, and then click View Plans.
   A window opens listing all the Plans in the selected Product.
4. Alongside the Plan that you want to work with, click the options icon.
   You can then select from the following options:
   - View Product: a window opens listing the Product that contains the Plan. If required, you can click the options icon to work with the Product. For details of the available options, see Managing your Products.
   - View APIs: a window opens listing the APIs in the Plan. If required, you can click the options icon alongside an API to work with that API. For details of the available options, see Working with APIs.
   - View Subscriptions: a window opens listing the subscriptions to the Plan. If required, you can click the options icon alongside a subscription to work with the subscriptions. For details of the available options, see Working with application subscriptions.

Working with consumer organizations

Manage the consumer organizations that access your APIs and Plans when their users sign up to use the IBM® API Connect Developer Portal .

About this task

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
Application developers in consumer organizations access the Developer Portal and sign up to use the Plans in the Products you create in the API Manager. You can create more than one consumer organization and each organization has one owner. Application developers are added through the Developer Portal UI.

You can also create groups of consumer organizations. A consumer organization group is an efficient way of grouping application developers together to publish Products to, making it easier to control who has access to the Plans in the Products.

Use the following tasks to administer your consumer organizations and consumer organization groups:

- **Creating a consumer organization**
  If you have permission to manage developers, you can create new consumer organizations in a Catalog. consumer organizations contain the application developers that subscribe to use the APIs that are published to the Catalog
- **Editing a consumer organization**
  You can change the title of an IBM API Connect consumer organization, and also transfer ownership to a new organization owner.
- **Deleting a consumer organization**
  When you delete a consumer organization, all of the resources in that organization are removed from the cloud. However, the account of the organization owner remains in IBM API Connect.
- **Working with the applications in a consumer organization**
  You can work with the developer applications that have been registered in a consumer organization.
- **Working with the subscriptions in a consumer organization**
  You can work with the Plan subscriptions that have been created by the developer applications registered in a consumer organization.
- **Working with consumer organization groups**
  A *consumer organization group* is a collection of consumer organizations, and provides an efficient way of controlling who can see, and subscribe to, the APIs in your Products. By using a consumer organization group, you can define this access for all the developers in the organizations in that group in a single operation, rather than having to define access for the organizations separately.
- **Sending messages to consumer organization owners**
  You can send email messages to the owners of consumer organizations. You can also style the email to match your business theme.

Creating a consumer organization

If you have permission to manage developers, you can create new consumer organizations in a Catalog. consumer organizations contain the application developers that subscribe to use the APIs that are published to the Catalog

Before you begin

Your IBM® API Connect Developer Portal must be enabled to perform this task. For more information, see Creating and configuring Catalogs.

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

About this task

You can create a consumer organization in either of the following ways:

- Invite a user to be a consumer organization owner, in which case they receive an invitation email with an activation link, and can complete the creation of the consumer organization and specify the title.
- Create the consumer organization yourself, specifying the owner and title. There are two ways you can specify the owner:
  - Specify the user ID of an existing user.
  - If you are using a Local User Registry, specify a new user ID; the user is added to the registry and becomes the owner of the consumer organization.

If Spaces are enabled in your Catalog, when you create a consumer organization, it is added to the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. To invite a user to be a consumer organization owner, complete the following steps:
   a. Click Add > Invite organization owner.
   b. Enter the email address of the organization owner.
   c. Click Invite.
   The new consumer organization is added to the list, and an email invitation is sent to the owner; by using the activation link, the owner specifies the title of the organization. The status is shown as `Pending` until the recipient of the email clicks the link in the email to complete the creation of their Developer Portal account, after which the status changes to `Enabled`.
5. To create the consumer organization yourself, complete the following steps:
   a. Click Add > Create organization.
   b. Enter the organization Title. A Name is entered automatically.
   The value in the Name field is a single string that is used to identify the consumer organization in developer toolkit CLI commands. The title is used for display.
   To view the CLI commands to manage consumer organizations, see the toolkit CLI reference documentation.
   c. Select the required user registry.
   d. Specify the organization owner; complete one or other of the following steps, either to specify an existing user, or to create a new user:
      - To specify the user ID of an existing API Connect user who is in the selected user registry, complete the following steps:
        - For the Type of user, select Existing.
        - In the Username field, enter the user ID of the organization owner
        After the consumer organization is created, the specified user can immediately log in to the Developer Portal associated with the Catalog.
      - If you selected a Local User Registry, then to specify a new user ID, complete the following steps:
        - For the Type of user, select New User.
        - In the Username field, enter the new user ID.
        - Enter the Email, First Name, Last Name, and Password.
        After the consumer organization is created, the new user will have been added to the selected registry and can immediately log in to the Developer Portal associated with the Catalog, by using the specified user ID and password.
   e. Click Create to complete the creation of the consumer organization.

Editing a consumer organization

You can change the title of an IBM® API Connect consumer organization, and also transfer ownership to a new organization owner.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

About this task

If you transfer ownership, the new organization owner can be an existing user, or you can create a new user. When the ownership changes, the new owner is assigned administration privileges for the organization, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Administering members and roles.

If Spaces are enabled in your Catalog, when you edit the details of a consumer organization, the updates are applied to the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

To change the title of a consumer organization, or to transfer ownership to a new organization owner, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.

   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the name of the consumer organization that you want to work with.
5. To change the title, enter a new title in the Title field, then click Save.
6. To transfer ownership, select the user registry for the consumer organization owner you want to transfer ownership to.
   The remaining procedure varies according to the type of the selected user registry, as follows:
   - Local User Registry
     - Select whether the user is an Existing user or a New User.
       - For an existing user, complete the following steps:
         - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
         - Click Save.
       - For a new user, complete the following steps:
         - Enter a unique user name for the new user.
         - Supply an email address, name details, and a password.
         - Click Save.
   - LDAP
     - Enter the name of a user that exists in the selected user registry.
     - Click Save.
   - Authentication URL and OIDC
     - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must ensure they have been invited to the organization first.
     - Click Save.

Results

If the title of the consumer organization is changed, all application developers that are members of that consumer organization will see the title change reflected in the Developer Portal user interface.

Related tasks

- Publishing a Product

Deleting a consumer organization

When you delete a consumer organization, all of the resources in that organization are removed from the cloud. However, the account of the organization owner remains in IBM® API Connect.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

Important: If you delete a consumer organization, client IDs and secrets associated with applications that were registered by users in the consumer organization can no longer be used to call APIs. However, the account of the organization owner remains in API Connect.

About this task

When you delete a consumer organization, it is removed permanently and users can no longer access that organization.
If Spaces are enabled in your Catalog, when you delete a consumer organization, it is deleted from the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

To delete a consumer organization, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.

   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon ⋮ alongside the consumer organization you want to work with, then click Delete.
5. Click Confirm to delete the consumer organization.
   Note: If the consumer organization is the only one specified in the custom visibility settings for a published Product, the deletion operation will fail. For more information, see Changing the availability of a Product.

Working with the applications in a consumer organization

You can work with the developer applications that have been registered in a consumer organization.

Procedure

To work with applications, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon for the consumer organization that you want to work with, then click View Applications.
   A window opens listing all the developer applications that have been registered in the consumer organization
5. To view and edit the details of an application, click the title of the application.
6. Further options are available by clicking the options icon alongside the application you want to work with. For details, see Working with developer applications.

Working with the subscriptions in a consumer organization

You can work with the Plan subscriptions that have been created by the developer applications registered in a consumer organization.

Procedure

To work with Plan subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon for the consumer organization that you want to work with, then click View Subscriptions.
   A window opens listing all the Plan subscriptions that have been created by the developer applications registered in the consumer organization. If required, you can click the options icon alongside a subscription to work with that subscription. For details of the available options, see Working with application subscriptions.

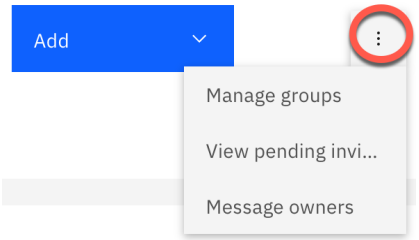
Working with consumer organization groups

A *consumer organization group* is a collection of consumer organizations, and provides an efficient way of controlling who can see, and subscribe to, the APIs in your Products. By using a consumer organization group, you can define this access for all the developers in the organizations in that group in a single operation, rather than having to define access for the organizations separately.

About this task

A consumer organization group might represent particular business partners, internal organizations, or other groups of application developers.

When you create a Product, you can define which application developers can access the APIs in that Product. You can configure the following types of access:



- Visibility, which specifies the application developers who can see the APIs in the Developer Portal .
- Subscribability, which specifies the application developers who can create subscribe to use the APIs.

You configure this access by selecting the required consumer organizations, and Consumer organization groups. You can also change the visibility and subscribability settings for a Product after it has been published. For more information, see Creating a draft Product and Changing the availability of a Product.

Procedure

To work with consumer organization groups, you first navigate to the Consumer organization groups page. You then create new groups, send an email to the owners of the consumer organizations in a group, and edit or delete existing groups.

- Navigating to the required consumer organization groups page.
  1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
  2. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
     a. Click the Spaces tab.
     b. Select the space that you want to work with.
  3. Click the Consumers tab, then click the options menu in the page header and select Manage Groups.

- Creating a consumer organization group.
  1. Click Add.
  2. Enter a Title for the new group and, optionally, a Summary. A Name is entered automatically. The title is used for display.
  3. Use the Search orgs/groups field to search for, and select, the consumer organizations that you want to add to the group.
     Note: To prevent excessive search results lists, only the first 10 matches are displayed when you begin typing in the field; lengthen your search string to shorten the list for locating the required consumer organization.
  4. Click Save to create the group.
- Editing a consumer organization group.
  1. Click the options icon ⋮ for the consumer organization group that you want to work with, then click Edit.
  2. Make the required updates, then click Save.

  Note: If you remove a consumer organization from a group, and that group is specified in the custom visibility settings for a Product, applications in that consumer organization can no longer subscribe to the Product. However, any existing subscriptions are not affected. For information on managing visibility and subscribability settings, see Editing a draft Product.
- Deleting a consumer organization group.
  1. Click the options icon ⋮ for the consumer organization group that you want to work with, then click Delete.
  2. Click Confirm to delete the group.
- Sending an email to the owners of the consumer organizations in a consumer group
  1. Click the options icon ⋮ for the consumer organization group that you want to work with, then click Message owners.
     The Send message window opens, and the email addresses of the consumer organization owners are displayed as the recipients.
  2. Enter the subject of the message in the Subject field.
  3. Enter the content of the message in the Message field, then click Send.

Sending messages to consumer organization owners

You can send email messages to the owners of consumer organizations. You can also style the email to match your business theme.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

Email messages contain a sender name and address that is based on a hierarchical search of the configured sender details in API Connect. Depending on the email sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used are the first set of configured details that are found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see Sending messages to consumer organization owners.

Note: You can also send email messages by using the developer toolkit CLI, or by using the API Connect REST APIs. See API development and management commands, or API Connect REST APIs, for more information.

Procedure

To send a message, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.

   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. You can either send a message to the owner of a specific consumer organization, or to the owners of multiple selected consumer organizations.
   - To send a message to the owner of a specific consumer organization, click the options icon ⋮ alongside the consumer organization you want to work with, then click Message owner. The Send Message window opens, and the email address of the consumer organization owner is displayed as the recipient.
   - To send a message to the owners of multiple selected consumer organizations, complete the following steps:
     - Click the options icon ⋮ alongside the Add button, then click Message owners.
     - Select the required consumer organizations, then click Next. The Send Message window opens, and the email addresses of the selected consumer organization owners are displayed as the recipients.
5. Enter the subject of the message in the Subject field.
6. Select the Content type that you want to use for the entering the content of the message, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 1. Allowed HTML tags and attributes

HTML tag	Attribute
<a>	"class", "href", "hreflang", "style"

HTML tag	Attribute
`<em>`	`"class", "style"`
`<strong>`	`"class", "style"`
`<cite>`	`"class", "style"`
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a `<img src="https://path/to/image.png"/>` tag in the template. The `src` attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images. They must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

7. Enter the content of the message.
8. Click Send.

Working with developer applications

You can work with the applications that have been registered in the Developer Portal associated with a Catalog.

About this task

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Procedure

To work with developer applications, complete the following steps.

1. In the navigation pane of the API Manager UI, click  Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Click the Applications tab.
   All applications that have been registered in the Developer Portal associated with this Catalog are listed.
4. To view and edit the details of an application, click the title of the application.
5. Further options are available by clicking the options icon ⋮ alongside the application you want to work with, as follows:
   - Client ID: lists the Client IDs for the application. You can add new client ID/client secret credentials; you can copy the client secret only at creation time. An option is provided for deleting any of the credentials from the application.
   - Create Subscription: subscribe the application to a Plan in a Product; select the required Plan and Product, then click Create Subscription.
   - View Subscriptions: a window opens listing summary details of all the Plan subscriptions for the application. If required, you can click the options icon ⋮ alongside a subscription to work with that subscriptions. For details of the available options, see Working with application subscriptions.
   - View Consumer Organization: a window opens listing the consumer organization that the application belongs to. If required, you can click the options icon ⋮ to work with the consumer organization. For details of the available options, see Working with consumer organizations.

Working with application subscriptions

You can work with the subscriptions to the Plans in all the Products in a specific Catalog. Plan subscriptions are created by application developers in the Developer Portal.

Procedure

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
To work with application subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all the products available in that catalog are displayed.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Click the Subscriptions tab.
   A window opens listing all subscriptions to the Plans in all the Products in the Catalog.
4. Alongside the subscription that you want to work with, click the options icon ⋮.
   You can then select from the following options:
   - View Consumer Organization: a window opens listing the consumer organization that the subscribing application belongs to. If required, you can click the options icon ⋮ to work with the consumer organization For details of the available options, see Working with consumer organizations.
   - View Application: a window opens listing the subscribing application. If required, you can click the options icon ⋮ to work with the application. For details of the available options, see Working with developer applications.
   - View Plan: a window opens listing the Plan that the application is subscribed to. If required, you can click the options icon ⋮ to work with the Plan. For details of the available options, see Working with Plans.
   - View Product: a window opens listing the Product that contains the Plan that the application is subscribed to. If required, you can click the options icon ⋮ to work with the Product. For details of the available options, see Managing your Products.

Security and authentication

In API Manager, you can use TLS profiles to secure the transmission of data between the management server and other API Connect subsystems and external services, and also configure user registries to securely authenticate your catalogs and APIs.

For details of authentication in IBM API Connect, see the following subtopics:

- **Creating a TLS client profile**
  Create a TLS client profile to secure communication within your API Connect deployment and to external services.
- **Authenticating by using your enterprise user registry**
  IBM API Connect supports various user registry types for authenticating users and securing APIs.
- **Configuring a native OAuth provider**
  Your cloud configures and manages native OAuth providers.
- **Configuring a third-party OAuth provider**
  Enter the secure endpoints to provide OAuth authentication from a third party.
- **OAuth concepts for API Connect**
  OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Creating a TLS client profile

Create a TLS client profile to secure communication within your API Connect deployment and to external services.

Before you begin

One of the following roles is required to configure TLS profiles:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

About this task

API Connect provides pre-configured TLS client profiles that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new client profiles with your own TLS certificates.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
Note: If you update a TLS profile that is associated with a Gateway service, the updates are not automatically propagated to Gateway servers. For instructions on configuring the toolkit command-line tool to use TLS certificates when connecting to API Manager, see Configuring the command-line tool to use TLS certificates.

Procedure

To create a TLS profile, complete the following steps:

1. In the API Manager, click  Resources.
2. Select Crypto Material.
3. Click Create in the TLS client profile table.
4. Enter the fields to configure the TLS client profile:

Field	Description
Title	Enter a title for the profile.

Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
	To view the CLI commands to manage a TLS client profile, see the toolkit CLI reference documentation.
	
	Important: The name of the TLS client profile as saved on the DataPower® Gateway, depending on the gateway type, is as follows:
	• DataPower API Gateway:
	`provider-org-name_catalog-name_tlsp-tls-profile-nameV1.0.0`
	• DataPower Gateway (v5 compatible):
	`provider-org-name-tls-profile-nameV1.0.0`
	
	where
	• *tls-profile-name* is the value of the auto-generated name field for the TLS client profile in API Connect.
	• *provider-org-name* is the name of the provider organization that contains the TLS client profile.
	• *catalog-name* is the name of the catalog, in that provider organization, that contains the TLS client profile.

Version	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, `MyProfile 1.0` and `MyProfile 1.1`.
Summary	Enter a description of the profile.
Protocols	Select one or more supported TLS protocol versions. The default is 1.2 and 1.3
Server Connection	Specify whether to support weak or insecure credentials. • Allow insecure server connections - Insecure server connections can mean connections that use self-signed, expired, corrupted, or are from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections. • Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates that are presented on the same IP address using different hostnames. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.
Keystore	The keystore is a repository containing public and private key pairs. Select the keystore where you store the certificates for the profile. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your uploaded certificates before they expire.
Truststore	The truststore is a repository containing verified public keys. Truststores contain the list of certificates that your TLS client profile trusts. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your uploaded certificates before they expire.
Ciphers	Cipher suites are encryption algorithms that are used to secure TLS communication. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

5. Click Save.

- **Creating a keystore**
  Keystores contain matched pairs of public certificates and private keys that are used to secure TLS connections.
- **Creating a truststore**
  Create a truststore that contains a list of certificates that your TLS client profile trusts.
- **Using OpenSSL to generate and format certificates**
  Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.
- **Viewing certificate details and adding certificates to a keystore or truststore**
  You can view details for the certificates in an existing keystore or truststore and add more certificates.
- **Defining elliptic curve cryptographic schemes for a TLS client profile**
  You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

Related tasks

- Working with user registries

Creating a keystore

Keystores contain matched pairs of public certificates and private keys that are used to secure TLS connections.

Before you begin

Your private and public keys must be in PEM or P12 format files.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure keystores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

Procedure

Complete the following steps to create a keystore:

1. In the API Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the keystore table.

Field	Description
Title	Enter a title for the keystore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Private key & public key: Step 1: Upload private key	Upload the file that contains the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).
Private key password	If the private key has a password, then enter it here.
Private key & public key: Step 2: Upload public key	If the public key is contained in a separate file, upload it in Step 2. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).

4. Click Save.
   Note: Uploaded keys and certificates cannot be download from API Connect.

Related tasks

- Creating a TLS client profile
- Creating a truststore

Creating a truststore

Create a truststore that contains a list of certificates that your TLS client profile trusts.

Before you begin

Your public keys must be in PEM or P12 format files.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure truststores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

Procedure

1. In the API Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the truststore table.

Field	
Title	Enter a title for the truststore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Upload truststore certificates	Upload the file that contains the public key certificate.

4. Click Save.

Using OpenSSL to generate and format certificates

Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.

OpenSSL is an open source toolkit that can be used for generating and validating TLS certificates.

This topic covers how to generate a self-signed TLS certificate by using the OpenSSL toolkit, and how to convert certificates in PEM format to P12 format.

Creating a self-signed certificate with OpenSSL

Use the following command to create a private key and public certificate with OpenSSL:

```
openssl req -newkey rsa:2048 -nodes -keyout private_key.pem -x509 -days 365 -out public_certificate.pem
```

The OpenSSL command asks for the following information to create your private key and public certificate (example values shown):

- Country Name (2 letter code) []: US
- State or Province Name (full name) []: California
- Locality Name (eg, city) []: Sacramento
- Organization Name (eg, company) []: exampleorganization
- Organizational Unit Name (eg, section) []:
- Common Name (eg, fully qualified host name) []: gateway.exampleorganization.com
- Email Address []:

Common Name must be set to the fully qualified domain name of the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example. **`192.16.183.131`** or **`gateway.exampleorganization.com`**).

To review the generated public certificate run:

```
openssl x509 -text -noout -in public_certificate.pem
```

To combine the generated private_key and public_certificate PEM files into a password protected P12 file, run:

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12
```

To validate a P12 file, run:

```
openssl pkcs12 -in certificate.p12 -noout -info
```

Creating PKCS#12 (P12) certificate from PEM files

PKCS#12 (P12) defines an archive file format for storing cryptographic objects as a single file. Use OpenSSL to create a password protected P12 file from your PEM files.

Prerequisites:

- Private key file. For example: private_key.pem.
- CA signed certificate. For example: public_certificate.pem.
- If you have intermediate certificates from your CA, concatenate them into a single .pem file to create a ca_chain.pem file:

  ```
  cat ca1.pem ca2.pem ca3.pem > ca_chain.pem
  ```

  the ca_chain.pem file should look like this:

  ```
  -----BEGIN CERTIFICATE-----
  MIIEpjCCA46gAwIBAgIQEOd26KZabjd+BQMG1Dwl6jANBgkqhkiG9w0BAQUFADCB
  ...
  lQX7CkTJn6lAJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
  -----END CERTIFICATE-----
  -----BEGIN CERTIFICATE-----
  MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NUmXJTANBgkqhkiG9w0BAQUFADBv
  ...
  -----END CERTIFICATE-----
  -----BEGIN CERTIFICATE-----
  MIIENjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQQGEwJTRTEU
  ...
  -----END CERTIFICATE-----
  ```

- If you have multiple end-entity (leaf) certificates in one file, then split them into separate files and create separate P12 files for each certificate.

Create the P12 file with the following OpenSSL command (if you don't have CA certificates to include, then omit **`-CAfile <filename> -chain`**):

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

Related tasks

Viewing certificate details and adding certificates to a keystore or truststore

You can view details for the certificates in an existing keystore or truststore and add more certificates.

Before you begin

One of the following roles is required to edit keystores and truststores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

Procedure

To work with existing keystores and truststores:

1. In the API Manager, click Resources.
2. Select Crypto Material.
3. Click the name of the keystore or truststore.
4. Edit the name and summary if needed.
5. The Subject, Finger Print, and Expiration date are shown for each certificate in the keystore or truststore. Click > to view the certificate details.
6. Add additional private or public keys if needed.
7. Click Save.
   Note: Uploaded keys and certificates cannot be download from API Connect.

Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include **`elliptic_curve_auto_negotiation`** and **`elliptic_curve`** properties in a YAML file definition for the TLS client profile. The **`elliptic_curve`** property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When **`elliptic_curve_auto_negotiation`** is set to **`true`**, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any **`elliptic_curve`** property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The **`elliptic_curve_auto_negotiation`** option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

  Table 1.

API enforcement on the gateway	API Connect server access security
secp192r1	prime192v1
secp256r1	prime256v1

  Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
       .
       .
       .
  - secp256r1
  - prime256v1
       .
       .
       .
```

Procedure

Complete the following steps to create a TLS client profile with elliptic curve cryptographic schemes defined:

1. Create a YAML file definition for your TLS client profile, with the required **`elliptic_curve`** property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see Logging in to a management server.
3. Create the TLS client profile by using the following command:

   ```
   apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
   ```

   where:
   - *mgmt_endpoint_url* is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
   - *organization_name* is either **`admin`**, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
   - *tls_client_profile_yaml_file* is the name of the YAML file that contains the definition for your TLS client profile.

   Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.
   For reference details of all the **`apic tls-client-profiles`** commands, see the toolkit CLI reference documentation.

   You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Authenticating by using your enterprise user registry

IBM® API Connect supports various user registry types for authenticating users and securing APIs.

You can use your enterprise user registry for authentication in API Connect if it is of one of the following types:

LDAP directory
: If your user registry uses Lightweight Directory Access Protocol (LDAP), you can use it in API Connect for both user authentication and API security.

Authentication URL User Registry
: You can configure a non-LDAP user registry by using an authentication URL user registry. An authentication URL user registry enables integration with third-party authentication providers. You can use an authentication URL user registry in API Connect for both user authentication and API security.

Local User Registry
: You can authenticate users with a local user registry. A local user registry is an internal registry stored within API Connect.

OpenID Connect
: You can authenticate users through an identity provider that supports the OpenID Connect (OIDC) authentication protocol.

- **Working with user registries**
  To secure the APIs that are published to your IBM API Connect Catalogs, you authenticate with user registries.
- **Modifying the configuration details for a user registry**
  You modify the configuration details for a user registry by using the User Registries page in the API Manager user interface of IBM API Connect.
- **Password lockout criteria**
  You can be locked out of your account if you attempt to log in and fail consecutively.

Related tasks

- Working with user registries

Working with user registries

To secure the APIs that are published to your IBM® API Connect Catalogs, you authenticate with user registries.

About this task

Create user registry resources to secure your APIs, and authenticate with users.

Procedure

To configure a user registry, complete the following steps:

1. In the API Manager user interface, select Resources.
2. On the Resources page, select User Registries > Create.
3. Select the tile for the user registry type you want, and continue to the instructions for configuring user authentication for your selection.
   Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

   Authentication URL User Registry
   : For more information, see Creating an Authentication URL user registry.

   Custom user registry
   : For more information, see Creating an organization-specific custom user registry.

LDAP User Registry
: For more information, see Creating an LDAP user registry in API Manager.

Local User Registry
: For more information, see Creating a Local User Registry

OIDC User Registry
: For more information, see Creating an OIDC user registry in API Manager.

Results

The user registry information is added to API Manager.

What to do next

You can now use API Manager to chart and manage your Catalogs.

- **Creating an Authentication URL user registry**
  An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- **Creating an organization-specific custom user registry**
  You can configure an organization-specific custom user registry to provide user authentication for the Developer Portal.
- **Creating an LDAP user registry in API Manager**
  You can use the API Manager UI to configure an organization-specific LDAP user registry to provide user authentication and onboarding for the Developer Portal . APIs can also be secured with an LDAP user registry.
- **Creating a Local User Registry**
  A Local User Registry (LUR) can be created to provide user authentication for API Manager.
- **Creating an OIDC user registry in API Manager**
  Create an organization-specific OIDC user registry when multifactor authentication (MFA) is required.

Creating an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

About this task

This topic describes how to create a new Authentication URL user registry as a Resource in your organization. After the user registry is created, the user registry must be added to the Sandbox catalog.

One of the following roles is required to configure user registries:

- Administrator
- Organization Owner
- Custom role with the `Settings: Manage` permissions

Note:
API Connect issues an HTTP **`GET`** call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as **`https://myauthurl.example.com/user/authenticate`**:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of **`200`**, the user authenticates successfully. An HTTP status code other than **`200`** indicates a failed login attempt. API Connect forwards any HTTP Header starting with **`X-`** (with the exception of **`X-Client-Certificate`**), and Cookie to the Authentication URL identity provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
 X-Forwarded-For: 8.8.9.9
 X-Custom-Header-From-Customer: special
 Cookie: MyCookie=VGhpc0lzV2lja2VkQW1hemluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- **`username`**
- **`email`**
- **`first_name`**
- **`last_name`**

If the **`username`** field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The **`Content-Type`** must be **`application/json`**.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
```

```
{
  "username":"myuser",
  "email":"myuser@example.com",
  "first_name":"My",
  "last_name":"User"
}
```

Procedure

1. In the API Manager, click  Resources.
2. Select User Registries to see the list of current user registries in your organization.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Authentication URL User Registry and enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name that is used in CLI commands. The name is autogenerated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary (optional)	Enter a brief description.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface login, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
URL (required)	Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either `200 OK` or `401 Unauthorized` will be returned.
TLS Client Profile (optional)	Select a TLS Client Profile to allow secure authentication with a specific web server.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal .
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal , including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.
6. Add the user registry to the Sandbox catalog. See Creating and configuring Catalogs.

Results

The user registry can be used for Basic Authentication in the Security Definition for an API. For more information, see Defining basic authentication security schemes.

Creating an organization-specific custom user registry

You can configure an organization-specific custom user registry to provide user authentication for the Developer Portal.

Before you begin

Custom user registries can be used for authenticating users to the Developer Portal, but cannot be used to secure APIs.

To configure a custom user registry as a resource in API Manager, the external user directory must be created and available to use with your API Connect ecosystem.

Also, a custom user registry definition for your external user registry must already have been created on the Cloud Manager, as you need the information from this definition to set up the custom user registry. For more information, see Configuring a shared custom user registry.

One of the following roles is required to configure a custom user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create a custom user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure an organization-specific custom user registry. If you want to create a shared registry, see Configuring a shared custom user registry.
Note:

- You can also create and manage custom user registries by using the API Connect REST APIs. For more information, see API Connect REST API documentation.

You can use the following instructions to create a writable or a read-only custom user registry.

API Connect provides two methods for creating a custom user registry in the API Manager, as described in the following sections:

- Creating a custom user registry by using the API Manager UI
- Creating a custom user registry by using the developer toolkit CLI

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

Creating a custom user registry by using the API Manager UI

You configure a custom user registry by creating a new custom user registry resource, which references the custom user registry type that is defined in the Cloud Manager. To make the custom user registry available to the Developer Portal for user authentication, you must enable the registry in the associated Catalog. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the custom user registry type.

Creating a custom user registry resource

Use the following instructions to create a new custom user registry resource in the API Manager UI.

1. Click Create in the User Registries section of Resources.
2. Click the Custom user registry tile.
3. Enter the following information:

Property	Description
Custom type	The name of the custom user registry type. For example, *my-custom-user-registry-type*. Use the drop-down arrow to select different custom user registry types. The custom user registry type is defined in the Cloud Manager.
Title	A descriptive name to display in the UI.
Name	The name of the custom user registry. This name is autogenerated, and is used in CLI commands.
Summary	A brief description of the custom user registry.
Endpoint	Optional endpoint information.
Case sensitive	To ensure proper handling of username capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: • The Developer Portal does not support case-sensitive usernames. • After at least one user has been onboarded into the registry, you cannot change this setting.
User registry managed	Determines whether API Connect manages your user registry. Valid values are: • `true` - select the checkbox • `false` - clear the checkbox
User managed	Determines whether your user registry is writable or not. Select the checkbox to set to `true` for writable. Clear the checkbox for the nonwritable option.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site admin account.

4. Click Create. The new user registry is displayed in the User registries list.

Adding your custom user registry to the Developer Portal login

To make the custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Catalog settings > Onboarding. In the Catalog User Registries section, click Edit, select the custom user registry, and click Save. For more information, see Creating and configuring Catalogs.

Creating a custom user registry by using the developer toolkit CLI

You configure an organization-specific custom user registry by creating a new custom user registry resource that references the integration document that exists on the Cloud Manager. You use developer toolkit CLI commands to create the custom user registry, and to make the registry available to the Developer Portal, you must enable the registry in the associated Catalog. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the integration document.

Logging in to the management server CLI

Before you can define the custom user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For more information about the full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your custom user registry

You define the configuration of your custom user registry in a *`custom_config_file`*`.yaml` file, as shown in the following example.

```
name: 'custom_registry_name'
title: 'display_title'
registry_type: 'custom_user_registry'
integration_url: custom_integration_url
case_sensitive: true_or_false
user_managed: true_or_false
user_registry_managed: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: 'provider_title'
configuration:
  custom_config1: 'value1'
  customize: true
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the custom user registry. This name is used in the CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`registry_type`	The registry type that is configured in the `name` property in the integration document, for example *`custom_user_registry`*.
`integration_url`	The custom integration URL in your API Connect configuration. You can determine the custom integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable. Set to `false` if you don't want the registry to be writable.
`user_registry_managed`	Determines whether API Connect manages your user registry. Valid values are: • `true` • `false`
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.

Property	Description
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site admin account.
`identity_providers`	An array containing the details of your custom server, were: • `name` - is the name of the custom server and is the name that is used in CLI commands • `title` - is the display name of the custom server
`configuration`	The user-defined configuration based on the `configuration_schema` that is defined in the integration document.

Save your ***custom_config_file*.yaml** so that the **user-registries:create** command can access it in the following section.

Creating your custom user registry

To create your organization-specific custom user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org organization_name custom_config_file.yaml
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- **--org** *organization_name* means that the registry is created in your provider organization.
- *custom_config_file* is the name of the YAML file that defines the configuration of your custom user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

the *registry_name* is derived from the **name** property in the custom user registry YAML file. The *registry_url* is the URL with which the custom registry resource can be accessed.
Your organization-specific user registry is now created. See the following section for instructions on how to make the registry available to users.

Configuring your custom user registry in a Catalog

To make your custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Enter the following command (the hyphen character at the end means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_registry_url: custom_registry_url
   ```

   where *custom_registry_url* is the URL of your custom user registry, obtained in step 1.
4. Press **CTRL D** to stop the input.

Creating an LDAP user registry in API Manager

You can use the API Manager UI to configure an organization-specific LDAP user registry to provide user authentication and onboarding for the Developer Portal . APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in API Manager, the LDAP directory must be created and populated for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Organization Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure an organization-specific LDAP user registry. If you want to create a shared registry, see Configuring an LDAP user registry in the Cloud Manager for more information.
Note:

- You can also create and manage LDAP user registries by using the developer toolkit CLI. For more information, see Using the CLI to create an organization-specific LDAP user registry.
- The API Connect REST APIs can also be used to create and manage LDAP user registries; see the API Connect REST API documentation.
- You can map external LDAP groups to API Connect user roles to enable greater control of user access, but this configuration can be done only by using the developer toolkit CLI; see Using the CLI to create an organization-specific LDAP user registry for details.

You create an LDAP user registry by configuring a set of properties in the API Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. To make the registry available to the Developer Portal , you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see LDAP authentication.

Procedure

Follow these steps to configure a new LDAP user registry as a Resource in the API Manager UI.

Note: If you are using an **`Active Directory`**, you must indicate this by using the property **`"directory_type": "ad"`** in the LDAP config.

1. In the API Manager, click  Resources.
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select LDAP User Registry for the user registry type, and enter the following information:

Field	Description
Title	Enter a descriptive name to display on the screen.
Name	The name that is used in CLI commands. The name is autogenerated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface login, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Address	Enter the IP address or host name of the LDAP server.
Port	Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, `389`.
Select a TLS Client Profile (optional)	Select the TLS Client Profile that the LDAP server requires.
Select a protocol version	Select the version number for the LDAP protocol that you are using.
Remote directory is Microsoft Active Directory	Select this option if you use Active Directory.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** select Case sensitive if your backend LDAP server supports case-sensitivity. • Do **not** select Case sensitive if your backend LDAP server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal .
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal , including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
   - Compose DN - Select this format if you want users to login with a username that is also part of their LDAP Distinguished Name (DN). For example, using `` `uid` `` for user login where the user's LDAP DN is: `uid=<username>,ou=People,dc=company,dc=com`. If you are unsure whether Compose (DN) is the

correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose DN is not supported with the DataPower API Gateway.

- Compose UPN - Select this format if your LDAP directory supports binding with User Principal Names such as **`john@acme.com`**. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
  Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- Search DN - Select this format if you want users to login with a username that is not part of their LDAP DN. For example, if the user's LDAP DN was: `{{uid=<username>,ou=People,dc=company,dc=com but }}` you want them to login with the email. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.
  Optionally select a scope to specify which part of the directory information tree is examined:
  - Whole subtree (default)
  - Base object
  - Single level

For all of the authentication methods:

If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the DN that comes before the username for binding or authentication. For example, `bind_prefix: 'uid='`.
Suffix	Part of the DN that follows the username, specifying the user's location in the LDAP tree. For example, `bind_suffix: ',ou=users,dc=apic,dc=com'`. `uid=<username>,ou=People,dc=company,dc=com`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

6. For authentication method Compose UPN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Suffix	Part of the DN that follows the username for constructing the UPN. For example, `@domain.com`.
Use group authentication (optional)	Enter the Filter condition for the group.

7. For authentication method Search DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the search filter that comes before the username. The last attribute must be the one you chose to use for login. For example, `'(&(uid='`.
Suffix	Part of the search filter that follows the username. For example, `'))(objectClass=organizationalPerson)'`. Notice how it always begins with a `'))'` which is meant to close the attribute filter for the last attribute specified in `search_dn_filter_prefix`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.
9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:
   - LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
   - API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in **`[ ]`** with the value that the user supplies when signing up.

   The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

LDAP ATTRIBUTE NAME	API Connect VALUE
`dn`	`uid=[username],ou=users,dc=company,dc=com`

LDAP ATTRIBUTE NAME	API Connect VALUE
cn	[first_name] [last_name]
sn	[last_name]
mail	[email]
userPassword	[password]

You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.

10. Click Create.
    Your new LDAP registry is shown in the list of User Registries on the Resources page.

What to do next

If you use DataPower® API Gateway, your cloud administrator can optionally update the service and enable LDAP connection pooling to improve performance as explained in Registering a gateway service.

If you want to make the LDAP user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal . Click the relevant Catalog, then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring catalogs .

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Defining basic authentication security schemes.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

- **Using the CLI to create an organization-specific LDAP user registry**
  You can use the Developer Portal CLI to configure an organization-specific LDAP user registry to provide user authentication for the Developer Portal. APIs can also be secured with an LDAP user registry.

Using the CLI to create an organization-specific LDAP user registry

You can use the Developer Portal CLI to configure an organization-specific LDAP user registry to provide user authentication for the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in API Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for securing a catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
Note: If you are using an **`Active Directory`**, you must indicate by using the property **`"directory_type": "ad"`** in the LDAP config.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure an organization-specific LDAP user registry. For more information about hoe to create a shared registry, see Using the CLI to configure a shared LDAP user registry for more information.
Note:

- You can also create organization-specific LDAP user registries by using the API Manager UI. For more information, see Creating an LDAP user registry in API Manager.
- In addition, you can create and manage LDAP user registries by using the API Connect REST APIs; see the API Connect REST API documentation.
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable more control of user authorization by using the developer toolkit CLI. The following instructions explain how to set the **`external_group_mapping_enabled`** configuration on your LDAP user registry resource. For information about how to set external role mapping on your API Connect user roles, see Configuring LDAP group mapping on Cloud Manager user roles.

You create an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For more information about authenticating with LDAP, see LDAP authentication.

Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your LDAP configuration

You define the configuration of your LDAP user registry in an *`ldap_config_file`*`.yaml` file, as shown in the following example. The actual contents of your YAML file varies depending on the authentication method of your LDAP server, and this is explained in the following tables.
Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
user_managed: true_or_false
user_registry_managed: false
directory_type: ad
external_group_mapping_enabled: true_or_false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
configuration:
  authentication_method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
  admin_password: admin_password
  search_dn_base: "search_dn_base"
  search_dn_scope: search_dn_scope
  search_dn_filter_prefix: prefix
  search_dn_filter_suffix: suffix
  attribute_mapping:
    dn: "distinguished_name"
    cn: "common_name"
    sn: "last_name"
    mail: "email_address"
    userPassword: "password"
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the registry. This name is used in CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`integration_url`	The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable LDAP. You can change this setting to `false` if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
`user_registry_managed`	Must be set to `false` for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.
`directory`	Specify one of the of following values for the directory type: • `ad` - Indicates that the LDAP is Microsoft Active Directory • `standard` - (Default value) Indicates any other LDAP

Property	Description
`external_group_mapping_enabled`	Determines whether your user registry supports LDAP group mapping. Valid values are: • `true` • `false` The default value is `false`.
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your LDAP server, where: • `name` - is the name of the LDAP server and is the name that is used in CLI commands • `title` - is the display name of the LDAP server
`endpoint`	The endpoint of your LDAP server, made up of the url and port, for example: `"ldap://server.com:389"`
`tls_profile`	Optionally set the TLS Client Profile that the LDAP server requires.
`protocol_version`	Optionally set the version number for the LDAP protocol that you are using. Valid values are: • `2` • `3` Defaults to `3` if not explicitly set.

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- `compose_dn` - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, `compose_dn` is not supported with the DataPower API Gateway.
- `compose_upn` - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
  Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- `search_dn` - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method `compose_dn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`

Properties	Description
`bind_prefix`	Set the prefix to the DN, for example: `(uid=`
`bind_suffix`	Set the suffix to the DN, for example: `)`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name-value pair, specified as follows:
	
	`ldap_registry_attribute_name: "apic_ldap_attribute_value"`
	
	Where:
	
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect populates the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

For authentication method `compose_upn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_upn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example, `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`bind_suffix`	Enter the domain part of the user principal name. For example: `@acme.com`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name-value pair, specified as follows:
	
	`ldap_registry_attribute_name: "apic_ldap_attribute_value"`
	
	Where:
	
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect populates the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

For authentication method `search_dn`, set the following configuration properties:

Property	Description
`authentication_method`	`search_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example, `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`

Property	Description
`search_dn_scope`	Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are: • `base` • `one` • `sub` (default value)
`search_dn_filter_prefix`	Set the prefix to the DN, for example: `(uid=`
`search_dn_filter_suffix`	Set the suffix to the DN, for example: `)`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name-value pair, specified as follows:
	`ldap_registry_attribute_name: "apic_ldap_attribute_value"`
	Where:
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect populates the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

Save your `ldap_config_file.yaml` to access it from the `user-registries:create` command in the following section. See the Example section for an example configuration file.

Creating your LDAP user registry

To create your organization-specific LDAP user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org organization_name ldap_config_file.yaml
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the `name` property of your provider organization.
- *ldap_config_file* is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

the *registry_name* is derived from the `name` property in the configuration YAML file. The *registry_url* is the URL with which the registry resource can be accessed. Your LDAP user registry is now created, see the following section for instructions on how to make the registry available in the Developer Portal.

Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Log in to the management server as a member of a provider organization; enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.

For more information about the **apic login** command, see Logging in to a management server.

3. Enter the following command (the hyphen character at the end means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: ldap_registry_url
   ```

   where *ldap_registry_url* is the URL of your LDAP registry, obtained in step 1.
5. Press **CTRL D** to stop the input.

Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the **user_managed** property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

   the command returns a list of all the user registries for that organization, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example **https://company.com/api/user-registries/x-x-x-x-x/*registry_id***.
2. Enter the following command (the hyphen character at the end means that the command takes input from the command line):

   ```
   apic user-registries:update --server mgmt_endpoint_url --org organization_name registry_name_or_id -
   ```

   where ***registry_name_or_id*** is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

   ```
   Reading USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_managed: true_or_false
   ```

   where **true** makes the registry writable, and **false** makes the registry read only.
4. Press **CTRL D** to stop the input.

If you are changing your registry from read only to writable, you must also set the **attribute_mapping** configuration, as described in the previous registry property tables.

Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

For more information about the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
directory_type: standard
case_sensitive: false
identity_providers:
  - name: ldap
    title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

Creating a Local User Registry

A Local User Registry (LUR) can be created to provide user authentication for API Manager.

About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can use API Manager to create additional Local User Registries for use with your provider organization.

One of the following roles is required to configure user registries:

- Administrator
- Organization Owner
- Custom role with the `Settings: Manage` permissions

Procedure

Follow these steps to configure a new LUR:

1. In the API Manager, click Resources.
2. Select User Registries to see the list of current user registries in your organization.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Local User Registry as the type for the user registry and enter the following information:

Field	Description
Title (required)	Enter a descriptive name for use on the screen.
Name (required)	The name that is used in CLI commands. The name is autogenerated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface login, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Case sensitive	Select this setting if user names are case-sensitive. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited. Note: Every account in the Developer Portal , including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.
6. Add the user registry to the Sandbox Catalog. See Creating and configuring Catalogs.

Results

New local user registry is now available in API Manager.

Creating an OIDC user registry in API Manager

Create an organization-specific OIDC user registry when multifactor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used

for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create an organization-specific registry. For more information about how to create a shared registry, see Configuring an OIDC user registry in Cloud Manager.

Important: If you are using X (formerly known as Twitter) as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your X application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.
API Connect provides two methods for creating an OIDC user registry in API Designer, as described in the following sections:

- Using the UI to create an OIDC user registry
- Using the CLI to create an OIDC user registry

Using the UI to create an OIDC user registry

Use the API Designer user interface to create an organization-specific OIDC user registry when multifactor authentication (MFA) is required.

1. In the API Designer navigation page, click Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create.
   Many of the registry settings are preconfigured to simplify the configuration steps.

   Provider Type
   : Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

Field	Description
Provider Type	OIDC provider. Select one of the following supported OIDC providers: • Facebook • GitHub • Google • LinkedIn • Slack • X (formerly known as Twitter) • Windows Live • Standard OIDC (default value allows you to specify another provider)
Title	Provide a descriptive name for display purposes.
Name	Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary	Provide a brief description of the new registry.
Email required	Select this option if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the Developer Portal.
Unique email address	Select this option if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

   Provider Endpoint
   : Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

   Token Endpoint
   : Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.
TLS	Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

   UserInfo Endpoint
   : Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint. For LinkedIn, the endpoint changed and now uses the following value: `https://api.linkedin.com/v2/me` If you previously configure the OIDC registry using the legacy LinkedIn OIDC protocol, you do not need to specify this endpoint.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

   Email Endpoint
   : Required for the legacy LinkedIn OIDC protocol.
   Due to changes in LinkedIn, the configuration settings for the OIDC registry in API Connect also changed. If you are configuring a new OIDC registry for LinkedIn, you can leave the Email Endpoint field blank.

   If you previously configured an OIDC registry for use with the legacy LinkedIn OIDC protocol, update your configuration by providing the Email endpoint settings as described in Table 4. The new setting is required for the legacy LinkedIn OIDC protocol.

Table 4. Email Endpoint settings

Field	Description
URL	For the legacy LinkedIn OIDC protocol, this field defaults to the following value: `https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))` You can override the setting by typing in a new value.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

JWKS Endpoint

Fill in the settings as described in Table 5.

Table 5. JWKS Endpoint settings

Field	Description
URL	Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Logout

You can configure either of the following types of logout support, but not both:

- Logout redirect:
  Allows you to specify what the user sees after logging out of API Connect; for example, you might want to "redirect" the user to the OIDC provider's logout endpoint, or to another address. When the user logs out of API Connect, the browser is redirected to the specified URL for further processing by the specified URL.
- RP-initiated logout:
  Provides a more secure form according to the OpenID Connect RP-Initiated Logout 1.0 Profile. When the user logs out of API Connect, API Connect issues a POST request to the specified endpoint URL to clear the user's session. With this option, you can optionally provide an RP logout redirect endpoint URL as well.

Fill in the settings as described in Table 6.

Table 6. Logout options

Field	Description
Logout redirect URL	Optional. Provide a URL to redirect the browser when the user logs out of API Connect. If you use this option, do not enable the OIDC RP logout.
Enable OIDC RP logout	Select this option to use the RP-initiated logout instead of the conventional logout redirect. If you use this option, do not provide a Logout redirect URL. With the RP-initiated logout, you can optionally specify an RP-logout redirect URL.
URL endpoint that the RP will issue a POST request	Provide the URL to the endpoint where the POST request will be executed; for example, the authorization endpoint of the OpenID provider.
TLS	Select the TLS profile to use when sending the POST request to the OpenID provider endpoint.
RP logout redirect endpoint URL	Optional. Provide a URL where the OIDC provider can redirect after the logout operation. The URL functions as the `post_logout_redirect_uri`, as described in the OpenID Connect RP-Initiated Logout 1.0 Profile.
Include refresh_token in logout	Optional. Allow the refresh_token to be included, in addition to the id_token_hint, per the OpenID Connect RP-Initiated Logout 1.0 Profile.

Client Information

Fill in the settings as described in Table 7.

Table 7. Client Information settings

Field	Description
Client ID	Provide the client ID of the application that is registered with the selected OIDC provider.
Client Secret	Provide the client secret of the application that is registered with the selected OIDC provider. This field is optional when you create an OIDC directory of type Standard and set the Client Authentication Method to Data encoded form body. If you are not using the Client Secret, ensure that mutual TLS is configured with the OIDC provider. To enable mutual TLS, create a TLS profile and include it in the OIDC user registry setup.
Response Type	Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.
Scopes	Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.
Client Authentication Method	Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: • HTTP Basic authentication schema • Data encoded form body

Additional Support

Optional. Select the additional security parameters described in Table 8.

Table 8. Additional security options

Security parameter	Setting name for CLI	Description
NONCE	`nonce`	Enable the NONCE extension to prevent compromised requests from being used again (replayed).
Proof Key for Code Exchange (PKCE)	`pkce`	Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted.

Advanced Features

Optional. Select the advanced features described in Table 9.

Table 9. Advanced features

Feature / UI Label	Setting name for CLI	Description
Auto onboard	`auto_onboard`	Allow users to executes calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. Note: Does not apply to consumer organizations.

Feature / UI Label	Setting name for CLI	Description
Always use the userinfo endpoint	`userinfo`	Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.
Use Portal as Endpoint for external OIDC provider traffic	`proxy_redirect`	When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager. When enabled, the redirect URI for the Developer Portal should be set to `/ibm_apim/oidcredirect`. For details, see the Redirect URI.
Return third-party access token	`proxy_access_token`	Include the third-party OIDC access token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party id_token	`proxy_id_token`	Include the third-party OIDC id_token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party access_token and id_token as separate claims	`proxied_token_as_separate_claim`	Include the third-party OIDC tokens (the `proxy_access_token` and `proxy_id_token`) in the response as separate claims instead of adding them to the access_token issued by API Connect. To use this feature, you must enable at least one of the Return third-party access token and Return third-party id_token options. Separating the third-party tokens prevents them from affecting the size of the access_token issued by API Connect.
Token Relay	`token_relay`	Allow `access_token/refresh_token` to send in 302 redirect for logout
Userinfo POST	`post_userinfo`	If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint. Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.
Use IBM APIC token expiration setting from cloud	`override_provider_ttl`	Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see Configuring timeouts for access tokens and refresh tokens.
Disable hash verification (CLI only)	`disable_hash_verification`	Disable `at_hash`, `c_hash`

User Mapping

Fill in the settings as described in Table 10.

Note: The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 10. User mapping settings

Field	Description
Username	The name of the field in the response token that contains the user's user name. Note: The Username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed.
Email	The name of the field in the response token that contains the user's email address.
First name	The name of the field in the response token that contains the user's given name.
Last name	The name of the field in the response token that contains the user's surname.

Redirect URI

The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.

Note: If the Developer Portal is publicly accessible and you select the `proxy_redirect` option, you must configure your OIDC provider to use the following redirect URI:

- URI path: `/ibm_apim/oidcredirect`
- Full URL example: `https://<your-developer-portal-domain>/ibm_apim/oidcredirect`

Where:

`<your-developer-portal-domain>` is the actual hostname of your public-facing Developer Portal; for example, `developer.example.com`.

This configuration ensures that the OIDC provider can correctly redirect authenticated users back to the Developer Portal as part of the login flow.

Enabling the OIDC user registry

Complete the following steps to enable the new user registry for a specific catalog in the Developer Portal. Repeat this procedure for each catalog that will use the new registry.

1. On the navigation pane, click Manage.
2. Select the catalog for which you will enable the new OIDC user registry.
3. On the navigation pane, click the Catalog settings tab.
4. On the Settings page, click Onboarding.
5. On the Onboarding page, click Edit in the Catalog User Registries section.
6. On the Edit User Registry page, select the new OIDC user registry to enable for your catalog.
7. Click Save.

Using the CLI to create an OIDC user registry

Use the developer toolkit CLI to create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
Configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated catalog.
Note:

- An OIDC registry cannot be used to secure APIs on the gateway.
- If you are using an OIDC user registry for login, The Management server handles the interaction with the third-party OIDC provider. The management server is considered the application from the perspective of the third-party OIDC provider. Therefore, your OIDC redirect endpoint on the management server, which the third-party authorization server uses to send the token, must be accessible to the OIDC provider. To ensure login functions, you must allow access if your API Connect environment is secured behind a firewall. This is true for user login on both API Manager and Cloud Manager.
- If OIDC user registry is used for consumer login at the Developer Portal and Developer Portal is in the DMZ, you can use the `proxy_redirect` property. This allows the Developer Portal to act as the endpoint for proxying communication between the OIDC provider and API Connect.
- When you register your application with the third-party OIDC provider, you are required to supply the associated OIDC redirect URI, https://consumer.mycompany.com/consumer-api/oauth2/redirect for example. However, you cannot access this information until you create your OIDC user registry in API Connect. First, register your application without this information and then update it later, as detailed in the instructions on this page.

Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

Defining your OIDC registry configuration

Define the configuration of your OIDC user registry in a YAML file. At a minimum, the YAML file must include the settings from the following list. For additional settings, see the tables provided with the UI version of the procedure in this topic.

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type
```

where:

- *registry_title* is your chosen descriptive title for the user registry.
- *oidc_integration_url* is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

  ```
  apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
  ```

- *case_sensitivity_setting* determines whether your user registry is case-sensitive. Valid values are:
  - `true`
  - `false`

  To ensure proper handling of user name capitalization, ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:
  - Only set `case_sensitive` to `true` if the backend OIDC provider supports case-sensitivity.
  - Set `case_sensitive` to `false` if the backend OIDC provider does not support case-sensitivity.

  Note: After at least one user has been added to the registry, you cannot change this setting.
- *email_required* determines whether an email address is required as part of the user onboarding process. Valid values are:
  - `true`
  - `false`

  If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding.
  Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
- *email_unique_if_exist* determines whether email addresses must be unique within the user registry. Valid values are:
  - `true`

- `false`

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

- *app_client_id* is the client ID of the application that is registered with the OIDC server, and must be in string format.
- *my-client-secret* is the client secret of the application that is registered with the OIDC server, and must be in string format.
- *oidc_provider_type* is the type of OIDC provider; specify one of the following values:
  - `facebook`
  - `github`
  - `google`
  - `linkedin`
  - `slack`
  - `twitter`
  - `windows_live`
  - `standard`

    Note:
    - Use the `twitter` provider type if your OIDC provider is X (formerly known as Twitter).
    - Use the `standard` provider type for any OIDC provider that is compliant with the OIDC standard.

      If the provider type is `standard`, you must include the following additional properties in the `configuration` section of your YAML file:

      ```
      authorization_endpoint: 'oidc_auth_endpoint'
      token_endpoint:
        endpoint: 'oidc_token_endpoint'
      ```

      where:
      - *oidc_auth_endpoint* is the authorization endpoint on the OIDC server, and must be in string format.
      - *oidc_token_endpoint* is the token endpoint on the OIDC server, and must be in string format.

Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file.

Note: Endpoints are subject to change; when you create a registry you must verify the default endpoint provided by API Connect.
API Connect makes the best effort to update endpoints for the known OIDC user registry types. However the OIDC provider can change the endpoint at any time. It is the customer's responsibility to confirm that the endpoints provided by API Connect are supported by the OIDC provider and to update the OIDC configuration as needed.

The default configurations are as follows:

- Facebook

```
authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
token_endpoint:
  endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://graph.facebook.com/me'
scope: email public_profile
field_mapping:
  username: email
  email: email
  last_name: last_name
  first_name: first_name
```

- GitHub

```
authorization_endpoint: 'https://github.com/login/oauth/authorize'
token_endpoint:
  endpoint: 'https://github.com/login/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://api.github.com/user'
scope: 'read:user user:email'
field_mapping:
  username: login
  email: email
  last_name: name
  first_name: name
```

- Google

```
authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'
token_endpoint:
  endpoint: 'https://www.googleapis.com/oauth2/v4/token'
scope: openid profile email
field_mapping:
  username: email
  email: email
  last_name: family_name
  first_name: given_name
```

- LinkedIn

  Some settings differ between the legacy configuration and the newer configuration. Be sure to use the correct settings for the LinkedIn protocol that you are using.

  - New OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
  credential_location: form_body
  field_mapping:
    email: email
    username: name
    first_name: given_name
    last_name: family_name
  scope: openid profile email
  token_endpoint:
```

```
    endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
  userinfo_endpoint:
    endpoint: 'https://api.linkedin.com/v2/me'
```

- Legacy OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
token_endpoint:
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
userinfo_endpoint:
  endpoint: 'https://api.linkedin.com/v2/me'
email_endpoint:
  endpoint: 'https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))'
scope: r_liteprofile r_emailaddress
field_mapping:
  username: emailAddress
  email: emailAddress
  last_name: localoizedLastName
  first_name: localizedFirstName
credential_location: form_body
```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'
token_endpoint:
  endpoint: 'https://slack.com/api/oauth.access'
userinfo_endpoint:
  endpoint: 'https://slack.com/api/users.identity'
scope: identity.basic identity.email
field_mapping:
  username: user.email
  email: user.email
  last_name: user.name
  first_name: user.name
```

- X (formerly known as Twitter)

```
request_endpoint: https://api.x.com/oauth/request_token'
authorization_endpoint: https://api.x.com/oauth/authenticate'
token_endpoint:
    endpoint: 'https://api.x.com/oauth/access_token'
userinfo_endpoint:
    endpoint: 'https://api.x.com/1.1/account/verify_credentials.json'
oauth_signature_method: 'HMAC-SHA1'
field_mapping:
    email: email
    first_name: name
    last_name: name
    username: screen_name
```

- Windows Live

```
authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
  endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
scope: openid offline_access profile email
field_mapping:
  email: email
  username: preferred_username
  first_name: name
  last_name: name
```

- Standard

```
response_type: code
scope: openid
field_mapping:
  username: sub
  email: email
  last_name: family_name
  first_name: given_name
credential_location: auth_header
```

  Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

apic user-registries:create --server ***mgmt_endpoint_url*** **--org** ***organization_name oidc_config_file***

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the **name** property of your provider organization.
- *oidc_config_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

registry_name registry_url

By default, the *registry_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry_url* is an internal URL that API Connect assigns to the registry.
After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc_redirect_uri** value is in the **consumer:** section; for example:

```
consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect
```

Enabling your OIDC registry in a Catalog

To make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required catalog. The command displays

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_registry_url: oidc_registry_url
   ```

   where *oidc_registry_url* is the URL of your OIDC registry, obtained in step 1.
4. Press **CTRL D** to stop the input.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Modifying the configuration details for a user registry

You modify the configuration details for a user registry by using the User Registries page in the API Manager user interface of IBM® API Connect.

About this task

If you want to authenticate an API Connect Catalog with a user registry that is not yet defined in API Connect, you define the registry when you configure the Catalog; for details, see Working with user registries.
Note: User registries shared from the Cloud Manager cannot be edited.
To modify the configuration details for a user registry that is already defined, you use the User Registries page.

Procedure

To modify the configuration details for a user registry, complete the following steps:

1. In the API Manager, click Resources, and then select User Registries.
2. On the User Registries page, click the options icon for the user registry that you want to edit, then click Edit.
   The details of the registry are displayed.
3. Modify the configuration details as required, then click Save to save your changes.

Password lockout criteria

You can be locked out of your account if you attempt to log in and fail consecutively.

Note: Account lock-out applies only for local user registries.
The length of time that you are locked out of using the account is based on the number of consecutive attempts that you fail. The length of time increases as the number of consecutive failed attempts increases.

For example, you can be locked out for 15 seconds if you have five consecutive failed attempts, or 32 minutes for 12 consecutive failed attempts.
Note: External user registries, such as LDAP, might enforce their own lockout criteria.

Configuring a native OAuth provider

Your cloud configures and manages native OAuth providers.

About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth security definition references an OAuth provider object to protect an API. API Connect natively performs he OAuth operations when a native OAuth provider is used.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example,

- If you change the name of autogenerated assembly actions in the source code, the assembly is prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the **`oauth-provider-settings-ref`** field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client_id checks:
If you are calling an OAuth endpoint, the sequence of **`client_id`** checks in the token request is as follows:

1. Check both body and query.
   - If found in only the body, validate and return a **`200`** or appropriate return code.
   - If found in only the query, return a **`wrong location`** error.
   - If found in both the body and the query, return a **`more than one location`** error.
2. When not found in the body or the query, check the **`Authorization`** header.
   - If found in this header, validate and return a **`200`** or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the **`client_id`** is in the request body.
One of the following roles is required to configure a native OAuth provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

Note:

- The OAuth provider logs analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

Procedure

1. In the API Manager, click Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
   a. Complete the following parameters for the first screen, then click Next.

Field	Description
Title	Enter a title for the native OAuth provider.
Name	The system autopopulates this field.
Description (optional)	Enter a brief description.
Base path (optional)	The API shares a base path, which is the URL segment common to all operations. It does not include the hostname or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For more information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. In the next screen, enter the following additional configuration parameters, then click Next.

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to log in to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." does not require user security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The client exchanges the user's username and password directly for an access token, and only first-party clients can use this flow.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

d. Enter the parameters for user security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User security is not required for the Application grant type. Click Next when done.

Field	Description

Identity extraction	Determines how the user credential is extracted:
	• Basic Authentication - HTTP basic authentication (requires no additional configuration)
	• Default HTML Form - Use default login form for username and password
	•  Context variable - Specify which variable contains the username and password. API Connect OAuth context variables as listed here API Connect context variables
	Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible).
	• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security.
	• Redirect - If you select Redirect , enter the following parameters:
	  • End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL
	  • Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark symbol (?), usually consisting of key-value pairs separated by ampersand symbol (&).
	  Note: To ensure the query parameter that you entered is applied to the gateway, republish your OAuth provider.
	  • Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements.
	•  Disabled - do not collect the user credential
	Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.

Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL user registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.
Authorization	The following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use the default HTML form to authorize. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML authorization form for user security. •  Disabled - Disable authorization.

3. Review the Summary for the native OAuth provider configuration.
4. Click Back to make changes.
5. Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.
   If you want to specify the native OAuth Provider in your Catalog, see Specifying the OAuth Providers.

Results

You can use the OAuth Provider to secure the APIs in the catalog.

- **Configuring basic settings for a native OAuth provider**
  You can update the identification details and basic configuration settings for a native OAuth provider.
- **Configuring scopes for a native OAuth provider**
  Access tokens contain authorization for specific scopes.
- **Configuring user security for a native OAuth provider**
  Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- **Configuring tokens for a native OAuth provider**
  Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- **Configuring token management and revocation for a native OAuth provider**
  Select whether to use a native gateway (DataPower) or third-party endpoint for token revocation.
- **Configuring introspection for a native OAuth provider**
  Define an introspection path to allow the metadata for an access token to be examined.
- **Configuring metadata for a native OAuth provider**
  Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Configuring the OIDC parameters for a native OAuth provider**
  Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.
- **Editing a native OAuth provider by using the API Editor**
  You can edit the source and assembly policies for the Native OAuth Provider that uses the API editor.

Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. To modify the identification details, click information in the sidebar menu, then update the following fields as required:

Field	Description
Title	Enter a title for the native OAuth provider.
Name	The system autopopulates this field.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the hostname or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to log in to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client credentials." does not require user security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The client exchanges the user's username and password directly for an access token, and only first-party clients can use this flow.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
	
	Tip: If you plan to configure OpenID Connect (OIDC) for a Native OAuth provider, include at least one of the following grant types: Implicit, Access code.

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:

   a. Click User Security in the sidebar menu, then click Edit.
   b. Update the user security settings as required; for more details, see Configuring user security for a native OAuth provider.
   c. Click Save when done.

3. Click Save when done.

Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

About this task

The client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see The OAuth 2.0 Authorization Framework.

One of the following roles is required to configure scopes for a native OAuth Provider:

- Organization Administrator
- Owner

- Custom role with the Settings > Manage permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

   In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.
   If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

2. Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are started after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and overwrite any previous scopes.

Field	Description
Application scope check	Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS profile to use for an application scope check.
Owner scope check	Further refine the scope with an additional check. Enter the endpoint and an optional TLS profile to use for an owner scope check.

   For more information about scope, see Scope
3. Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

Field	Description
Enabled	Select the checkbox to enable the advanced scope check after token validation. Enter an optional default validator endpoint.
Use endpoint from API	Select the checkbox to use the endpoint from the API, or clear the checkbox to override the endpoint from the API.

   For more information about scope, see Scope
4. Click Save when done.

Results

You can use the OAuth Provider with these scopes to secure the APIs in catalog.

Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click User Security in the sidebar menu.
2. Specify the following parameters for user security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

Field	Description

Field	Description

Identity extraction	Determines how the user credential is extracted:
	• Basic Authentication - HTTP basic authentication (requires no additional configuration)
	• Default HTML Form - Use default login form for username and password
	• API Gateway only Context variable - Specify which variable contains the username and password. API Connect OAuth context variables as listed here API Connect context variables
	• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security.
	• Redirect - If you select Redirect , enter the following parameters:
	  • End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL
	  • Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark (?) symbol, usually consisting of key-value pairs separated by ampersand symbol (&).
	  Note: To ensure the query parameter that you entered is applied to the gateway, republish your OAuth provider.
	  • Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements.
	• API Gateway only Disabled - do not collect the user credential
	Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.

Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL user Registry.
Authorization	Various methods can be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use the default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. • API Gateway only Disabled - Disable authorization.

3. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in catalog.

Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any amount of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Tokens in the sidebar menu.
2. Define the settings to configure tokens.

Field	Description
Access tokens time to live	Enter the expiration time period in seconds for access tokens.

Field	Description
API Gateway only One-time use access token	Click the checkbox to enable one-time use for the access token. Access tokens are multiple use by default, which allows them to be used for multiple requests. When one-time use is enabled, the access token will be consumed after one use. The OAuth flow needs to be repeated to obtain another access token. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Refresh tokens	Click the checkbox to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.
One-time use refresh token	Clear the checkbox to disable one-time use for the refresh tokens. Refresh tokens are one time use by default, which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one-time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Maximum consent	Click the checkbox to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.
API Gateway only Token secret	Click the checkbox to select the Shared Secret, which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter a key name and key value to use as the token secret.
API Gateway only Proof Key for code Exchange	Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. You can enable this extension when deploying with the DataPower® API Gateway. For more information, see RFC 7636. Select the options for your OAuth Providers: • Enable proof key for code exchange If selected, enforces PKCE when submitted in Authorization Code grant requests. • Always required If selected, requires PKCE in all Authorization Code grant requests. • Allow plain Select this checkbox to allow the plain challenge method in Authorization Code grant requests.

3. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third-party endpoint for token revocation.

About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation that uses a native gateway (DataPower) or a third-party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third-party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 OAuth 2.0 Token Revocation.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. To enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

One of the following roles is required to configure token management and revocation for a native OAuth provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the checkbox.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.

Note: If you are using the API Manager user interface, then for the External option to be available, you must be using DataPower® API Gateway version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see Creating and configuring Catalogs

4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
   - Resource owner revocation path-Uses the standard OAuth revocation path to allow the resource owner (user) to revoke the application permission.
   - Client revocation path-Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.

   For more information about managing tokens with the Native DataPower Gateway, see Token management with the native DataPower Gateway.
5. For External, the settings depend on the gateway type, as follows:
   DataPower API Gateway:
   - Endpoint-the URL of the external management endpoint.
   - TLS client profile (optional)-the TLS client profile to secure connections.
   - Security-how to secure connections. The only supported method is basic authentication.
   - Basic authentication username (optional)-the username for authentication.
   - Basic authentication password (optional)-the password for authentication.
   - Basic authentication request header name (optional)-the request header that contains the authentication string, if you supply both a request header name and username or password, the request header authentication method is used.
   - Custom header pattern (optional)-the name pattern of the headers to use for sending additional information to the external management service.
   - Cache type-the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
   - Fail on error-if selected, processing is stopped if the connection to the external management service fails.

   Note: For more information about the JSON format that is required when exchanging messages with the external management service, see JSON format to exchange messages with the external management service.
   DataPower Gateway (v5 compatible):
   - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine whether the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see Token revocation.
   - TLS client profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

Results

You can use the OAuth provider to secure the APIs in a catalog.

Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

About this task

Token introspection allows an authorized holder of an access token to examine the contents of tokens that use an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See OAuth 2.0 Token Introspection.

One of the following roles is required to enable introspection for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Introspection in the sidebar menu.
2. Select the checkbox to enable Introspection. The OAuth standard path for introspection /oauth2/introspect is automatically entered. This path is used when another entity inspects the token contents.
3. Click Save when done.

Results

Tokens are queried that uses the /oauth2/introspect path. You can use the OAuth Provider to secure the APIs in a catalog.

Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

About this task

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see OAuth external URL and authentication URL.

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see Authentication URL user registry.
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5. API Gateway only If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as **`metadata`**.
6. API Gateway only If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as **`miscinfo`**.
7. Save the OAuth Provider.
8. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the System > Manage permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types, see Configuring basic settings for a native OAuth provider.
You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click OpenID Connect.
2. Select Enable OIDC and then enter the following parameters as appropriate:

Field	Description
Support hybrid response types	Optional: The administrator selects the response types that this OAuth provider supports for the OpenID Connect hybrid flow.
Auto Generate OIDC API Assembly	Optional. Select this option to generate the full OIDC assembly. Leave this option unselected to simply enable OIDC support in the OAuth provider, and allow developers to implement their own assemblies.
ID token issuer	Descriptive text to indicate the source of the key.
ID token signing crypto object	The cryptographic object to use to sign the token.
ID token signing key	The JSON Web Key (JWK) to be used to sign the ID token.
ID token signing key identifier	The key ID used for signing the token.
ID token signing algorithm	The algorithm used to sign the token.
OpenIDConnect Discovery path	A URL that is exposed by the provider and allows a client to send a request for information about the provider's publicly visible configuration.

3. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog. You can edit the policies using the API Editor.

Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider that uses the API editor.

About this task

If you have configured an OIDC template, you can customize it in the API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example,

- If you change the name of autogenerated assembly actions in the source code, the assembly is prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

Select the API Editor page to modify the native OAuth provider configuration on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click API Editor.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag editor to add additional policies to the OIDC behavior.
   Note: If you add a policy that references a TLS profile, an **`invoke`** policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For more details about how to enable a TLS profile in a Catalog, see Creating and configuring Catalogs.
4. Save the edits.
5. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

About this task

One of the following roles is required to configure OAuth Providers:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

Procedure

1. In the API Manager, click Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
   a. Complete the following parameters for the first screen and click Next.

Field	Description
Title	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name	This field is auto-populated by the system and used as the internal field name.
Supported grant types	Select from the following options: • Implicit: An access token is returned immediately without an extra authorization code exchange step. • Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require user security. • Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code. • Resource owner - Password: The client exchanges the user's username and password directly for an access token, and only first-party clients can use this flow. • API Gateway only Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants. Note: To use the Resource owner - JWT option, complete the following steps: • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT. • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type. For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. Specify configuration settings for the endpoints, and then click Next.

Field	Description
Authorization URL	An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example: `https://example.com/oauth2/authorize`
Token URL	A token request URL where the client application exchanges an authorization grant for an access token. Example: `https://example.com/oauth2/token`
Introspect URL	The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example: `https://example.com/oauth2/introspect` For more information on integrating third party OAuth providers for introspection, see OAuth introspection for third-party OAuth providers.
API Gateway only Introspect cache type	The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: • No cache (default): Responses are not cached. • Protocol: Defined by the `cache-control` header in the provider response. • Time to live: Defined by the provider.
API Gateway only Cache Time to Live	The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.
TLS Profile (optional)	Select an optional TLS profile for communicating with the third party provider.
Security	Default is Basic Authentication.
Basic authentication request header name	The `x-introspect-basic-authorization-header` is available to provide a user-configured HTTP Basic authorization header.
API Gateway only Basic authentication username (optional)	The default username for HTTP Basic authentication.
API Gateway only Basic authentication password (optional)	The default password for HTTP Basic authentication.
API Gateway only Token validation	Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: • Connected: The query is successful if the status return code is `200`. • Active (default): The query is successful if the status return code is `200` and the response JSON body includes the property `active: true`.
API Gateway only Custom header pattern (optional)	A regular expression for request headers that are to be passed to the third-party provider; for example, `x-Introspect-*`.
API Gateway only Authorization header pass through	Select this checkbox if you want to retain the `Authorization` header for a bearer token. The default behavior is to remove this header.

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
sample_scope_2	Scope for token
additional scopes	Scope for token

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.

OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multinode cluster, OAuth operation fails if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **OAuth user scenario**
  Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- **OAuth introspection for third-party OAuth providers**
  OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.
- **OAuth external URL and authentication URL**
  You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Scope**
  Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- **Tokens**
  Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- **Authentication URL user registry**
  You can use an authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides extra metadata to be embedded in the token.
- **Custom forms for user security**
  You can create custom forms for the authorization and identity extraction phase of OAuth.
- **Securing an API with a JSON Web Token**
  There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM API Connect.
- **Troubleshooting OAuth**
  You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

- The OAuth 2.0 Framework

OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

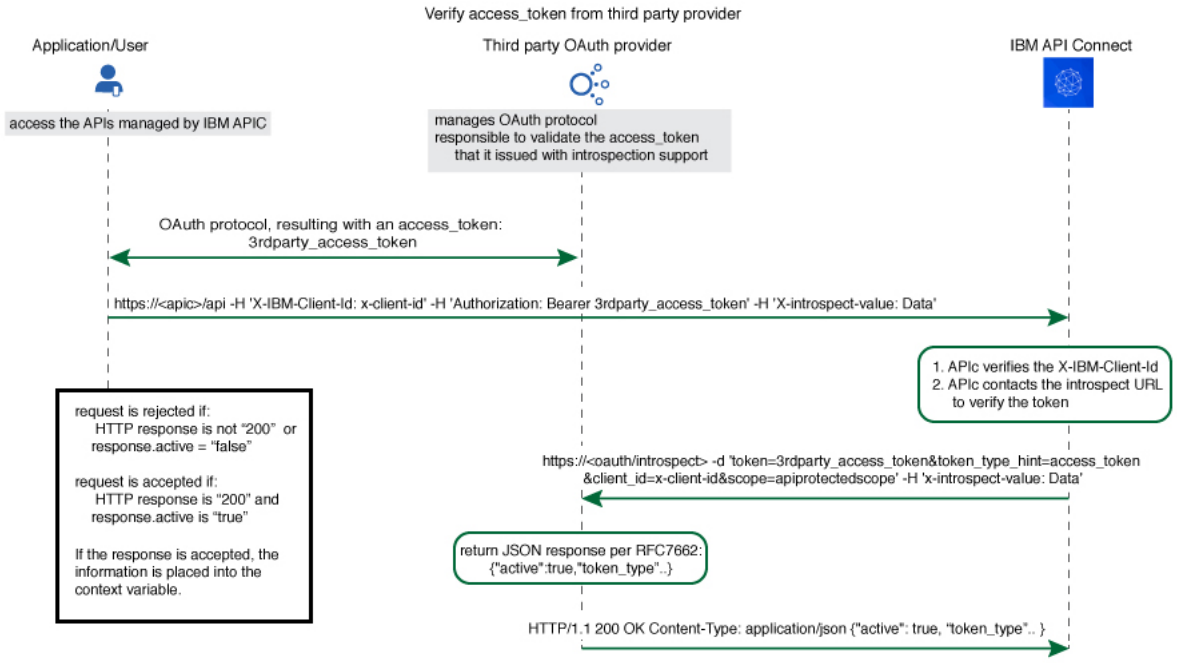
The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This

OAuth request is used to invoke the API proxy operation.

Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.



OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in RFC 7662. In addition to the specification, the **`x-Introspect-`** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.

The Introspect URL is configured in the Third Party OAuth provider configuration. See Configuring a third-party OAuth provider.

When an API is protected by a third-party OAuth provider, API Connect extracts the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as **`x-introspect-*`**.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider. The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be **`x-Introspect-`**.

API Connect issues this POST request to the introspection endpoint specified in **`x-tokenIntrospect`**, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
```

```
    x-Introspect-name: simon
    x-custom-apic: petstore123
    token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider responds with `HTTP 200` indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
  HTTP/1.1 200 OK
   Content-Type: application/json;charset=UTF-8
   Cache-Control: no-store
   Pragma: no-cache

   { "active":true,
      "token_type":"bearer",
      "client_id":"xxx-xxx",
      "username":"John Smith",
      ...
   }
```

If the value of the active claim is `false`, the token is treated as invalid.

```
    HTTP/1.1 200 OK
    Content-Type: application/json;charset=UTF-8
    Cache-Control: no-store
    Pragma: no-cache

    {
      "active":false
    }
```

A response code other than **`HTTP 200`** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see API Connect context variables.

When contacting the introspection endpoint, API Connect uses **`client_id`**/**`appId`** and **`client_secret`**/**`appSecret`** to construct the HTTP Basic authorization header.

By default, if **`x-introspect-basic-authorization-header`** exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcnR5LWNsaWVudF9pZDozcmQtcGFydHlfY2xpZW50X3NlY3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format ***`user:password`***, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and username and password details are not supplied in the third party OAuth provider configuration, but **`client_id`** and **`client_secret`** values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider.
If either, or both, of scope and **`scope validate url`** are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect further enforces the scope validation in the following order:

1. If **`scope`** is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If **`scope validation url`** is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see Creating an OAuth security definition.

For more information, see Scope.

DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a **`suppress-parameters`** header as follows:

  `suppress-parameters: client_id`

  `suppress-parameters: scope`

  or

  `suppress-parameters: client_id scope`

  depending on which parameters you want to suppress.
- Define an API property called **`suppress-parameters`** in the API definition itself, with one of the following string values:

`client_id`

`scope`

or

`client_id scope`

depending on which parameters you want to suppress. For information on how to define API properties, see Setting API properties.

OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL- when you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL-When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.
  See: Authentication URL.

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

  `X-API-OAUTH-METADATA-FOR-PAYLOAD`

  `X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`

  Note: The headers before this are the default header names for the DataPower API Gateway but you can override them, see Configuring metadata for a native OAuth provider.
- DataPower Gateway (v5 compatible):

  `API-OAUTH-METADATA-FOR-PAYLOAD`

  `API-OAUTH-METADATA-FOR-ACCESSTOKEN`

The response header value from `X-API-OAUTH-METADATA-FOR-PAYLOAD` or `API-OAUTH-METADATA-FOR-PAYLOAD` is placed in the response payload and indicated as `metadata`.

The response header value from `X-API-OAUTH-METADATA-FOR-ACCESSTOKEN` or `API-OAUTH-METADATA-FOR-ACCESSTOKEN` is placed within the access token and indicated as `miscinfo`.

The two metadata response headers are case-insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
"token_type":  "bearer",
"access_token":  "AAEkNzhjDHYyyYy...cL0Mv6ctl37w7ZU",
"metadata":  "m:metadata-for-payload_content"
"expires_in":  3600,
"scope":  "read",
"refresh_token":  "AAEnj5SynCMybF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with `"miscinfo"` containing the metadata information.

```
{
"active":  true,
"token_type":  "bearer",
"client_id":  "78c2f10f-799a-4e1f-8e0a-098634997a35",
"username":  "Fred Smith",
"sub":  "fred",
"exp":  1479850049,
"expstr":  "2016-11-22T21:27:29Z",
```

```
"iat":  1479846449,
"nbf":  1479846449,
"nbfstr":  2016-11-22T20:27:29Z",
"scope":  "read",
"miscinfo":  "m:metadata-for-accesstoken_content",
"client_name":  "MobileApp"
}
```

Input to the External URL

The following request headers are sent to the External URL.
Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **x-existing-metadata-for-payload** and **x-existing-metadata-for-access-token**. The Metadata URL can use this information to create a new set of metadata values.
The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload     payload-from-auth-url
X-existing-metadata-for-access-token     token-from-auth-url
X-URI-in     /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in     POST
X-POST-Body-in     client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP     IP_address
X-X-Global-Transaction-ID     ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **X-POST-Body-in** header is not supported.

Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **miscinfo** field can be accessed in the Assembly with the **oauth.miscinfo** context variable, as in the example.

```
apim.setvariable('message.body',apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

Refresh tokens and metadata

The Authentication URL (if configured for authentication) is started first, during authentication of the resource owner. The External URL is started as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not started. The metadata from the refresh token is retained and then copied into the newly generated access token.

Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with **m:**
- Metadata from the Authentication URL is prefixed with **a:**

Note: When revocation is enabled, some internal details are also stored in the **miscinfo** field, in brackets within the access token as shown in the following example:

```
"miscinfo": "[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in the following sections.

Certain characters are not allowed in metadata

Metadata from the authentication URL is stored temporarily when using Authorization code or implicit grant with consent.

API Connect internally uses two prefixes - **!ma** and **!mp** to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - **!ma** and **!mp** should not be used as the metadata itself.

Grant types and metadata

The OAuth grant types described in the following sections include **authorization code (access code)**, **implicit**, and **client credentials (application)**.

Authorization code grant type

- In a three-legged Authorization code flow, metadata from the Authentication URL is stored in **dp-state** and carried over to the authorization code and access token. Around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the **dp-state**. In addition, if revocation is enabled, it is also part of the token metadata. The combined size of the token metadata, the payload metadata (including internal data), and internal revocation details cannot exceed 512 bytes in total.

If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "`metadata too large`" as shown in the example.

```
"metadata":"m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
"miscinfo":"[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
```

The size restriction does not apply when metadata is sent from the Metadata URL and not from the Authentication URL because the metadata is not stored in **`dp-state`** or in the authorization code.

Example of the **`authorization code (access code)`** grant type:

```
 $ curl -k -d
"grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
https://9.70.153.90/fei/sb/introspectp1/oauth2/token
{ "token_type":"bearer",
"access_token":"AAEkOThlZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ20ZN5Tl_TqYFeIfB7BFf6HFgibEoOjWXXEA84oFsWuE4NY-
RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_1YKm3ahrfhR5kI3sPO0uADEoseIP5-O9anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
PHBialoRkBD5qca6kO0fV2M", "metadata":"a:[Authorization Code-Test-auth-url-payload]", "expires_in":3600,
"scope":"scope_introspect", "refresh_token":"AAFAg1EVMbwicr_L0fTZ4q6HZ-
RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNGl5C1GbIe3dwhXJdiWA0Go-
dduhVtCbG26sJRRXyYrMeRxWnJsylBETPI8HQEN4a_D7fmxKcTVRZBvq86byg95qe1ZKyERi0Lhxdd_O4Nvss" }

$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
{ "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746", "username":"anyuser",
"sub":"anyuser", "exp":1484766368, "expstr":"2017-01-18T19:06:08Z", "iat":1484762768, "nbf":1484762768,

auth-url-payload]

$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
                { "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746",
"username":"anyuser", "sub":"anyuser", "exp":1484768365, "expstr":"2017-01-18T19:39:25Z", "iat":1484764765,
"nbf":1484764765, "nbfstr":"2017-01-18T18:39:25Z", "scope":"scope_introspect", "miscinfo":"[r:gateway]a:[Implicit-
Test-auth-url-token]", "client_name":"oauth_app" }
```

Client credentials grant type

Authentication URL cannot start when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL is included as metadata.

Behavior when retrieving metadata with both an external URL and an authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "`error on metadata url`" is written for metadata in both the payload and the access token.

If the remote server does not send specified HTTP response headers, blank values are written for metadata.
Attention: An External URL overwrites existing values from Authentication URL including blank values.
If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

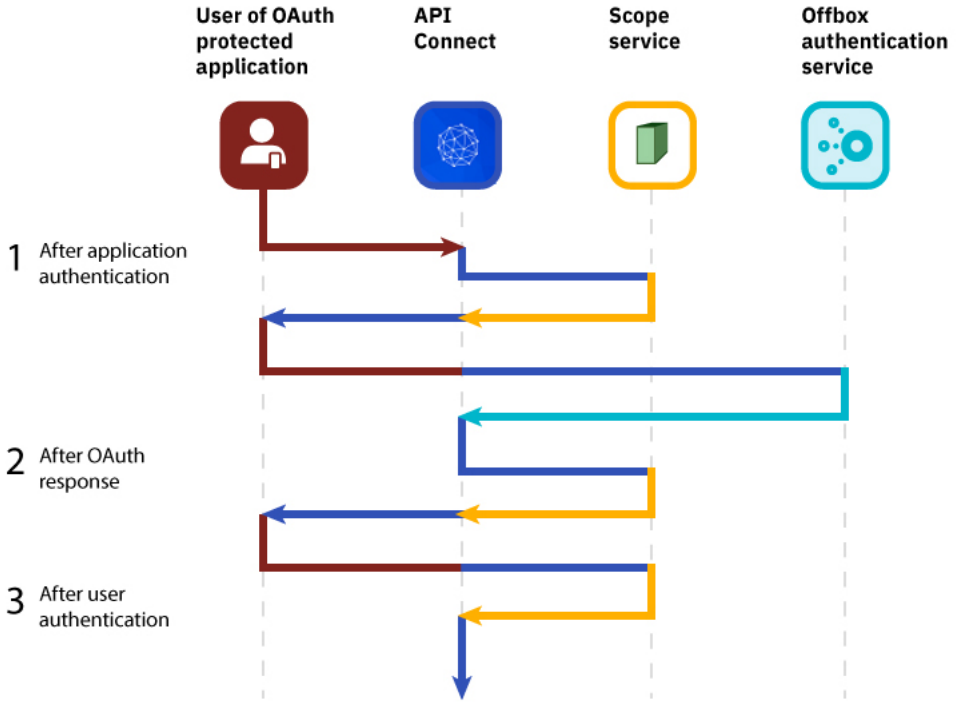
Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.
Note:

- An OAuth Provider must have at least one scope.
- An OAuth token will not be granted unless a default scope is configured at the provider, or one or more predefined scopes are included in the grant request.
- If no default scope is defined, and the request does not contain a scope, an invalid scope error is returned for the request.

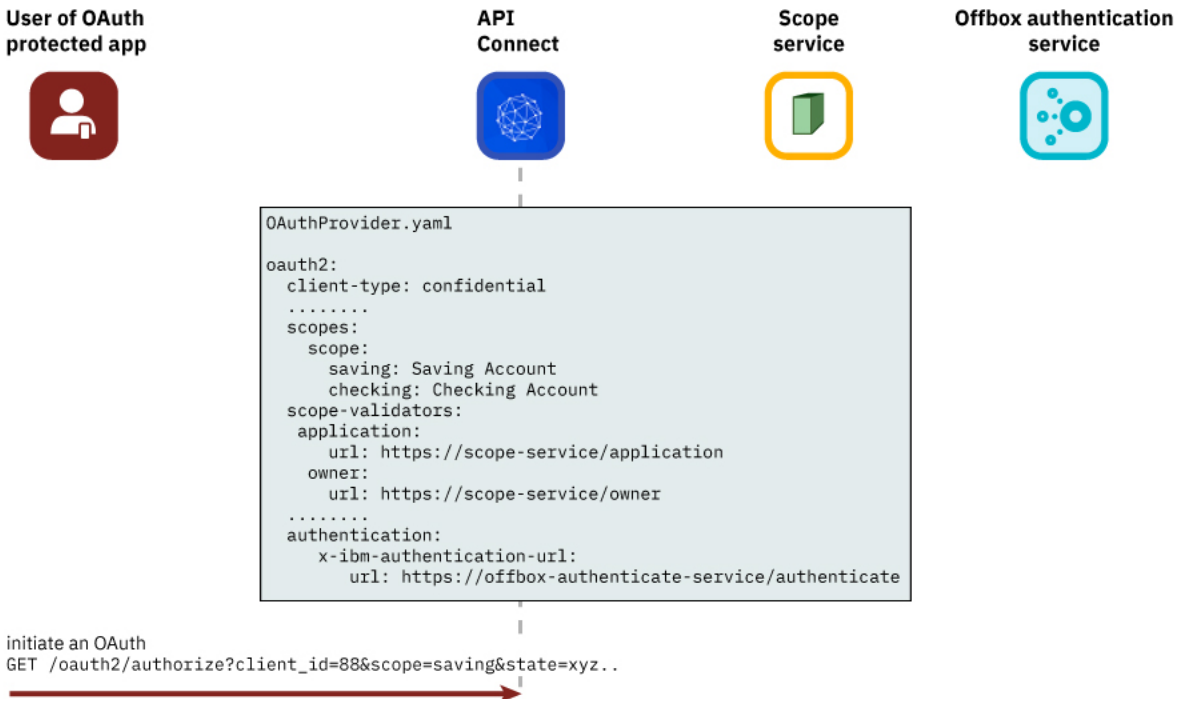
OAuth provider



To provide more refined support for the OAuth scope handling, API Connect allows the Authentication URL user registry extension to modify the scope value.

When you define an OAuth provider, the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.



1. After the application successfully authenticates, and if OAuth Native provider > Advanced scope check > Application scope check is configured, API Connect makes a call to allow extra verification and uses the contents of **`x-selected-scope`** to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.
2. If OAuth Native provider > User Security > Authentication is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in Authentication URL user registry. When the response code is `HTTP 200`, and the response header **`x-selected-scope`** is present, the value that is configured in **`x-selected-scope`** is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, **`x-selected-scope`** is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider > Advanced scope check > Owner scope check is enabled and configured with a valid URL, API Connect makes a call to allow the content of **`x-selected-scope`** to refine the scope value. When Owner scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.

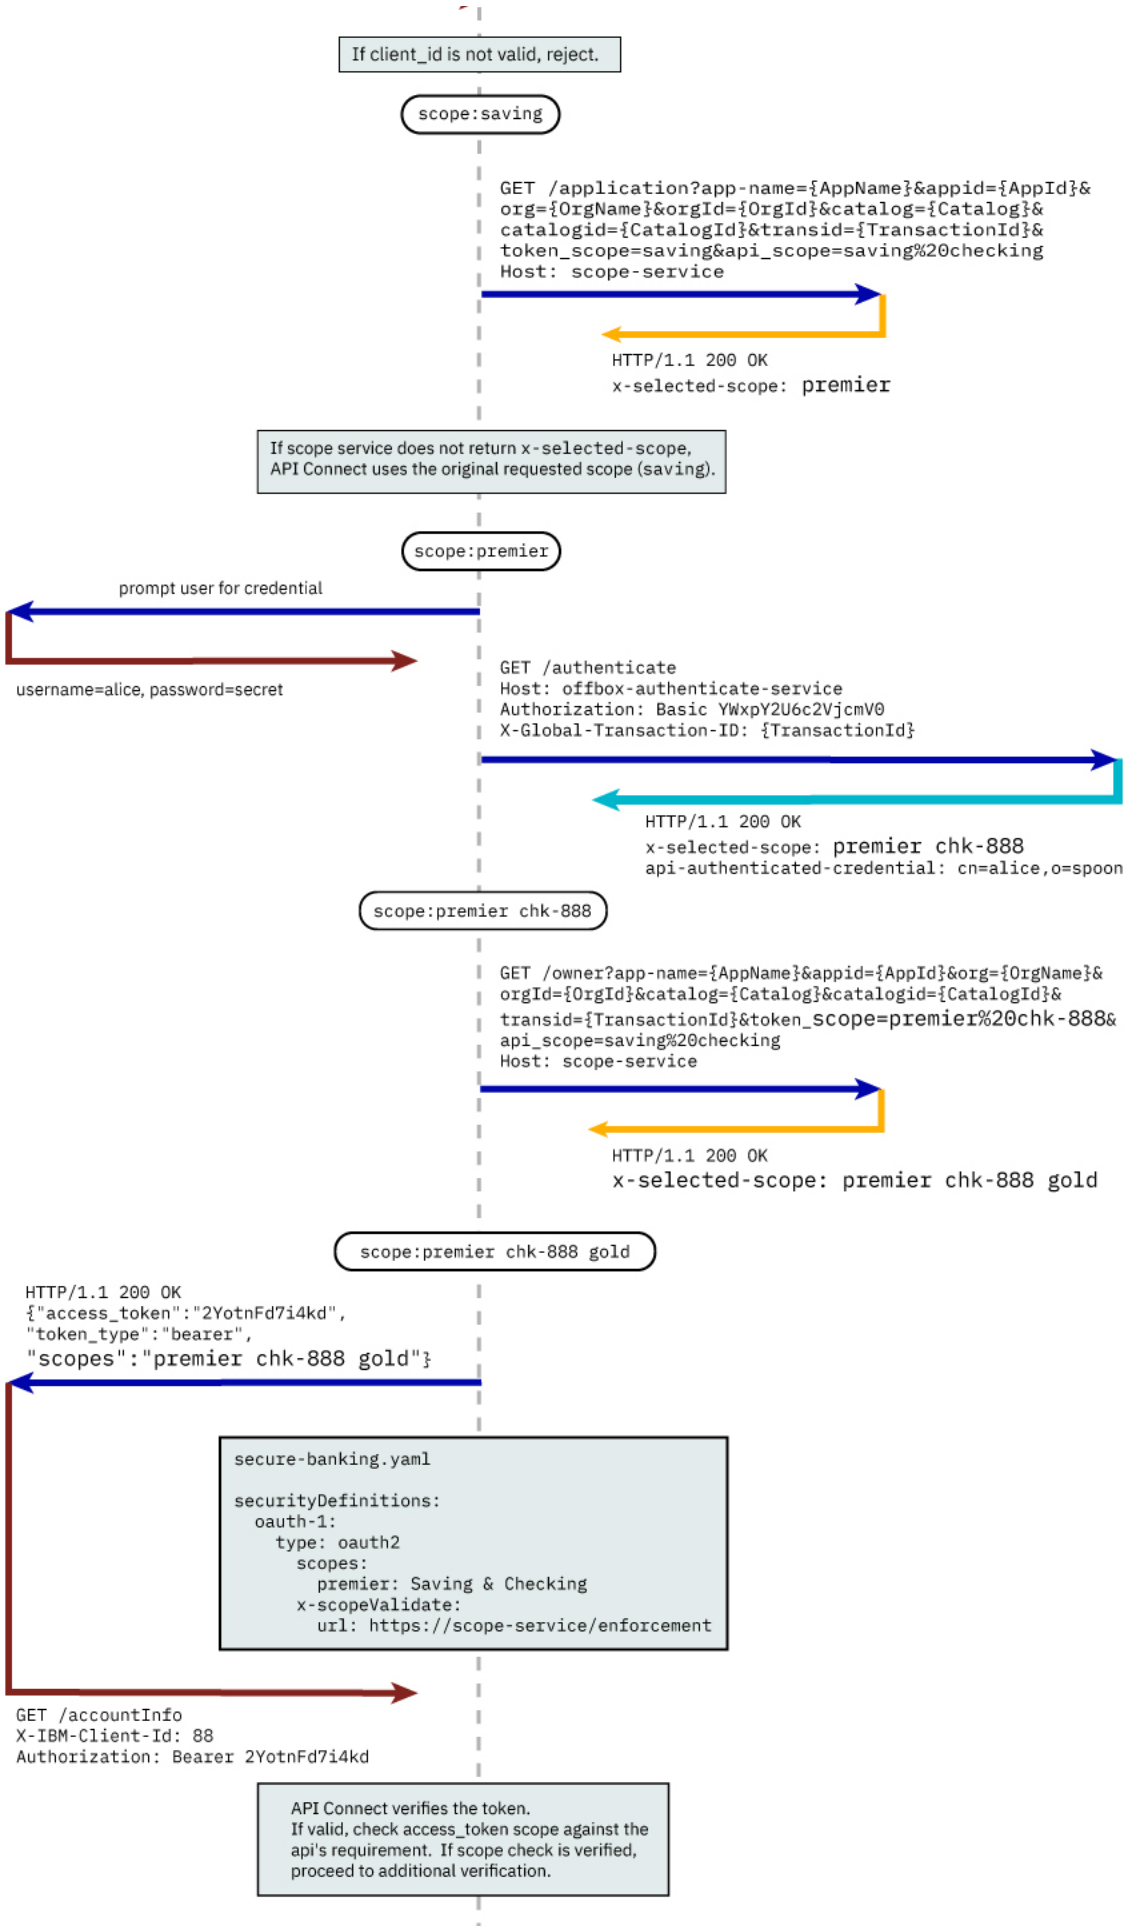


Figure 1. OAuth advanced scope overview

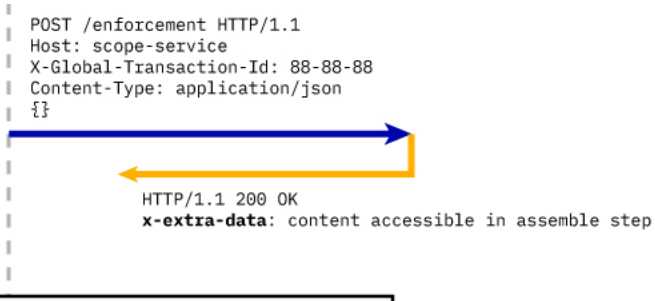

The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. Figure 2 shows a more detailed view of the transaction flow with examples that show when **`x-selected-scope`** provides a new scope value.

Figure 2. OAuth advanced scope detail

If client_id is not valid, reject.
scope:saving
GET /application?app-name={AppName}&appid={AppId}&

api_scope=saving%20checking
Host: scope-service
HTTP/1.1 200 OK
x-selected-scope: premier chk-888 gold
scope:premier chk-888 gold
HTTP/1.1 200 OK
{"access_token":"2YotnFd7i4kd",
"token_type":"bearer",
"scopes":"premier chk-888 gold"}
secure-banking.yaml
securityDefinitions:
oauth-1:
type: oauth2
scopes:
premier: Saving & Checking
x-scopeValidate:
url: https://scope-service/enforcement
GET /accountInfo
X-IBM-Client-Id: 88
Authorization: Bearer 2YotnFd7i4kd
API Connect verifies the token.
If valid, check access_token scope against the
api's requirement. If scope check is verified,
proceed to additional verification.

If API Connect receives HTTP 200, any HTTP headers in the response that start with "x-" will be accessible at oauth.advanced-consent.<value>
For the above example, x-extra-data is accessible at oauth.advanced-consent.x-extra-data.
If other than HTTP 200 is returned, it has the same effect as if the access token does not contain neccesary permissions to access the resource.

Consumer API enforcement

Standard scope validation
To access the API /getaccount the application must send a **GET** request with an access token that contains the scope, or scopes, defined in the OAuth provider. If the request doesn't contain a scope, you must specify a default scope to use. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file secure-banking.yaml defines the scope, or scopes, that must exist in the token to be granted access to the API /getaccount.

secure-banking.yaml

```
securityDefinitions:
   scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
security:
  - scope-only:
      - checking
  - scope-only:
      - saving
      - mutual
```

In the examples, the access token **AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ** is able to access the API because it contains one, or a combination of **scope-only** that is defined in secure-banking.yaml such as:

- **checking**
- **saving mutual**
- **checking saving mutual**

Advanced Scope Check
Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes **x-scopeValidate** as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
    x-scopeValidate:
      url: 'https://advanced-scope-check.bk.com/validate-scope'
      tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an **HTTP POST** request to the **x-scopeValidate** endpoint similar to the following example. Response code HTTP 200 from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
     POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
     Host: advanced-scope-check.bk.com
     Content-Type: application/json
```

```
   {"context-root" : checking,
    "resource" : accountinfo,
    "method" : GET,
    "api-scope-required" : [jointaccount],
    "access_token" : {"client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
                      "not_after" : 174364070,
                      "not_after_text" : "2017-07-11T02:27:50Z",
                      "not_before" : 174360470,
                      "not_before_text" : "2017-07-11T01:27:50Z",
                      "grant_type" : "code",
                      "consented_on" : 1499736470,
                      "consented_on_text" : "2059-07-11T01:27:50Z",
                      "resource_owner" : "cn=spoon,email=spoon@poon.com",
                      "scope" : "jointaccount mutual",
                      "miscinfo" : "[r:gateway]"
                     }
}
```

An example of successful response follows.

```
     HTTP/1.1 200 OK
     Cache-Control: no-store
     Pragma: no-cache
     X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "**x-**" is kept as the context variable **oauth.advanced-consent**. Based on the example successful response, **X-Custom-For-Assemble-Process: audit** becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options
You can optionally use additional fields for validation:

Request Header
: Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable
: Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format **oauth.advanced-consent.***.

- IETF RFC 6749

Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- **Refresh tokens**
  If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- **Token revocation**
  In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- **Authenticating and authorizing through a redirect URL**
  You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- **Token management with the DataPower Gateway (v5 compatible)**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- **Token management with the DataPower API Gateway**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the expires_in property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYy1hbGxlhdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens > Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see Configuring a native OAuth provider.

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management > Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml

<?xmlversion="1.0" encoding="UTF-8"?>
<token>
   <token_type>bearer</token_type>
   <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
   <expires_in>3600</expires_in>
   <scope>3600</scope>
   <resource-owner>alice</resource-owner>
   <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

Provide token information on revocation request

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET  <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET  <revocationURL>GET  HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a `200 OK` response to the Gateway.

Revoking tokens issued to Alice up to and including a specific date

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Revoking all tokens issued up to and including a specific date

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
<oauth-revocation>
```

Putting it all together

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
HTTP/1.1 200 OK
Content-Type: application/xml
Cache-Control: public, max-age=120
Date: Fri, 08 May 2015 21:49:03 GMT

<?xml version-"1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

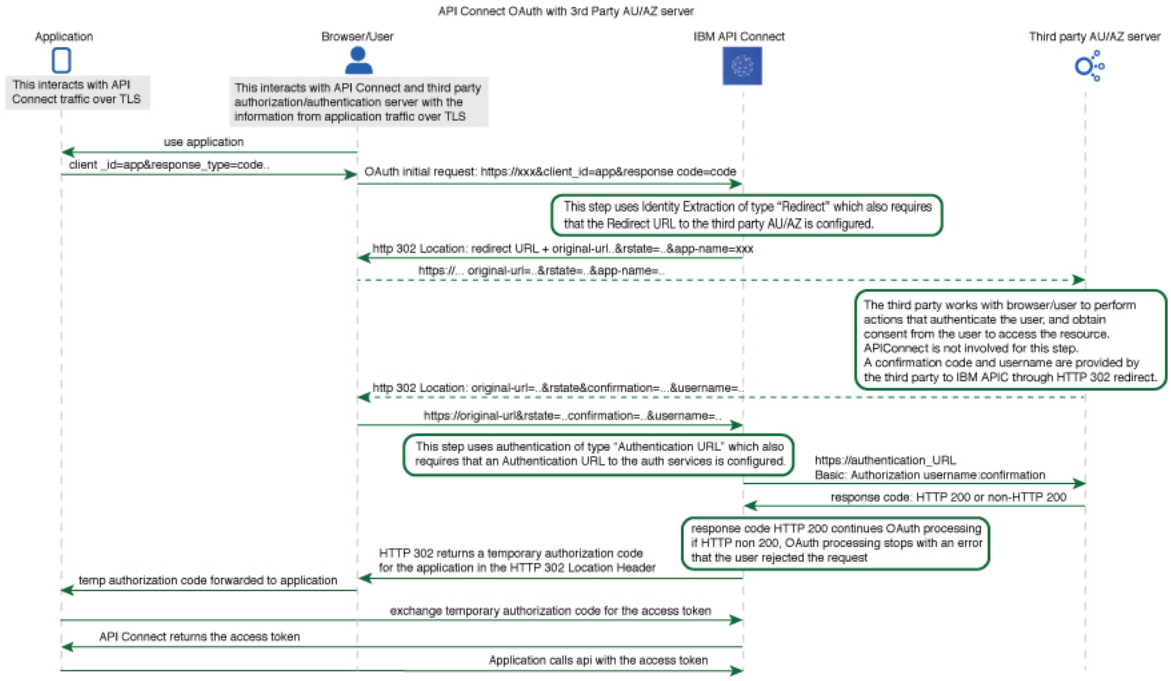
Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The `before` attribute uses the `xs:dateTime` syntax.

Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

Before you begin



To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see Creating an OAuth security definition.

About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow

1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an `HTTP 302` redirect based on `identity extraction -> redirect -> redirect-url`, for user authentication (and optional authorization).
2. The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an `HTTP 302` redirect that uses the `original-url` from the request, with the username and confirmation code appended.
3. API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on `authentication -> x-ibm-authentication-url`, to confirm user identity before the request is completed.
4. An `HTTP 200` response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the `grants` type.
   - `- accessCode` returns a temporary code to the application.
   - `- implicit` returns the access token to the application.

   For any response other than HTTP 200, the request fails with a statement added to the error log.

Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

1. Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
   a. To include elements in your form that are provided by API Connect, use the following query parameters from the URL that your user is redirected to. Note: With the exception of `original-url`, none of these parameters are included in the URL automatically; you must add them as required.

      app-name

The name of the application requesting access, as provided through the Developer Portal.

appid
: The id of the application requesting access.

catalog
: The name of the catalog where the product is being used by the application.

catalogid
: The id of the catalog where the product is being used by the application.

catalogtitle
: User-friendly display name for the catalog.

org
: The name of the consumer organization that hosts the application.

orgid
: The id of the consumer organization that hosts the application.

orgtitle
: User-friendly display name for the organization.

original-url
: The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the state_nonce is appended. The state_nonce is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the **`state_nonce`** should remain unchanged.

provider
: The name of the API provider organization.

providerid
: The id of the API provider organization.

providertitle
: User-friendly display name for the provider organization.

requested-scope
: [optional] If Application Scope check is enabled and replaces the **`scope`** from the initial application request, this field holds the **`scope`** value from the initial application request, and the new replacement scope value is put into **`original-url`**.

transid
: transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

```
Redirect_URL?original-url=Original_URL&state_nonce=R_State&app-name=Application_Name
```

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

b. Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the *Original_URL* and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect.
Original URL requires the following form:

```
Original_URL&username=User_Name&confirmation=Confirmation_Code
```

where all variables are as described previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=spoon&confirmation=12345678
```

c. To send your own error responses after the authentication and authorization service, redirect the user to the *Original_URL* and append an error code. You can also append a user name. Use the following form:

```
Original_URL&username=User_Name&error=Error_Response
```

where *Error_Response* is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as `200 OK` if you want to allow access, or non-`200 HTTP` response code, such as `401 Unauthorized` to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2.
For more information on configuring an OAuth Provider, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See Quota enforcement.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:
If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.
- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see Configuring the quota enforcement server.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke `access_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Revoke `refresh_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Note: The steps described in this topic are required if you are using the appliance version of the gateway. For the API Connect supplied Kubernetes deployment, the API Security Token Manager is preconfigured provided that, in the gateway service custom resource file, v5 compatibility mode is disabled and the token management service is enabled:

```
      .
      .
      .
spec:
      .
      .
      .
  apicGatewayServiceV5CompatibilityMode: false
  tokenManagementService:
    enabled: true
      .
      .
      .
```

For more information, see Installing the DataPower Gateway subsystem.
Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

In order to manage tokens with the DataPower® API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Note: This setting is also required when you use a third-party OAuth provider and **`Introspect cache type`** is set to **`protocol`** or **`Time to live`**.
For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.
6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see Defining the API security token manager and Creating a gateway peering instance.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user **`cn=spoon,o=ibm`** with username **`spoon`** and password **`spoon`** using a registered administration application of **`5287fe53-8747-438a-8262-681ec75b79c5`**.

- Request:

```
GET /oauth2/issued
HTTP/1.1
      Host: apic.ibm.com
      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request
```

```
"owner": "cn=spoon,o=ibm",

"clientName": "PetStore Application",

"scope": "listpet",

"issuedAt": 1503327054,

"consentedOn": 1503327054,

"expiredAt": 1503330654,

"refreshTokenIssued": false,

"appId": "d2031f0f27339315333734ab9",

"org": "PetStoreOrg",

"orgTitle": "Katie Pet Grooming Inc",

"orgId": "5887803de4b06e6998c4b2c7",

"providerTitle": "Simon SuperStore",

"providerId": "5887803de4b06e6998c4b2c7",

"catalog": "publicapi",

"catalogTitle": "For public",

"catalogId": "5887803de4b06e6998c4b2d3"

} => delete second item

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

     { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache
```

```
    { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Authentication URL user registry

You can use an authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides extra metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs in with username: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **cn=spoon,o=eatery**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **access_token**.
- Overriding the **scope** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the authentication URL endpoint can replace the **scope** value that the application receives. For example, you can provide a specific resource owner an account number within the **scope** header response for use in future processing steps.

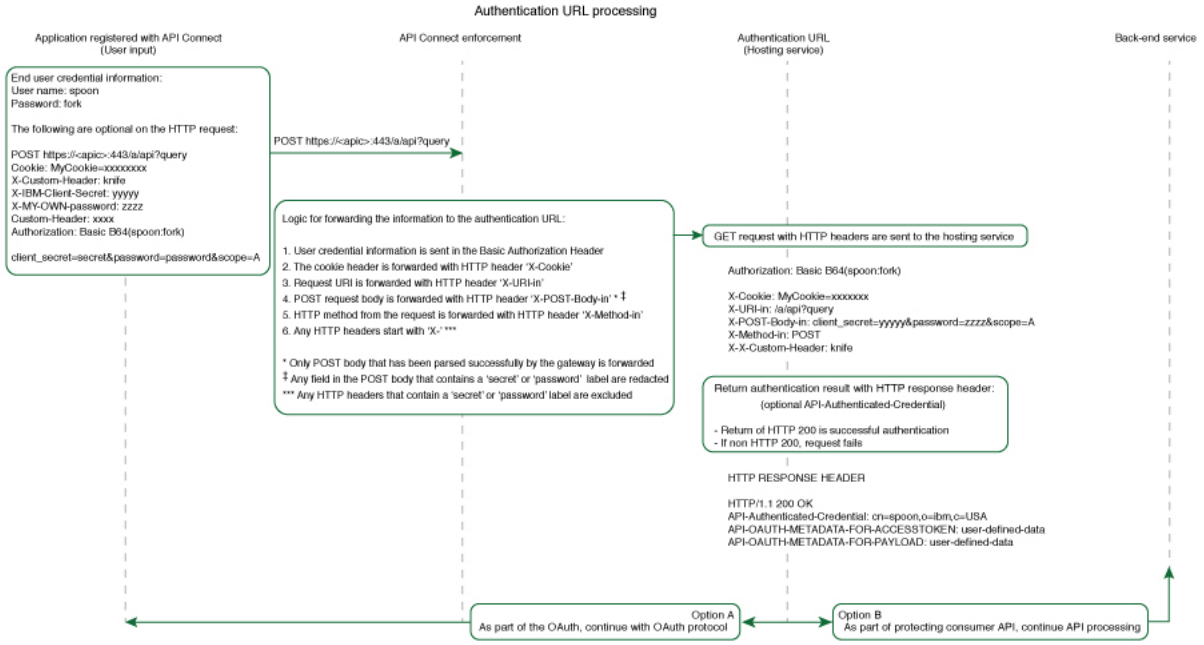
When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect uses **cn=spoon,o=eatery** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.



API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested **scope** from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

About this task

The Native OAuth provider configuration provides the capability for requiring another authentication and authorization steps for user security. Custom HTML forms can be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- **Creating a custom HTML login form for user security**
  Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- **Creating a custom HTML authorization form for user security**
  Custom HTML forms can be created for user security during the authorization stage in OAuth.

Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. For more information, see Configuring a native OAuth provider. This topic describes how to create the Custom HTML form for identity extraction.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. API Connect parses a well-formed XHTML document to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example,

```
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.
   For example,

```
<button
id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.apionprem.doc_oauth_custom_login_form_2_login_
button" type="submit" name="login" value="true">Log in</button>
```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing steps 1 through to 8 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>
  <body>
    <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
      <h1>Please sign in</h1>
      <p>Username </p>
      <p ><input type="text" name="username" required="required" /> </p>
      <p>Password </p>
      <p ><input type="password" name="password" required="required" /> </p>
      <EI-INJECT-HIDDEN-INPUT-FIELDS/>
      <p > <button
id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.apionprem.doc_oauth_custom_login_form_2_login_
button" type="submit" name="login" value="true">Log in</button> </p>

      <EI-LOGINFIRSTTIME>
        <p>If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFIRSTTIME>

      <EI-LOGINFAILED>
        <p >At least one of your entries does not match our records.
          If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFAILED>

      <EI-INTERNAL-CUSTOM-FORM-ERROR/>

    </form>
  </body>
</html>
```

11. Make your form available at a URL of your choice.
12. If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Related tasks

- Creating a custom HTML authorization form for user security

Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You can select how to authorize application users and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. This topic describes how to create the custom HTML form for authorization.

About this task

In three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user grants permission to an application to access their data through an authorization form. You can present a custom form or a default form. Your custom form must fulfill certain requirements.
Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

1. Create a well-formed XHTML document. This is parsed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example,

```
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
```

3. Add the line `<AZ-INJECT-HIDDEN-INPUT-FIELDS/>`. This line is a placeholder that API Connect replaces with input fields necessary for the completion of the OAuth process.
4. Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

```
<button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
<button class="submit" type="submit" name="approve" value="true">Allow Access</button>
```

5. Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<AZ-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the user.
6. Optional: You can add to the form HTML elements that load features from external sources, such as images or JavaScript.
   For example, `<script src="http://www.example.com/example.js" />`
7. Insert spacing and extra elements as you require. Completing steps 1 through to 6 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><title>Request for permission</title></head>
  <body class="customconsent">
    <div>
      <div>
        <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
          <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
          <p>Greeting..</p><DISPLAY-RESOURCE-OWNER/>
          <p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
          <div>
            <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
            <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
          </div>
        </form>
      </div>
      <AZ-INTERNAL-CUSTOM-FORM-ERROR/>
    </div>
  </body>
</html>
```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a custom HTML form for authorization for user security. Provide the URL as the endpoint at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM® API Connect.

About this task

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the **jwt-generate** command, and then augment the response payload with your generated token replacing the **id** token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

Procedure

Create a **jwt-generate** policy in the assembly.

a. In API Manager, open the Assembly tab.
b. Add a jwt-generate policy to the assembly for the API.

Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

You can use the following links to go to the topics:

- OAuth 2.0 support in the Developer Portal test tool
- OAuth requires quorum in a multi-node cluster

OAuth 2.0 support in the Developer Portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see Testing an API using the Developer Portal test tool.

OAuth requires quorum in a multi-node cluster

In a multinode cluster, OAuth operation fails if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

API Analytics

You can use API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.

API analytics is built on the OpenSearch open source real-time distributed search and analytics engine.

The content of the API event data depends on the logging policy that is set for the operation. For more information about the fields that are displayed in an API event record, see API event record field reference. For information about how to configure your logging preferences for API events, see activity-log policy and Including elements in your assembly.

To monitor your API usage with API Connect analytics, see Analytics: understand your API usage.

- **Catalogs, spaces, and analytics**
  Understand how syndication and the use of catalogs and spaces affects the use of the features in API Connect analytics.
- **Accessing analytics**
  Analytics data is displayed in dashboards in the API Manager UI. Dashboards are scoped at the provider organization, catalog, and space level. To access analytics data at the cloud scope, use the Cloud Manager UI. Analytics data is also accessible by using the Toolkit CLI and REST API.
- **Analytics dashboards**
  IBM API Connect analytics provides dashboards for viewing your analytics data.

Catalogs, spaces, and analytics

Understand how syndication and the use of catalogs and spaces affects the use of the features in API Connect analytics.

The data for analytics is collated from API events that are logged when API operations are invoked. Analytics data for an API is scoped to the catalog or space where that API resides, and is only included in search results (and thus, visualizations and dashboards) for the owning catalog or space.

Access to the analytics data, and to the analytics functions in the API Manager user interface, can be managed through the use of catalogs and spaces, and the roles and permissions that are assigned to the users (or *members*) of the provider organization.

The cloud admin user can view aggregated analytics data for all catalogs, spaces, in all provider organizations, in the admin UI.

Catalogs, spaces, and permissions

Catalogs act as deployment targets through which APIs (in their containing plans and products) are staged and published to consumer organizations. API Manager users in the provider organization can be assigned the following access to the analytics component for a catalog:

- A role that has the Analytics > View permission for a catalog: These users can view the analytics data generated for the APIs in the catalog within *dashboards*, export dashboard data in its raw format or as event records, and apply filters to the data shown within the dashboards.
- A role that has the Analytics > Manage permission for a catalog: This is a legacy permission and has the same permissions as the View permission.

The IBM® API Connect syndication feature provides a way for you to partition a catalog into multiple deployment targets (or *spaces*) through which separate groupings of APIs (in their containing plans and products) can be staged and published. Each space can be allocated to a separate group of users who need to manage their products independently, and the analytics data in each space is scoped to those products only. API Manager users in the provider organization can be assigned the following access to the analytics component for a space:

- A role that has the Analytics > View permission for a space: These users can view the analytics data generated for the APIs in the space within dashboards, export dashboard data in its raw format, and apply filters to the data shown within the dashboards.
- A role that has the Analytics > Manage permission for a catalog: This is a legacy permission and has the same permissions as the View permission.

For more information about assigning catalog or space permissions to a role, see Managing Catalog membership and Managing Space membership.

For more information about the default API Manager roles and permissions, see API Connect user roles.

Accessing analytics

Analytics data is displayed in dashboards in the API Manager UI. Dashboards are scoped at the provider organization, catalog, and space level. To access analytics data at the cloud scope, use the Cloud Manager UI. Analytics data is also accessible by using the Toolkit CLI and REST API.

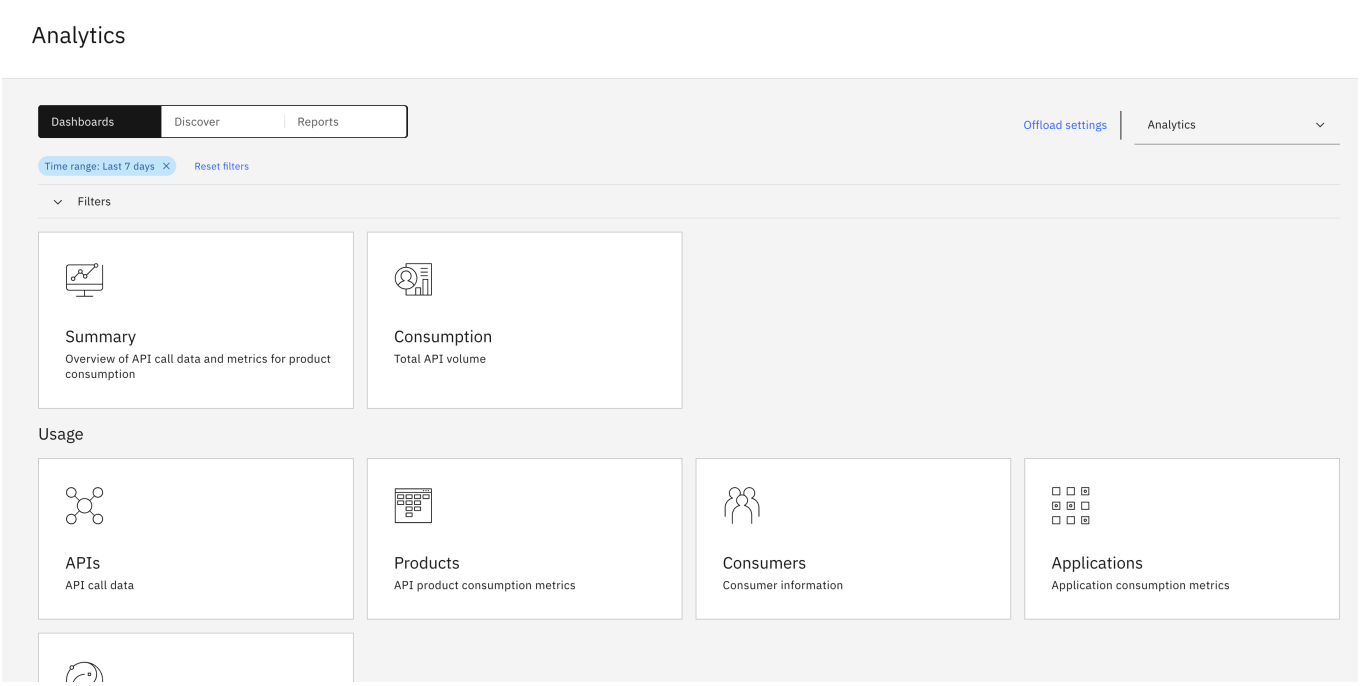
The ability to access analytics data at a catalog or space level depends on your assigned roles and permissions. For more information about catalogs and spaces, see Working with Catalogs and Using syndication in API Connect.

To access analytics data from the API Manager UI, select the Analytics tab when viewing a catalog. For more information about the analytics data viewable from the API Manager UI, see Accessing analytics from the API Manager UI.

Restriction: If the visualizations in your dashboards are empty or display no recent data, a possible reason might be that access to analytics data within API Connect is deactivated. Contact your administrator for confirmation.
To export your analytics data, see Export your analytics data.

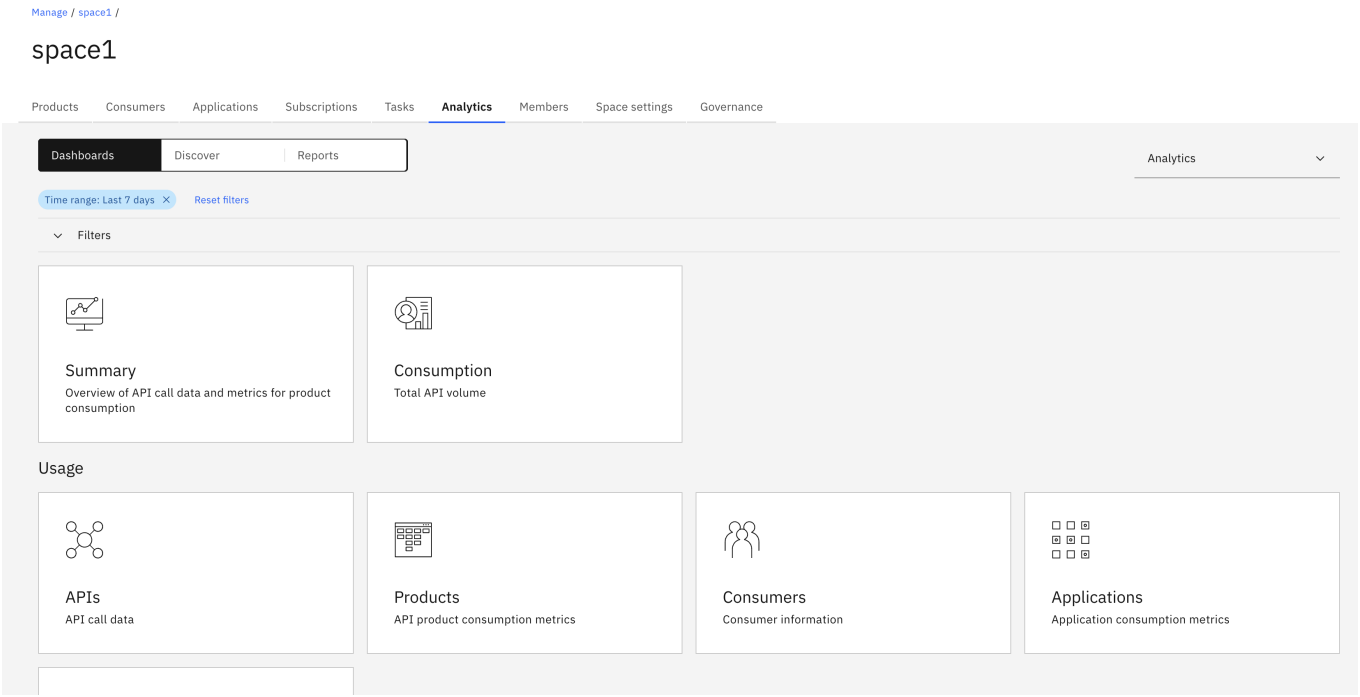
To use the toolkit CLI or REST API to access your analytics data, see:

- Analytics CLI.
- Analytics REST API.



Analytics dashboards

IBM® API Connect analytics provides dashboards for viewing your analytics data.



Analytics dashboards

The analytics dashboards in the API Manager UI show the API event data at the scopes of provider organization, catalog, and space. The scope of the analytics data shown depends on how you access the analytics dashboards, see: Accessing analytics.

The provider organization scoped dashboards are accessed from the Analytics icon in the navigation pane:

The space scoped dashboards are accessed from the Analytics tab when viewing the space:

12 dashboards are available:

Summary
: View high-level metrics, including call volumes, latency, and time-based trends.

Consumption
: Track the total number of API calls processed by gateways over time. Use this data for consumption-based licensing.

APIs
: Identify which APIs are being called and which are not.

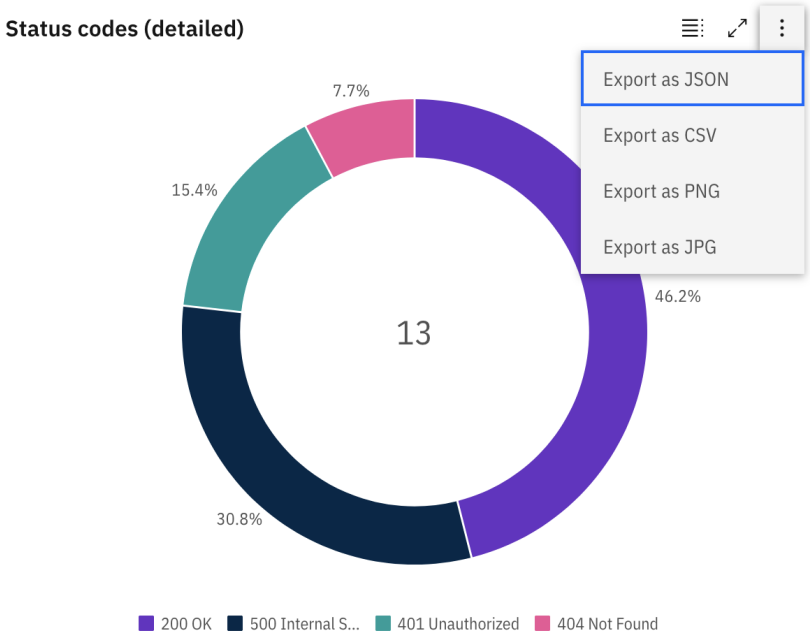
Products
: See which products are most popular overall and how their usage changes over time.

Consumers
: Determine which consumer organizations make the most API calls, both in total and over time.

Applications
: Analyze which applications generate the highest number of API calls, overall and over time.

AI Usage
: Monitor usage of your AI services. Track token counts and AI model usage by consumer.

Status
: Review API call success and failure rates over time. Includes an HTTP response code breakdown.



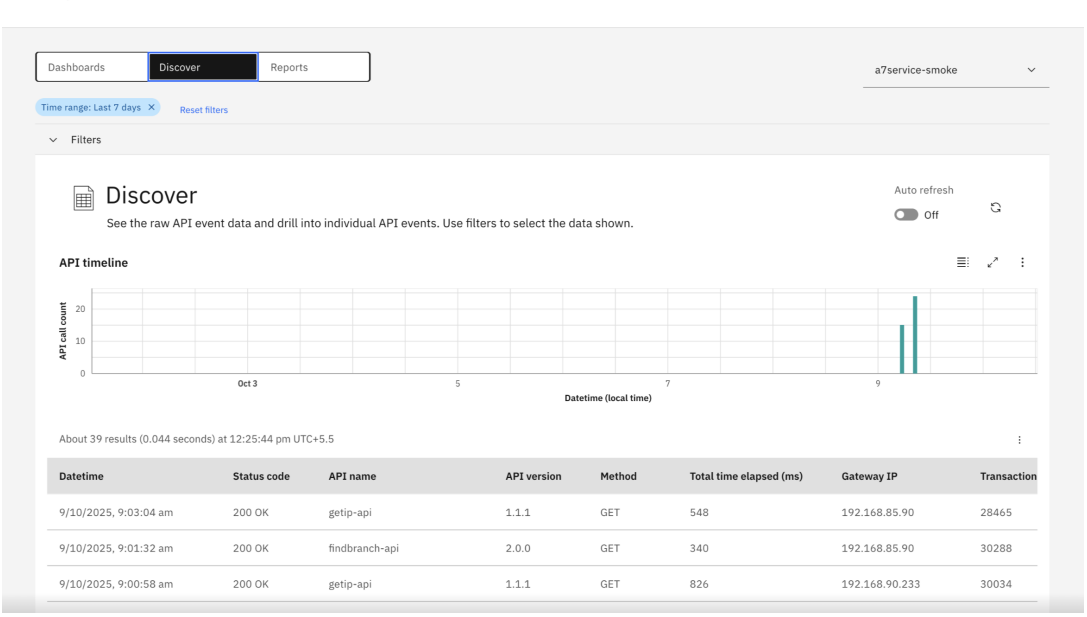
Latency
: Measure API response times. Identify the fastest and slowest APIs and track changes in response time over time.

Data Transfer
: Analyze request and response payload sizes. Identify APIs, consumers, and applications responsible for the largest payloads.

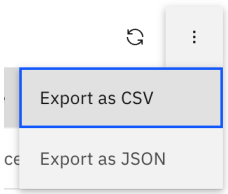
Client Information
: See who is calling your APIs and from which devices.
Note: Only internet-accessible IP addresses can be resolved to a geographic location. Internal IP addresses are ignored. The GeoIP database is updated with each API Connect fix pack. Apply the latest fix pack to maintain accuracy.

Gateway Operations
: View call volume and latency for each gateway in each gateway service. Use this data to check load distribution and identify underperforming gateways.

Each chart in the dashboards can be exported as a PNG or JPG image. The source data for each chart can be exported as a JSON or CSV file. To export a chart, click



Actions at the upper right:

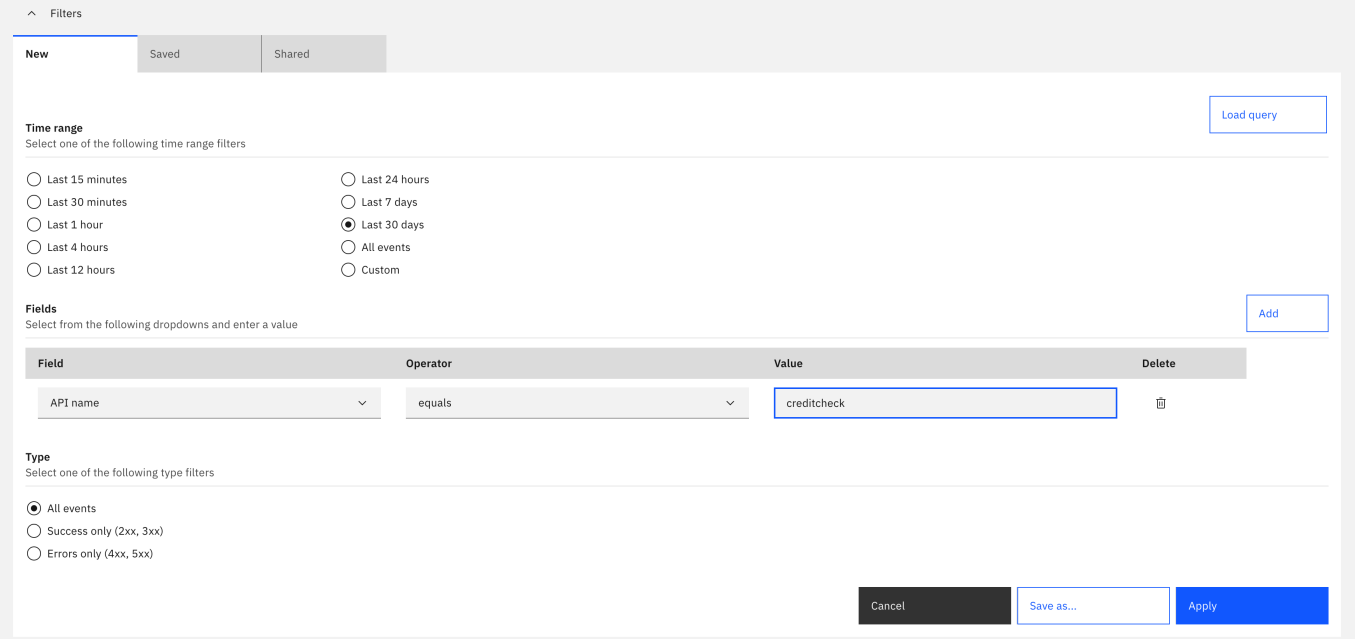


It is also possible to enlarge the chart to full-screen by clicking . To see the source data in tabular form click .

Discover view

By default the Dashboards tab is displayed. To view your API event data in tabular form, select Discover:

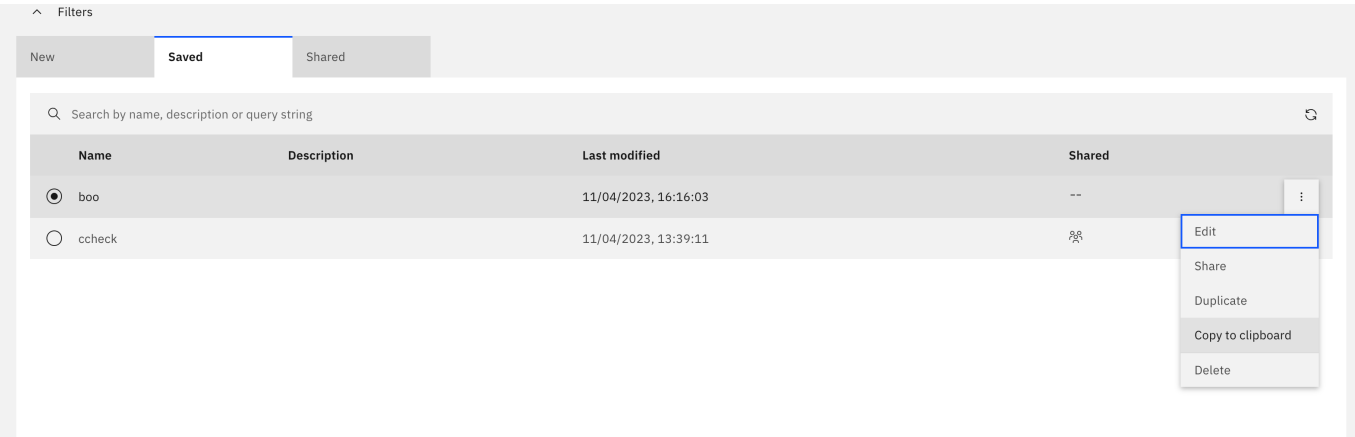
The maximum number of API events that can be accessed from the UI is 10,000. The maximum number of event records that can be displayed per page on the Discover view is 200.



You can export the API event data from this view by clicking Actions at the upper right:

Note: When you export from the Discover view, only the data displayed on the current page of results is exported. If you want to export the data from all pages, you must export separately from each page.

Filtering displayed data



You can filter the data that is displayed in the Dashboards and Discover view by defining queries. Expand the Filters section to view, define, and apply analytics queries to your displayed data:

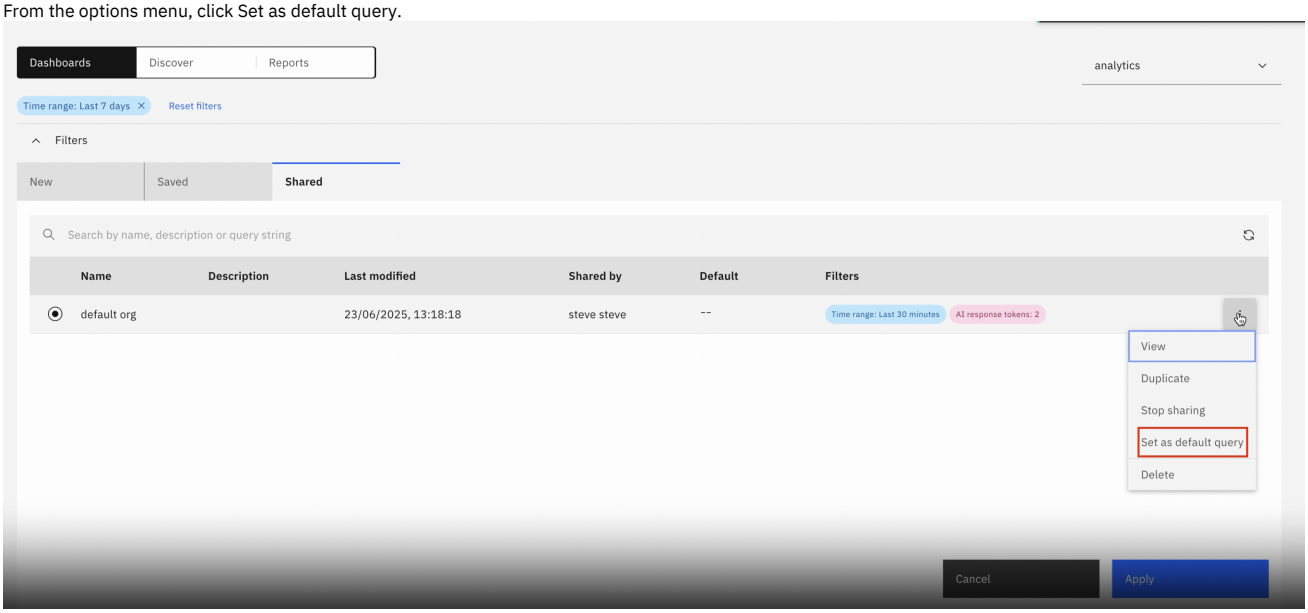
You can save and share the queries that you define:

- Shared queries are visible to all users at the same scope. They are not visible to users in a different scope. For example, a query that is shared by a Cloud Manager UI user is not visible to an API Manager UI user. Within the API Manager UI, a query that is created at catalog scope is not visible to users viewing analytics data at provider organization scope.
- Other users cannot edit or delete queries that you share, but they can create a duplicate query, which they can edit and share.
- All queries have a name and an optional description. The name does not need to be unique.

Saved queries can be exported as strings for use in REST API and toolkit CLI queries, for example:

copies the following string to the clipboard:

```
api_name=equals:boo&timeframe=last30days
```



Set a default query in analytics

You can now set a default query that is automatically applied when you visit the Dashboard or Discover pages in Analytics. The default query is configured per user and per scope (organization, catalog, or space).
Note:

- Only shared queries can be set as default queries.
- Each scope can have one default query per user. A different default query can be set for each catalog and space.

1. Ensure that the query you want to set as default is saved.
2. To share the saved query, complete the following steps.
   - Click Saved tab.
   - From the options menu, click Share.
   - In Share query window, click Share.
3. Click Shared tab.

4. From the options menu, click Set as default query.

5. In Default query window, click Default.
6. To apply the default query immediately. Click Apply. The default query is applied immediately for all users in that scope. If you do not click Apply after setting the default query, it is automatically applied the next time you visit the Dashboard or Discover tabs.

Configuring governance in the API Manager

How to add custom governance rulesets to your API development process to validate and enforce organizational governance policies and best practices in your provider organization.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. For more information, see Enabling governance on Kubernetes for more information. If governance is enabled in your deployment, the Governance icon is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

One of the following roles is required to be able to configure governance:

- Organization administrator
- Owner
- Custom role with the **`Settings: Manage`** permission.

About this task

The governance service is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices in your API development process. You configure governance by creating one or more custom rulesets that contain a collection of rules that can then be used to check Swagger, OpenAPI, and AsyncAPI documents, as well as product documents. You can also run validation scans on your catalogs and spaces; for more information, see Scanning your catalogs and spaces.

The governance service contains the following types of rulesets:

API

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
- Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. The Spectral ruleset names are prefixed with spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
- Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Tags can be added to API rulesets that, when matched with the same tag in an API, help ensure that the appropriate rulesets are preselected for your validation scans. In this way, the governance process can be run more quickly and effectively. These preselected rulesets can be deselected from the scan if required.

Note:

- Governance in API Connect supports the creation of custom rulesets that contain rules that use only the built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions. The use of custom functions, for example rules that use functions that you created yourself in JavaScript files, is not supported. Also, the following Spectral OpenAPI rules aren't supported as they might identify false positives:
  - `oas2-unused-definition`
  - `oas3-unused-component`
- Some of the Spectral rules within the Global rulesets contain the property `recommended: false`, which means that those rules are ignored during validation. However, if you create a new ruleset from one of these rulesets by using the Save as new ruleset option, the `recommended` property isn't transferred to the new ruleset. Therefore, all the rules are used in the validation, unless you delete those rules from the ruleset. The Spectral ruleset names are prefixed with spectral-.
- Dereferencing, which means not introspecting a referenced definition within an API, is not supported in the governance service. Instead, a referenced object can be explicitly validated by using custom rules.
- You can also configure governance rulesets in the Cloud Manager. For more information, see Configuring governance in the Cloud Manager.

The following methods can be used to configure both API and product rulesets:

- Create a new ruleset by using the UI
- Import a ruleset
- Create a ruleset by using the CLI

Procedure

- To create a new API or product ruleset by using the API Manager or API Designer UI, complete the following steps.

1. In the side menu bar, click  Governance.
   The Governance page is displayed.
2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
   The manage rulesets page is displayed.
3. In the Provider organization rulesets section, click Add > Create from scratch.
   The Create provider organization ruleset wizard opens.
4. Provide the following Ruleset info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the ruleset. This name is displayed in the list of global rulesets.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Version	Yes	The version number defaults to 1.0.0, but can be edited. You can have rulesets with the same name, but with different version numbers. The version number must be in the format `major.minor.patch`.	String
Description	No	An optional description of the ruleset.	String

5. Optional: For API rulesets, you can add one or more tags to your ruleset by clicking Add, and completing the tag Name and Description.
   Adding matching tags to your rulesets and APIs, means that validation scans can preselect which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For more information about how to add tags to APIs, see Adding tags to an API.
6. Click Next, and then add an initial rule to your ruleset.
7. Provide the following Rule info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the rule.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Description	Yes	A description of the rule.	String
Message	No	Provide a message to help users understand what the goal of the rule is. If no message is provided, the value of the Description property is used for the message output of the validation scan.	String
Severity	Yes	Select a severity level from the following options: • error • warn • info • hint • off error is selected by default.	String

8. In the Given section, specify one or more values for the parts of the API or product document to target. To add more values, click Add. Values must be written in JSONPath.
9. In the Then section, specify the function type and options that will be used to evaluate the target values in the API or product document. Write this section in YAML syntax.
   In the following API rule example, for a Given value of `$` (which means root level of the document), the Then section uses the Spectral core `truthy` function to check that the `info.contact` property value is not `false`, `""`, `0`, `null`, or `undefined`.

```
- field: info.contact
  function: truthy
```

   The Then section can also contain a list of functions to be applied to the Given part of the document. In the following API rule example, for a Given value of `$.info.version` (which refers to the `version` property inside the `info` property at the root level of the document), the Then section uses both the `truthy` function, and the Spectral core `pattern` function that checks that the `info.value` matches the regex expression that is given by `functionOptions.match`.

```
- function: truthy
- function: pattern
  functionOptions:
    match: "^[0-9]+.[0-9]+.[0-9]+(-[a-z0-9+.-]+)?"
```

   For a complete list of the Spectral core functions that you can use in your custom API rules, along with examples of these functions, see https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
10. Click Create to create your draft ruleset.

Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon .

11. You now have the following options:
    - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon ⊕ alongside Rules in the navigation page. Remember to click Save when you finish editing.
    - If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the API governance overview page.

- To import an existing API or product ruleset, complete the following steps. The rules in your imported ruleset can contain only built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.

  1. In the side menu bar, click Governance.
     The Governance page is displayed.
  2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
     The manage rulesets page is displayed.
  3. In the Provider organization rulesets section, click Add > Import.
     The Import ruleset wizard opens.
  4. Drag a file into the Upload file box, or click in the Upload file box to select a file to upload. The maximum file size is 100 kb, and the supported file types are YAML, YML, and JSON.
  5. Click Next.
  6. Edit the Ruleset info details as required, and click Import.
     Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon .
  7. You now have the following options:
     - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon ⊕ alongside Rules in the navigation page. Remember to click Save when you finish editing.
     - If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the API governance overview page.

- To create an API or product ruleset by using the toolkit CLI, complete the following steps.
  1. Create a JSON file that contains the new ruleset.
     The following JSON shows the contents of an example API document Spectral ruleset file:

```
{
    "name": "short-draft-ootb",
    "title": "short-draft-ootb",
    "description": "short ruleset",
    "ruleset_type": "custom",
    "tags": [
      {
        "name": "general",
        "description": "general work"
      }
    ]
    "rules": [
      {
        "name": "sec-array-boundaries-2",
        "description": "Array size should be limited to mitigate resource exhaustion attacks.\nThis can be done using
`maxItems` and `minItems`, like in the example\nbelow.\n\n```\nLimited:\n  type: array\n  maxItems: 10\n  items:\n
type: string\n    format: date\n```\n\nYou should ensure that the schema referenced in  `items` is constrained
too.\n\nIf you delegate input validation to a library or framework,\nbe sure to test it thoroughly and ensure that it
verifies `maxItems`.",
        "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
        "formats": [
          "oas3"
        ],
        "severity": "warn",
        "recommended": true,
        "given": [
          "$..[?(@.type==\"array\")]"
        ],
        "then": [
          {
            "field": "maxItems",
            "function": "defined"
          }
        ]
      }
    ]
  }
```

     The following JSON shows the contents of an example product document ruleset file:

```
{
  "type": "ruleset",
  "ruleset_type": "custom",
  "api_version": "2.0.0",
  "id": "dbb5f400-e707-412e-b081-ac36f5afbbb9",
  "name": "test-product",
  "title": "Test Product",
  "description": "",
  "ruleset_version": "1.0.0",
  "ruleset_state": "draft",
  "ruleset_format_type": "2",
  "rule_urls": [
    "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b"
  ],
  "created_at": "2024-05-22T17:19:02.820Z",
  "updated_at": "2024-05-22T17:24:59.000Z",
  "url": "https://my.manager.com/governance/orgs/myorg/rulesets/dbb5f400-e707-412e-b081-ac36f5afbbb9",
```

```
  "rules": [
    {
      "api_version": "2.0.0",
      "id": "ca6ef7d9-a503-498e-8f53-4e3aa35d086b",
      "name": "subscribe",
      "version": "1.0.0",
      "title": "subscribe",
      "description": "subscribe enabled",
      "message": "subscribe not enabled",
      "given": [
        "$.visibility.subscribe.enabled"
      ],
      "severity": "error",
      "created_at": "2024-05-22T17:19:02.000Z",
      "updated_at": "2024-05-22T17:24:59.000Z",
      "url": "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b",
      "then": [
        {
          "function": "pattern",
          "functionOptions": {
            "notMatch": "/true"
          }
        }
      ]
    }
  ]
}
```

2. Log in to the toolkit as the owner or admin of the provider organization that owns the new ruleset.
   For example,:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

3. Run the `rulesets:create` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:create --org <target_org> --server <server_url> RULESET_FILE
   ```

   Where:
   - *<target_org>* is the name of the organization that owns the new ruleset.
   - *<server_url>* is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and file name of the JSON file that contains the ruleset.

Results

Your draft API or product ruleset is now listed in the table of Provider organization rulesets.

What to do next

When you finish editing your ruleset, you can publish it to your provider organization. Click the options menu icon ⋮ either next to the ruleset that you want to publish, or from within the ruleset viewer. Select Publish, and then click Publish again to confirm. The status of your ruleset changes from Draft to Published, and can now be used by developers to validate their API and product documents. For more information, see Validating an API document by using governance.

To validate an API or product document by using a published ruleset, click Validate, select the APIs or products to validate, then select the rulesets and rules that you want to use, and click Validate again. If the API that you want to validate includes a tag that has a matching tag in one or more rulesets, then those rulesets are automatically selected for the scan. However, you can edit the ruleset selection to your requirements. The results of the validation are displayed in a scorecard.

You can also run validation scans on your catalogs and spaces; for more information, see Scanning your catalogs and spaces.

Note:

- After a ruleset is published, the ruleset information and rules can no longer be edited. If you need to update this information, you must create a new version by clicking the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer, and selecting Save as new ruleset.
- **The governance ruleset lifecycle in the API Manager**
  When you manage your custom governance rulesets in the API Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

- **Updating rulesets and rules with the toolkit CLI**
  Use the API Connect toolkit CLI to update a ruleset or individual rules.

  How to use the governance service to run validation scans on your catalogs and spaces. You can run scans on both the APIs and the products within your catalogs and spaces.

The governance ruleset lifecycle in the API Manager

When you manage your custom governance rulesets in the API Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

The following sections describe the various lifecycle states for a custom governance ruleset.

Note:

- Approval is not required for any of the lifecycle state transitions.
- Global rulesets are pre-configured rulesets that contain the rules that are shared with your provider organization, and cannot be edited. These rulesets are always in the Published state.

Draft

The draft state for a ruleset is when the ruleset is not published, and isn't visible to your provider organization. The ruleset can continue to be edited, and its Status is shown as Draft.

Published

When you publish a ruleset, it is made visible to your provider organization, and cannot be changed. The ruleset Status is shown as Published. Any changes to the ruleset require a new version to be created by using the Save as new ruleset option.

Archived

When you archive a ruleset, it becomes a ready-only, fixed version of the ruleset that cannot be used for validation by your provider organization. The ruleset Status is shown as Archived.
Note: If you cannot see your Archived ruleset, ensure that the Edit filters option on the ruleset table is set to include Archived.
You can restore archived rulesets by using the Restore option, after which the Status returns to Published.

Also, you can delete Archived rulesets by using the Delete option.

Updating rulesets and rules with the toolkit CLI

Use the API Connect toolkit CLI to update a ruleset or individual rules.

Updating a ruleset

1. Create a JSON file that defines the updated ruleset.
   The following example shows an updated ruleset:

   ```
   {
       "title": "custom-ruleset-2",
       "description": "short ruleset updated",
       "ruleset_type": "custom"
   }
   ```

   where:
   - `title` is updated to a new title for the ruleset.
   - `description` is updated to a new description for the ruleset.
   - `ruleset_type` is updated to be custom for the ruleset.
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the ruleset.
3. Run the `rulesets:update` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:update --org <target_org> --server <platform_api_host_name> RULESET RULESET_FILE
   ```

   where:
   - *`<target_org>`* is the name of the organization that owns the ruleset.
   - *`<platform_api_host_name>`* is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `RULESET_FILE` is the path and filename of the JSON file that contains the updated ruleset.
   - `RULESET` is the name or the unique ID of the updated ruleset.
     To determine the ID of a ruleset, run the following command:

     ```
     apic -m governance rulesets:list --org <target_org> --server <platform_api_host_name>
     ```

Updating a rule

1. Create a JSON file that defines the updated rule.
   The following example shows an updated rule:

   ```
   {
     "description": "Updated the rule",
     "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
     "formats": [
       "oas3"
     ],
     "severity": "warn",
     "recommended": true,
     "given": [
       "$..[?(@.type==\"array\")]"
     ]
   }
   ```

   where:
   - **description** is updated to a new title for the rule
   - **message** is updated to a new message for the rule
   - **formats** array is replaced to have only the format oas3 for the rule
   - **severity** is updated to the warn value for the rule
   - **recommended** is updated to have a new value for the rule
   - **given** array is replaced to have new values for the rule
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the rule.
3. Run the **rules:update** toolkit command in **governance** mode.
   There are two ways to specify the updated rule in the command, depending on whether you provide the rule name and version, or the rule ID:

   Specify the rule name and version in the update command

   ```
   apic -m governance rules:update --org <target_org> --server <platform_api_host_name> --ruleset <ruleset_name or ruleset_id> NAME:VERSION RULE_FILE
   ```

   where:
   - ***<target_org>*** is the name of the organization that owns the rule.
   - ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
   - ***<ruleset_name or ruleset_id>*** is the name or the unique ID of the ruleset to which the updated rule belongs.
   - **NAME** is the name of the updated rule.
   - **VERSION** is the version of the updated rule; increase the version when you update the rule, using the **major.minor.patch** format as in "1.0.1".
   - **RULE_FILE** is the path and filename of the JSON file that contains the updated rule.

   Specify the rule ID in the update command

   Instead of providing the rule's name and version, you can provide its unique ID instead by running the following command:

   ```
   apic -m governance rules:update --org <target_org> --server <platform_api_host_name> --ruleset <ruleset_name or ruleset_id> --id <rule_id> RULE_FILE
   ```

   where:
   - ***<target_org>*** is the name of the organization that owns the rule.
   - ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
   - ***<ruleset_name or ruleset_id>*** is the name or the unique ID of the ruleset to which the update rule belongs.
   - **RULE_FILE** is the path and filename of the JSON file that contains the updated rule.
   - ***<rule_id>*** is the value of the updated rule's unique ID.
     To determine the ID of a rule, run the following command:

     ```
     apic -m governance rules:list --org <target_org> --server <platform_api_host_name> --ruleset <ruleset_name> RULE_NAME
     ```

Scanning your catalogs and spaces

How to use the governance service to run validation scans on your catalogs and spaces. You can run scans on both the APIs and the products within your catalogs and spaces.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. For more information, see Enabling governance on Kubernetes for more information. If governance is enabled in your deployment, the Governance icon  is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

One of the following roles is required to be able to run validation scans:

- Organization administrator
- Owner
- Custom role with the **Settings: Manage** permission.

About this task

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API development process. The governance service contains the following types of rulesets:

The governance service contains the following types of rulesets:

API

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
- Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. The Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
- Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

You can create your own provider organization rulesets to validate your swagger, OpenAPI, and AsyncAPI documents against, as well as product documents, or use any global rulesets that are provided by default. For more information about configuring rulesets, see Configuring governance in the API Manager.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Validation scanning can be run on one or more API or product documents, or on a single catalog or space. The following instructions describe how to run validation scans on a catalog or space by using the API Manager UI, or the toolkit CLI. For more information about how to run validation scans on one or more API or product documents, see Validating an API or product document by using governance.

Note:

- You can select only one catalog or space to run each validation scan on. However, you can run multiple scans at the same time.
- You can also run a validation scan from within a catalog or space. Open the catalog or space that you want to scan, and then select the Governance tab. Ensure that the Scans is selected, click API or Product depending on what you want to scan, and then click New scan, and follow the scan wizard.
- Validation scanning by catalog or space is not available in the API Designer UI.

- Running a validation scan using the API Manager UI.
- Running a validation scan using the toolkit CLI.

CAUTION:
Scanning catalogs or spaces that contain more than a hundred API or product documents, and using many rulesets for the scan, can take hours to complete, and might time out before completion depending on the workload on your server. Only one document can be scanned at a time, and the more rulesets that are applied, the longer each individual scan will take. In this scenario, consider selecting only a few rulesets for each scan.

Procedure

- Running a validation scan by using the API Manager UI.
  1. In the side menu bar, click Governance.
     The Governance page is displayed.
  2. Ensure the Scans tab is selected, click API or Product depending on what you want to scan, and click New scan.
     The New validation scan wizard opens.
  3. Select the catalog that you want to scan, and click Next.
  4. Optional: If spaces are enabled on the catalog, you can then select the space that you want to scan, and click Next.
  5. Select one or more rulesets, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select one or more rules, and click Next.
  7. Enter a title for the scan, or accept the default title, and click Start scan.
     Your scan is started, and appears in the list of scans in the Catalog and space validation table. The scan Status is initially set to Queued, then changes to In progress, and then changes to Complete when it's finished. Note that scans containing a lot of data can take a long time to complete.
  8. When your scan is finished, you have the following options:
     - You can see a Summary of the scan in the table. If there were findings in the report, the summary displays the number of Errors, Warnings, or Hints in the validation, and also how many Rulesets were run in the scan.
     - You can click the scan Title, or click the options menu icon ⋮ next to the scan and select View to view the scan dashboard. The dashboard shows a scorecard summary of the scan, as well as detailed information about any messages and their severity.
- Running a validation scan by using the toolkit CLI.
  1. Create a JSON COMPLIANCE_REQUEST_FILE that specifies the location of the catalog or space and the rulesets to use during the validation scan.
     For example,:

```
{
  "collectionUrl": "https://server/api/catalogs/org/catalog",
  "config": {
    "rulesets": [
      {
        "rulesetName": "spectral-oas",
        "disabled": ["info-contact"]
      },
      {
        "rulesetName": "spectral-owasp",
        "disabled": []
      }
```

```
    ]
  }
}
```

Where:

- **collectionUrl** is the URL of the catalog or space that contains the API documents that you want to run a validation scan on, where ***server*** is the server URL, ***org*** is the name or ID of the provider organization, and ***catalog*** is the name or ID of the catalog or space. For example: **https://localhost:3003/api/catalogs/alpha/sandbox**.
- **rulesets** contains a list of the rulesets to be applied to the APIs during the validation scan.
  For each ruleset in the list, you can optionally add the **disabled** property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization.
   For example,:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
   For full details of the **apic login** command, see Logging in to a management server.

3. In the **governance** mode, run the **compliance:scan** command:

```
apic --mode governance compliance:scan --scope org --org <target_org> --server <platform_api_host_name>
COMPLIANCE_REQUEST_FILE
```

   Where:

   - **scope** is the scope of the scan, and must be set to **org** for a catalog or space validation scan.
   - ***<target_org>*** is the name of the provider organization that contains the catalog or space that you want to rescan.
   - ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
   - ***COMPLIANCE_REQUEST_FILE*** is the path and file name of the JSON file that contains the configuration details for the validation scan. For example, ./documents/validate-apis.json.

   This command runs a scan on your APIs.
   To run a scan on your products, you must add the optional parameter of **--scan_type** with a value of **product** to the command. For example,

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name
./documents/validate-products.json --scan_type product
```

   you can use the value **api** to scan only APIs, or **product** to scan only products. If omitted, only APIs are scanned.
   The following optional parameter enables you to refine the results of this command.

   - **--scantitle *scan_title*** is an optional flag that changes the retrieved scan's title to the value that you provide.

   For example,

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name
./documents/validate-apis.json --scantitle scan1
```

4. After the scan is finished, the results of the scan are printed to the screen. For more information about toolkit scan commands, see Using the toolkit CLI to scan your catalogs and spaces.

Results

Your validation scan is now listed in the Catalog and space validation table in the API Manager UI.

What to do next

When your scan is complete, the following options are available from within the dashboard UI:

- Click Export to export all of the scan data as a .csv file.
- Click Re-run scan to generate a new scan report based on the same configuration data. Each run of the same scan generates a new report.
- The date and time of each scan report is displayed at the beginning of the dashboard, and if you have run more than one scan, you can select which scan report you want to view from the Scanned date list.
- From the options menu ⋮, you can select Rename or Delete.
- You can view each of the scorecard charts in tabular form, and download that data as .csv files.
- You can use the filter options on the table of messages to display the data that you require, and you can also change the sort order of the columns.

- **Using the toolkit CLI to scan your catalogs and spaces**
  How to use the IBM API Connect toolkit CLI to run governance validation scans on your catalogs and spaces.

Using the toolkit CLI to scan your catalogs and spaces

How to use the IBM® API Connect toolkit CLI to run governance validation scans on your catalogs and spaces.

About

API governance is an API Connect service that can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your catalogs and spaces. For more information about validation scanning, see Scanning your catalogs and spaces.

The following sections detail how to run validation scan commands by using the toolkit CLI.

CAUTION:
Scanning catalogs or spaces that contain more than a hundred API or product documents, and using many rulesets for the scan, can take hours to complete, and might time out before completion depending on the workload on your server. Only one document can be scanned at a time, and the more rulesets that are applied, the longer each individual scan will take. In this scenario, consider selecting only a few rulesets for each scan.

Logging in to the toolkit CLI

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server platform_api_host_name --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

Running compliance:scan commands

The following commands detail how to run a compliance scan on a catalog or space.

1. Create a JSON COMPLIANCE_REQUEST_FILE that specifies the location of the catalog or space and the rulesets to use during a validation scan.
   For example,:

   ```
   {
     "collectionUrl": "https://server/api/catalogs/org/catalog",
     "config": {
       "rulesets": [
         {
           "rulesetName": "spectral-oas",
           "disabled": ["info-contact"]
         },
         {
           "rulesetName": "spectral-owasp",
           "disabled": []
         }
       ]
     }
   }
   ```

   Where:
   - `collectionUrl` is the URL of the catalog or space that contains the API documents that you want to run a validation scan on, where `server` is the server URL, `org` is the name or ID of the provider organization, and `catalog` is the name or ID of the catalog or space. For example: `https://localhost:3003/api/catalogs/alpha/sandbox`.
   - `rulesets` contains a list of the rulesets to be applied to the APIs during the validation scan.
     For each ruleset in the list, you can optionally add the `disabled` property with a comma-delimited list of rules to ignore during validation.

2. Run a validation scan by using the **compliance:scan** command.

   ```
   apic --mode governance compliance:scan --scope org --org <target_org> --server <platform_api_host_name>
   COMPLIANCE_REQUEST_FILE
   ```

   Where:
   - `scope` is the scope of the scan, and must be set to `org` for a catalog or space validation scan.
   - `<target_org>` is the name of the provider organization that contains the catalog or space that you want to rescan.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").

Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
- ***COMPLIANCE_REQUEST_FILE*** is the path and file name of the JSON file that contains the configuration details for the validation scan. For example, ./documents/validate-apis.json.

This command runs a scan on your APIs.
To run a scan on your products, you must add the optional parameter of **--scan_type** with a value of **product** to the command. For example,

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name ./documents/validate-products.json --scan_type product
```

you can use the value **api** to scan only APIs, or **product** to scan only products. If omitted, only APIs are scanned.
The results of the scan are printed to the screen.
The following optional parameter enables you to refine the results of this command.
- **--scantitle *scan_title*** is an optional flag that changes the retrieved scan's title to the value that you provide.

For example,

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name ./documents/validate-apis.json --scantitle scan1
```

3. Rerun an existing validation scan by using the **compliance:rescan** command.
A scan rerun creates a new report for that scan, but uses the same configuration of catalog or space and rulesets that was used in the previous scan.

```
apic --mode governance compliance:rescan --scope org --org <target_org> --server <platform_api_host_name> --scan <scan_name_or_scan_id>
```

Where:
- **scope** is the scope of the scan, and must be set to **org** for a catalog or space validation scan.
- ***<target_org>*** is the name of the provider organization that contains the catalog or space that you want to rescan.
- ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
- ***scan_name_or_scan_id*** is the name or ID of the existing scan that you want to run again.

The following optional parameter enables you to refine the results of this command.
- **--scantitle *scan_title*** is an optional flag that changes the title of the rescan to the value you provide.

For example:

```
apic --mode governance compliance:rescan --scope org --org my_org --server my_platform_api_host_name ./documents/validate-apis.json --scantitle scan2
```

Running scans commands

The following commands detail how to manage and update your validation scans.

1. List all validation scans that exist for a specific provider organization by using the **scans:list** command.
The return includes information about all of the validation scans, and some information about their scan reports, but if you want more detailed information about the reports, use the **scan-reports:list** command.

```
apic --mode governance scans:list --scope org --org <target_org> --server <platform_api_host_name>
```

Where:
- **scope** is the scope of the scan, and must be set to **org** for a catalog or space validation scan.
- ***<target_org>*** is the name of the provider organization that you want a list of scans for.
- ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).

The following example shows the sample output for a list containing two scans, one of APIs, and one of products:

```
total_results: 2
results:
  - type: 'scan'

```
    url: 'https://test.ibm.com/governance/orgs/6d3d9ffa-37e3-4da7-be6b-a1c34b41476f/scans/ddc5da81-0db0-425c-b74c-5fc8300934e6'
```

Where `scan_type: '1'` refers to an API scan, and `scan_type: '2'` refers to a product scan.
The following optional parameters enable you to refine the results of this command.

- `--status status_number` is a comma separated list of status codes to filter the list of scans by.

  Table 1. Table of valid status codes

Code	Status
0	Queued
1	Complete
2	In progress
-1	Error

- `--type catalog_or_space` lists the scans that are of the type `catalog` or `space`.
- `--scan_type api_or_product` is an optional flag to specifically list the scans of only APIs or only products. Use the value `api` to list only API scans, or `product` to list only product scans. If omitted, both API and product type scans are listed.
- `--collections list_of_collections` is a comma separated list of catalog or space IDs or names to filter the list of scans by.
- `--limit number_of_results` specifies how many scan results to return.
- `--fields list_of_fields` is a comma separated list of field names to return. Note that no spaces are allowed after a comma, and if you want to return only one field you must omit the comma. For example, running the following command:

  ```
  apic --mode governance scans:list --scope org --org <target_org> --server <platform_api_host_name> --fields id,title
  ```

  Returns the data in the following way:

  ```
  total_results: 2
  results:
    - id: 'e0b8afbd-e5fa-486e-8800-343e1e31faf1'
      title: 'e0b8afbd-e5fa-486e-8800-343e1e31faf2'
    - id: '436d9db5-ea45-4d91-96c4-cef5957a2c34'
      title: '436d9db5-ea45-4d91-96c4-cef5957a2c34'
  ```

For example:

```
apic --mode governance scans:list --scope org --org demo -s test.ibm.com --collections cat1 --type catalog --status 1
```

2. Get a specific scan using the **scans:get** command:

   ```
   apic --mode governance scans:get --scope org --org <target_org> --server <platform_api_host_name> SCAN
   ```

   Where:
   - `scope` is the scope of the scan, and must be set to `org` for a catalog or space validation scan.
   - `<target_org>` is the name of the provider organization that contains the scan that you want to get.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `SCAN` is the ID or name of the scan that you want to retrieve.

   The scan results are downloaded to the directory where the command was run.
3. Update the scan `title` and `summary` properties by creating a SCAN_FILE with the information to be updated, and running the `scans:update` command.

   ```
   apic --mode governance scans:update --scope org --org <target_org> --server <platform_api_host_name> SCAN SCAN_FILE
   ```

   Where:
   - `scope` is the scope of the scan, and must be set to `org` for a catalog or space validation scan.
   - `<target_org>` is the name of the provider organization that contains the scan that you want to update.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `SCAN` is the ID or name of the scan that you want to update.
   - `SCAN_FILE` is the path to a JSON file that contains the properties to be updated.

   The `SCAN_FILE` can contain the following properties:

   ```
   {
     "title": "<updated_title>",
     "summary": "<updated_summary>"
   }
   ```

4. Delete a scan by using the **scans:delete** command. This command deletes the specified scan and all of its reports.

   ```
   apic --mode governance scans:delete --scope org --org <target_org> --server <platform_api_host_name> SCAN
   ```

   Where `SCAN` is the ID or name of the scan that you want to update.
5. Delete all of the scans for a particular provider organization by using the **scans:clear** command. This command clears all of the scans and all of their reports for the specified organization.

   ```
   apic --mode governance scans:clear --scope org --org <target_org> --server <platform_api_host_name> --confirm organisation_confirmed
   ```

   Where `organisation_confirmed` is the name of the provider organization again, to confirm that you want to clear all of the scans from this organization.

Running scan-reports commands

The following commands detail how to manage and update your scan reports.

1. List all of the scan reports for a particular provider organization by using the **scan-reports:list** command.

```
apic --mode governance scan-reports:list --scope org --org <target_org> --server <platform_api_host_name>
```

The following optional parameters enable you to refine the results of this command.

- `--fields list_of_fields` is a comma separated list of field names to return. Note that no spaces are allowed after a comma, and if you want to return only one field you must omit the comma. For example, running the following command:

  ```
  apic --mode governance scan-reports:list --scope org --org <target_org> --server <platform_api_host_name> --fields id,title
  ```

  Returns the data in the following way:

  ```
  total_results: 2
  results:
    - id: '3e3189a3-6359-4113-9cf9-9bde9f303884'
      title: '3e3189a3-6359-4113-9cf9-9bde9f303882'
    - id: '58a975cf-a503-4297-9450-237db102cb24'
      title: '58a975cf-a503-4297-9450-237db102cb24'
  ```

- `--limit number_of_results` specifies how many scan report results to return.

2. Get a specific scan report by using the **scans:get** command.

   ```
   apic --mode governance scan-reports:get --scope org --org <target_org> --server <platform_api_host_name> SCAN_REPORT
   ```

   Where `SCAN_REPORT` is the ID or name of the scan report.
   The scan report results are downloaded to the directory where the command was run.

3. Update the scan report `summary` property by creating a SCAN_REPORT_FILE with the information to be updated, and running the `scan-reports:update` command.

   ```
   apic --mode governance scan-reports:update --scope org --org <target_org> --server <platform_api_host_name> SCAN_REPORT SCAN_REPORT_FILE
   ```

   Where:
   - `SCAN_REPORT` is the ID or name of the scan report that you want to update.
   - `SCAN_REPORT_FILE` is the path to a JSON file that contains the properties to be updated.

   The `SCAN_REPORT_FILE` can contain the following properties:

   ```
   {
     "summary": "updated_summary"
   }
   ```

4. Delete a scan report by using the **scan-reports:delete** command. This command deletes the specified scan report, and removes the reference to it from the scan. Note that you cannot delete the last report in a scan. If you want to delete all of the reports of a scan, you must delete the scan itself by using the **scans:delete** command.

   ```
   apic --mode governance scan-reports:delete --scope org --org <target_org> --server <platform_api_host_name> SCAN_REPORT
   ```

   Where `SCAN_REPORT` is the ID or name of the scan report that you want to delete.

Administering user access

If you have permission to administer users in IBM® API Connect, you can add and delete users. After users are removed from an organization through deletion, the user account remains in API Manager.

About this task

You can also authorize users to perform different roles within your organization. To make any changes to the users that can access your organizations, use the followings tasks:

- **Setting the expiration for invitations**
  Set a timeout for invitations to expire.
- **Configuring notifications**
  Specify the sender name and email address to use for email notifications. If necessary, you can preview the templates and customize the text if required. You can also style the notifications to match your business theme.
- **Viewing your user information**
  You can view the users that can access your IBM API Connect organization.
- **Adding provider organization users and assigning roles**
  If you have the permissions that are required to edit users in API Connect, you can add users to your provider organization, remove users, assign roles and perform other user administration tasks.
- **Creating custom roles**
  If you have permission to edit roles in IBM API Connect, you can create custom roles, and assign permissions, in a provider organization. You can create as many custom roles as you want.
- **Removing a user from a provider organization**
  If you have permission to edit users, you can remove a user from a provider organization.
- **Configuring LDAP group mappings on API Manager user roles**
  As an API Manager administrator, you can configure LDAP group mapping on API Connect roles in a provider organization by using the developer toolkit CLI.

Setting the expiration for invitations

Set a timeout for invitations to expire.

About this task

Invitations contain a link, which expires after the specified timeout.

Procedure

1. In API Manager, click Settings.
2. In the Settings navigation list, click Onboarding, then click Edit.
3. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
4. Click Save.

Configuring notifications

Specify the sender name and email address to use for email notifications. If necessary, you can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

About this task

The API Manager emails are sent automatically when certain system events occur. The scope determines how the email templates are organized, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
catalog	Activities related to Catalogs; such as application lifecycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations.
space	Invitations.

Email notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used are the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see Configuring sender details for email notifications.

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Settings:Manage` permission

Note: You can also customize notifications by using the developer toolkit CLI, or by using the API Connect REST APIs. For more information, see API development and management commands or API Connect REST APIs.

Procedure

1. In API Manager, click Settings.
2. In the Settings navigation list, click Notifications, then click Edit.
3. Specify a sender by entering a Name and Email address, then click Save.
   To configure sender details at the Space or Catalog levels, you must use the developer toolkit CLI. For more information, see Configuring sender details for email notifications.
4. Optional: To enable template customization, move the Customize notification templates slider to the On position.
   Note: You can reload all the default notifications, as configured by a cloud administrator, by disabling and reenabling template customization. However, doing so overwrites any customizations that have been made. For more information about customizing notifications as a cloud administrator, see Customizing email notification templates.
5. To preview the text for a template, select Preview from the options menu alongside the template name.
6. To edit the text for the template, either click the template name, or select Edit in the options menu alongside the template name.
   When a template is opened, an attempt is made to get the language from the browser setting, but if this isn't possible the template defaults to English.

   The text includes variables; for example, `{{catalog}}`. The notification text is based on handlebars syntax. Most variables are enclosed in double curly braces `{{ }}`, but can be enclosed in triple curly braces `{{{ }}}` to disable HTML escaping, when the variable is a URL link for example. For more information about handlebars, see https://handlebarsjs.com/.

   To obtain the complete list of variables that are available for a particular notification template, complete the following steps:
   a. Log in to the management server from the command line as a member of a provider organization. For more information, see Logging in to a management server. You can use the same management server URL, username, and password in the login command that you use to log in to the API Manager user interface.
   b. Enter the following command:

      ```
      apic notification-templates:get template_name --server mgmt_endpoint_url --scope org --org provider_organization --subcollection template_scope --fields variables --output -
      ```

      Where:
      - *template_name* is the name of the required notification template, as displayed in the Template column in the user interface.
      - *template_scope* is the scope name displayed in the Scope column alongside that template.
      - *provider_organization* is the value of the `name` field for your provider organization.

      For example,

```
apic notification-templates:get member-invitation --server https://myserver.com --scope org --org myorg --
subcollection catalog --fields variables --output -
```

The variables that are available for the template are displayed, for example:

```
variables:
  - org
  - catalog
  - activationLink
  - expiresAt
  - originator
  - originatorFirstName
  - originatorLastName
  - originatorEmail
  - username
  - email
  - firstName
  - lastName
```

The **--output -** parameter causes the command output to be written to the command line. You can specify **--output *filepath*** to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.

7. To view and edit the notification template in a different language, select one of the following supported languages from the View template in drop-down list:
   - Chinese (Simplified)
   - Chinese (Traditional)
   - Czech
   - Dutch
   - English (US English)
   - French
   - German
   - Italian
   - Japanese
   - Korean
   - Polish
   - Portuguese
   - Russian
   - Spanish
   - Turkish
8. Edit the Subject as required.
9. Select the Content type that you want to use for the template, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
10. Edit the body of the template as required.
    For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 2. Allowed HTML tags and attributes

HTML tag	Attribute
<a>	**"class", "href", "hreflang", "style"**
****	**"class", "style"**
****	**"class", "style"**
<cite>	**"class", "style"**
<blockquote>	**"class", "cite", "style"**
<code>	**"class", "style"**
** **	**"class", "type", "style"**
** **	**"class", "start", "type", "style"**
** **	**"class", "style"**
<dl>	**"class", "style"**
<dt>	**"class", "style"**
<dd>	**"class", "style"**
<h1>	**"class", "id", "style"**
<h2>	**"class", "id", "style"**
<h3>	**"class", "id", "style"**
<h4>	**"class", "id", "style"**
<h5>	**"class", "id", "style"**
<h6>	**"class", "id", "style"**
<p>	**"class", "style"**
** **	**"class", "style"**
** **	**"class", "style"**
****	**"class", "style"**
<img>	**"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"**
<table>	**"class", "id", "style"**
<tr>	**"class", "id", "style"**
<td>	**"class", "id", "style"**

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **** tag in the template. The **src** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images. They must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

11. Click Save when done.
    Note: Edits made to a template are saved only for the specific language version that is edited.

- **Configuring sender details for email notifications**
  Understand how the hierarchical search works for the email notification sender details, and how you can configure sender details at the Space and Catalog level.

Configuring sender details for email notifications

Understand how the hierarchical search works for the email notification sender details, and how you can configure sender details at the Space and Catalog level.

Before you begin

One of the following roles is required to configure sender details for email notifications:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` or `Settings:Manage` permission

For more information about the notification templates, their scope, and how to customize them, see Configuring notifications at the Provider Organization level, and Customizing email notification templates at the Cloud Manager level.

About this task

API Connect sent email notifications automatically when certain system events occur. These notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template that's being sent, the search can start at the Space level, the Catalog level, the Provider Organization level, or the Cloud level. The sender details that are used are the first set of configured details that are found during the hierarchical search.
The following table shows the starting point for the sender details hierarchical search for each email template, ordered by the scope of the template, where:

- Cloud: emails are sent from the details that are configured in the Settings > Notifications section of the Cloud Manager.
- Org: the search for sender details starts at the Provider Organization level; if not available, the Cloud details are used.
- Catalog: the search for sender details starts at the Catalog level; if not available, the Org details are used, and if they're not available, the Cloud details are used.
- Space: the search for sender details starts at the Space level; if not available, the Catalog details are used, if they're not available, the Org details are used, and if they're not available, the Cloud details are used.
- Space or Catalog: in these cases the search starts at the Space level, or at the Catalog level, depending on the user that made the request, as shown in the following list:
  - When a user starts the product lifecycle change in a Space, the search for sender details starts at the Space level.
  - When a user starts the product lifecycle change in a Catalog, the search for sender details starts at the Catalog level.
  - When a user approves the product lifecycle in a Space, the search for sender details starts at the Space level.
  - When a user approves the product lifecycle change in a Catalog, the search for sender details starts at the Catalog level.

Table 1. Starting point for the sender details search for each email template

Scope	Template name	Email subject	Sender details
admin	mail-server-test-connection	Test message from IBM® API Connect.	Cloud
admin	member-invitation	Invitation to an admin organization in IBM API Connect.	Cloud
admin	password-changed	Password changed for your user account in IBM API Connect.	Cloud
admin	password-reset	Password reset request for your user account in IBM API Connect.	Cloud
provider	invitation	Invitation to create an API provider organization in IBM API Connect.	Cloud
provider	member-invitation	Invitation to an API provider organization in IBM API Connect.	Org
catalog	app-lifecycle-cancelled	Request withdrawn to *{{action}}* app *{{appName}}*.	Catalog
catalog	app-lifecycle-request	Request for approval to *{{action}}* app *{{appName}}*.	Catalog
catalog	invitation	Invitation to create an API catalog in IBM API Connect.	Org
catalog	member-invitation	Invitation to an API catalog in IBM API Connect.	Catalog
catalog	task-consumer-onboard-request	Consumer onboarding request in the *{{catalog}}* Developer Portal .	Catalog
catalog	task-product-lifecycle-approved	Request approved to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-cancelled	Request withdrawn to *{{action}}* an API product in the *{{catalog}}* catalog.	Space or Catalog
catalog	task-product-lifecycle-denied	Request denied to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-pending	Request received to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-request	Request for approval to *{{action}}* an API product in the *{{catalog}}* catalog.	Space or Catalog
catalog	task-subscription-cancelled	Request withdrawn to subscribe to an API product in the *{{catalog}}* catalog.	Catalog
catalog	task-subscription-request	Request for approval to subscribe to an API product in the *{{catalog}}* catalog.	Catalog
space	invitation	Invitation to create an API space in IBM API Connect.	Catalog
space	member-invitation	Invitation to an API space in IBM API Connect.	Space
consumer	account-approved	*{{catalogTitle}}* Developer Portal account registration is approved.	Catalog
consumer	account-denied	*{{catalogTitle}}* Developer Portal account registration is denied.	Catalog
consumer	account-pending-approval	*{{catalogTitle}}* Developer Portal account registration pending approval.	Catalog
consumer	app-lifecycle-approved	Request approved to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-lifecycle-denied	Request denied to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-lifecycle-pending	Request received to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-reinstated	*{{appName}}* app reinstated in the *{{consumerOrg}}* Developer Portal .	Catalog
consumer	app-suspended	*{{appName}}* app suspended in the *{{consumerOrg}}* Developer Portal .	Catalog
consumer	invitation	Invitation to create an API consumer organization in the *{{catalog}}* Developer Portal .	Catalog
consumer	member-invitation	Invitation to an API consumer organization in the *{{catalog}}* Developer Portal .	Catalog
consumer	password-changed	Password changed for your user account in *{{portalTitle}}* Developer Portal .	Catalog
consumer	password-reset	Password reset request for your *{{catalog}}* Developer Portal account.	Catalog
consumer	sign-up	*{{catalogTitle}}* Developer Portal account registration.	Catalog
consumer	task-subscription-approved	API subscription request approved for app *{{appName}}*.	Catalog

Scope	Template name	Email subject	Sender details
consumer	task-subscription-denied	API subscription request denied for app *{{appName}}*.	Catalog
consumer	task-subscription-pending	API subscription request received for app *{{appName}}*.	Catalog

The sender address details can be configured at four levels: Cloud, Provider Organization, Catalog, and Space, and you can set a different sender address for each Provider Organization, Catalog, or Space, as required. The sender address for the Cloud can be configured in the Cloud Manager UI; see Setting up notifications for details. The sender address for the Provider Organization can be configured in the API Manager UI; see Configuring notifications for details. However, the sender address for Catalogs and Spaces can be configured only by using the toolkit CLI, as explained in the following steps.

Procedure

1. Log in to the management server from the command line as a member of a provider organization. For more information, see Logging in to a management server. You can use the same management server URL, username, and password in the login command that you use to log in to the API Manager user interface.
2. To update the sender address details for a Space, run the following commands.
   a. Run the `apic space-settings:get` command to read the current Space settings and output them to a json file. For example, :

   ```
   apic space-settings:get --server my_mgt_server --org my_provider_org --catalog my_catalog --space my_space --format
   json
   ```

   Where:
   - *my_mgt_server* is your management server endpoint or URL.
   - *my_provider_org* is the name of your Provider Organization.
   - *my_catalog* is the name of your Catalog.
   - *my_space* is the name of your Space.

   b. Make a copy of the output file that you can then use to update the settings, for example:

   ```
   cp space-setting.json space-setting-update.json
   ```

   c. Edit the copied settings file to update the `email_sender` block. For example, :

   ```
   vi space-setting-update.json
   ...
     "email_sender": {
       "custom": true,
       "name": "NO REPLY: space sender name",
       "address": "space_sender_email@nomail.com"
     },
   ...
   ```

   Where:
   - `custom` must be changed from the default setting of `false` to `true`.
   - The `name` line must be added to the file, and the *space sender name* details completed.
   - The `address` line must be added to the file, and the *space_sender_email@nomail.com* address details completed.

   Note: Ignore other configuration details that are contained in this settings file.
   d. Run the `space-settings:update` command to update the Space settings with the new sender address details. For example, :

   ```
   apic space-settings:update --server my_mgt_server --org my_provider_org --catalog my_catalog --space my_space space-
   setting-update.json
   ```

   Where *space-setting-update.json* is the name of your updated settings file.
3. To update the sender address details for a Catalog, run the following commands.
   a. Run the `apic catalog-settings:get` command to read the current Catalog settings and output them to a json file. For example,

   ```
   apic catalog-settings:get --server my_mgt_server --org my_provider_org --catalog my_catalog --format json
   ```

   Where:
   - *my_mgt_server* is your management server endpoint or URL.
   - *my_provider_org* is the name of your Provider Organization.
   - *my_catalog* is the name of your Catalog.

   b. Make a copy of the output file that you can then use to update the settings, for example:

   ```
   cp catalog-setting.json catalog-setting-update.json
   ```

   c. Edit the copied settings file to update the `email_sender` block. For example:

   ```
   vi catalog-setting-update.json
   ...
     "email_sender": {
       "custom": true,
       "name": "NO REPLY: catalog sender name",
       "address": "catalog_sender_email@nomail.com"
     },
   ...
   ```

   Where:
   - `custom` must be changed from the default setting of `false` to `true`.
   - `name` line must be added to the file, and the *catalog sender name* details completed.
   - `address` line must be added to the file, and the *catalog_sender_email@nomail.com* address details completed.

   Note: Ignore other configuration details that are contained in this settings file.
   d. Run the `catalog-settings:update` command to update the Catalog settings with the new sender address details. For example:

   ```
   apic catalog-settings:update --server my_mgt_server --org my_provider_org --catalog my_catalog catalog-setting-
   update.json
   ```

   Where *catalog-setting-update.json* is the name of your updated settings file.

Results

You now understand how the hierarchical search works for the sender details for each email template, and can update the sender details at the Space and Catalog level as required.

Viewing your user information

You can view the users that can access your IBM® API Connect organization.

Procedure

To view your organization user information, complete the following steps:

In the navigation pane of the API Manager user interface, click Members.

What to do next

You can modify your user accounts; see Adding provider organization users and assigning roles. You can create custom roles; see Creating custom roles.

Adding provider organization users and assigning roles

If you have the permissions that are required to edit users in API Connect, you can add users to your provider organization, remove users, assign roles and perform other user administration tasks.

About this task

There are two ways to add a user:

- Invite member - send an invitation email with an activation link that enables the user to complete the addition operation.
- Add member - specify the user and add them as a member of the provider organization immediately.

Procedure

- To send an email invitation to a new user to register as a member of the provider organization, complete the following steps:
  1. In the navigation pane of the API Manager user interface, click Members.
  2. Click Add > Invite member.
  3. Enter the email address of the user.
  4. Select the roles that you want to assign to the user.
  5. Click Invite.
- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:
  1. In the navigation pane of the API Manager user interface, click Members.
  2. Click Add > Add member.
  3. Select the required user registry.

     Note: For a user registry to be available in the selection list, one of the following conditions must be satisfied:
     - The visibility of the user registry is set to Public.
     - The visibility of the user registry is set to Custom, and the specified list of provider organizations includes the one to which you are adding the user.

     For more information, see Setting visibility for a user registry.

     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Select the roles that you want to assign to the user, then click Add. The user is added and their membership is immediately enabled. The specified user can log in to the API Manager user interface.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Select the roles that you want to assign to the user, then click Add. The user account is created, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface with their LDAP user name.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface.

Results

The user is added to the list of provider organization members. If an email invitation was sent, the status is shown as `Pending` until the recipient of the email clicks the link in the email to complete the creation of their account, after which the status changes to `Enabled`.

What to do next

The new user can access the API Manager user interface. The user's authorization within API Manager is defined by the roles that are assigned to them.

Related tasks

- Creating custom roles

Creating custom roles

If you have permission to edit roles in IBM® API Connect, you can create custom roles, and assign permissions, in a provider organization. You can create as many custom roles as you want.

About this task

You create custom roles at the provider organization level; those roles are inherited by the Catalogs and Spaces in the provider organization. You can assign permissions at the provider organization, Catalog or Space level.

For a description of the permissions, and details of the default user roles and default permissions assigned to those roles, see API Connect user roles.

Note: In API Manager, the Organization Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

Procedure

To create a custom role, complete the following steps:

1. In the navigation pane of the API Manager user interface, click Settings
2. Click Roles, then click Add.
   The Create a Role page opens.
3. Enter a role Title and an optional Summary. A Name is entered automatically.
   Note: The value in the Name field is a single string that is used to identify the role in developer toolkit CLI commands. The Title is used for display.
   To view the CLI commands to manage roles, see the toolkit CLI reference documentation.
4. Use the check boxes to assign permissions to the new role.
5. When you are finished, click Save.
6. To delete a role, click the options icon ⋮ alongside the role that you want to delete, click Delete, then click Delete again to confirm the role deletion.
   Note:
   - You can create and delete a role only at the provider organization level. You cannot create or delete a role at the Catalog level. Nor can you create or delete a role at the Space level.
     You can, however, assign Catalog-specific permissions to the role; for details, see Creating and configuring Catalogs. You can also assign Space-specific permissions; for details, see Managing user access in a Space; for more information on Spaces, see Using syndication in API Connect.
   - If you assign Product-Drafts or Api-Drafts permissions to the role, these permissions are not inherited by the role in a Catalog or Space. These permissions apply to working with draft Products and APIs in a provider organization and are not relevant in a Catalog or Space.

Results

The custom role is created and assigned the permissions that you selected.

What to do next

Assign the custom role to a user.

Removing a user from a provider organization

If you have permission to edit users, you can remove a user from a provider organization.

About this task

After you have removed the user from your IBM® API Connect provider organization, their resources are deleted and the user cannot access any of the organization's artifacts.
Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the API Manager user interface but only information links are available; there is no access to view or manage any resources.
If you later invite the same user again, they can re-activate their account. If you are using a Local User Registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. For details on how to invite a user to join your organization, see Adding provider organization users and assigning roles.

Procedure

To remove a user from a provider organization complete the following steps:

1. In the navigation pane of the API Manager user interface, click Members.
2. Alongside the user that you want to delete, click the options icon , click Delete, the click Delete again to confirm the user deletion.
   Note: You cannot delete the owner of a provider organization.

Results

The user is removed from the provider organization, and the user account remains in API Manager.

Configuring LDAP group mappings on API Manager user roles

As an API Manager administrator, you can configure LDAP group mapping on API Connect roles in a provider organization by using the developer toolkit CLI.

Before you begin

You must have an LDAP user registry resource in the API Manager that has the **`external_group_mapping_enabled`** configuration set to **`true`**. See Using the CLI to create an organization-specific LDAP user registry for information.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Custom role with the `Settings: manage` permissions

Note: The provider organization roles apply only to API Manager users. If you want to apply LDAP group mapping to Cloud Manager users, see Configuring LDAP group mapping on Cloud Manager user roles. LDAP group mapping cannot be applied to Developer Portal users.

About this task

You can map external LDAP groups to the API Connect preconfigured user roles (except for the Owner and Member roles), as well as to any custom user roles, to reflect your business needs.

Notes:

- After LDAP group mapping is enabled on a role, user onboarding always honors the group mappings.
- Once on-boarded, user membership in API Connect is valid throughout the login period (**`access_token_ttl`**), irrespective of any changes in the external LDAP registry. Membership is updated only on the next login, when the LDAP information is fetched and refreshed.
- One or more API Connect roles can be mapped to one or more LDAP groups, and one or more LDAP groups can be mapped to a role.
- When multiple LDAP groups are mapped to a single role, it means that a user from any one of the LDAP groups can logon to API Connect.
- If a user is removed from the external LDAP user registry, to ensure quick removal from API Connect you must also delete the user membership in API Connect.
- In API Manager you can map roles at the provider organization, Catalog and, if appropriate, Space level. However, you can only map roles at the child level of Catalog, and then the Catalog's child level of Space, if the parent level also has group mapping defined. Mapping at a child level overrides the mapping for the same role at the parent level. For example:
  If the Administrator Role at the provider organization level is mapped to the LDAP group of **`cn=APIC-Administrators,ou=ibmgroups,o=ibm.com`**, and the Administrator Role at a Catalog level is mapped to the LDAP group of **`cn=APIC-Developers,ou=ibmgroups,o=ibm.com`**, then any user that is added as a Catalog member must belong to the **`cn=APIC-Developers,ou=ibmgroups,o=ibm.com`** group. Note that provider organization level members that belong to the **`cn=APIC-Administrators,ou=ibmgroups,o=ibm.com`** group can still access the Catalog due to inheritance.

You can configure LDAP group mappings using one of the following methods:

- Using the UI to configure LDAP group mappings
- Using the CLI to configure LDAP group mappings

Using the UI to configure LDAP group mappings

Use the API Manager UI to configure LDAP group mappings.

Procedure

1. Login to the API Manager as a user with the appropriate permissions.
2. Click Settings > Roles > Add a new Role or edit existing role .
3. Select the following settings:
   - Enable external group mapping - select to enable external group mapping for this role.
   - LDAP user Registry - LDAP user registry list which has external group mapping enabled. User must select one of the LDAP user registry from this list.
   - LDAP group names - add one or more LDAP group names that you want to map to the user role.
   - User group prefix - add the prefix for the LDAP user group.
   - User group suffix - add the suffix for the LDAP user group.
4. Save your changes.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the API Manager, and automatically be assigned the correct access permissions for their role.

Using the CLI to configure LDAP group mappings

Use the toolkit CLI to configure LDAP group mappings.

About this task

For detailed information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Procedure

Perform the following steps to map external LDAP groups to API Manager user roles.

1. Log in to the management server CLI.
   Before you can update the role configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   where `mgmt_endpoint_url` is the platform API endpoint URL.
   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the login command, see Logging in to a management server.

2. Run the following command to get the URL of the LDAP user registry resource in the API Manager that you want to map the user roles to:

   ```
   apic user-registries:get  ldap_user_registry --org organization_name --server mgmt_endpoint_url --output -
   ```

   where:
   - `ldap_user_registry` is the name or ID of your LDAP user registry resource.
   - `organization_name` is the value of the `name` property of your provider organization.
   - `mgmt_endpoint_url` is the platform API endpoint URL.

   This command outputs the configuration details of your LDAP user registry, and the `url:` is shown at the end of the list, for example:

   ```
   type: user_registry
   api_version: 2.0.0
   id: 35e75bad-1d89-4a65-a70f-xxxxxx
   name: ldap
   title: LDAP
   integration_url: >-
     https://server.com/api/cloud/integrations/user-registry/147b5fb1-e88e-41e3-90e9-xxxxxx
   registry_type: ldap
   user_managed: false
   user_registry_managed: false
   external_group_mapping_enabled: true
   ...
   url: >-
     https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
   ```

3. Create a role yaml file that contains the following LDAP group mapping configuration properties:

   ```
   external_group_mapping:
     user_registry_url: https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
     ldap_groups:
       - 'cn=apic-administrators,ou=ibmgroups,o=ibm.com'
       - 'cn=apic-developers,ou=ibmgroups,o=ibm.com'
     user_group_filter_prefix: (&(uniquemember=
     user_group_filter_suffix: )(objectClass=groupOfUniqueNames))
   ```

   Where:
   - `user_registry_url` is the URL of your LDAP user registry resource from Step #task_apim_role_mapping__ldap_url.
   - `ldap_groups` is a list of the LDAP group names that you want to map to the user role.
   - `user_group_filter_prefix` is the prefix for the LDAP user group.
   - `user_group_filter_suffix` is the suffix for the LDAP user group.

4. Run the following command to update the user role with the `external_group_mapping` configuration properties:

   ```
   apic roles:update role_name --scope org --org organization_name --server mgmt_endpoint_url mapping_properties_file
   ```

   Where:
   - `role_name` is the name of the user role that you want to add the LDAP group mapping to.
   - `--scope` is the organization level that you want the update to apply to. Valid values are:
     - `org` to apply the mapping at the provider organization level.
     - `catalog` to apply the mapping at the Catalog level.
     - `space` to apply the mapping at the Space level.

- ***organization_name*** is the value of the **name** property of your provider organization.
- ***mgmt_endpoint_url*** is the platform API endpoint URL.
- ***mapping_properties_file*** is the name of your mapping properties file from Step #task_apim_role_mapping__role_file, for example **role_mapping_file.yaml**.

If you prefer to enter the configuration properties interactively on the command line, you can substitute the ***mapping_properties_file*** for a terminating hyphen character **-**, and enter the information manually, followed by pressing **CTRL D** to terminate the input.
If you want to create a custom role that includes LDAP group mapping, you can include the **external_group_mapping** configuration section in the **role_file**, and then create the new role by using the **apic roles:create** command.

For more information about the **apic roles** commands, see the toolkit CLI reference documentation.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the API Manager, and automatically be assigned the correct access permissions for their role.

Changing your API Manager password

You can change your API Manager password in IBM® API Connect.

Procedure

To change your password, complete the following steps:

1. Log in to the API Manager user interface.
2. Click the User icon then click My Account.
3. In the Change password section, enter your current password and your new password, and confirm the new password.
   Passwords must satisfy the following requirements:
   - Cannot be re-used for at least 8 password cycles
   - Cannot contain more than 2 consecutive repeating characters
   - Must include at least 8 characters
   - Must include 1 or more characters from at least 2 of the following categories:
     - Lowercase letters
     - Uppercase letters
     - Numbers
     - Special characters – only the following special characters are allowed:

       ```
       !
       \"
       #
       $
       %
       &
       \
       (
       )
       *
       +
       ,
       -
       .
       /
       :
       ;
       <
       =
       >
       ?
       @
       [
       \\
       ]
       ^
       _
       `
       {
       |
       }
       ~
       ```
4. Click Change Password.

Results

Your password is changed.

Resolving login problems by increasing HTTP header size

You can resolve login problems for the API Manager UI by increasing the maximum HTTP client header size.

About this task

Login attempts to the user interface might fail with error **502 (Bad Gateway)**. This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaround this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

Procedure

1. **SSH** to your management system or appliance.
2. Enter the following commands:

```
kubectl get deployment -n namespace  | grep apim
kubectl edit deployment -n namespace management-apim
```

3. In the **env** section of the deployment configuration, change **--max-http-header-size=12000** to a larger value that works for your environment. For example:

```
 - name: NODE_OPTIONS
          value: --max-old-space-size=8094 --max-http-header-size=16000
```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `management-apim` pods are up and running.

API Gateway only

Reviewing processing status and downloading gateway logs

View and download the processing status information for the Gateway services that are enabled in your API Connect Catalogs and Spaces.

About this task

Check the status of API events processed by the gateway, and download gateway logs as needed. For example, you might want to check whether a Product was published and is available on the gateway before using one of its APIs. Or you might notice that API events are processing slowly and want to see if all events for a specific gateway service are affected.

When a user performs an action in API Manager, such as publishing, deprecating, or retiring a product. At this point, the status changes to an **in-progress** state:

- **published-in-progress**
- **deprecated-in-progress**
- **retired-in-progress**

API Manager then generates an event that corresponds to the action and sends it to the Gateway. Communication between API Manager and the Gateway is event-based and asynchronous.

After receiving the event, the Gateway attempts to apply the requested change:

- If the Gateway successfully applies the change, it sends a confirmation to API Manager. The product status then updates to a success state, such as **published-success**.
- If the Gateway fails to apply the change, it reports the failure to API Manager. The product status then updates to a failed state, such as **published-failed**.

For more information about the different statuses of a product compatible with DataPower® API Gateway, see Publishing a draft Product.
Use the API Manager user interface to view or download the processing status information for all the gateway services that are associated with a particular catalog or Space.

Notes: You can only obtain processing status information for the DataPower API Gateway. This feature is not supported for the DataPower Gateway (v5 compatible) service or the Event Gateway service.

Procedure

To check the status of API events processed by the gateway and download gateway logs, complete the following steps:

a. Log in to API Manager.
b. In the navigation pane, click Manage.
c. Select a catalog.
d. Click the Catalog settings tab or Spaces tab.
   - Catalog settings: if spaces are not enabled in your catalog, you can view the gateway processing status from the Catalog settings tab. To review the gateway processing status from the catalog settings tab, complete the following step:
     - On the Settings page, click Gateway services.
   - Spaces: If you enable the Spaces option for your catalog, you cannot see the status of gateway services in the catalog settings tab. To know the gateway services status from the Spaces tab, complete the following steps:
     - Select the space that you want to work with.
     - Click the Space settings tab.

- On the Space Settings page, click Gateway services.
- In the Event load column, you can see the current status.

e. A list of all of the gateway services for the selected catalog, including all of its Spaces, displays the gateway type and its endpoint URL. In addition, a status icon displays for each service name to provide a quick indication of that service's status:

- Normal: Between 0 and 10 events are waiting to be processed
- Increased: Between 10 and 20 events are waiting to be processed
- High: More than 20 events are waiting to be processed

You can view details about a service's status to gain insight into possible issues.

f. View the gateway status: On the Gateway services page, click ⋮ next to a service and select View status.
The Gateway processing status page displays a list of the events that were sent to the gateway. For each event, you can see the following information:

- Event type: The action performed by the event; for example, subscribing to a product, deleting an application, or creating a new consumer organization.
- Category: The feature area affected by the event; for example, subscriptions, applications, or consumer organizations.
- Time: The time when the event was processed by the gateway service.
- Status: The current event's processing status; for example, Queued (not yet sent for processing), Sent (but not processed yet), Processed (complete) or Failed (processing failed). For more information about the different statuses of a product compatible with DataPower API Gateway, see Publishing a draft Product.
  The number of events in the Queued and Sent states determine the status level for the service.

The display includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

g. To download Gateway logs, complete the following steps:

- Click ⋮ next to the gateway service and select Download logs.
- Downloads a .zip file to your computer with a name that uses the format <gateway-name>.zip for example v6gw.zip.

API gateway response codes

When an API is called, different HTTP status codes are returned by the gateway to indicate whether the request was successfully completed.

The response codes used in IBM® API Connect correspond to the registered HTTP status codes that are typically generated to provide informational (1xx), successful (2xx), redirection (3xx), client error (4xx), or server error (5xx) responses, as described at https://tools.ietf.org/html/rfc7231#section-6 and Hypertext Transfer Protocol (HTTP) Status Code Registry.

In API Connect, successful responses vary depending on the API being called. Other response codes can also be generated, depending on the implementation of the assembly and the response from the external systems. The standard reasons listed for the registered HTTP status codes are considered adequate for most responses that are returned; these response codes and their causes are therefore not listed here.

In certain cases, a client or server error response code can be caused by a condition that is specific to API Connect. The following table contains a list of these error response codes and identifies possible causes for these codes being returned. For some error codes, multiple causes are possible.

Table 1. Error codes and their causes

Error Code	Cause
401 Unauthorized	• The required client identification has not been successfully provided. • User authentication failed or did not take place.
403 Forbidden	• The application is not registered with the plan that is used. • The application is not active. • User authentication failed because multiple client IDs provided.
404 Not Found	• Information for the provider organization or environment was not found. • The API URL was not found in the organization or environment.
405 Method Not Allowed	The API URL was found, but no operation was found that supports the requested HTTP verb.
406 Not Acceptable	The API cannot produce any responses that are supported by the application.
429 Too Many Requests	The rate limit has been exceeded for the plan or operation being used.
500 Internal Server Error	An error occurred while executing this request.

Error Code	Cause
503 Service Unavailable	The status of an API was switched from online to offline, making the API unavailable across all Products in which it is contained. For more information, see Managing your Products in the API Manager UI and Managing API Products using the developer toolkit.

Troubleshooting your billing configuration

Some issues can occur when you are setting up billing integration in IBM® API Connect.

You can use the following links to browse the issues:

1. My customer payment is not completing with Stripe, but the Product is still being accessed.
2. My Product with billing is returning an error when I try to configure it with my Stripe account.
3. My customer previously had a Stripe subscription to a Product but can't access its billing details.

My customer payment is not completing with Stripe, but the Product is still being accessed.

When payment issues occur with the credit card payment provider, the credit card subscription is canceled, but the API Connect subscription is not canceled. You can disable an application until the payment issues are resolved by completing the following steps:

1. Navigate to the Settings page in the dashboard of your Stripe account.
2. In the Billing section navigate to the Subscriptions and emails page.
3. In the Manage failed payments section, change the Subscription status to If all retries for a payment fail, mark the subscription as unpaid.
4. Navigate to the Subscriptions page, and when the subscription has moved into the unpaid state open the subscription in the Stripe dashboard.
5. In the Metadata section, copy the subscription_url value.
6. Use the developer toolkit CLI, and the UUID from the subscription_url, to set the state of the application or subscription to disabled.

My Product with billing is returning an error when I try to configure it with my Stripe account.

The most common cause of this is that your
Developer Portal

cluster servers or your Management cluster servers cannot communicate with Stripe.
To resolve this, ensure that the Stripe API is enabled with HTTPS communication with your Management cluster servers and the Developer Portal on port 443. See Firewall requirements on Kubernetes for more information about this requirement.

Other causes might be issues with the subscription billing service, network stability, or the API keys might have been rolled and not updated in API Connect and the Developer Portal.

My customer previously had a Stripe subscription to a Product but can't access its billing details.

There is more than one possible cause and resolution for this situation.

- The credit card transaction might not be completing correctly. If this situation happens, the subscription might be canceled with Stripe, but the API Connect subscription is not canceled. For instructions about how to disable a subscription, see My customer payment is not completing with Stripe, but the Product is still being accessed.
- A recent change to a Product with billing might have triggered an action that was not completed correctly. Seemingly minor changes to the Product can start a number of actions that can overload a server. For example, when you replace a version of the Product with a new version, it starts an update to the Stripe server for every account that is subscribed to that Product. If the action fails to complete, the Plan's subscription status might not be reflected correctly with Stripe.
  You can identify this situation by viewing the Billing dashboard in the Resources section of the API Manager. The table displays the state of the job queue for the billing integration resource, and any issues with the job queue are displayed here. For more information about the job queue, and how to retry blocked jobs, see capim_mon_job_queue.html.

API Manager tutorials

Tutorials for using the API Manager user interface in IBM® API Connect.

Prerequisites

Because you are working online, using API Manager, to complete the following tutorials you must be the Organization Manager of an API Connect account. Or, you received an invite to join API Connect as an Administrator. See Working with consumer organizations for more information.

If you have received an email inviting you to create an API Connect user account, follow the instructions in your email to create your API Connect account.

Overview

In the following tutorials, you will use API Manager to create simple SOAP API definitions that can be accessed through the Developer Portal and called through the gateway in the same manner as other API Connect API definitions.

- **Tutorial: Creating a proxy REST API definition**
  This tutorial shows you how to define and implement a REST API definition that proxies an existing service.

- **Tutorial: Creating a SOAP API**
  This tutorial shows you how to create an API definition by using a SOAP service Web Service Definition Language (WSDL). This API definition simplifies creating and managing access to the SOAP service.
- **Tutorial: Creating a REST API definition that invokes an existing SOAP service**
  This tutorial shows you how to expose an existing SOAP service and transform the XML data that is returned by it into specified JSON data.
- **Tutorial: Mapping JSON Content**
  This tutorial shows you how to map message content from one format or schema to another format or schema.
- **Tutorial: Importing an API**
  This tutorial shows you how to import an existing OpenAPI 2.0 definition.
- **Tutorial: Supersede a Product**
  This tutorial shows you how to supersede a published product with another product.
- **Tutorial: Implementing OAuth Security**
  This tutorial shows you how to create a native OAuth provider using the API Manager user interface.
- **Tutorial: Implementing OIDC Security**
  This tutorial shows you how to add OIDC (OpenID Connect) capability to an existing native OAuth provider using API Manager.
- **Tutorial: Generate a JSON Web Token (JWT)**
  This tutorial shows you how to define and implement a REST API definition that generates a JSON Web Token (JWT).
- **Tutorial: Validate a JSON Web Token (JWT)**
  This tutorial shows you how to define and implement a REST API definition that validates a JSON Web Token (JWT).
- **Tutorial: Creating a Client Application**
  This tutorial shows you how to create a client application using the API Manager. The ability to create a new application using the API Manager allows members of a provider organization, such as API developers or testers, to create the environment needed to complete an API.
- **Tutorial: How to monetize an API Product**
  This tutorial shows you how to define a pricing plan for an API Product, and how API consumers can then subscribe to that monetized Product in the Developer Portal.

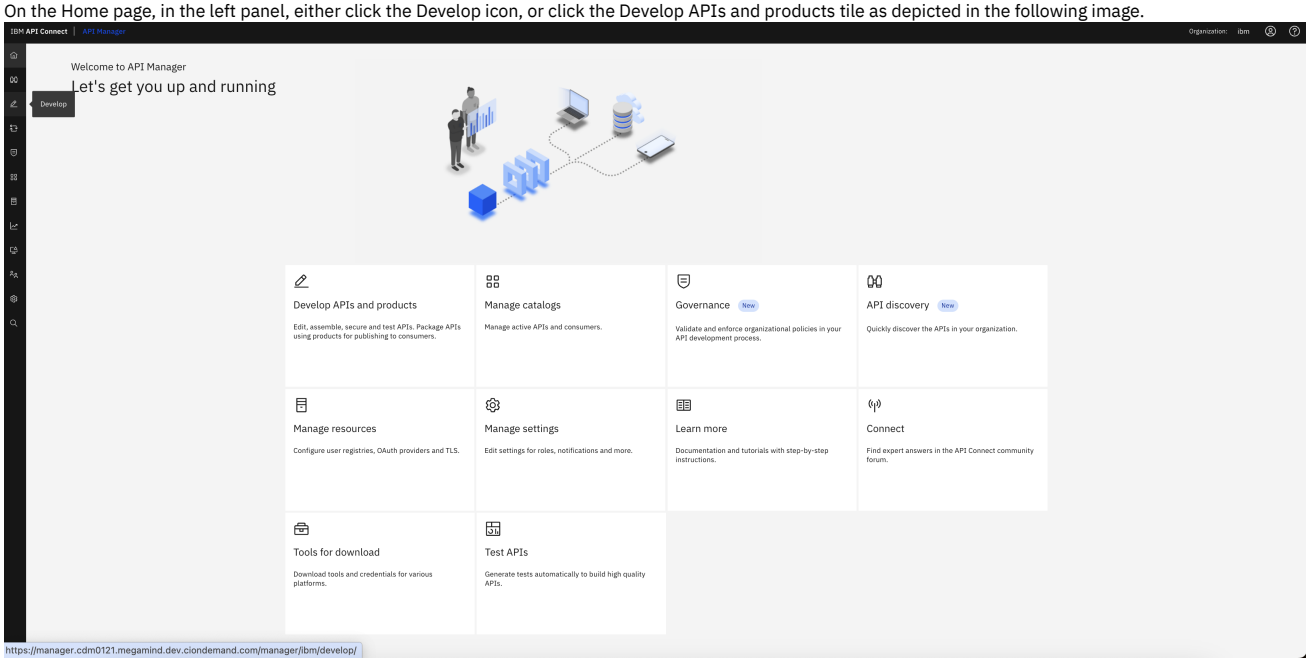
Tutorial: Creating a proxy REST API definition

This tutorial shows you how to define and implement a REST API definition that proxies an existing service.

About this tutorial

In this tutorial you will complete the following lessons:

1. Creating a REST API definition
2. Testing the REST API



Before you begin

Note: The Sandbox catalog must be configured to use either a DataPower® API Gateway, or a DataPower Gateway (v5 compatible), or both. For detailed information, see Creating and configuring Catalogs.

Creating a REST API definition

You can create and define a REST API that returns the branch details of a fictional bank, called BankA by using the following steps.

1. Log in to API Manager.
2. On the Home page, in the left panel, either click the Develop icon, or click the Develop APIs and products tile as depicted in the following image.

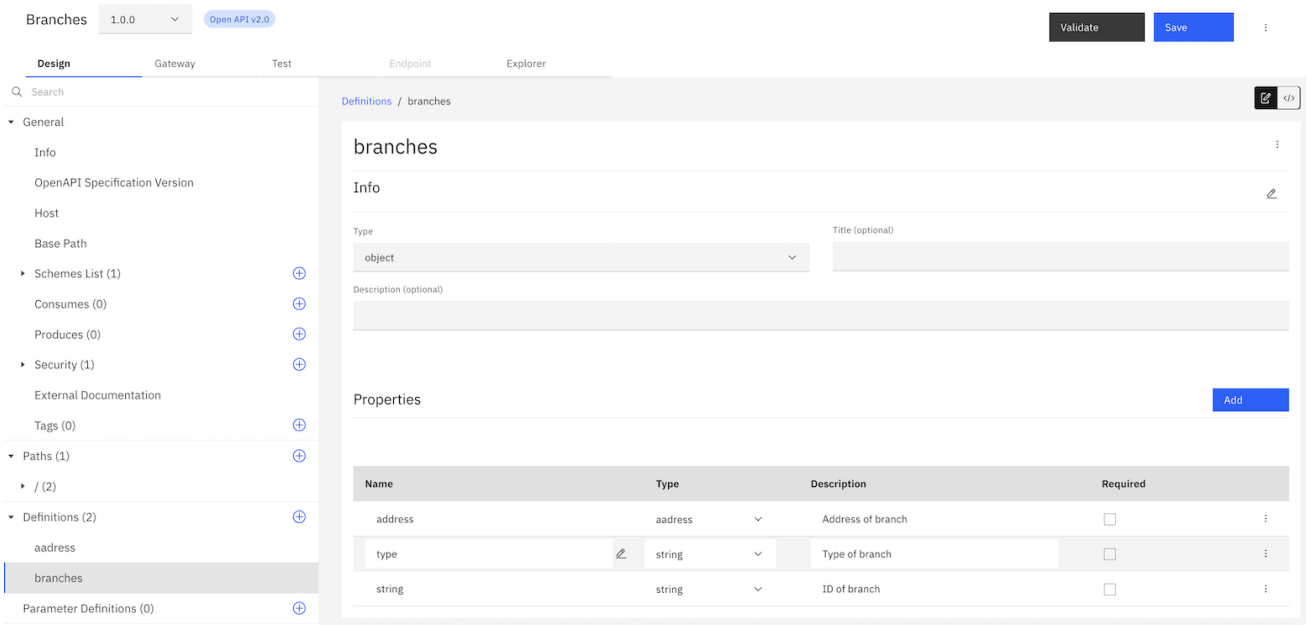
3. In the Develop screen, click Add > API.
4. In the OpenAPI 2.0 screen, select the OpenAPI 2.0 tab.
   Note: By default, the OpenAPI 2.0 tab is selected.
5. Under the Create section, select the From target service radio button.
6. Click Next.
7. In the Create API from target service screen, under the Info section, enter the following values to create a REST API from a target service.
   a. In the Title field, enter `Branches`.
      Note: The Name field is auto-populated with the value that you have entered in the Title field. In this case, the Name field is auto-populated with `branches`.
   b. Leave the Version field as `1.0.0`.
      The Base path field is auto-populated with `/branches`.
   c. In the Target service URL field, enter `https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches`
   d. Click Next.
8. Under the Secure section,
   a. Select the Secure using Client ID and CORS check boxes, if not already selected.
   b. Click Next.
9. Under the Summary section,
   a. Ensure that Generated OpenAPI 2.0 definition and Applied security marked with green color ticks.
      The green color ticks depict successful API creation.
   b. Click Edit API to continue configuring the API.
10. In the new screen, select the Design tab, if not already selected.
11. In the left panel of the Design view screen, click the + icon adjacent toDefinitions.
12. In the Add schema dialog box,
    a. In the Schema Name (Key) field enter `address`.
    b. From the Type drop-down list, select `object`.
    c. Click Add.
       The Add schema dialog box is now closed. In the right panel of the Design view screen, the address section is displayed.
    d. Under the address section, in the Description field, enter `The format of the address object`.
    e. In the top right corner, click Save.

    The schema for new object, address, is now displayed under the Definitions section.

13. To create properties for the new object, address,
    a. Under the Definitions section, select address.
       The address section is displayed in the right panel.
    b. Under the address section, click Add.
       The Add new property dialog box is displayed.
14. To configure the properties, in the Add new property dialog box, enter the following values.
    a. In the Name field, enter `street1`.
    b. From theType drop-down list, select `string`.
    c. In the Description field, add `The first line of the address`.
    d. Click Save.
       The new schema property is created, and is displayed in Definitions > address > Properties.
    e. To complete the properties configuration, click the Options icon (three dots) adjacent to street1 and then select Details.
       The View details for street1dialog box is displayed.
    f. In the View details for street1dialog box, perform the following steps.
       i. Click the Documentation tab.
       ii. In the Example Value field, enter `4660 La Jolla Village Drive`.
       iii. Click Save.
15. To create other new schema properties, repeat Step 14 and enter the values provided in Table 1.

Table 1. Address properties

SCHEMA NAME (KEY)	TYPE	DESCRIPTION	EXAMPLE VALUE
`street2`	`string`	`The second line of the address`	`Suite 300`
`city`	`string`	`The city of the address`	`San Diego`
`state`	`string`	`The state of the address`	`CA`
`zip_code`	`string`	`The zip code of the address`	`92122`



Note: The developers can find the schema definitions in the Developer Portal. These schema definitions contain information about the type of data that developers expect in their responses.

16. To create a second definition schema, repeat Step 11 to Step 12.
    For example, create a new definition schema named `branch`.
17. To configure properties of `branch`, repeat Step 13 to Step 14 and enter the values provided in Table 2.
    Note: To add and access the Example value of the schema definition you created, you must complete the process by clicking Save.

Table 2. Branch properties

SCHEMA NAME (KEY)	TYPE	DESCRIPTION	EXAMPLE VALUE
`address`	`address`	`The address of the branch`	
`type`	`string`	`The type of branch`	`atm`
`id`	`string`	`The ID of the branch`	`9d72ece0-7e7b-11e5-9038-55f9f9c08c06`

Note that, for the address property, the type section refers to the definition that you created within your API, and the example section is blank. Following this process, you can create complex data structures.

18. To add a new path, in the left panel of the Design view screen, click the + icon adjacent to Paths.
19. In the Add schema dialog box, perform the following steps.
    a. In the Path field, enter `/details`.
    b. Click Add.

    The new path called /details appears in the list of available paths.

20. In Paths > /details, click the + icon adjacent to Operations
21. In the Add schema dialog box, perform the following steps.
    a. From the Verb drop-down list, select get.
    b. Click Add.

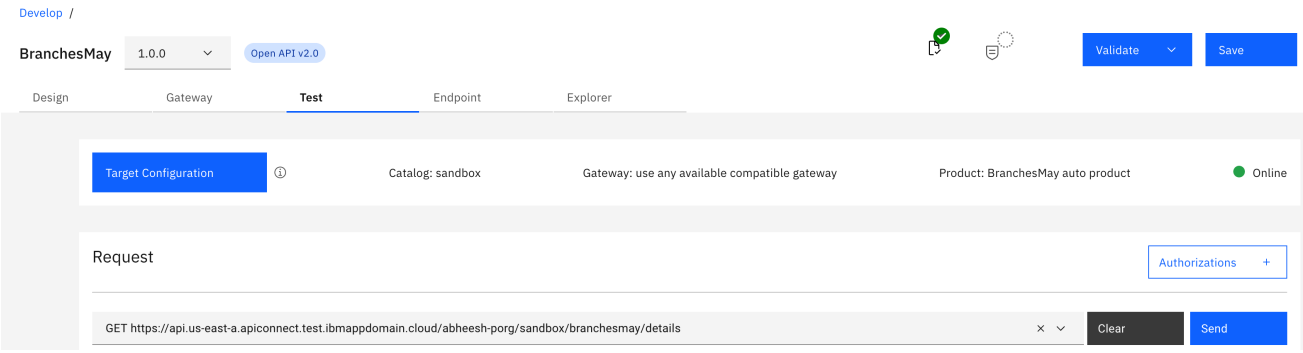
    The GET section is displayed in the right panel of the Design view screen.

22. Click Save in the right panel of the Design view screen.
23. To edit the GET operation in the Path, click /details.
24. To edit the GET operation in the Path, in the left panel of the Design view screen, under Paths > Operations, click GET.
25. In the right panel, in the GET section, scroll down to the Responses section.
26. To edit the response, perform the following steps.
    a. Click the Options icon (three dots) adjacent to 200 and then select Edit.
       A section named 200 is displayed in the right panel of the Design screen.

    b. Under the 200 section, perform the following steps.
       i. In the Name (Key) field, enter `200`.
       ii. In the Description field, enter `200 OK`.
       iii. Click Save.

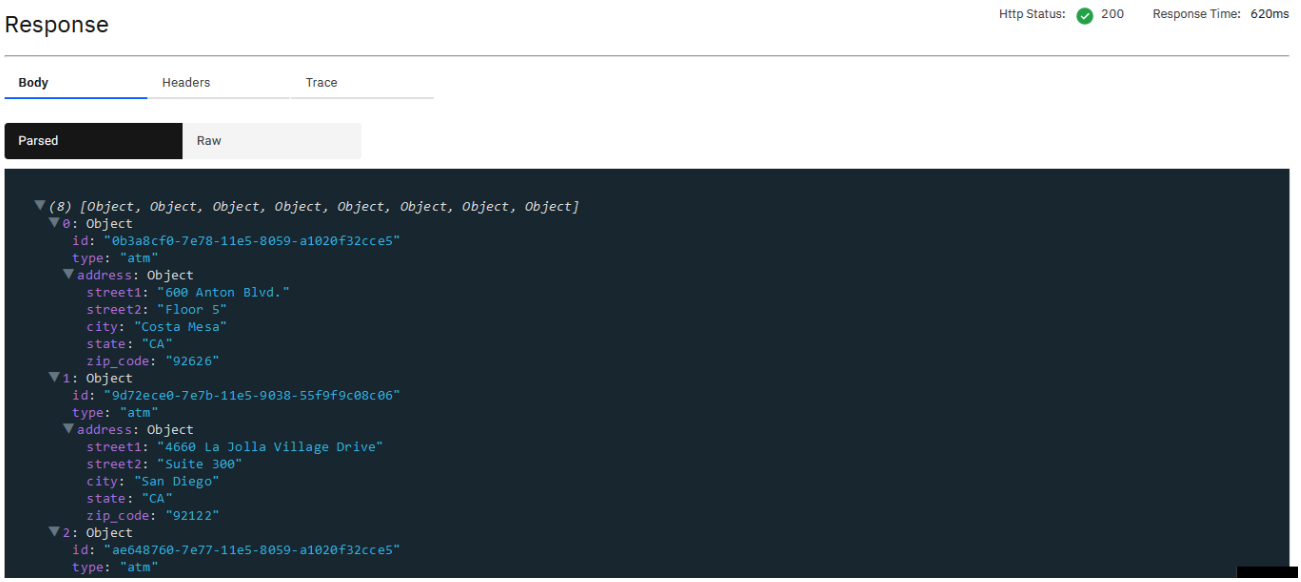
Now the API is online and available for use, so you can test it.

Testing the REST API



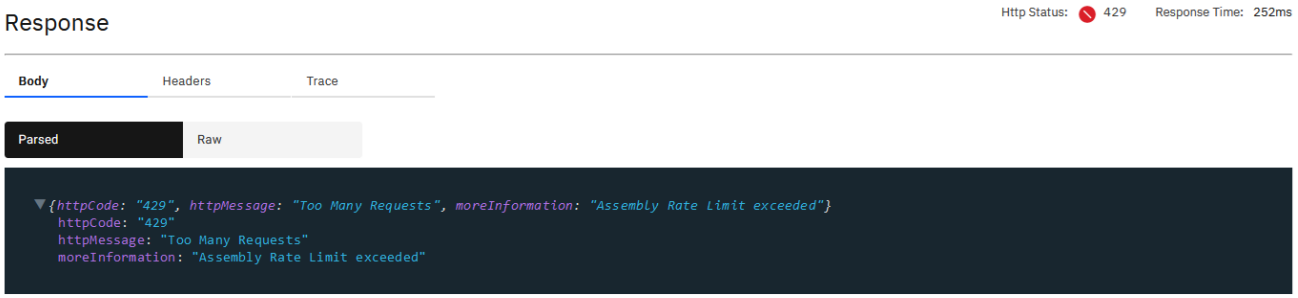
Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
Before you begin
Configure the gateway service before testing the REST API.

To test the REST API, complete the following steps.



1. On the Develop page, click the Menu icon (three dots), adjacent to the API, and then click Edit API.
2. Click the Test tab.
3. Click Target Configuration.
   The Preferences dialog box is displayed.

4. In the Preferences dialog box, perform the following tasks.
    a. Set the Auto-publish option to On.
    b. To set a Target product rate limit, perform the following tasks.
       i. Click Edit.
       ii. In the Choose a Rate Limit dialog box, select the Custom radio button.
       iii. In the Number of Calls text box, enter 5.
       iv. From the Per drop-down list, select hour.
       v. Click Choose Rate Limit.
    c. In the Preferences dialog box, click Save Preferences.
5. Click Develop on the top of the page.
6. On the Develop page, click the Menu icon (three dots), adjacent to the API that you want to edit, and then click Edit API.
7. Click the Test tab.



8. In the Test page's banner, ensure that the API is set to Online.

9. To execute an API call, under the Request section, click Send.
This tests the API. The response displays the status code that you defined (200) and the bank branch data that the API retrieved.

10. Click Send at least 5 more times so that you exceed the defined rate limit. Now the response returns the status code 429 "Too many requests" to indicate that you exceeded the rate limit.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a REST API definition.
- Tested the REST API.

Tutorial: Creating a SOAP API

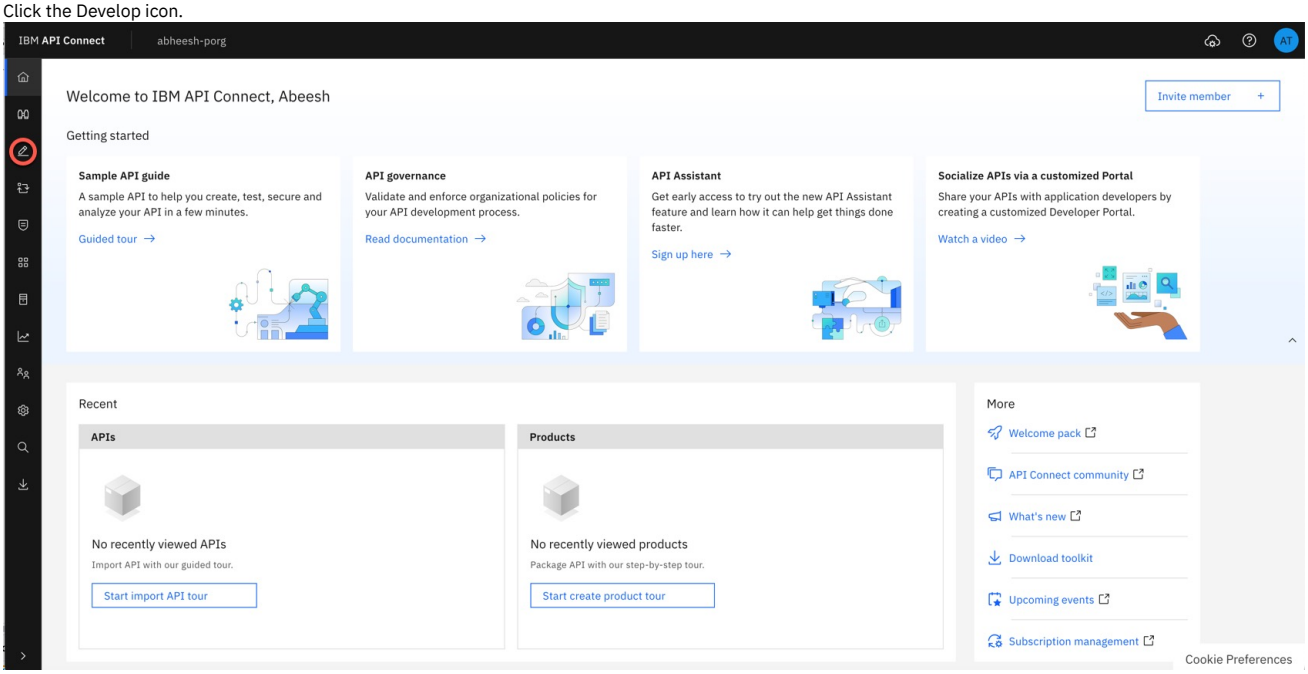
This tutorial shows you how to create an API definition by using a SOAP service Web Service Definition Language (WSDL). This API definition simplifies creating and managing access to the SOAP service.

About this tutorial

Follow this tutorial to create an API in API Manager by importing the WSDL for an existing SOAP service. Both SOAP 1.1 and SOAP 1.2 standards are supported by API Connect. When invoked, the API takes a SOAP request from the API caller and uses it to make its own request to the SOAP service. The API then returns the response of the SOAP service. In this tutorial, the SOAP service returns the balance of a fictional bank account for a particular user.

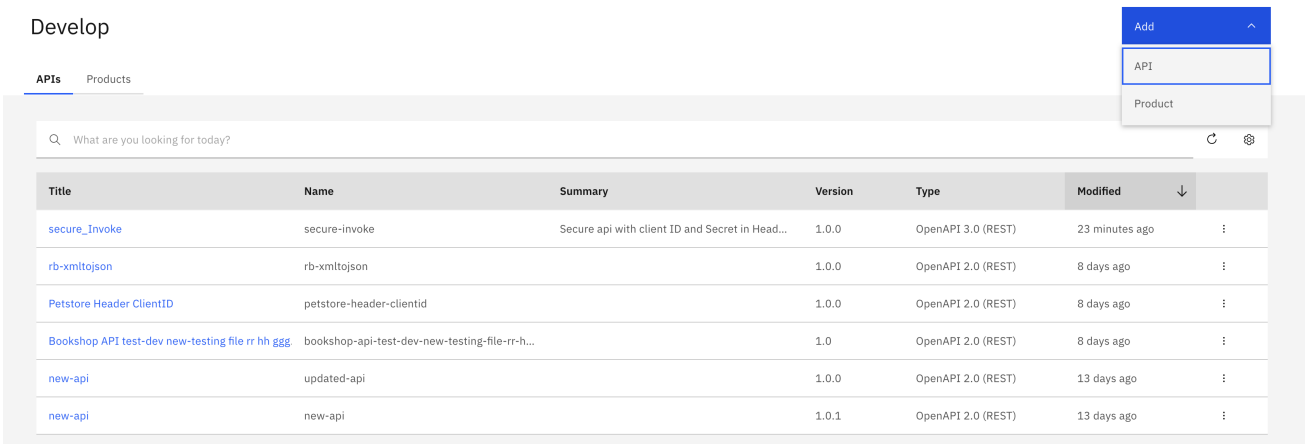
In this tutorial you will complete the following lessons:

1. Creating a SOAP API
2. Testing your SOAP API



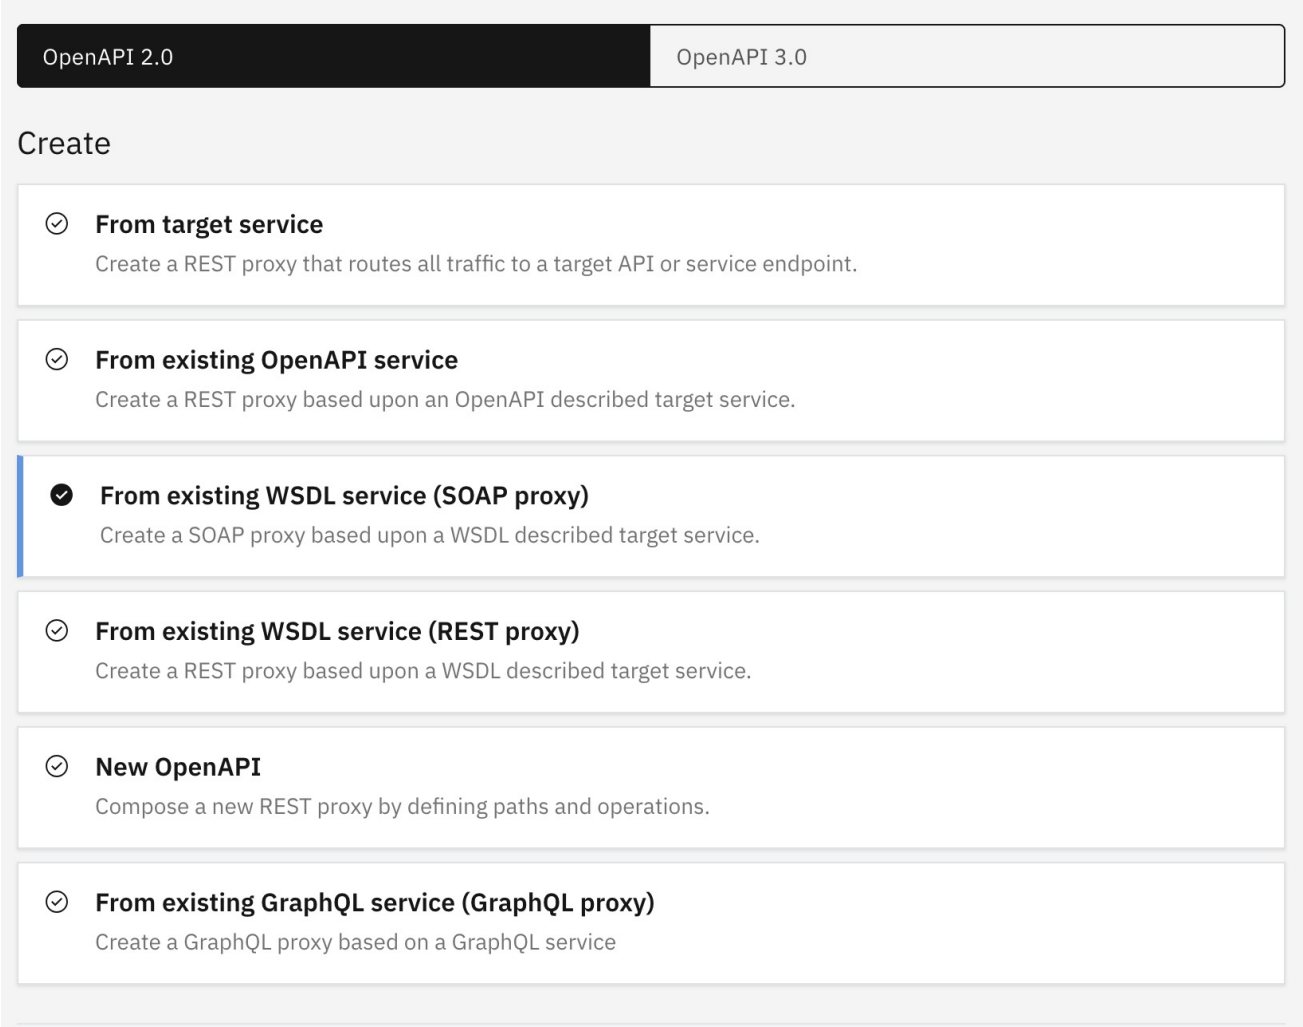
Before you begin

Note: The Sandbox catalog must be configured to use either a DataPower® API Gateway, or a DataPower Gateway (v5 compatible), or both. See Creating and configuring Catalogs.

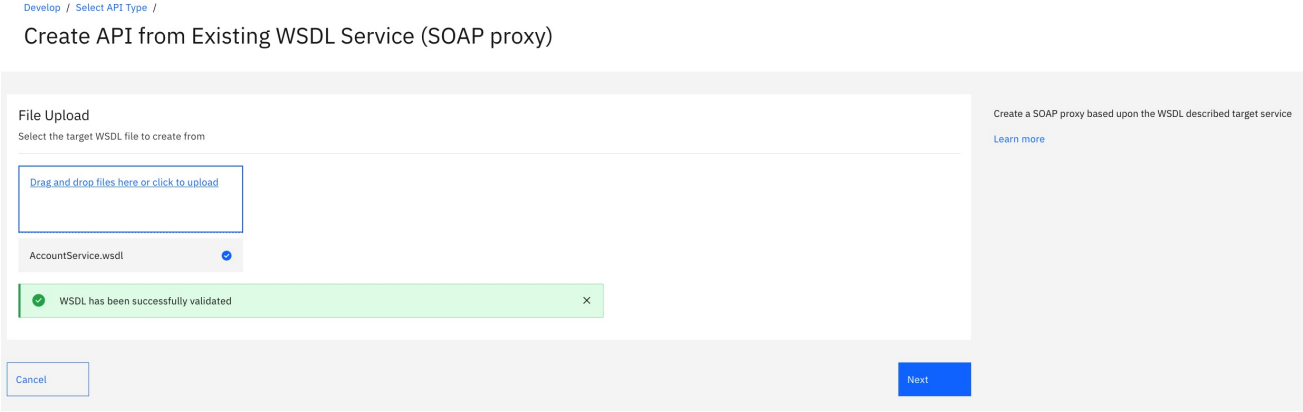


Creating a SOAP API

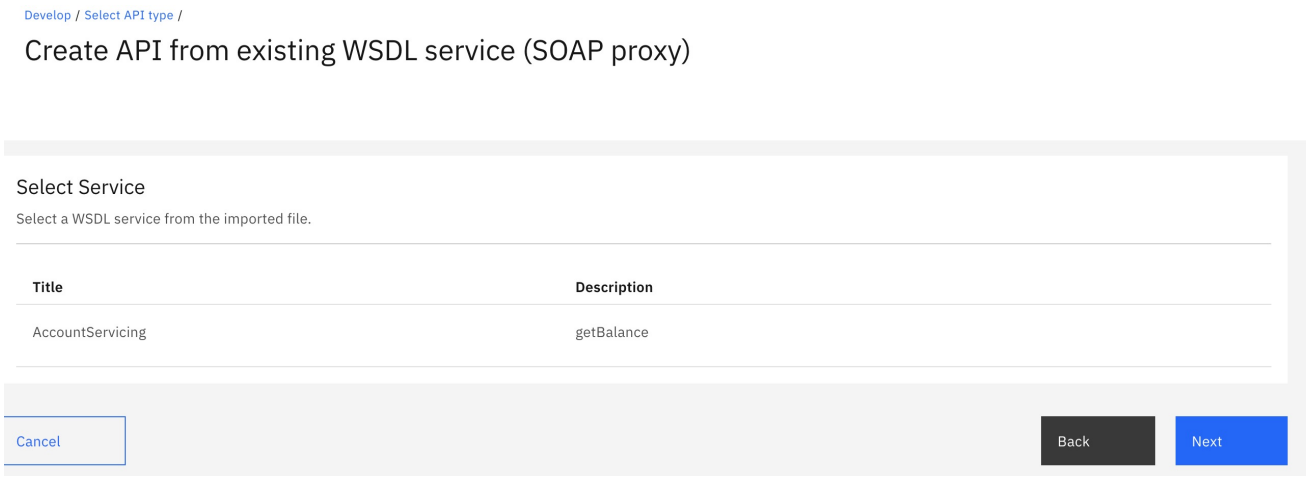
To create an API for an existing SOAP service, complete the following steps.



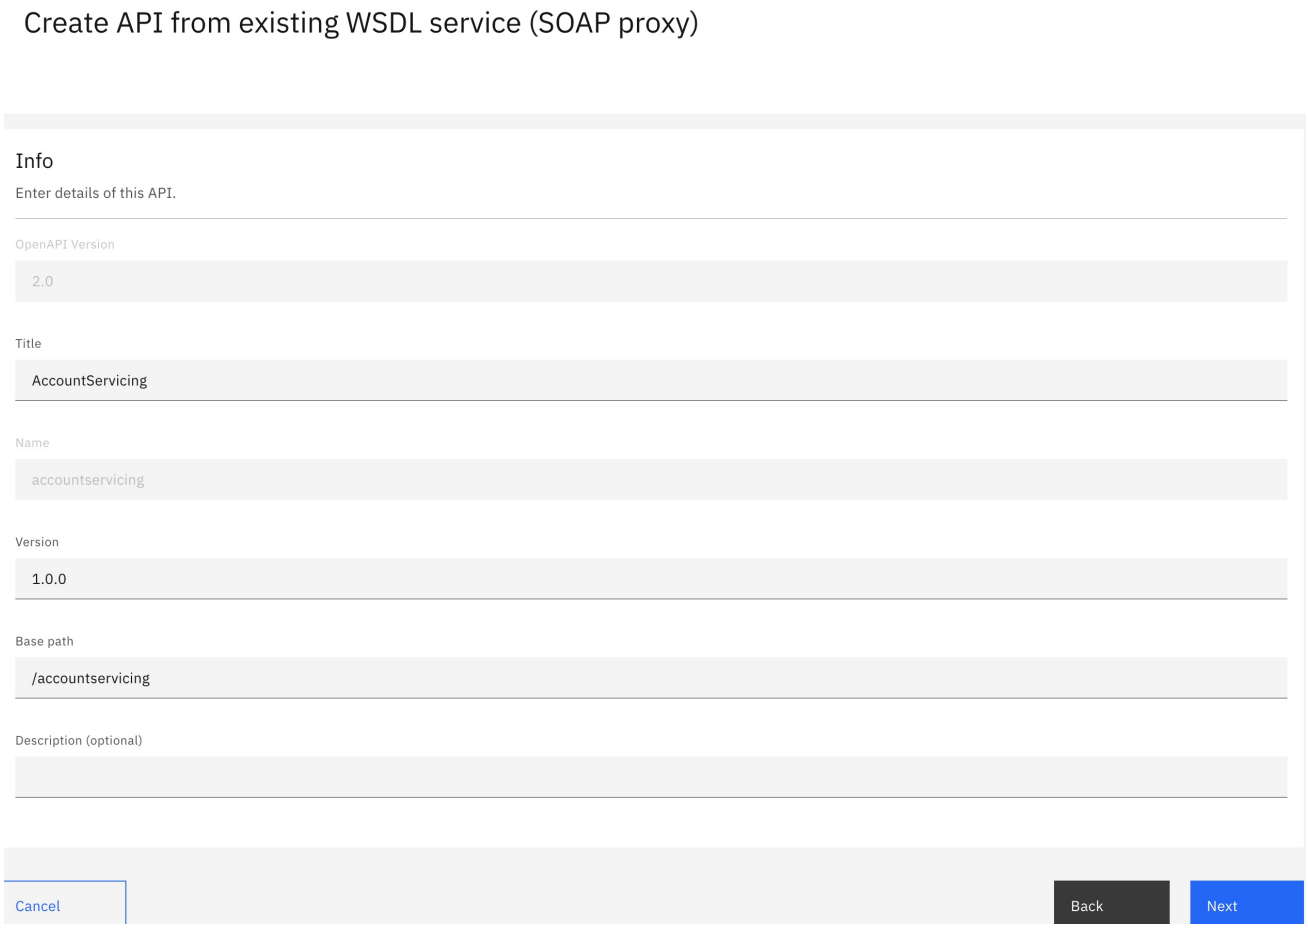
1. Download the SOAP WSDL file AccountServicing.txt. Rename this file `AccountServicing.wsdl`.
2. Log in to the API Manager UI.
3. Click the Develop icon.



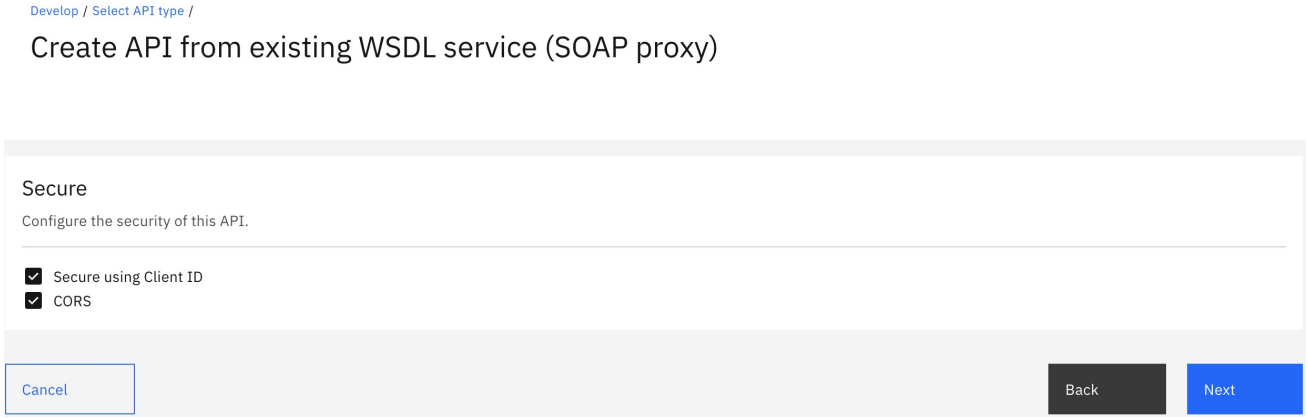
4. Click Add > API.



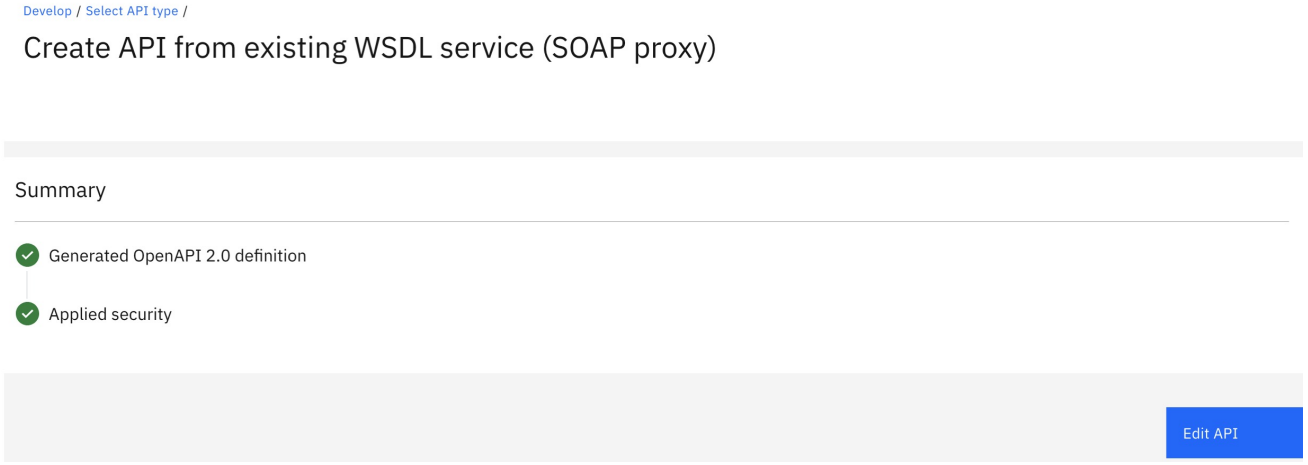
5. Ensure that OpenAPI 2.0 is selected.
6. Select From existing WSDL service (SOAP proxy). Click Next.



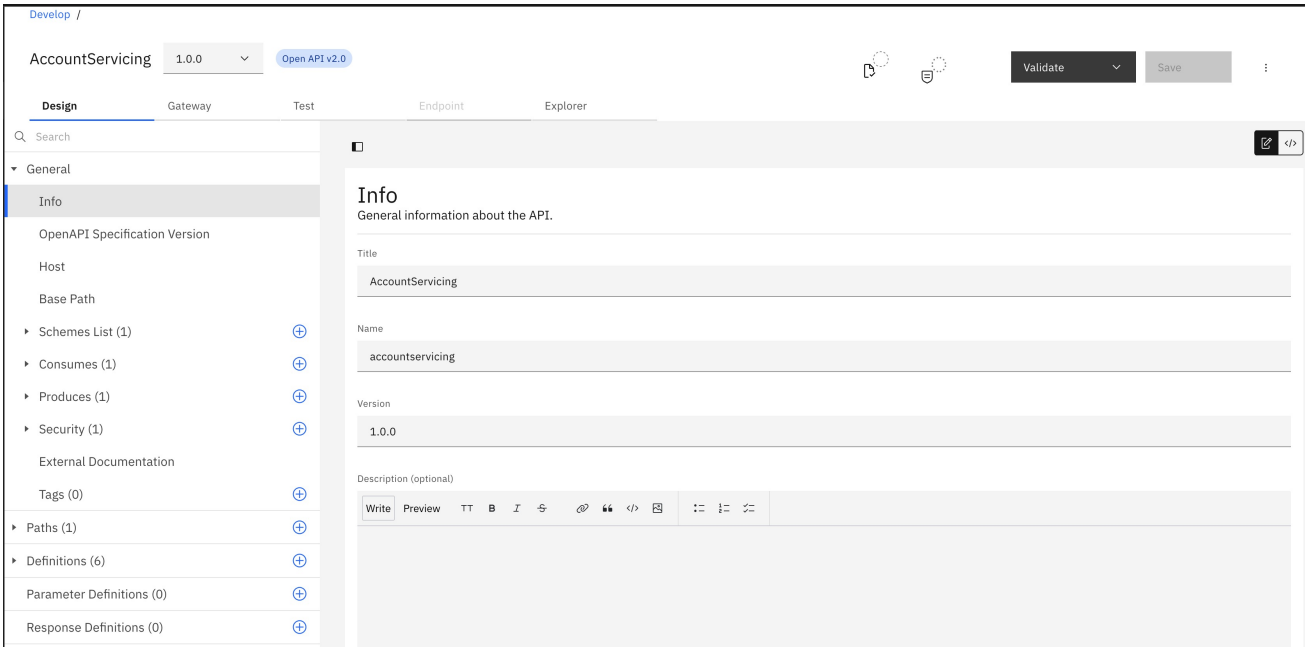
7. In the File Upload section, either drag and drop the `AccountServicing.wsdl` file, or click to upload from your filesystem.



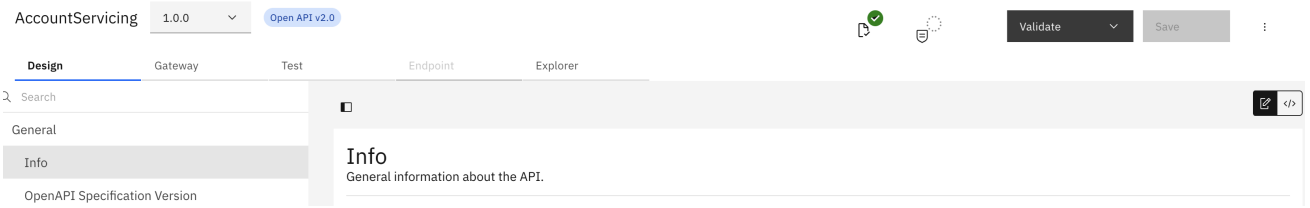
8. The file uploads, and is parsed by API Connect. A confirmation message is displayed. Click Next to continue.
9. The AccountServicing WSDL service gets selected, click Next.



10. Leave the values unchanged in the Info section, and click Next.



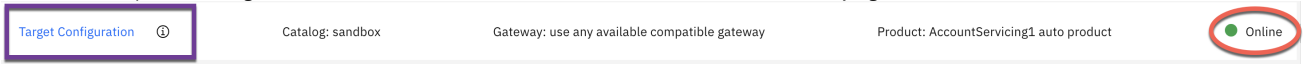
11. In the Secure section, ensure that Secure using Client ID and CORS check boxes are selected. Click Next.



12. A Summary screen is now displayed.

13. Click Edit API.

14. Click Validate > with Specifications. Your SOAP API is now online.



You successfully created a SOAP API. The WSDL file provided all the information that was needed to configure the API inputs and response.

Testing your SOAP API

To test your SOAP API, complete the following steps.

1. Click the Test tab of the AccountServicing API.
2. Click Target Configuration to open the Preferences dialog box.
3. Enable the Auto-publish setting and click Save Preferences. You will see the API is now online, indicated by a green marker.

4. Under Request, click Send to test the API. The API response is displayed in the Response section.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a SOAP API definition.

- Tested your SOAP API.

Tutorial: Creating a REST API definition that invokes an existing SOAP service

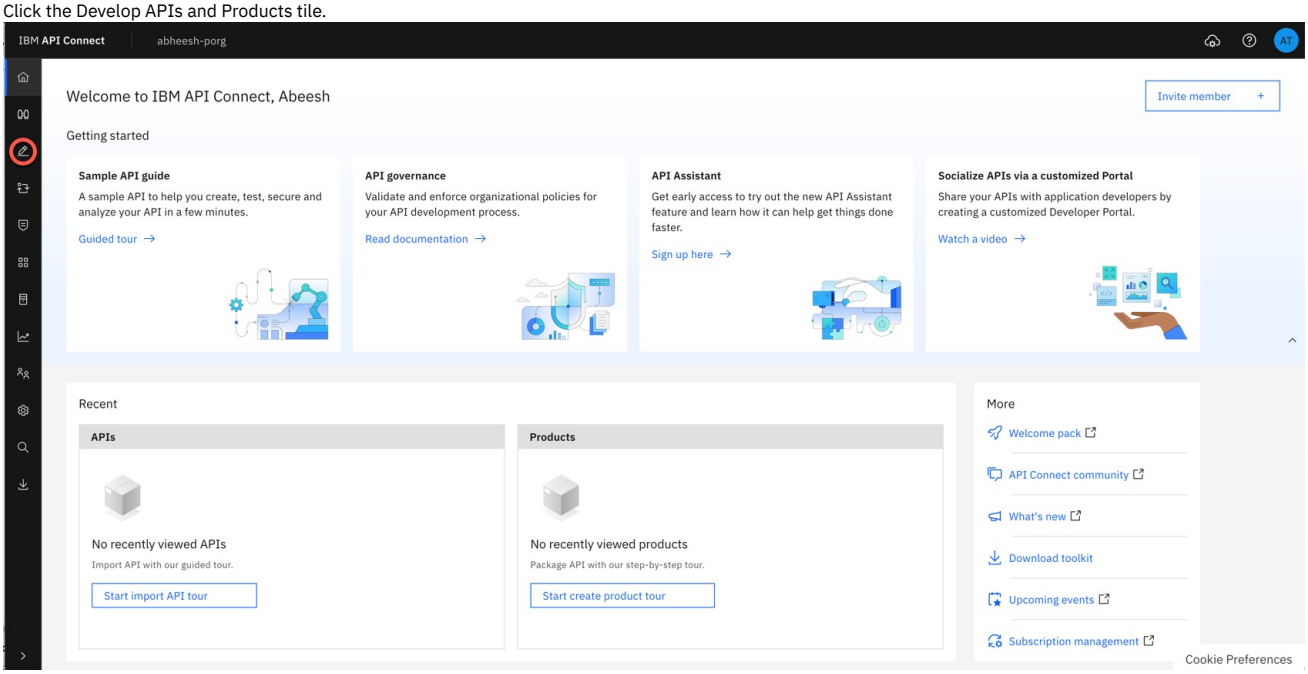
This tutorial shows you how to expose an existing SOAP service and transform the XML data that is returned by it into specified JSON data.

About this tutorial

Follow this tutorial to create a REST API in API Manager by importing the WSDL for an existing SOAP service. Both SOAP 1.1 and SOAP 1.2 standards are supported by API Connect. When invoked, the API returns the balance of a fictional bank account for a particular user.

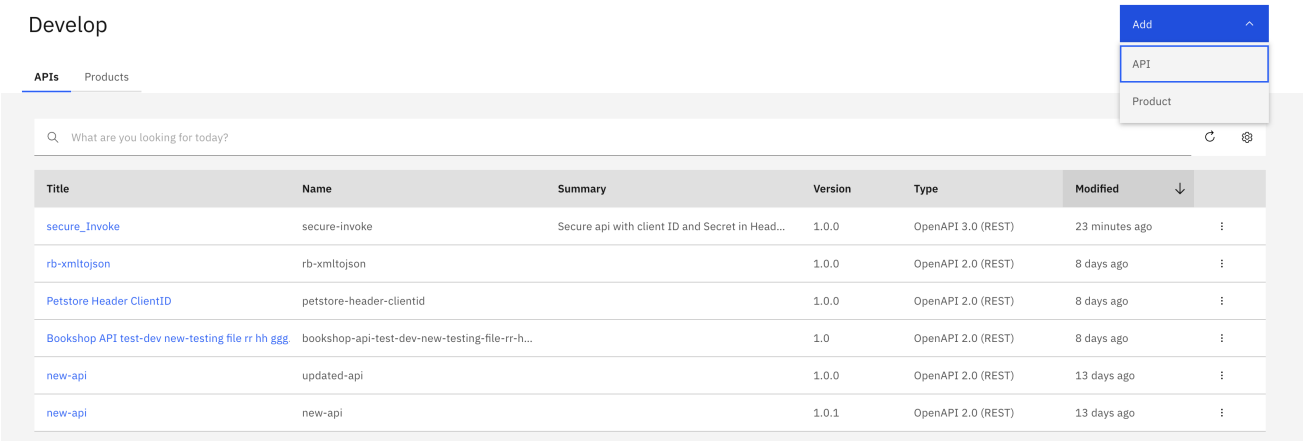
In this tutorial you will complete the following lessons:

1. Setting up a REST API definition
2. Testing your API definition



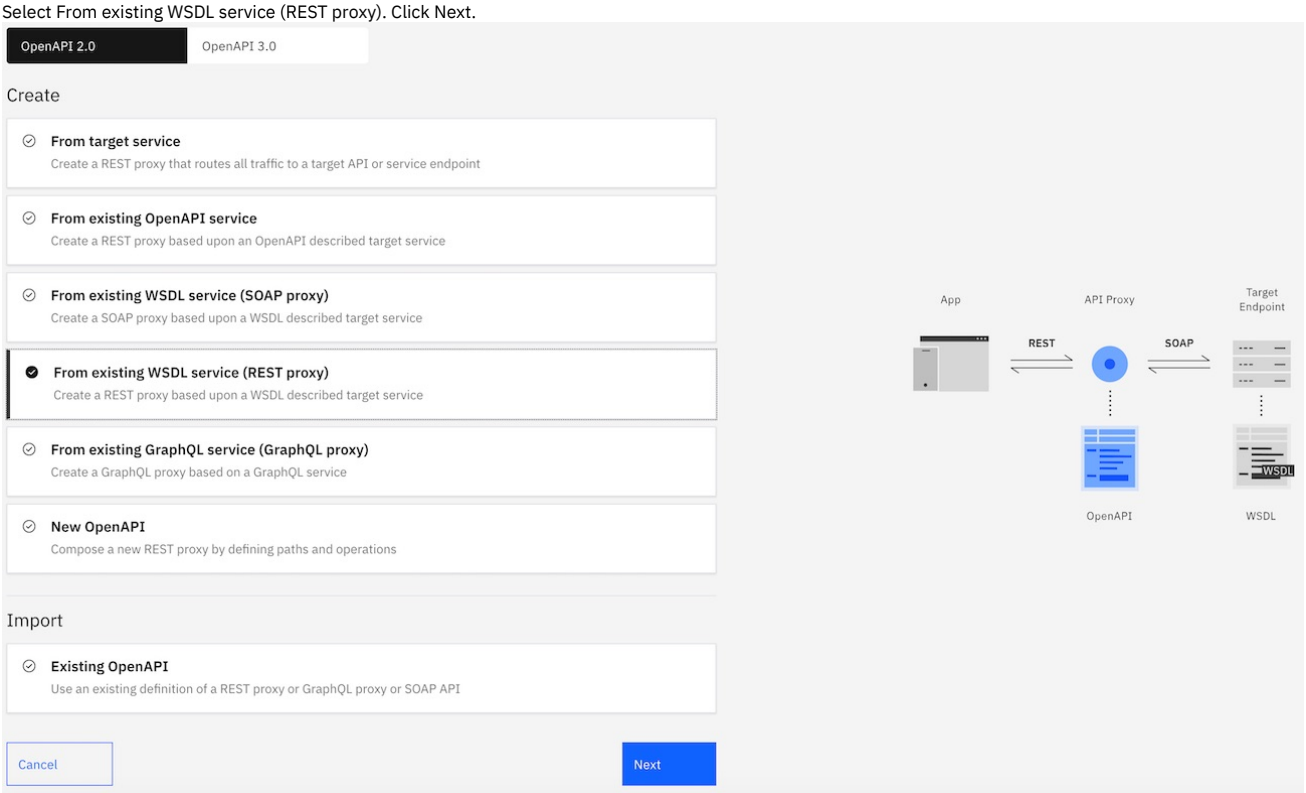
Before you begin

Note: The Sandbox catalog must be configured to use either a DataPower® API Gateway, or a DataPower Gateway (v5 compatible), or both. See Creating and configuring Catalogs.

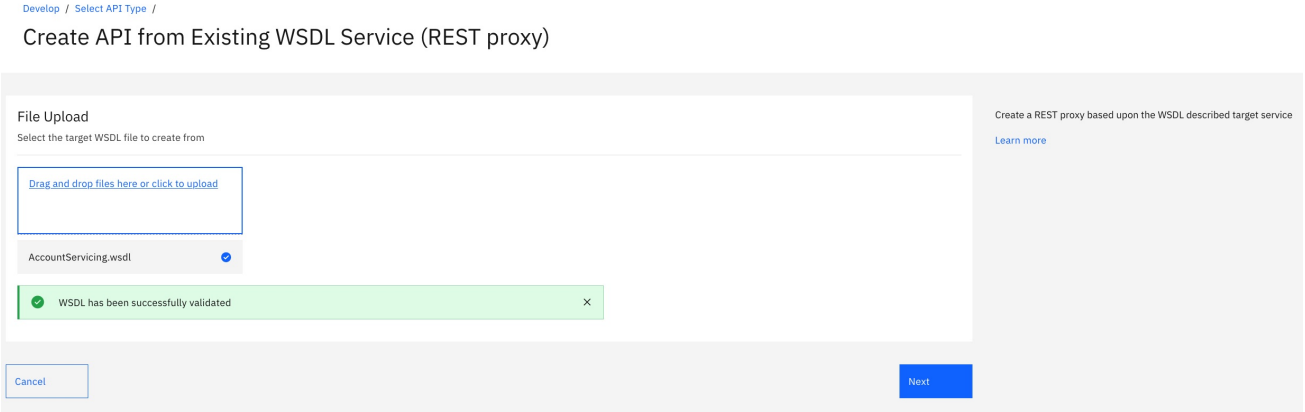


Setting up a REST API definition

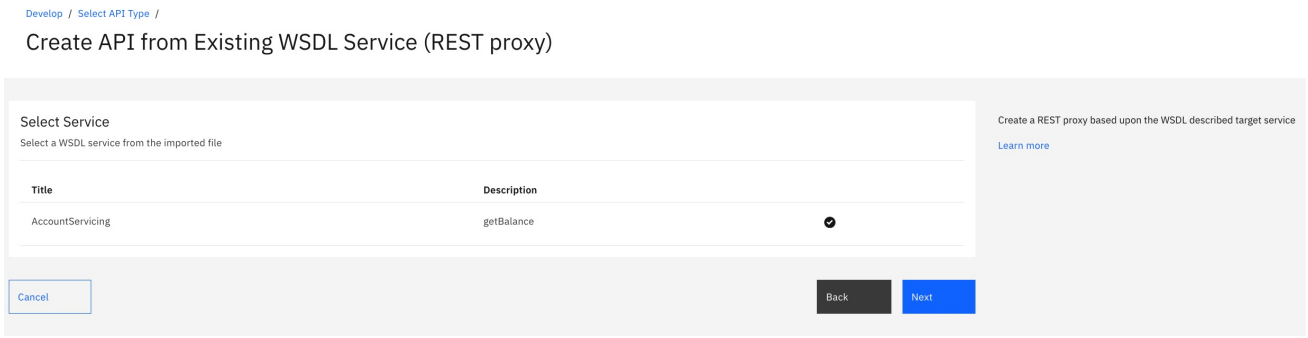
To set up a REST API that invokes an existing SOAP service, complete the following steps.



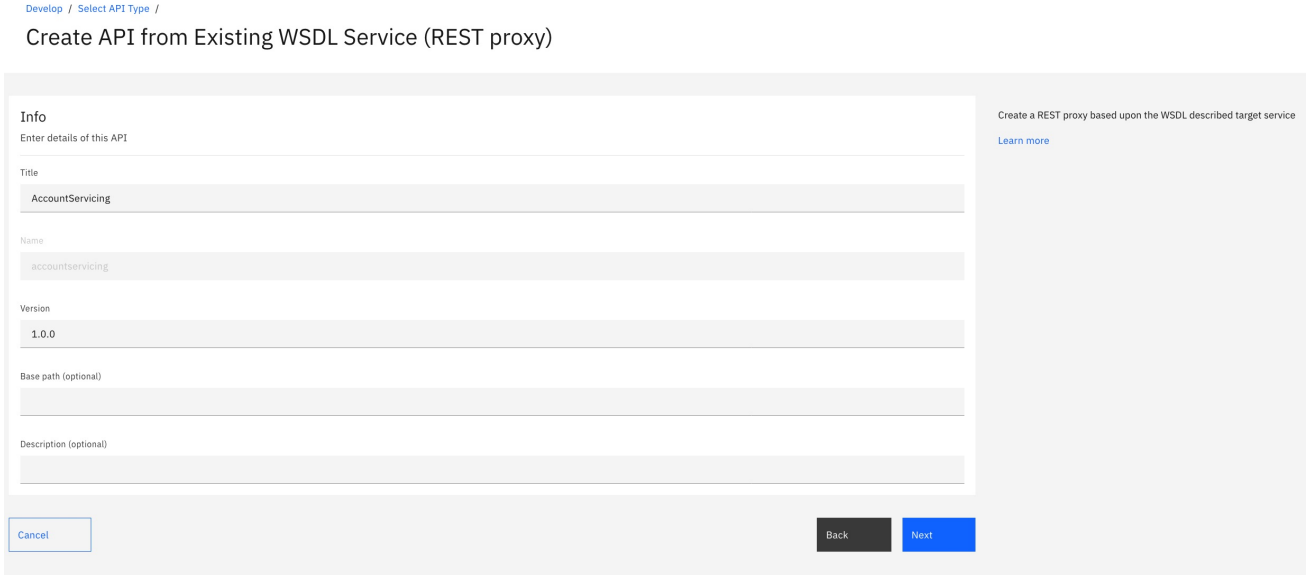
1. Download the SOAP WSDL file AccountServicing.txt. Rename this file `AccountServicing.wsdl`.
2. Log in to the API Manager UI.
3. Click the Develop APIs and Products tile.



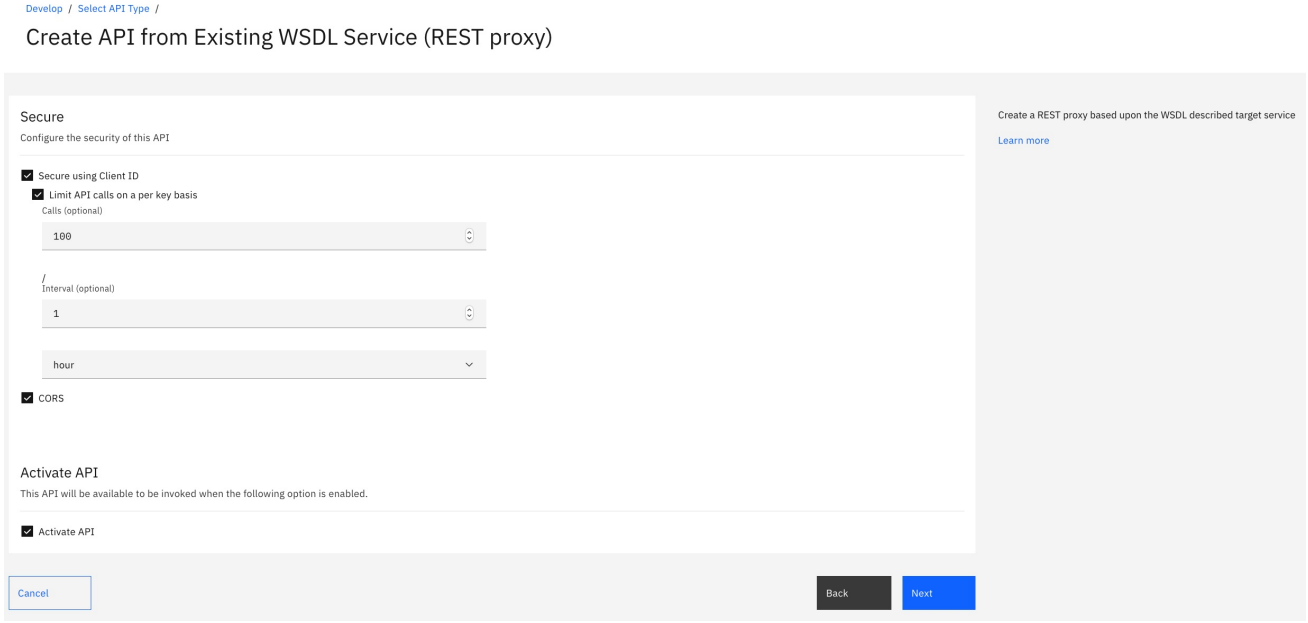
4. Click Add > API (from REST, GraphQL or SOAP).



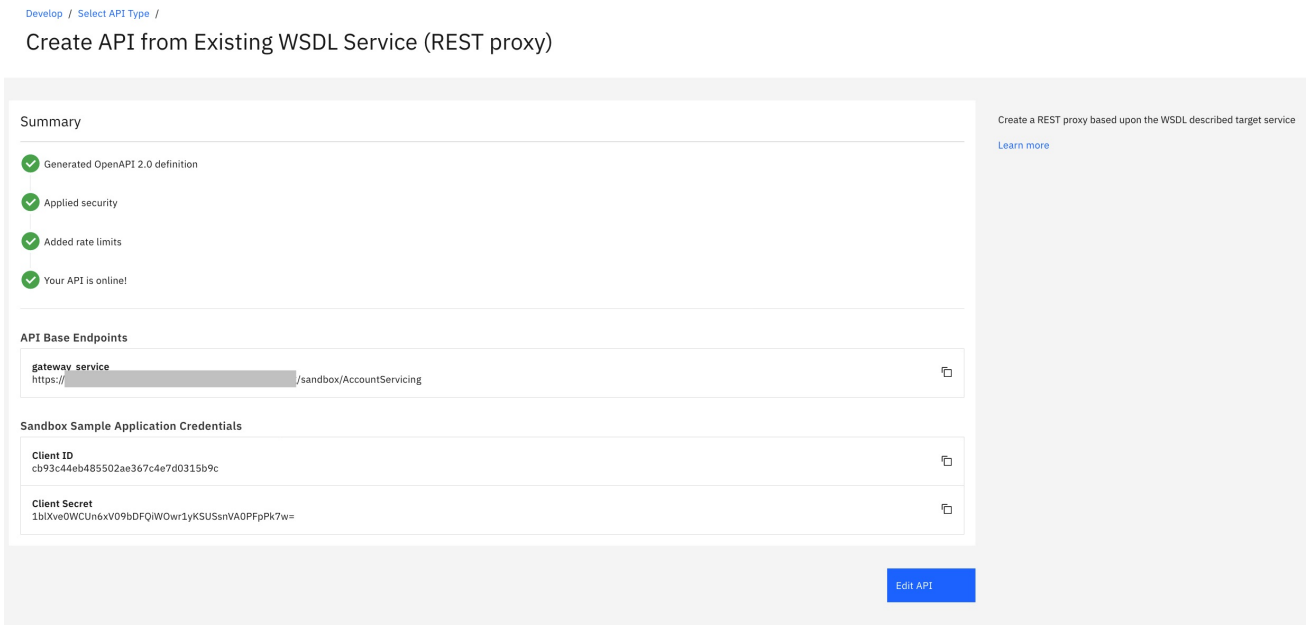
5. Ensure that OpenAPI 2.0 is selected.
6. Select From existing WSDL service (REST proxy). Click Next.



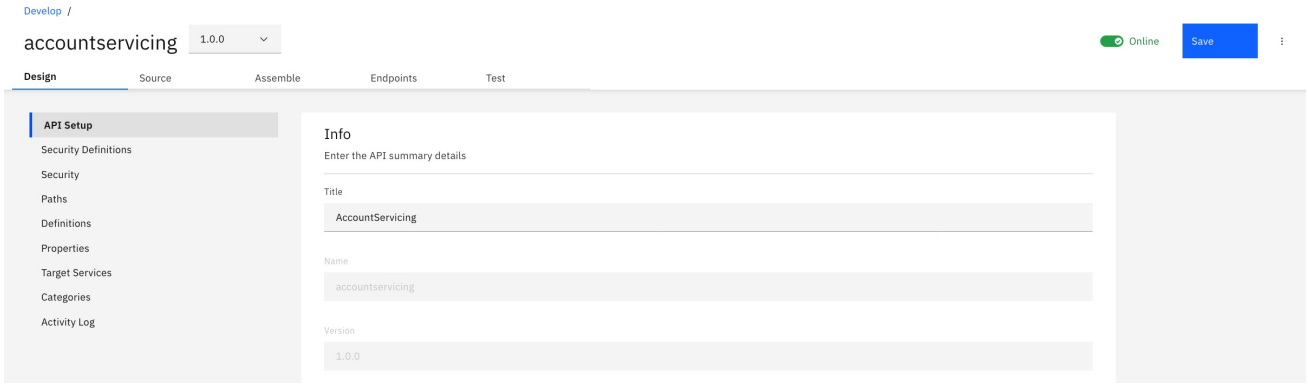
7. In the File Upload section, either drag and drop the `AccountServicing.wsdl` file, or click to upload from your filesystem.



8. The file uploads, and is parsed by API Connect. A confirmation message is displayed. Click Next to continue.
9. Select the AccountServicing WSDL service, and click Next.



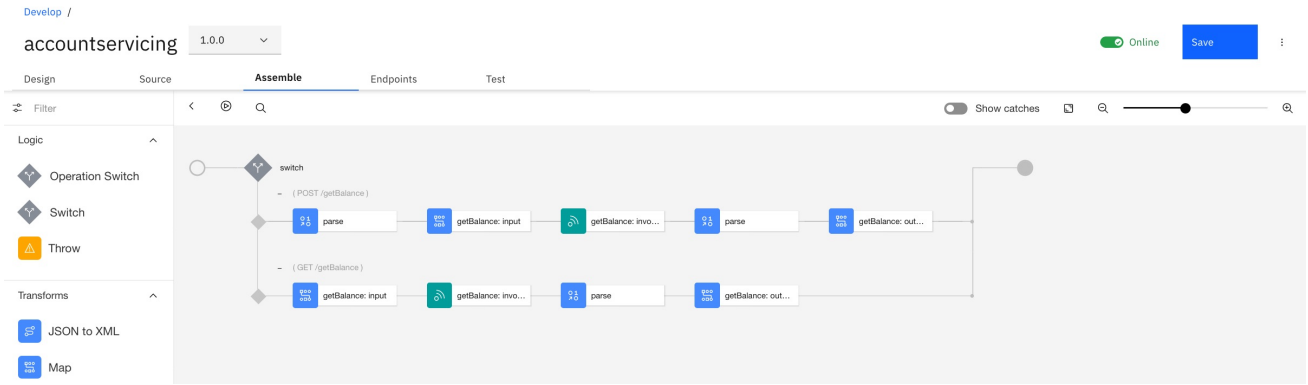
10. Leave the values unchanged in the Info section, and click Next.



11. In the Secure section, select the Limit API calls on a per key basis checkbox, and in the Activate API section, select the Activate API checkbox. Click Next.

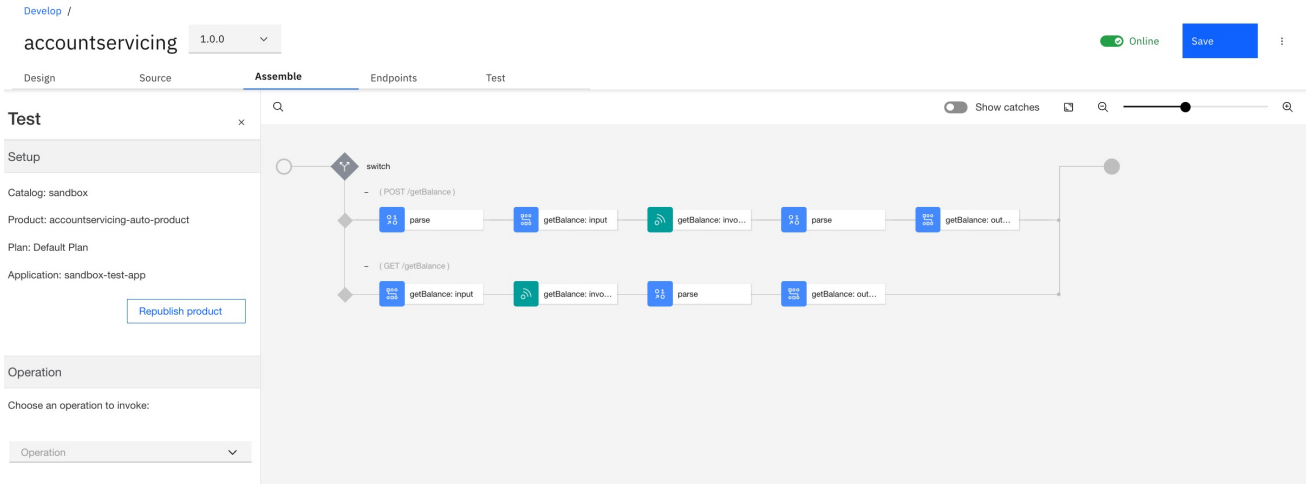
12. A Summary screen is now displayed, showing the steps to create and publish your new API. When this process is complete, you see a summary of the results, including the API Base Endpoint, and the credentials of the Sandbox Test Application that is automatically subscribed to the new API.

13. Click Edit API. Your new API is now online.



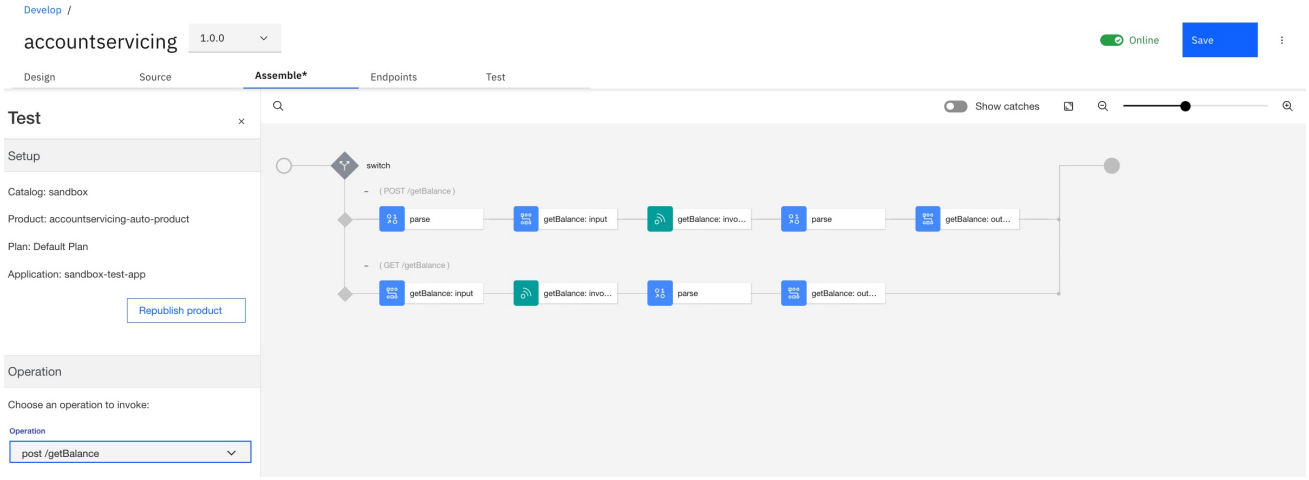
You successfully created a REST API that invokes an existing SOAP service, and included it in a Product and Plan ready for testing. The WSDL file provided all the information that was needed to configure the API inputs and response.

Testing your API definition

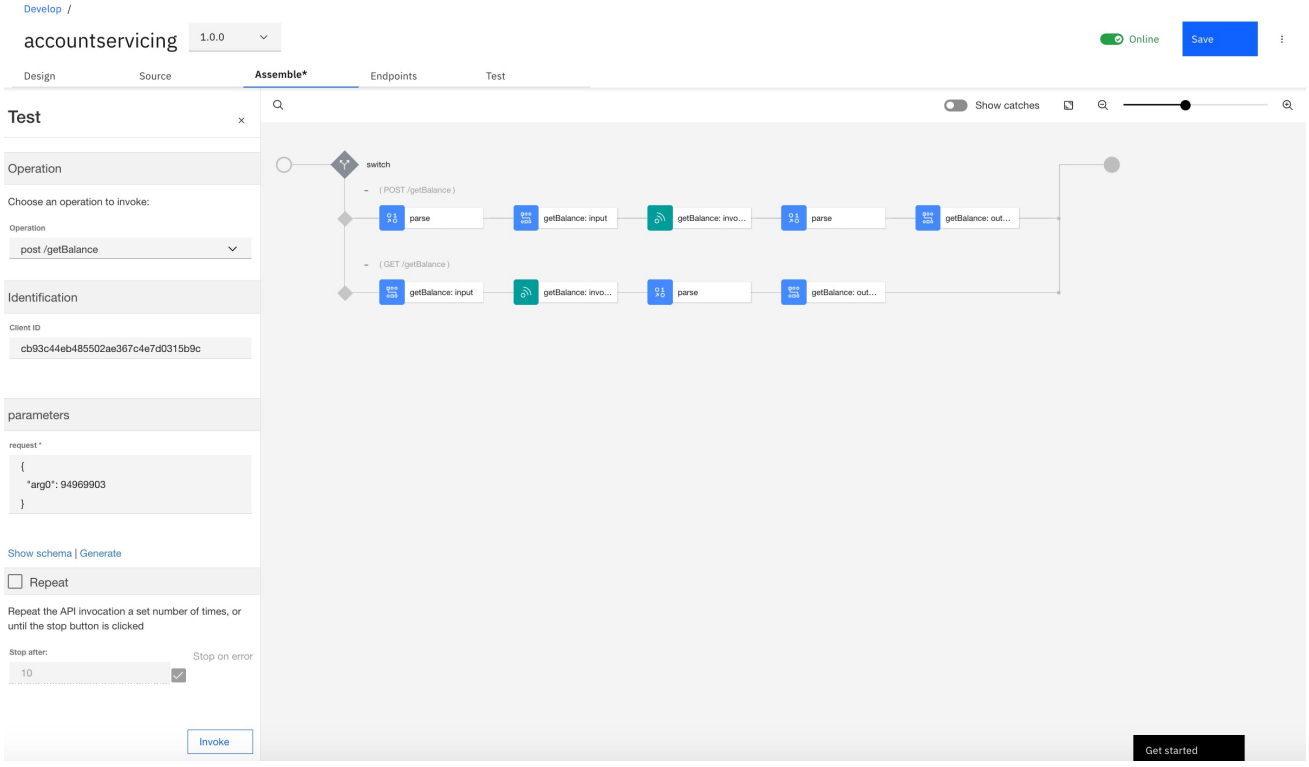


Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test your API definition by using the API Manager test tool, complete the following steps.

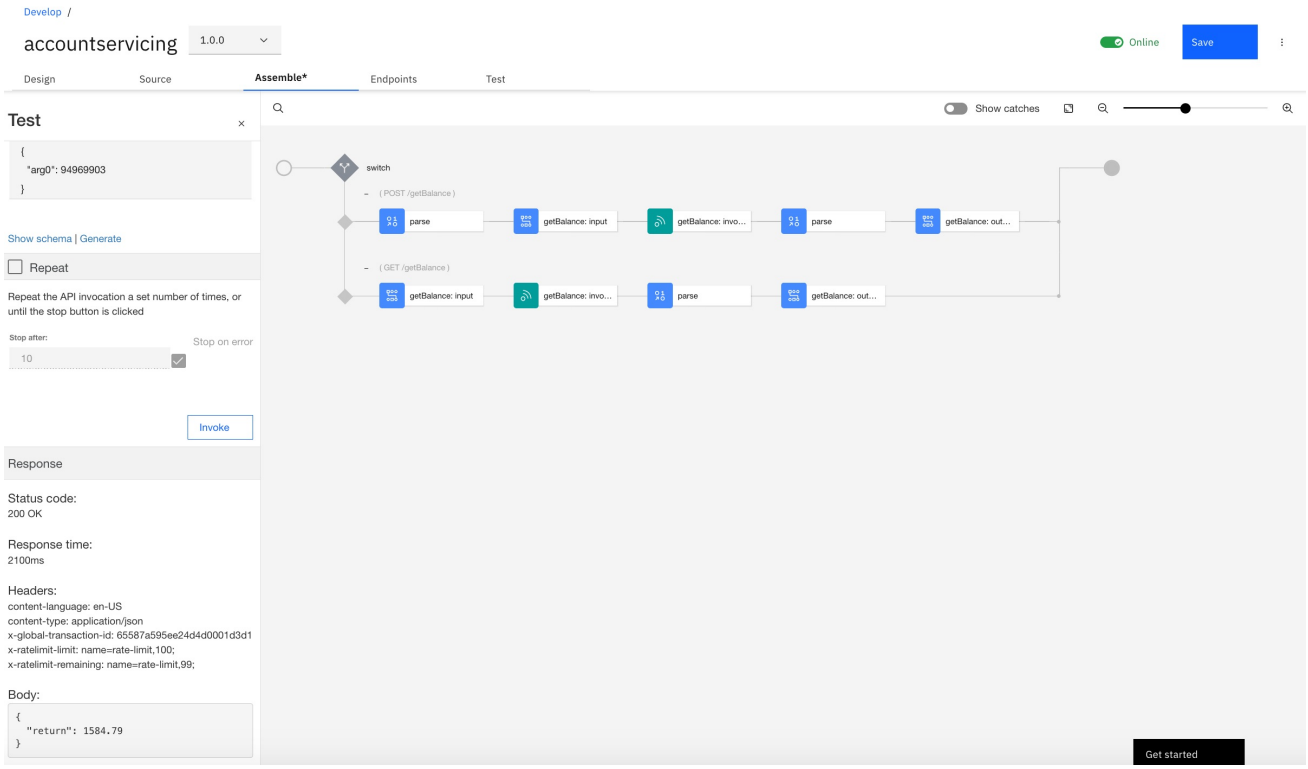
1. Click the Assemble tab of the AccountServicing API, to move to the Assemble view, and click the Test icon .



Note that the test panel is being deprecated, and will be moved to the Test tab in a future release.



2. The Test panel opens, and you can see that the default Product and Plan that are needed for the test setup are listed.



3. In the Operation section, select the post /getBalance operation to invoke.

4. Scroll down in the Test panel to the request field, and click Generate to auto-generate a sample request.

5. Click Invoke to test the API. The API response is displayed in the Response section. If you receive a message relating to an untrusted certificate, click the link provided, accept the certificate, then return to the test environment and click **Invoke** again.

The Response section successfully returns the balance of the account.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Set up a REST API definition.
- Configured the API based on a SOAP WSDL file, to invoke an existing web service and return its output.
- Tested your API definition.

Related information

- Tutorial: Creating a SOAP API

Tutorial: Mapping JSON Content

This tutorial shows you how to map message content from one format or schema to another format or schema.

Before You Begin

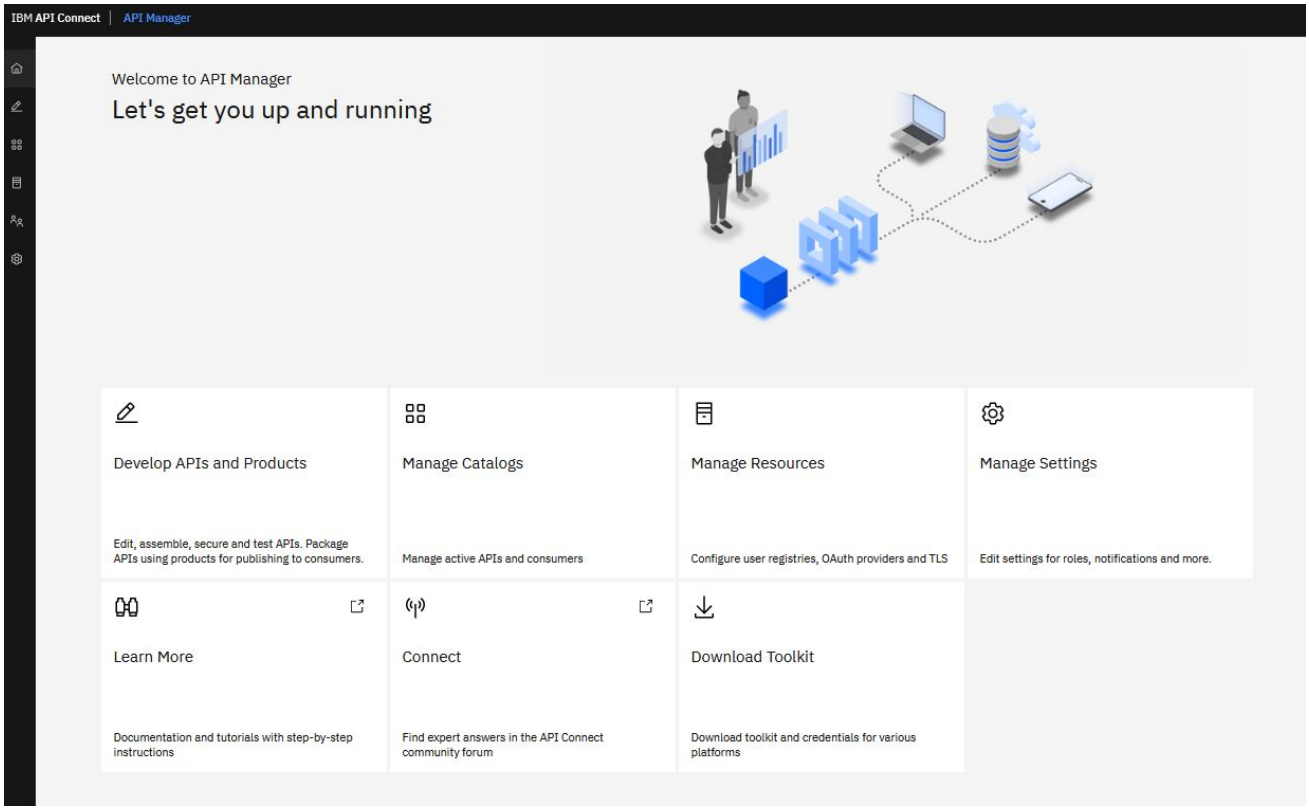
This task can be completed by users who are assigned one of the following roles:

- Catalog Owner
- Developer

Note: The Sandbox catalog must be configured to use either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway or both. See Creating and configuring catalogs.

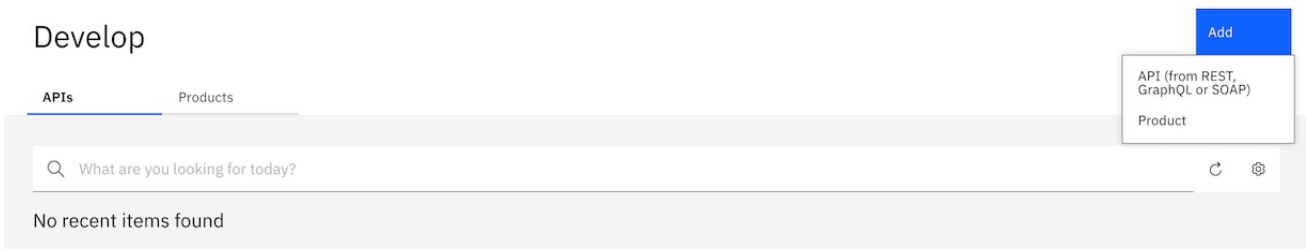
About this tutorial

In this tutorial you are going to complete the following lessons:



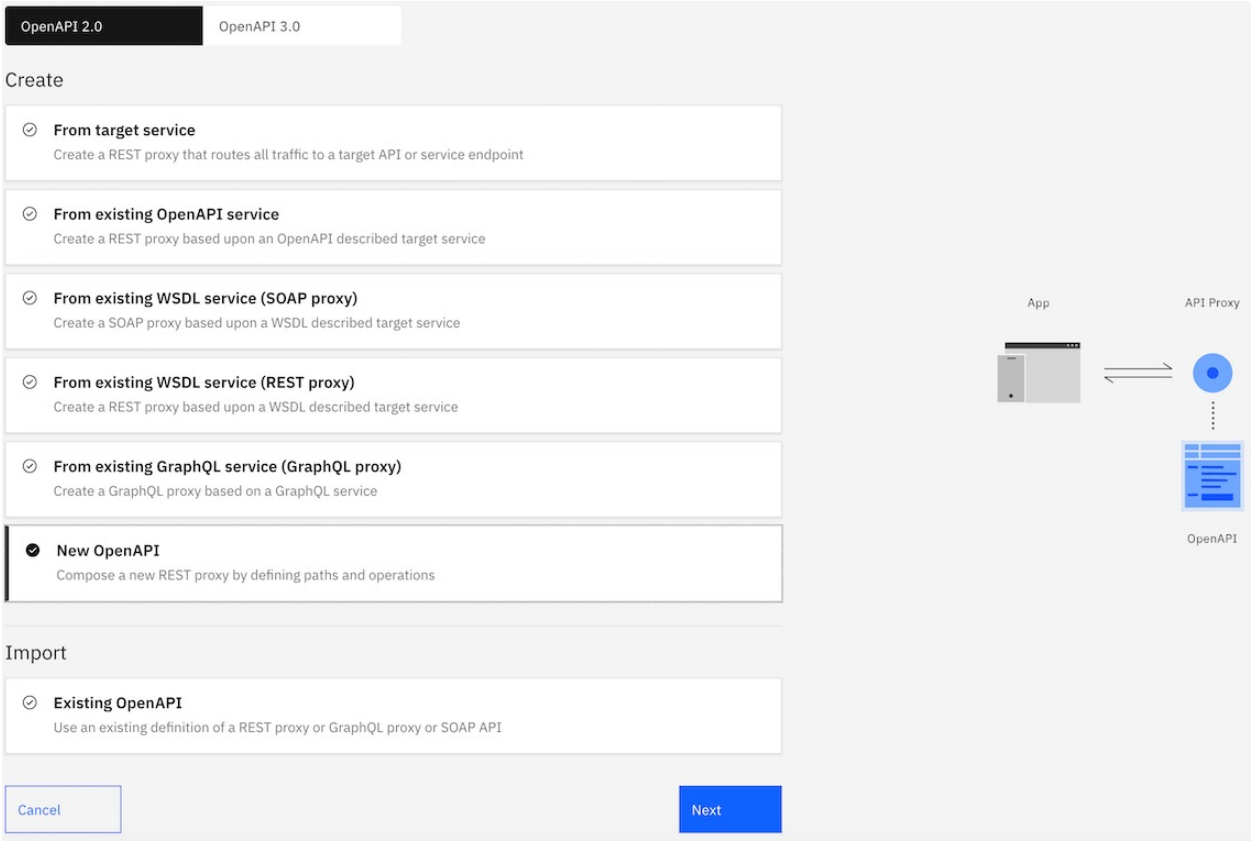
- Create a New API
- Map JSON Content

Create a New API

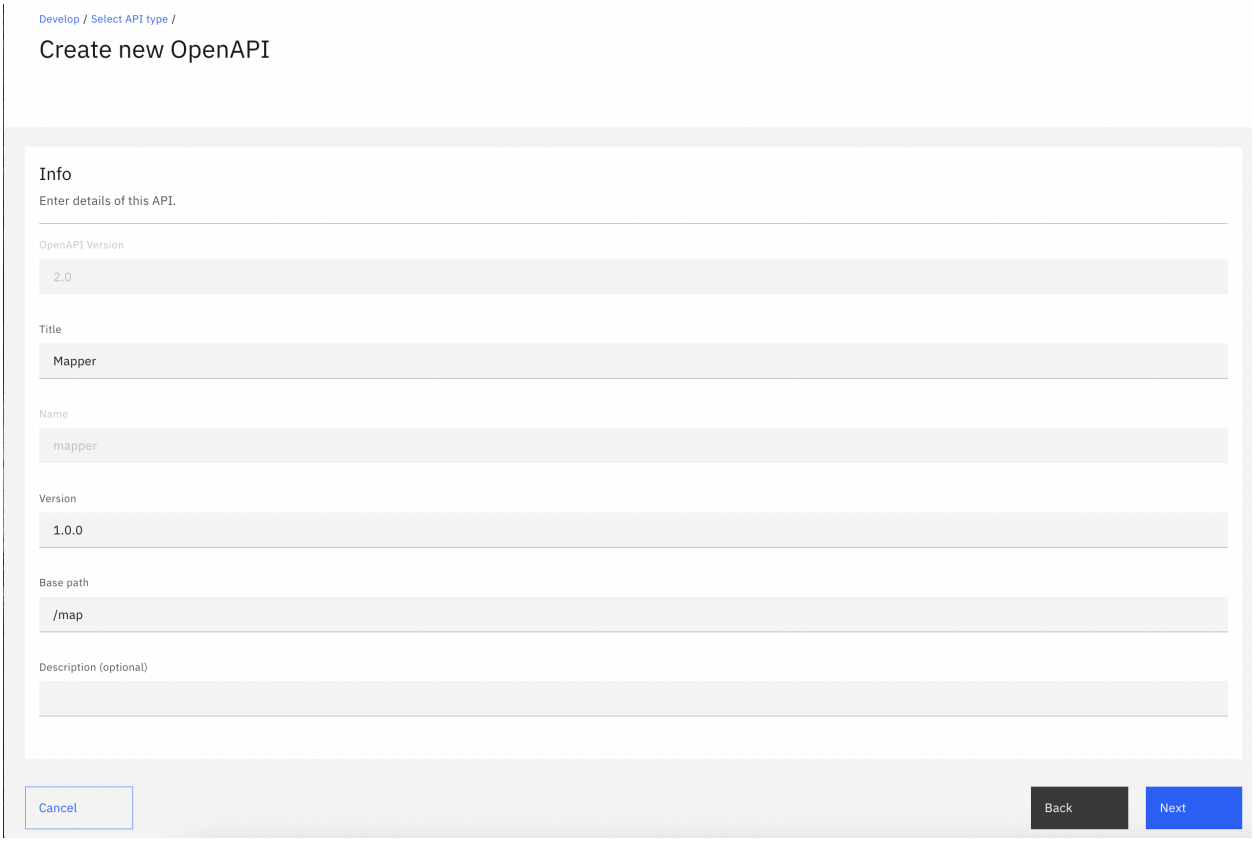


Take the following steps to create a new API.

1. Log in to API Manager.
2. In the Home page, click the Develop APIs and Products tile.

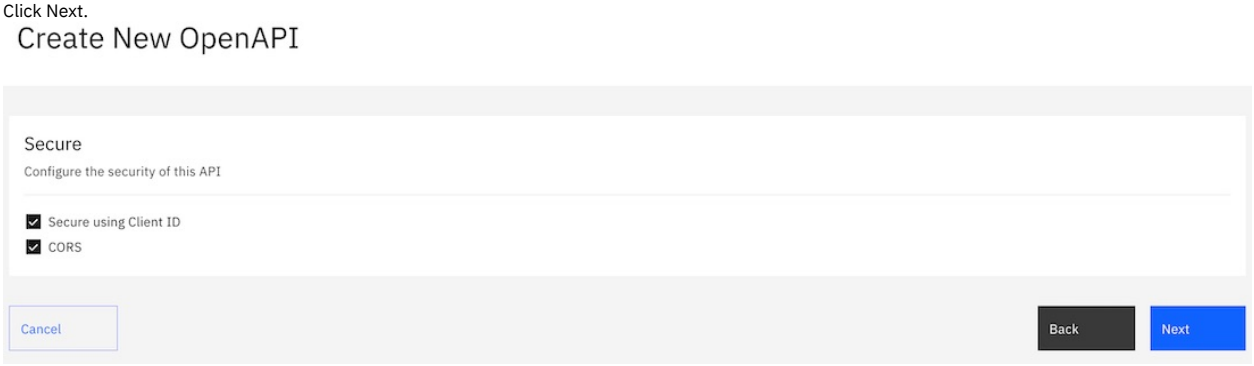


Alternatively, click the Develop icon on the left panel.

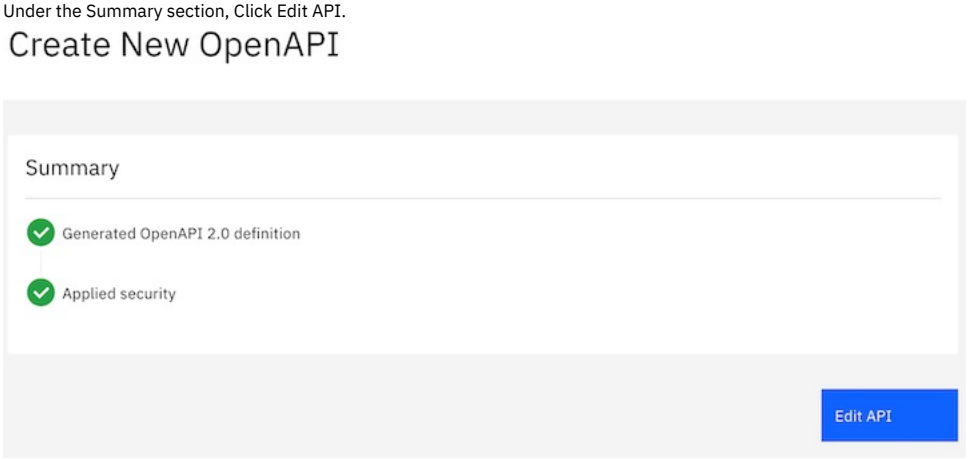


3. In the Develop page, click Add > API.

4. In the Select API type page,
   a. Ensure that OpenAPI 2.0 is selected.
   b. Select the New OpenAPI radio button.
   c. Click Next.

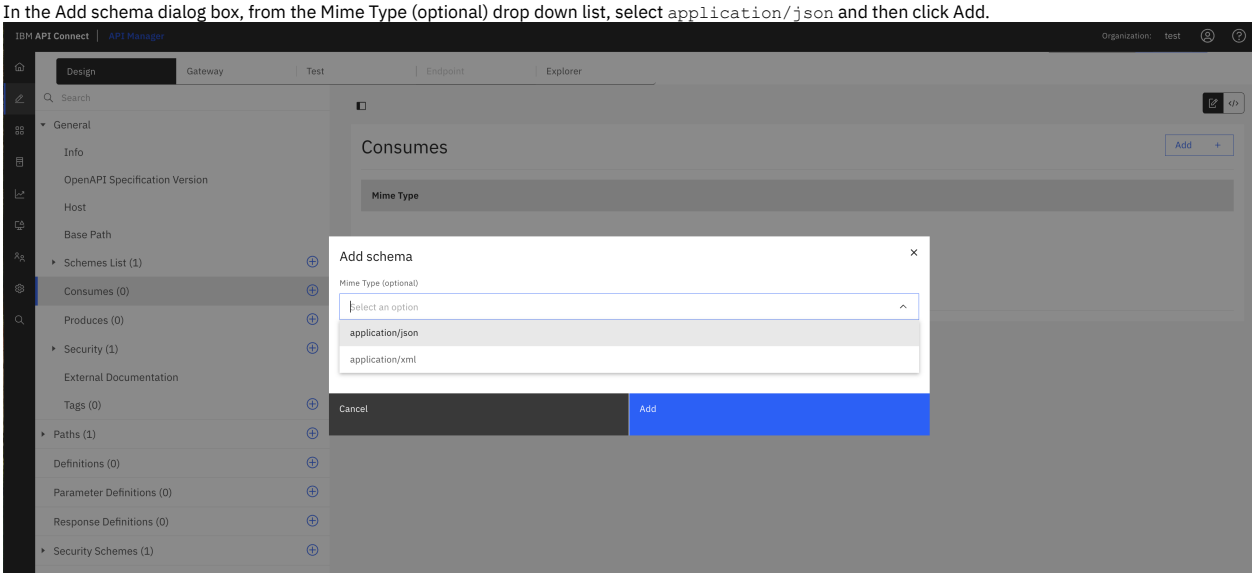


5. In the Create new OpenAPI page, enter the following information about the API.
   Note: The OpenAPI Version field is pre-defined. You can't update this field.
   a. In the Title field, enter `Mapper`.
      The Name field is filled with the value that you enter in the Title field.
   b. In the Version field, enter `1.0.0`.
   c. In the Base path field, enter `/map`.
   d. Click Next.



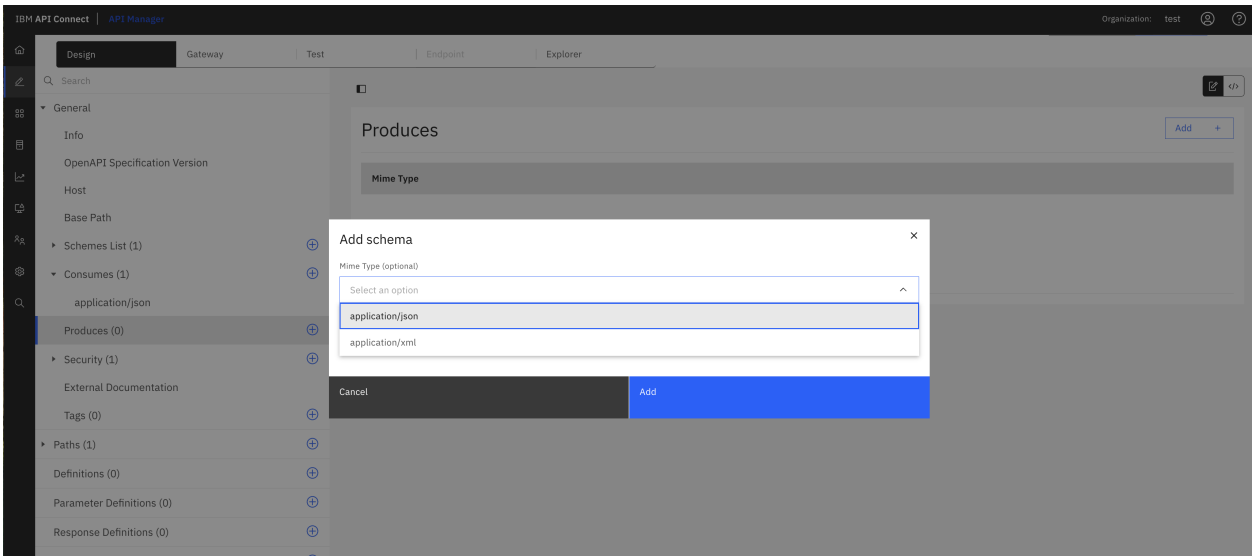
6. Under the Secure section,

a. The Secure using Client ID and the CORS check boxes are per-selected. Don't deselect the check boxes.
b. Click Next.

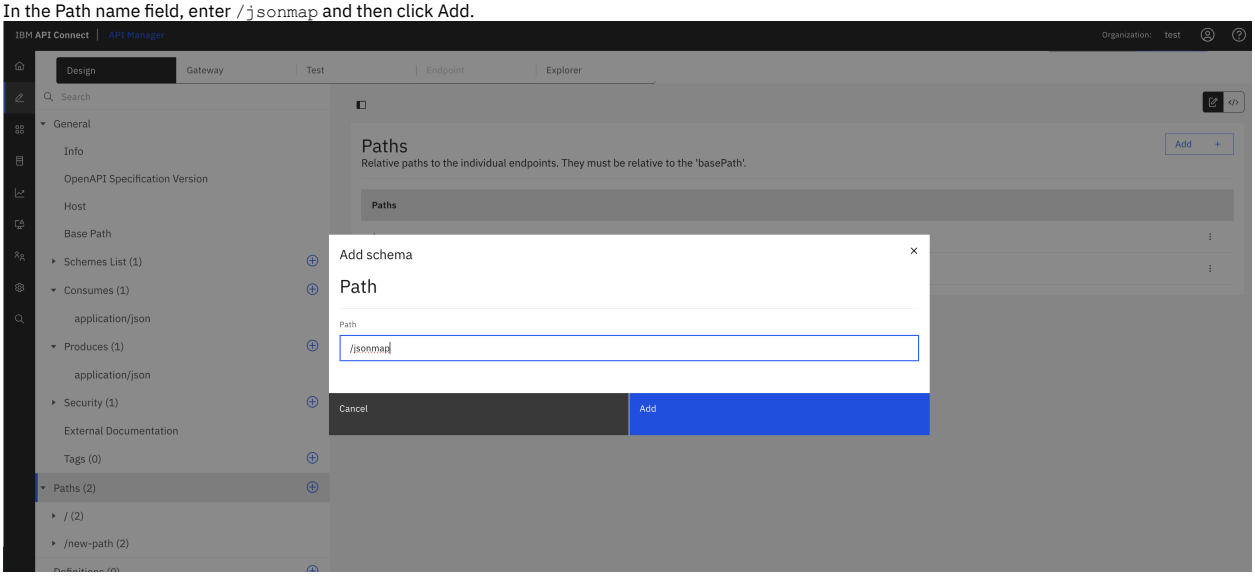


You see the progress as the new API is created. When the API is created, you see a Summary.

7. Under the Summary section, Click Edit API.

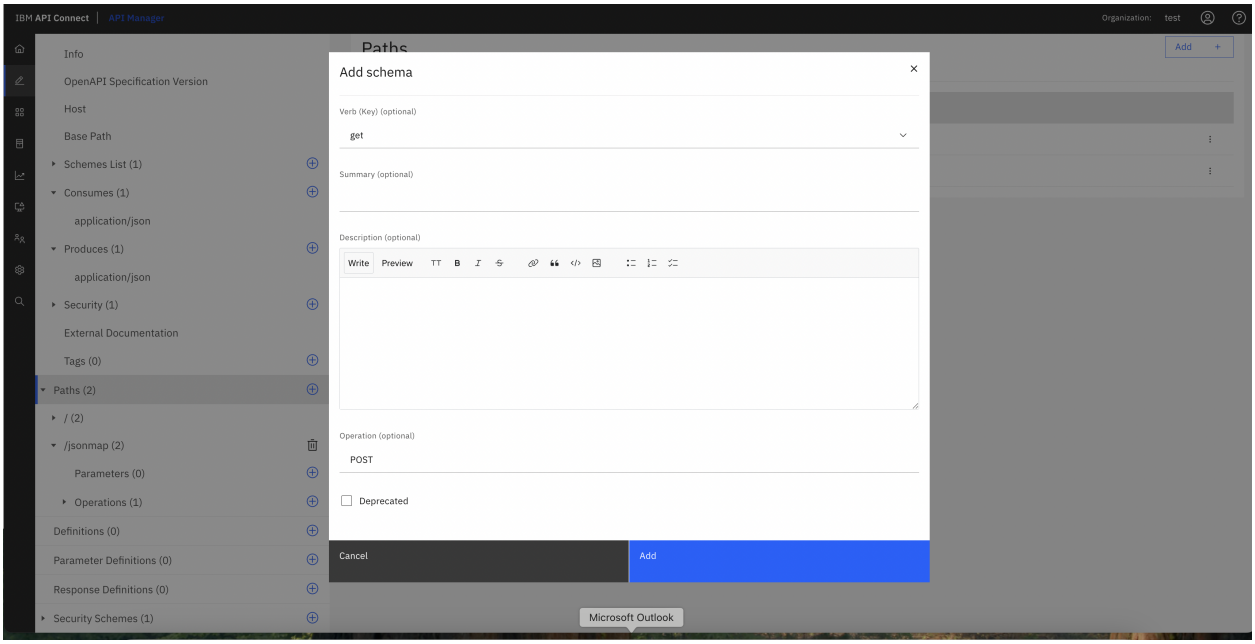


The Design tab for the draft of your API definition is displayed.

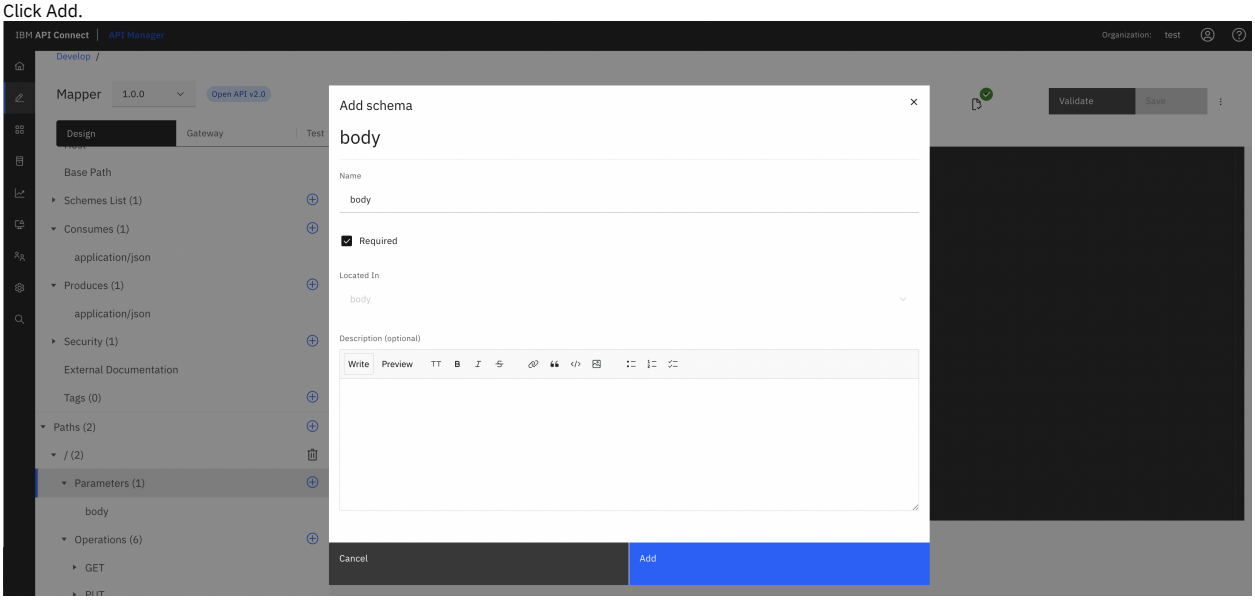


8. In the left panel, click Consumes.
9. In the right panel, in the Consumes section,
   a. Click Add +.
   b. In the Add schema dialog box, from the Mime Type (optional) drop down list, select `application/json` and then click Add.

10. In the left panel, click Produces.
11. In the right panel, in the Produces section,
    a. Click Add +.
    b. In the Add schema dialog box, from the Mime Type (optional) drop down list, select `application/json` and then click Add.

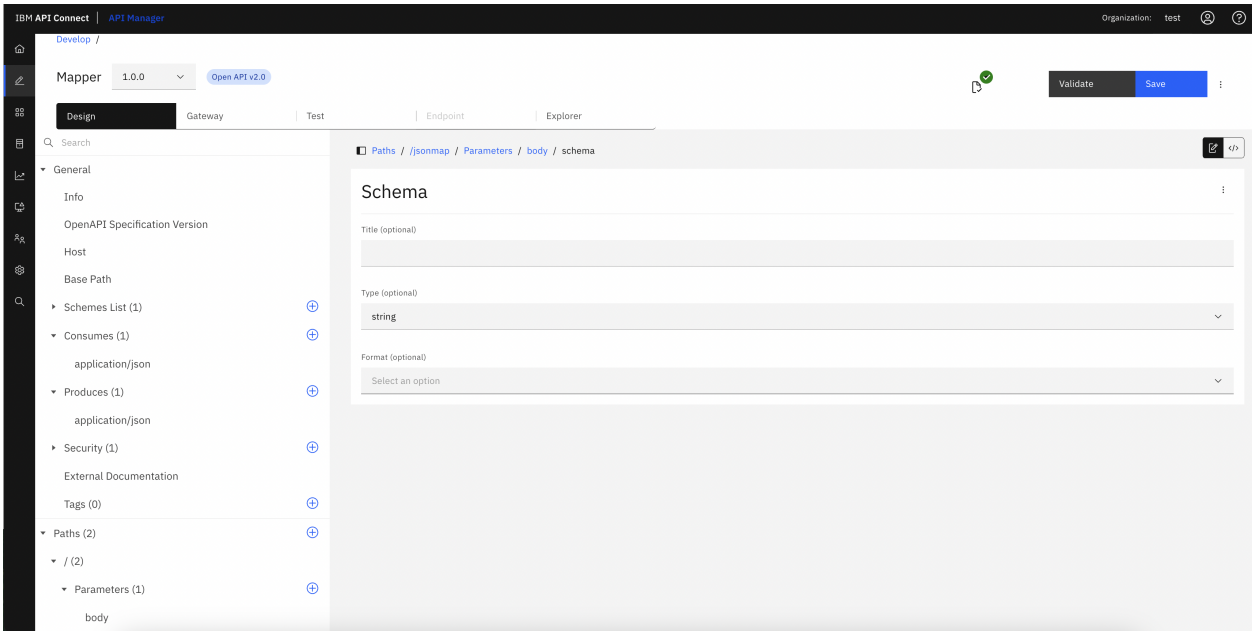


12. In the left panel, click Paths.
13. In the right panel, in the Paths section,
    a. Click Add +.
    b. In the Path name field, enter `/jsonmap` and then click Add.

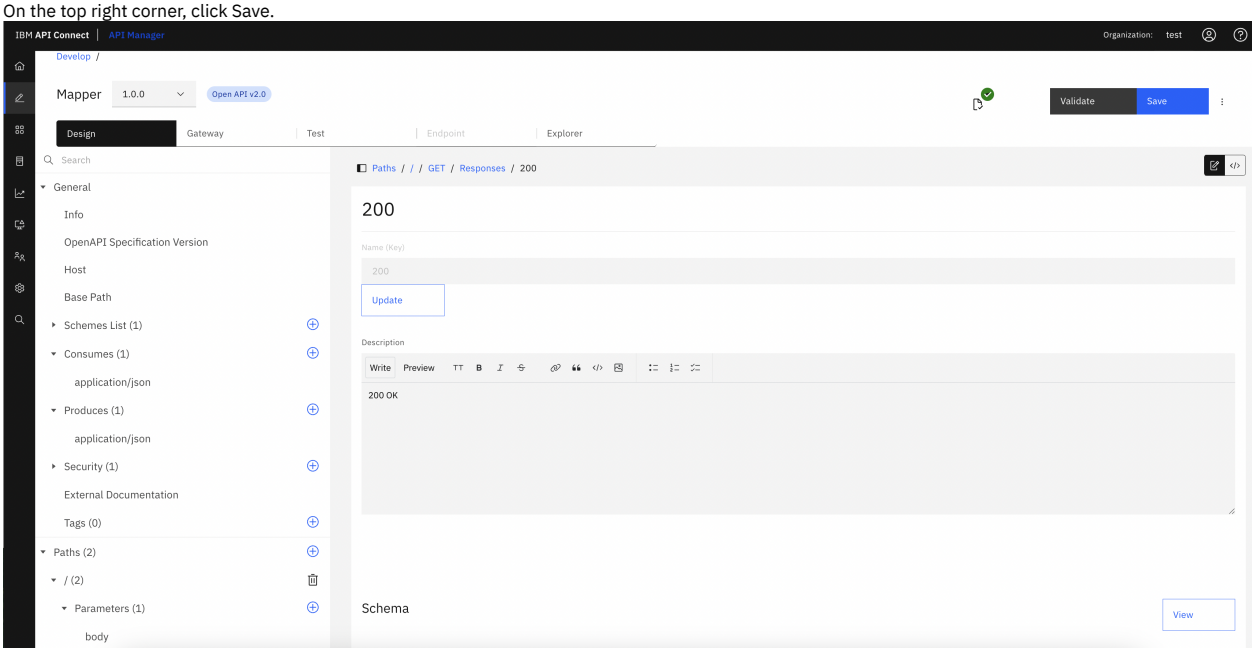


14. In the left panel, under the newly created path (/jsonmap), beside Operations, click the + icon.
    The Add schema dialog box is displayed.

15. In the Add schema dialog box, perform the following tasks.
    a. In the Verb(Key)(optional) field, enter `get`.
    b. In the Operation (optional) field, enter POST.
    c. Click Add.

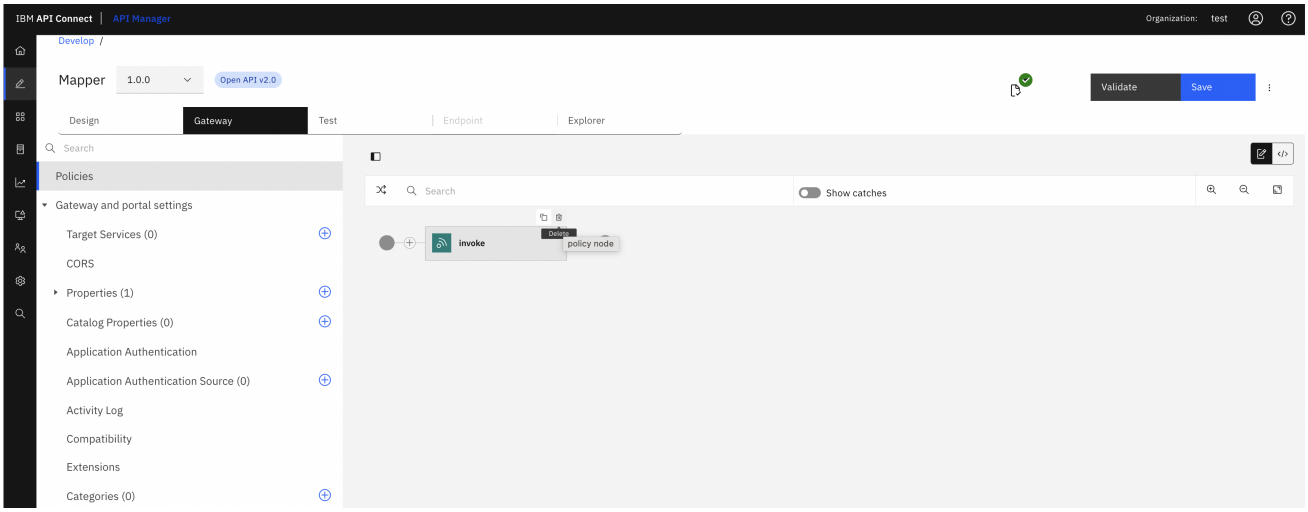


16. In the left panel, beside Parameters, click the + icon.
    The Add schema dialog box is displayed.

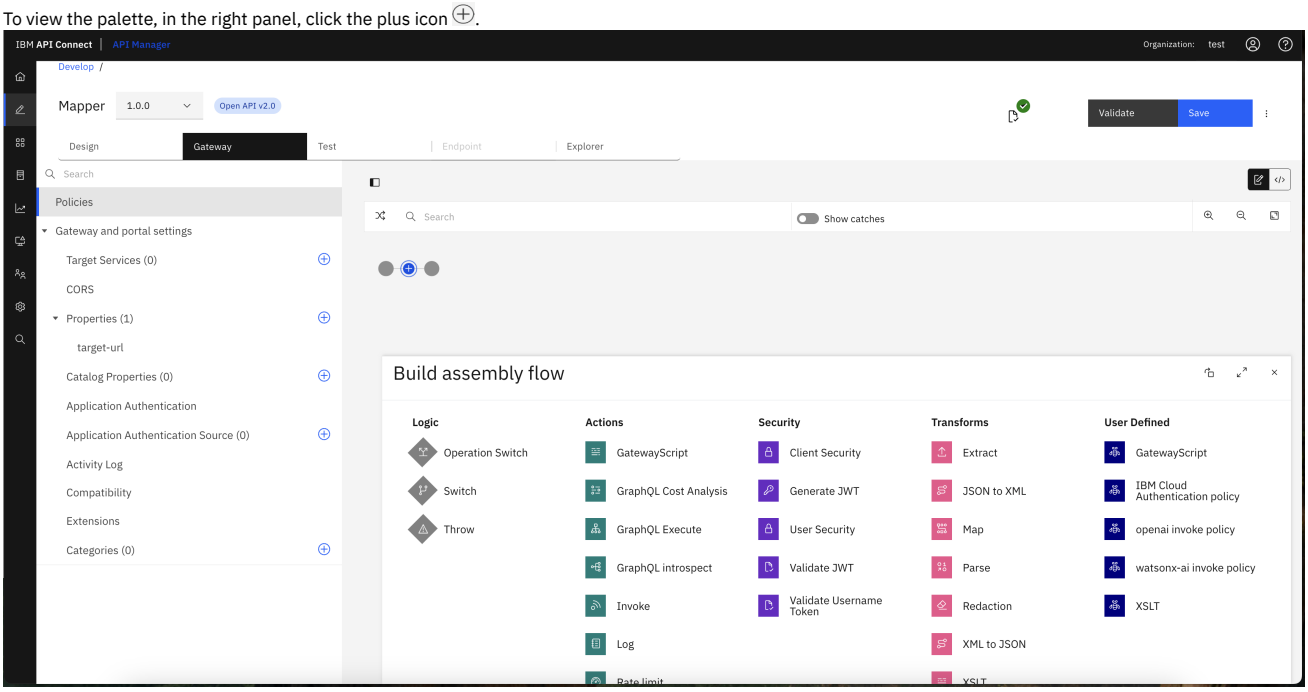


17. In the Add schema dialog box, perform the following tasks.
    a. In the Name field, enter `body`.
    b. Select the Required checkbox.
    c. From the Located In drop down list, select `body`.
    d. Click Add.

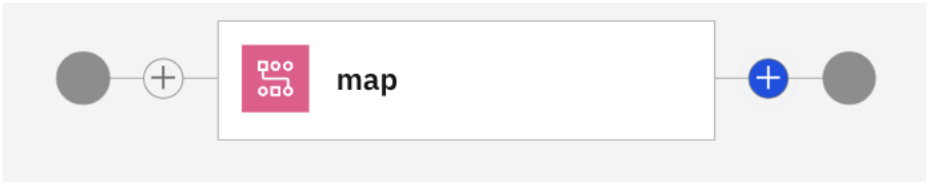
18. Scroll down to the Schema section and then click View.
19. Under the Schema section, perform the following tasks.
    a. In the Title (optional) filed, enter `body`.
    b. From the Type drop down list, select string.
    c. On the top right corner, click Save.



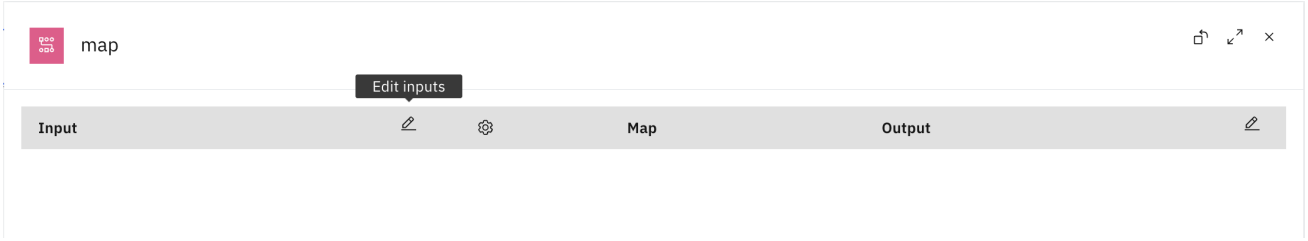
20. In the left panel, expand Paths > Operations > Responses.
21. Under Responses, click 200.
22. In the right panel, under the 200 section, perform the following tasks.
    a. In the Name (Key) filed, enter `200`.
    b. In the Description field, enter `200 OK`.
    c. On the top right corner, click Save.



Map JSON Content

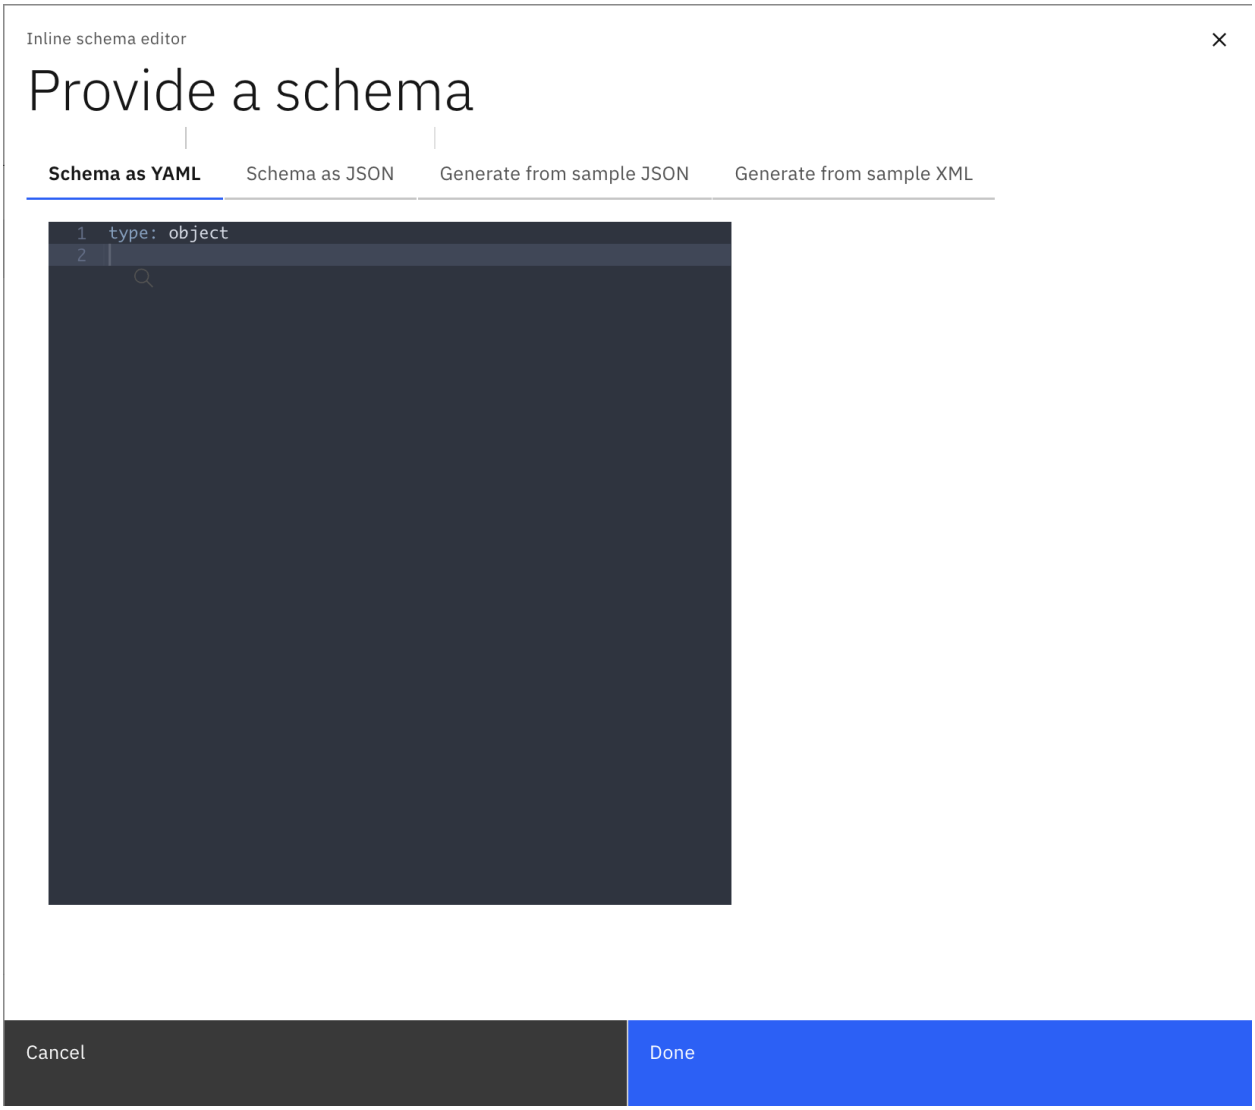


1. Click the Gateway tab.
2. Delete the existing policy on the canvas by hovering your cursor over the policy and then clicking the Delete icon .
   Note: If you are using the DataPower API Gateway, the policy is an invoke policy whereas if you are using the DataPower Gateway (v5 compatible), the policy is a proxy policy.



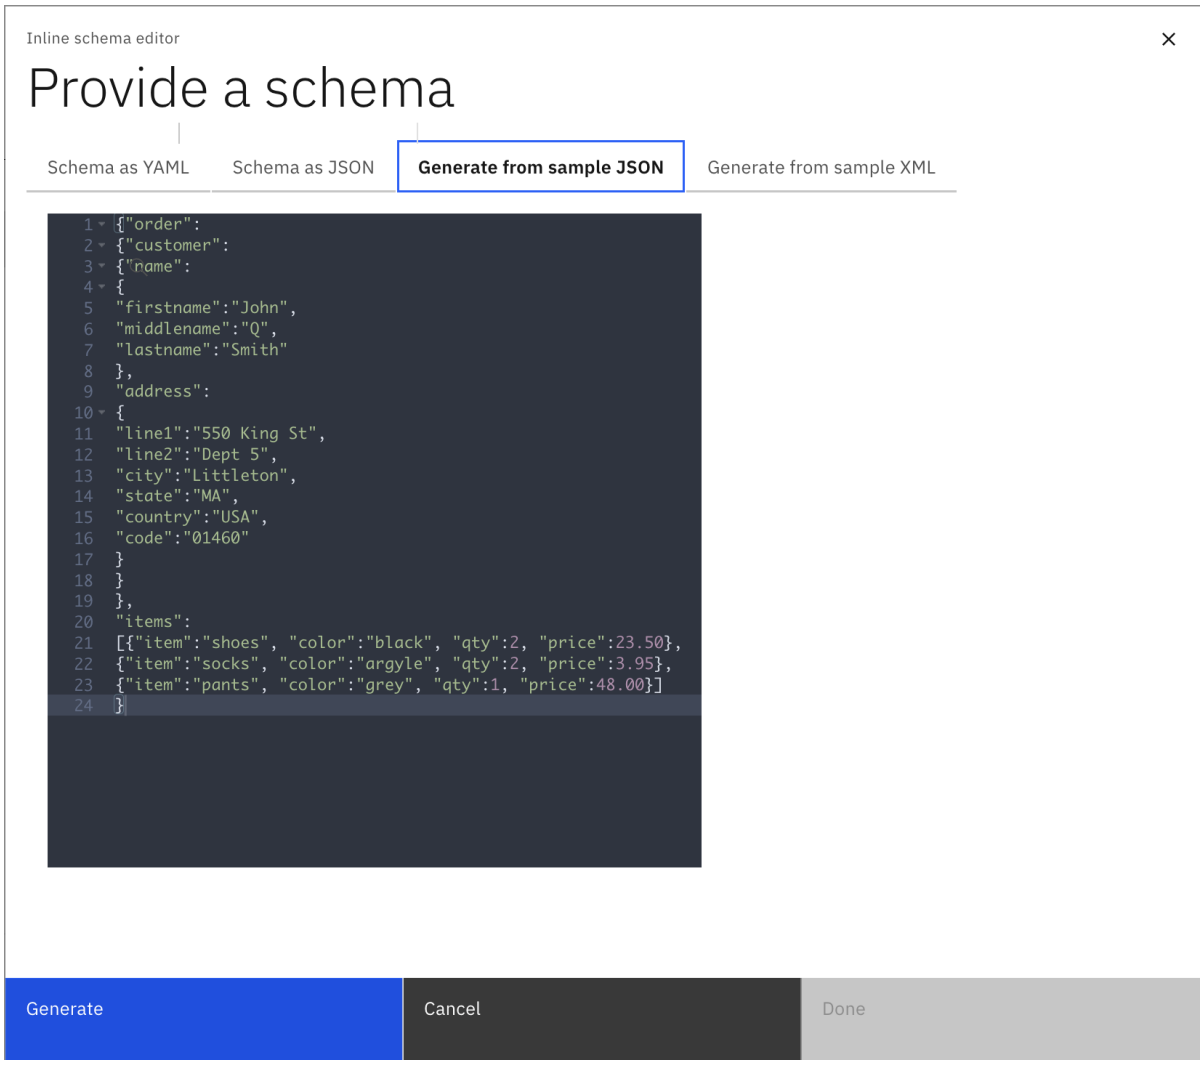
3. To view the palette, in the right panel, click the plus icon ⊕.

4. Under the Transforms column, select map.
   The map policy node is displayed on the canvas.



5. Click the map policy node to open the configuration dialog box.
6. Adjacent to Input, click the Edit inputs icon.

7. Click Add input.
8. Complete the map input configuration by entering the following values
   a. In the Context variable field, enter `request.body`.
   b. In the Name field, enter `input`.
   c. From the Content type drop down list, select `application/json`.

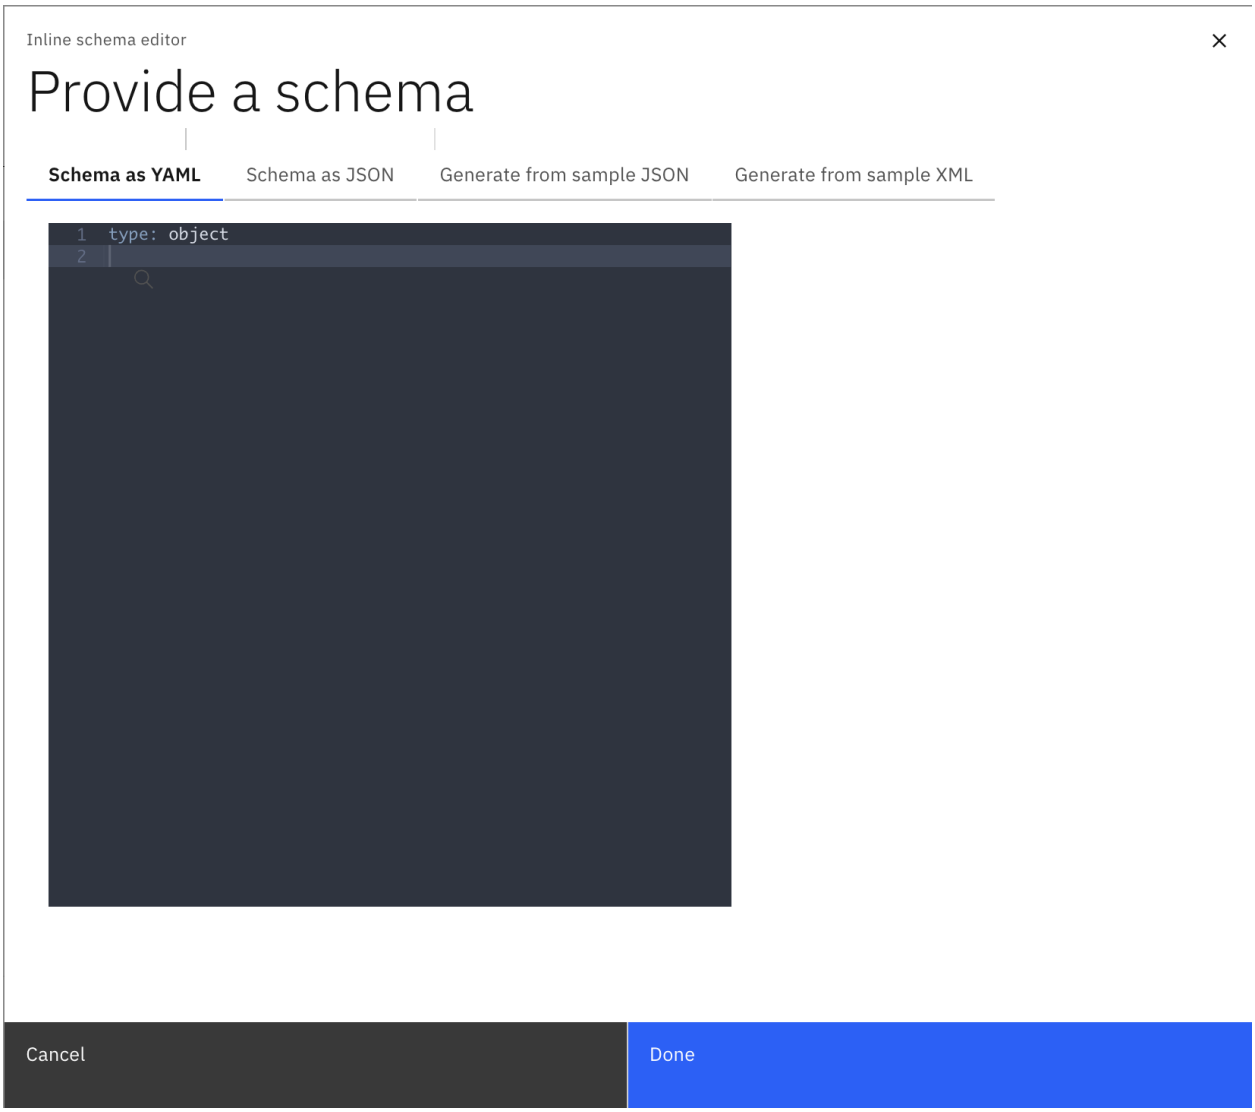


d. From the Definition drop down list, select `Inline schema`.
The Provide a schema pop up window is displayed.

e. In the Provide a schema pop up window, perform the following tasks.
   i. Select the Generate from sample JSON tab.
   ii. Paste the following sample JSON into the box.

```
{"order":
{"customer":
{"name":
{
"firstname":"John",
"middlename":"Q",
"lastname":"Smith"
},
"address":
{
"line1":"550 King St",
"line2":"Dept 5",
"city":"Littleton",
"state":"MA",
"country":"USA",
"code":"01460"
}
}
},
"items":
[{"item":"shoes", "color":"black", "qty":2, "price":23.50},
{"item":"socks", "color":"argyle", "qty":2, "price":3.95},
{"item":"pants", "color":"grey", "qty":1, "price":48.00}]
}
```

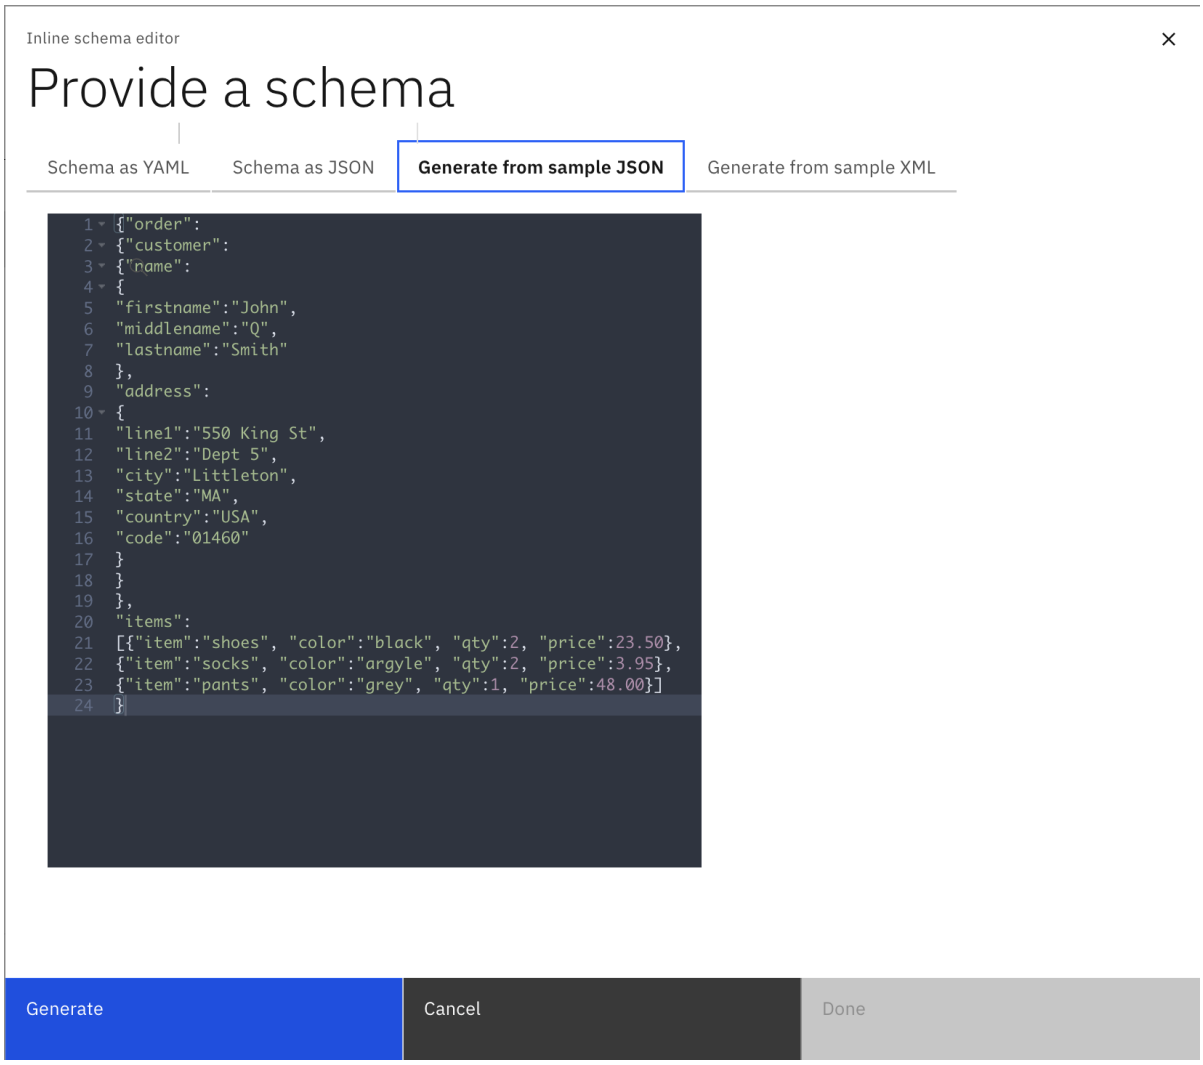
   iii. Click Generate.



iv. Click Done.
The pop up window is now closed.

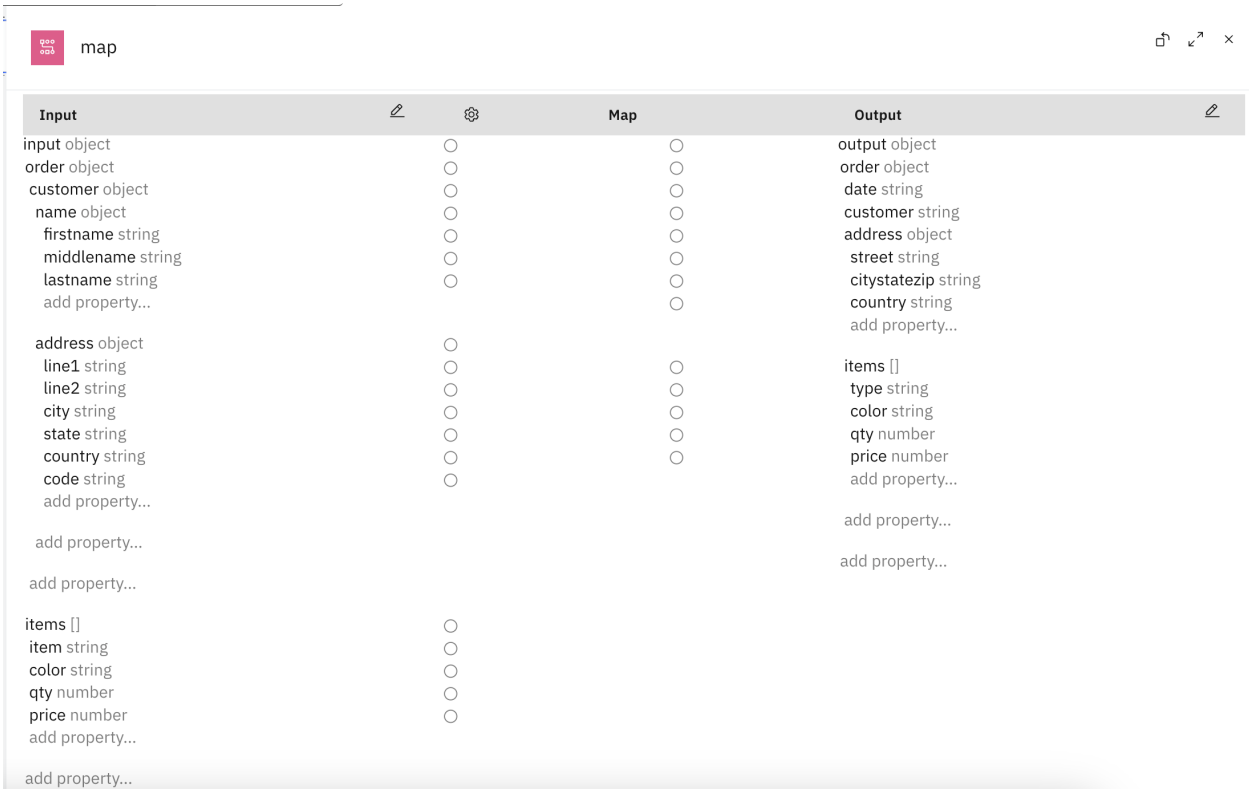
f. In the map policy configuration dialog box, click Done to complete the map configuration.

9. Adjacent to the Output column, click the Edit outputs icon .



10. Click Add output.
11. Complete the map output configuration by entering the following values
    a. In the Context variable field, enter `message.body`.
    b. In the Name field, enter `output`.
    c. From the Content type drop down list, select `application/json`.
    d. From the Definition drop down list, select `Inline schema`.
    The Provide a schema pop up window is displayed.

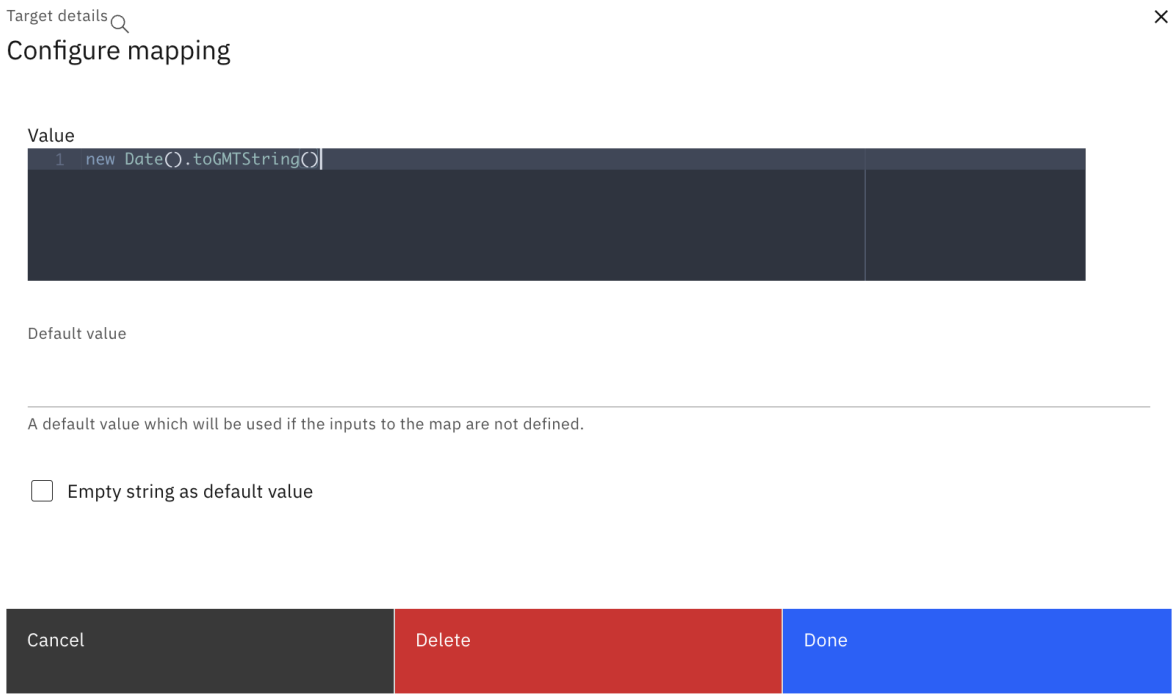
e. In the Provide a schema pop up window, perform the following tasks.
   i. Select the Generate from sample JSON tab.
   ii. Paste the following sample JSON into the box.



```
{"order":
{
"date":"12-12-12",
"customer": "John Smith",
"address":
{
"street":"king",
"citystatezip":"lit MA 01469",
"country":"USA"
},
"items":[{"type":"shoes", "color":"black", "qty":2, "price":23.50}]
}
}
```

   iii. Click Generate.

f. Click Done.
The pop up window is now closed.



g. In the map policy configuration dialog box, click Done to complete the map configuration.

12. Click Save.
13. In the map output configuration window, on the Output column, perform the following task.
    a. Select the date radio button.
    The Configure mapping dialog box is displayed.

        i. In the Configure mapping dialog box, enter the following sample JavaScript.
        ```
        new Date().toGMTString()
        ```

        ii. Click Done.

    b. Under the Input column, select the firstname radio button and then under the Output column, select the customer radio button.
    The Configure mapping dialog box is displayed.

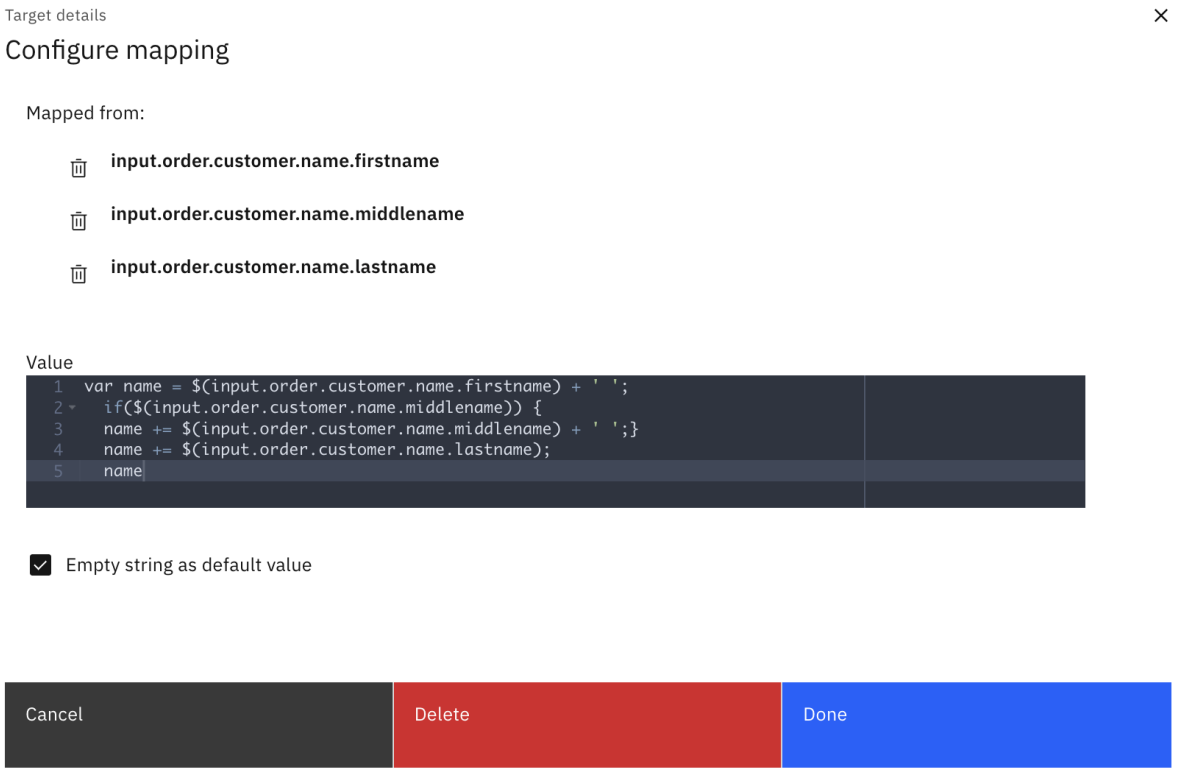
        i. In the Configure mapping dialog box, select the Empty string as default value check box.
        ii. Click Done.
    c. Under the Input column, select the middlename radio button and then under the Output column, select the customer radio button.

The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, select the Empty string as default value check box.
ii. Click Done.

d. Under the Input column, select the lastname radio button and then under the Output column, select the customer radio button.
The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, select the Empty string as default value check box.
ii. Click Done.

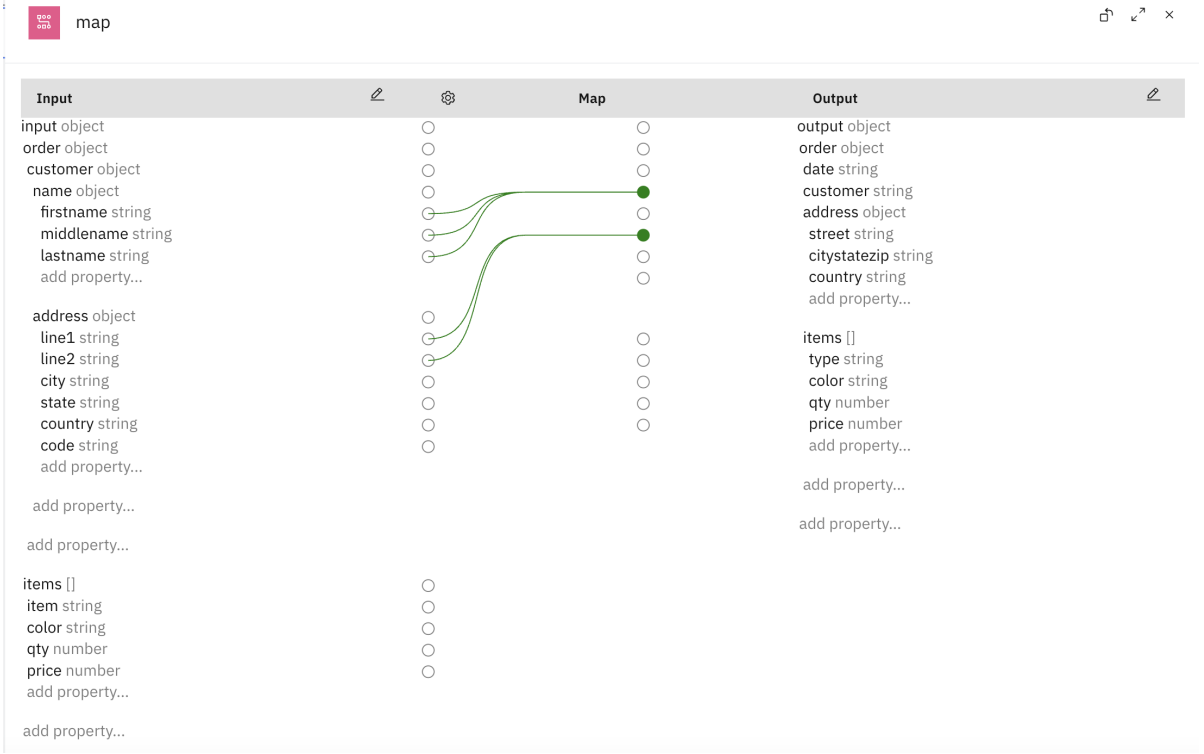


e. Under the Output column, select the customer radio button.
The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, in the Value field, enter the following sample code.

```
var name = $(input.order.customer.name.firstname) + ' ';
  if($(input.order.customer.name.middlename)) {
  name += $(input.order.customer.name.middlename) + ' ';}
  name += $(input.order.customer.name.lastname);
  name
```

ii. Click Done.

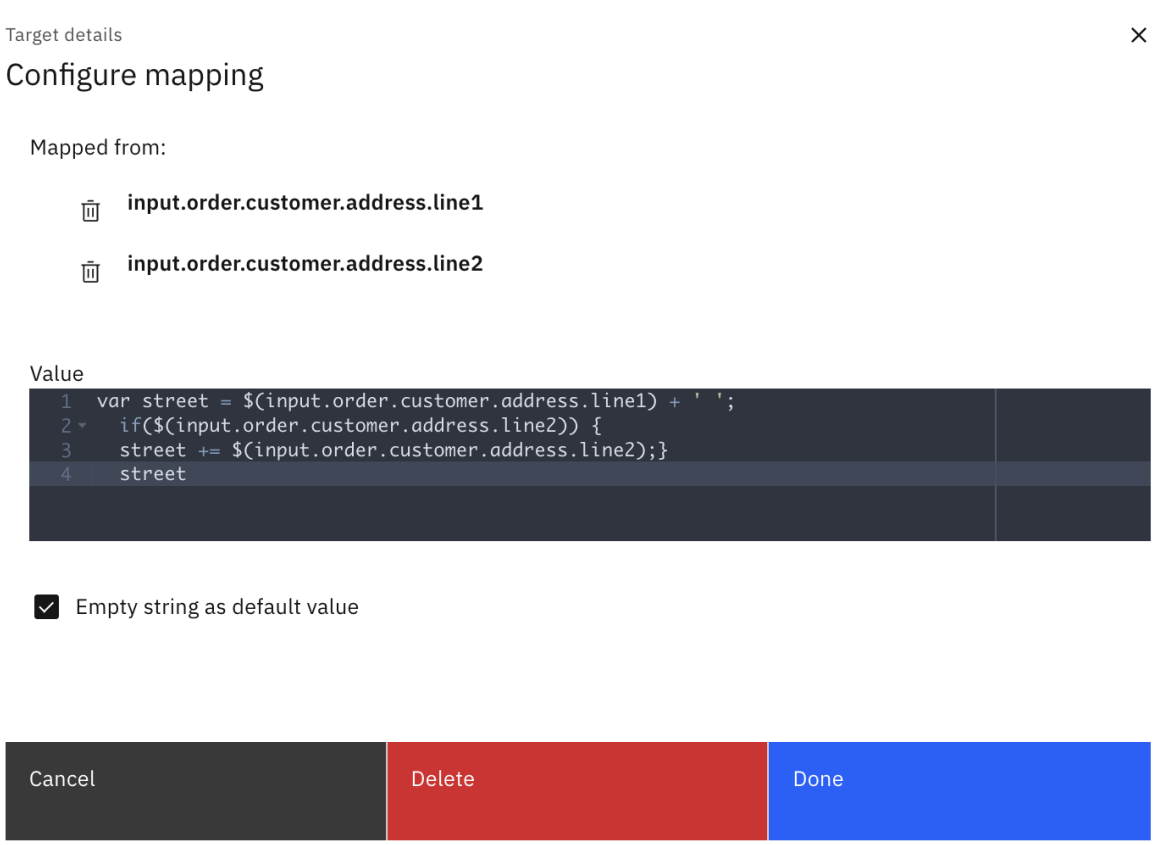


f. Under the Input column, select the address > line1 radio button and then under the Output column, select the street radio button.
The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, select the Empty string as default value check box.
ii. Click Done.

g. Under the Input column, select the address > line2 radio button and then under the Output column, select the street radio button.
The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, select the Empty string as default value check box.
ii. Click Done.



h. Under the Output column, select the street radio button.
The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, in the Value field, enter the following sample code.

```
var street = $(input.order.customer.address.line1) + ' ';
  if($(input.order.customer.address.line2)) {
  street += $(input.order.customer.address.line2);}
  street
```

ii. Click Done.

i. Under the Input column, select the city radio button and then under the Output column, select the citystatezip radio button. The Configure mapping dialog box is displayed.

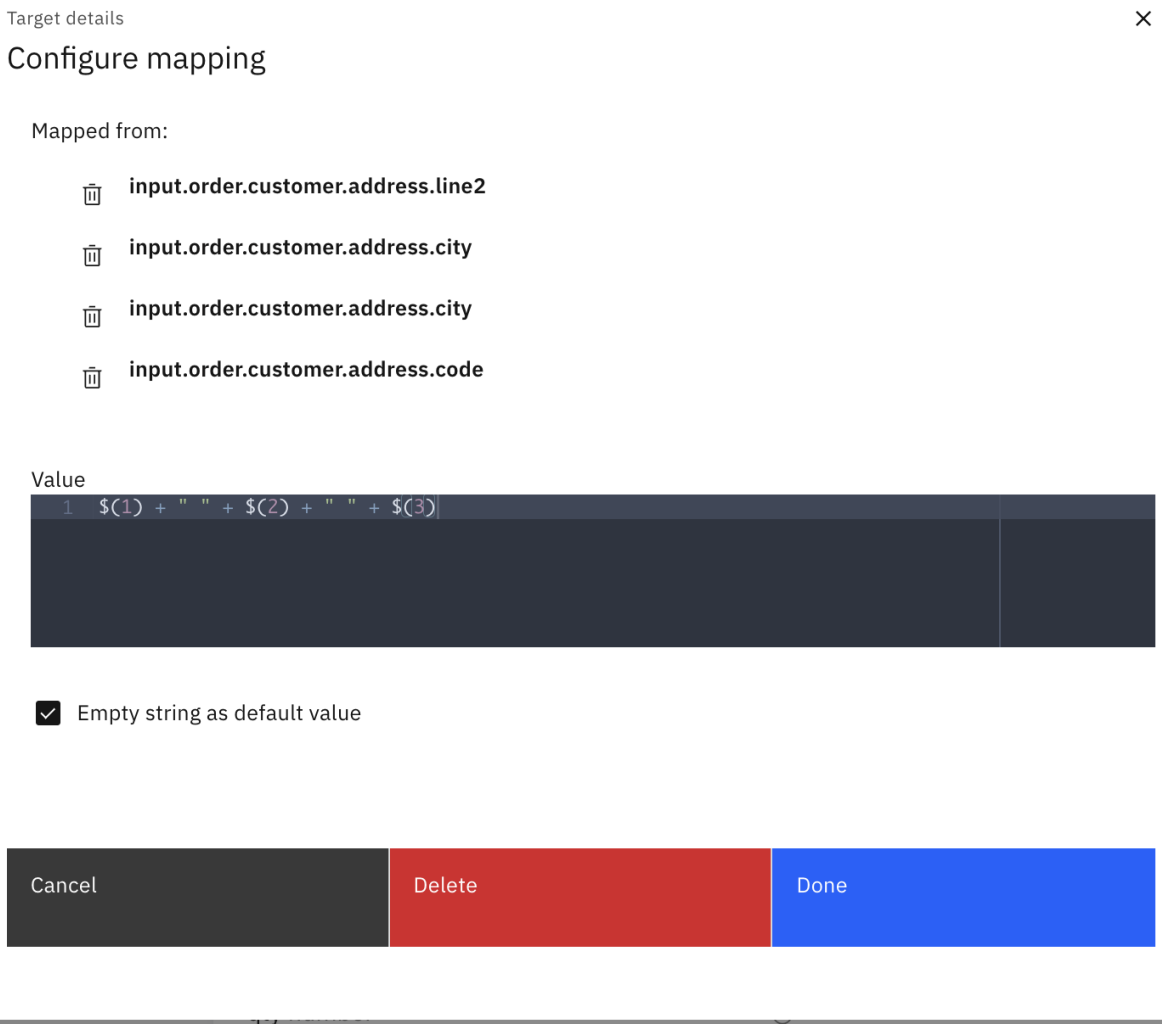
   i. In the Configure mapping dialog box, select the Empty string as default value check box.
   ii. Click Done.

j. Under the Input column, select the state radio button and then under the Output column, select the citystatezip radio button. The Configure mapping dialog box is displayed.

   i. In the Configure mapping dialog box, select the Empty string as default value check box.
   ii. Click Done.

k. Under the Input column, select the code radio button and then under the Output column, select the citystatezip radio button. The Configure mapping dialog box is displayed.

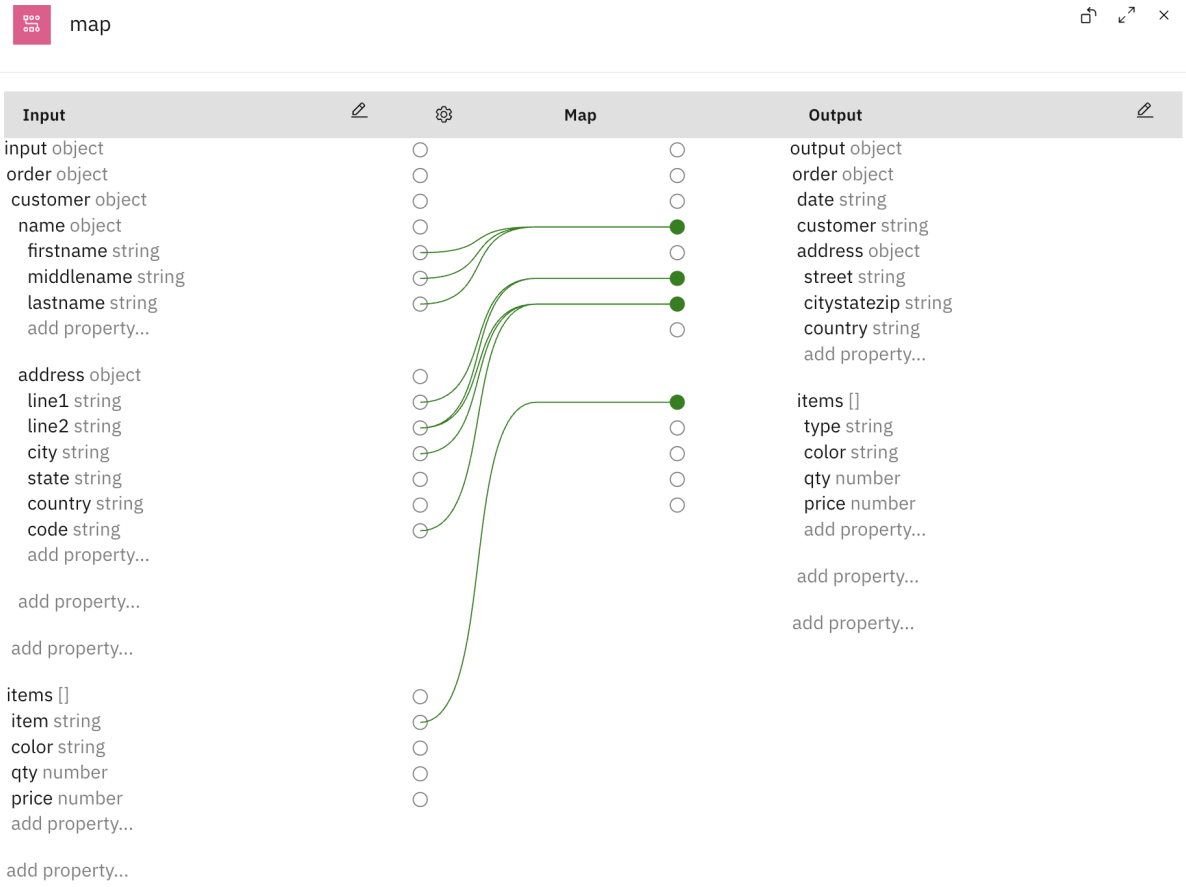
   i. In the Configure mapping dialog box, select the Empty string as default value check box.
   ii. Click Done.



l. Under the Output column, select the street radio button.
The Configure mapping dialog box is displayed.

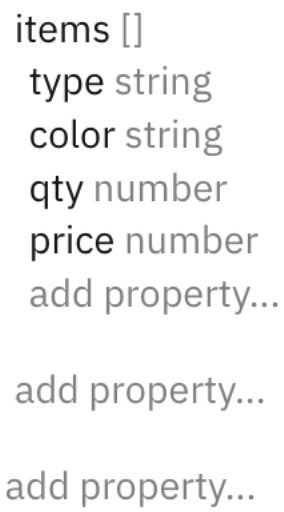
i. In the Configure mapping dialog box, in the Value field, enter the following sample code.

```
$(1) + " " + $(2) + " " + $(3)
```



Note: The variable references are positional; $(1) refers to the first mapped value (`input.order.customer.city`), and so on.

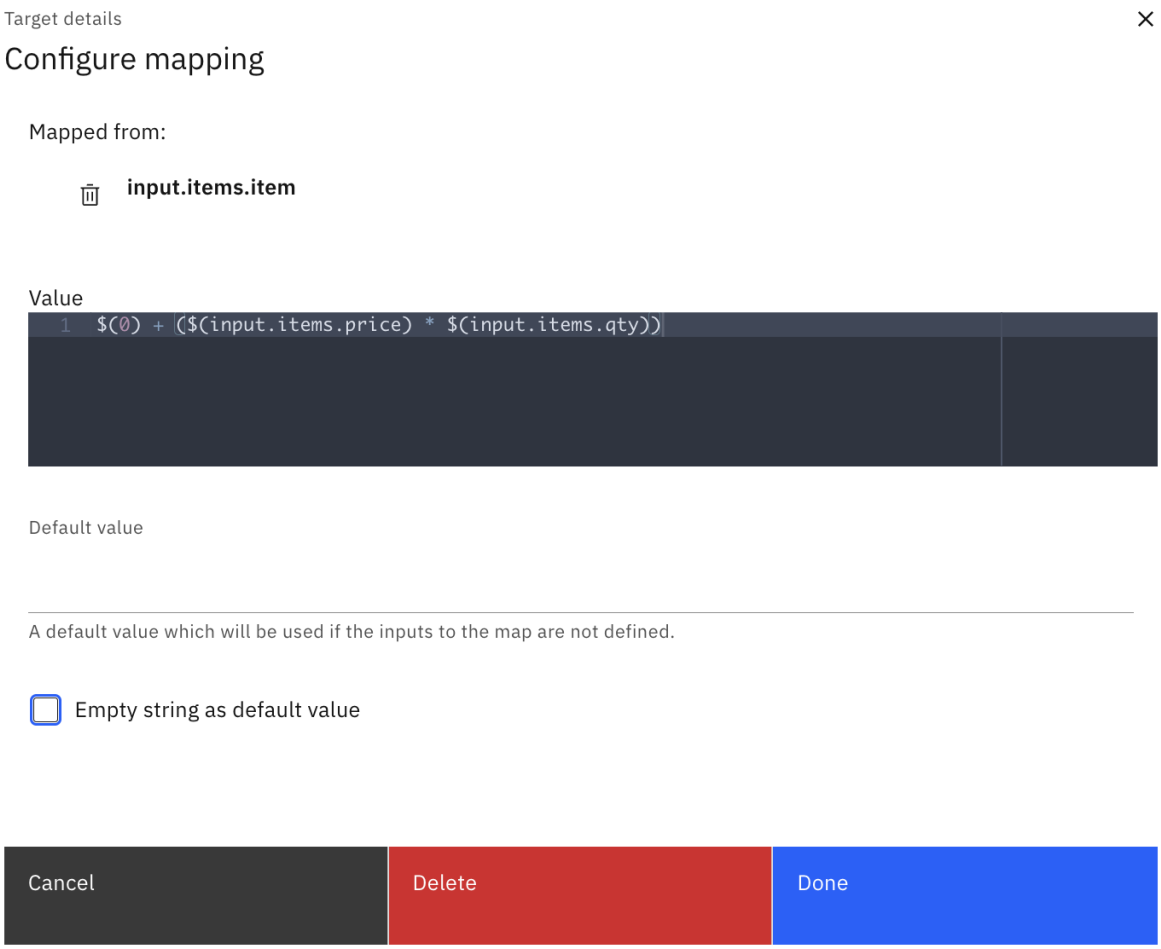
ii. Click Done.



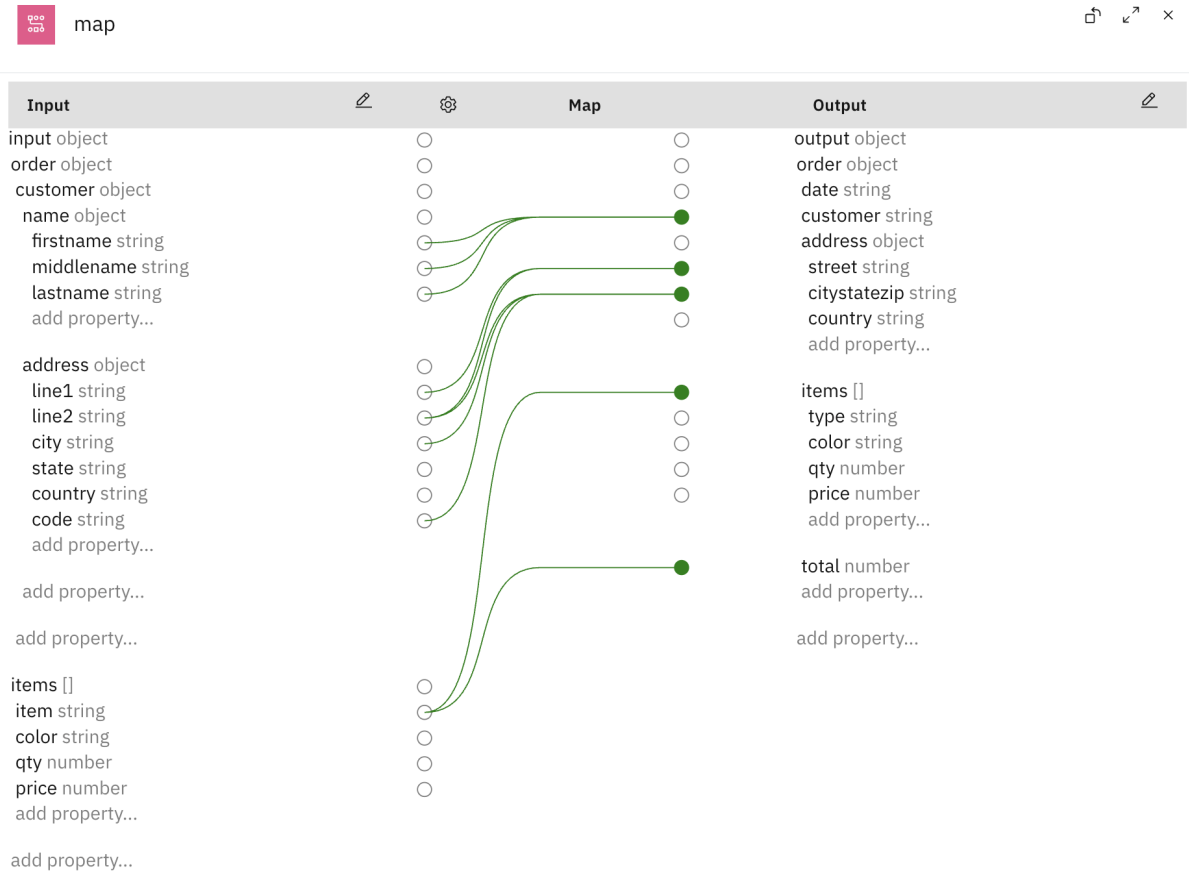
m. Under the Input column, select the items[*].item radio button and then under the Output column, select the items radio button.
The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, select the Empty string as default value check box.
ii. Click Done.

n. Under the Output column, click the second add property.



i. In the first field, enter `total`.
ii. From the drop down list, select `float`.
iii. Click the + icon.



o. Under the Input column, select the items radio button and then under the Output column, select the total radio button.
The Configure mapping dialog box is displayed.

i. In the Configure mapping dialog box, in the Value field, enter the following sample code.

```
$(0) + ($(input.items.price) * $(input.items.qty))
```

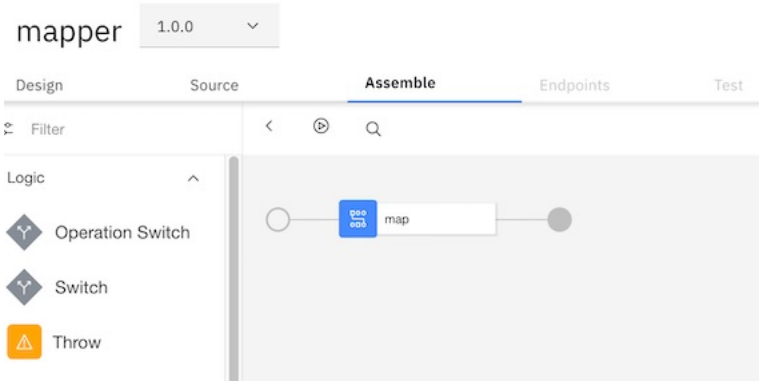
ii. Click Done.

p. On the map policy node output page, click Save.

14. Click Source.
15. Scroll down and locate the code where total is calculated.

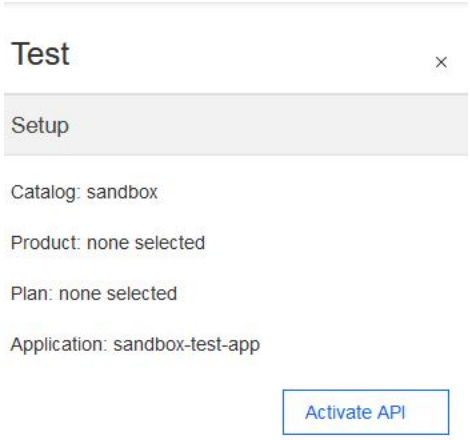
```
- create: output.order.items
  foreach: input.items
  from: input.items
  actions:
    - set: $item
      from: $item
- set: output.order.total
  from: input.items
  value: $(0) + ($(input.items.price) * $(input.items.qty))
```

16. Insert a new line with the code `foreach: input.items`.



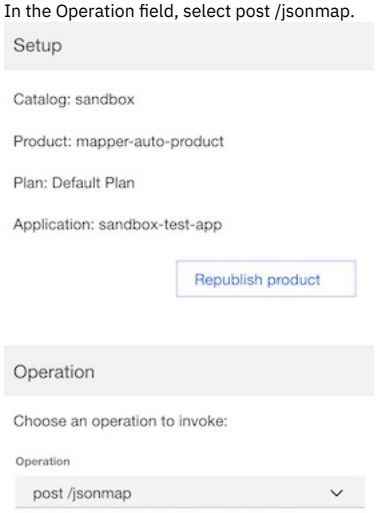
```
- set: output.order.total
  foreach: input.items
  from: input.items
  value: $(0) + ($(input.items.price) * $(input.items.qty))
```

17. Click Save.



Testing your API definition

Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test your API definition by using the API Manager test tool, complete the following steps:



1. Click the Assemble.

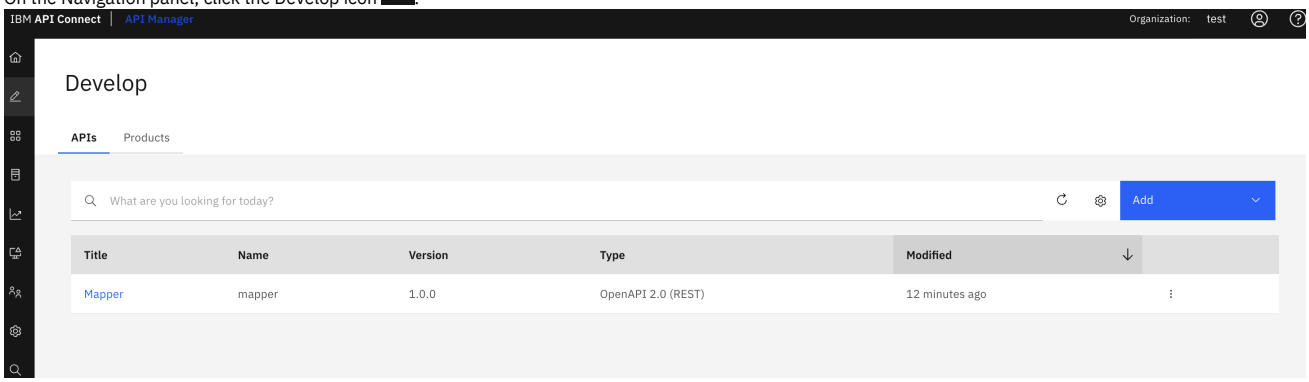
2. Click the Test icon ⓟ. The test tool opens.
3. Click Activate API.

4. In the Operation field, select post /jsonmap.

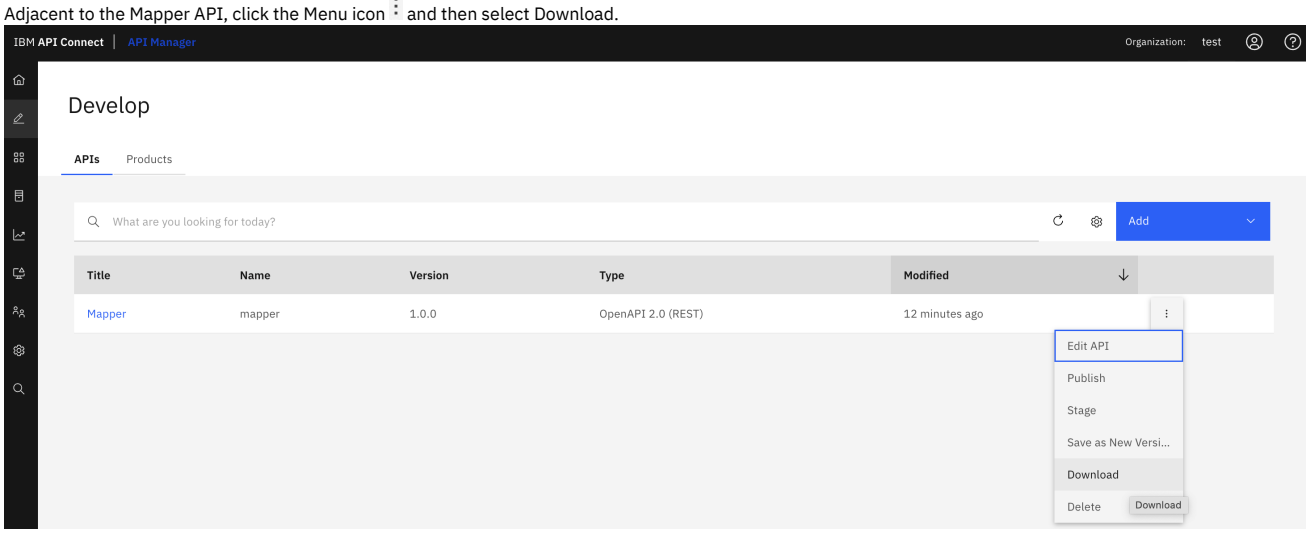
5. In the body field, enter the following JSON text.

```
{"order":
{"customer":
{"name":
{
"firstname":"John",
"middlename":"Q",
"lastname":"Smith"
},
"address":
{
"line1":"550 King St",
"line2":"Dept 5",
"city":"Littleton",
"state":"MA",
"country":"USA",
"code":"01460"
}
}
},
"items":
```

```
[{"item":"shoes", "color":"black", "qty":2, "price":23.50},
{"item":"socks", "color":"argyle", "qty":2, "price":3.95},
{"item":"pants", "color":"grey", "qty":1, "price":48.00}]
}
```



6. Click Invoke. The response is displayed. Note that the values of the **`date`**, **`street`**, **`citystatezip`**, and **`total`** fields reflect the mapping formulas that you defined previously.
   Note: If you are using a self-signed certificate, you might be prompted to visit a provided URL. Click the link and then accept the certificate before returning to API Manager and clicking Invoke again.



Manage your API definition

With your new API now working as expected, you can begin managing it. To see your immediate options, perform the following steps.

1. On the Navigation panel, click the Develop icon .

2. Adjacent to the Mapper API, click the Menu icon and then select Download.

What you did in this tutorial

- Created a new API
- Mapped content from one JSON schema to another schema.

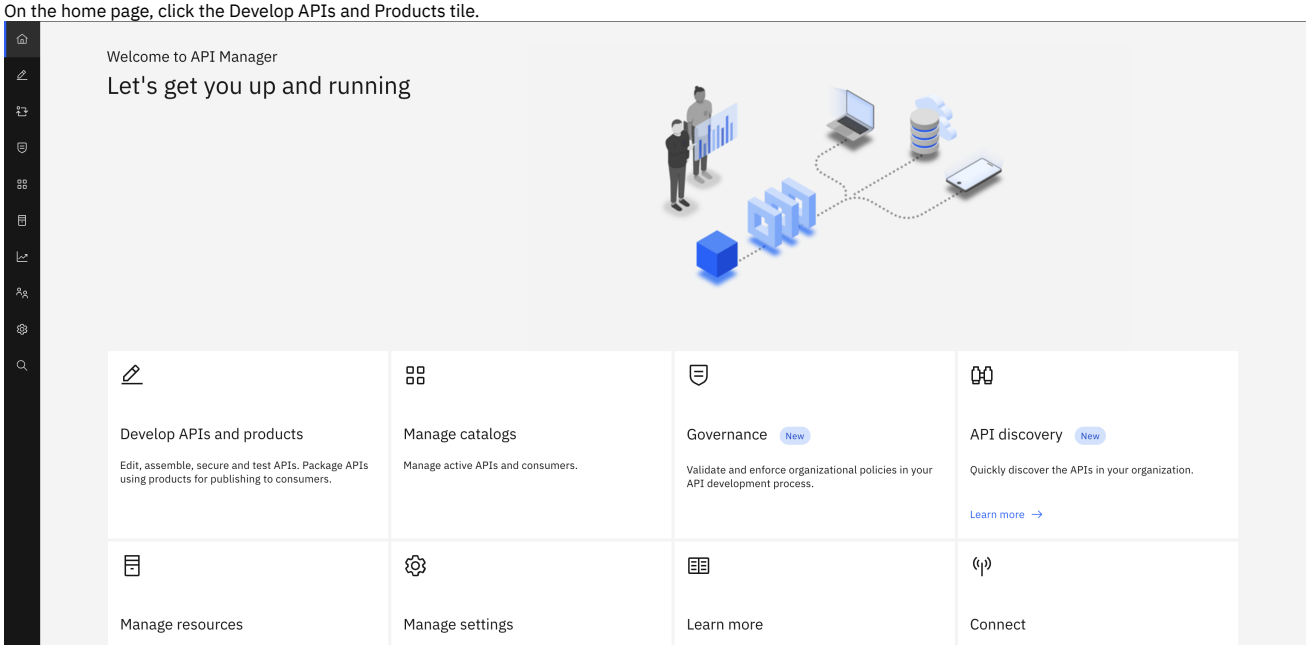
Tutorial: Importing an API

This tutorial shows you how to import an existing OpenAPI 2.0 definition.

About this tutorial

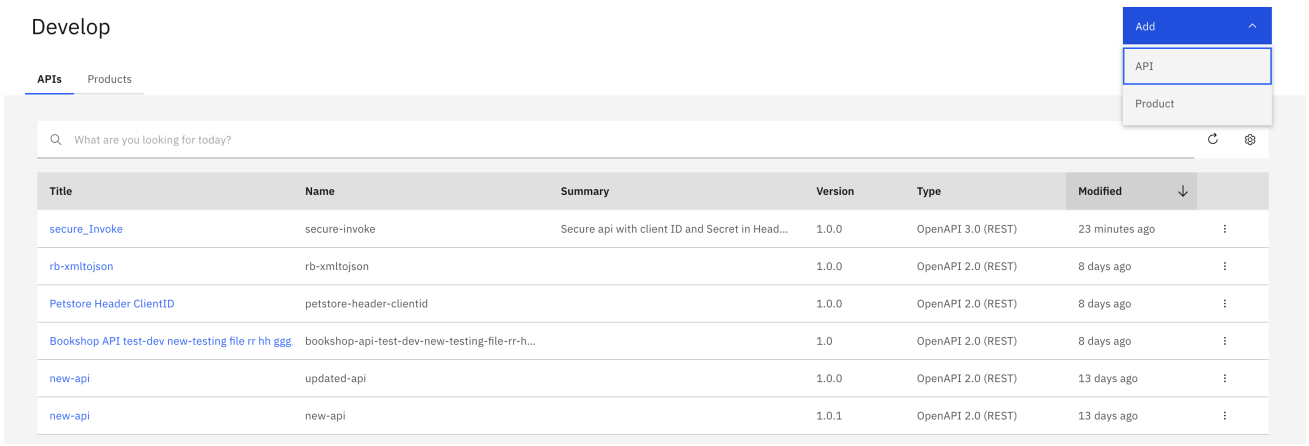
This tutorial includes the following lessons:

1. Importing an API
2. Testing the imported API



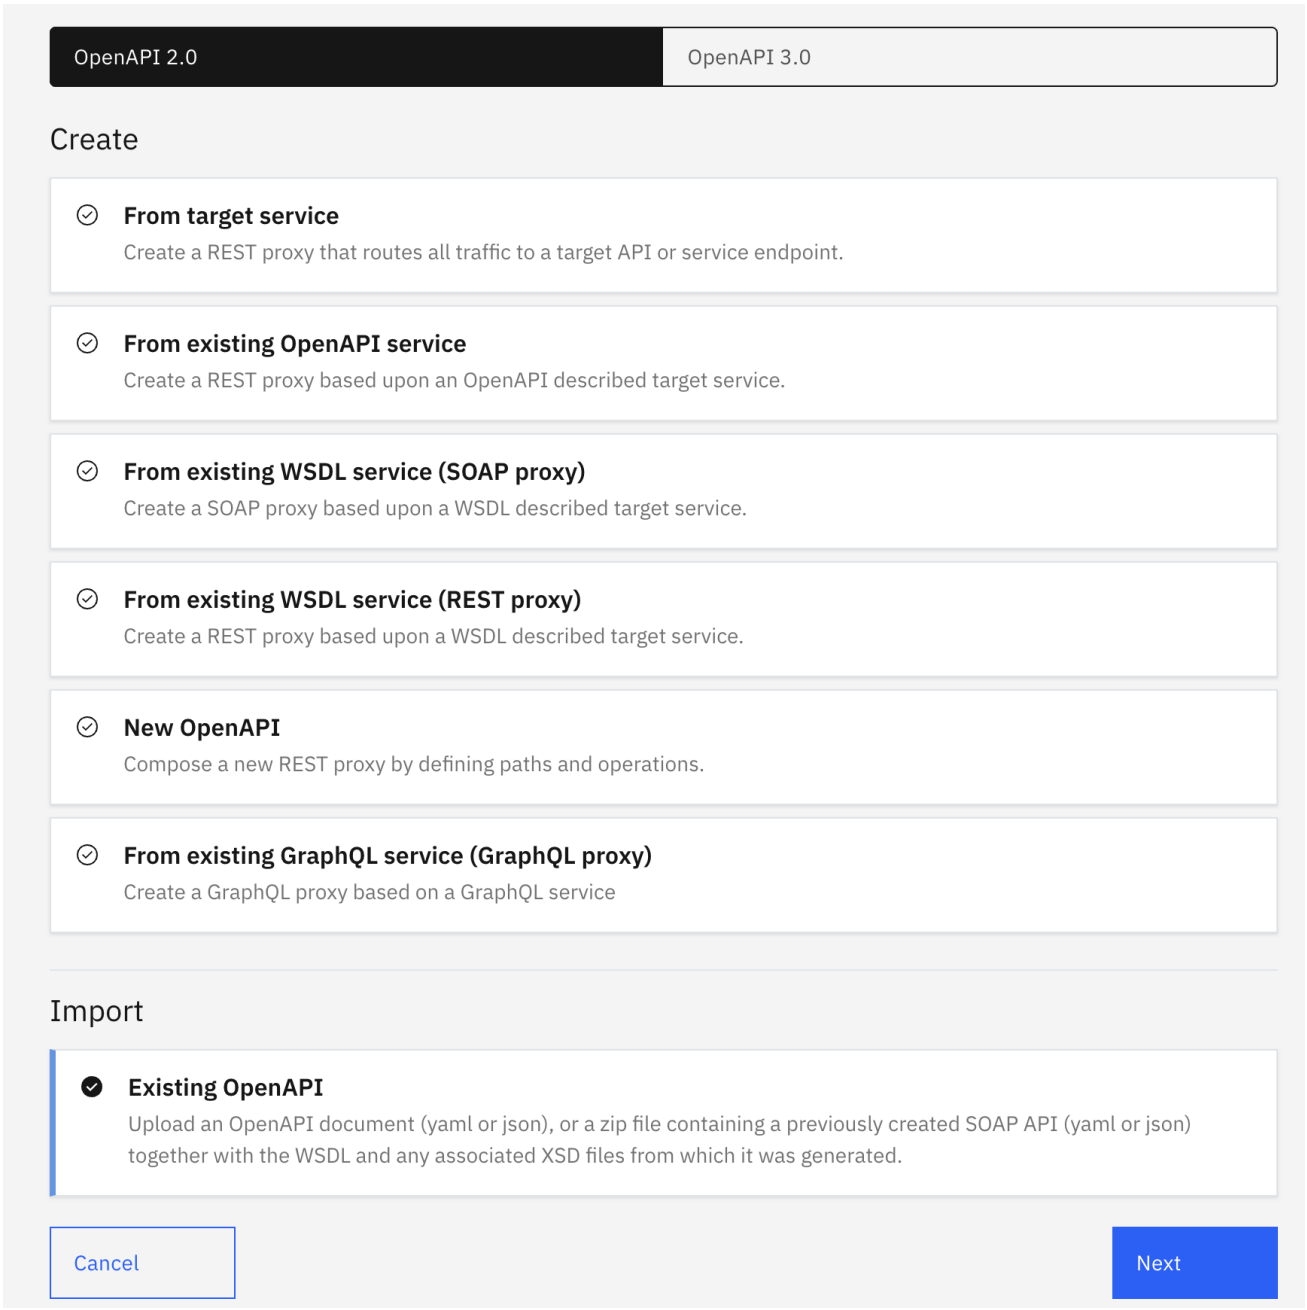
Before you begin

Note: The Sandbox catalog must be configured to use either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway or both. See Creating and configuring catalogs.
If your Sandbox catalog uses a DataPower Gateway (v5 compatible), download the findbranch_v6.txt file to your local file system. Rename this file `findbranch.yaml`.

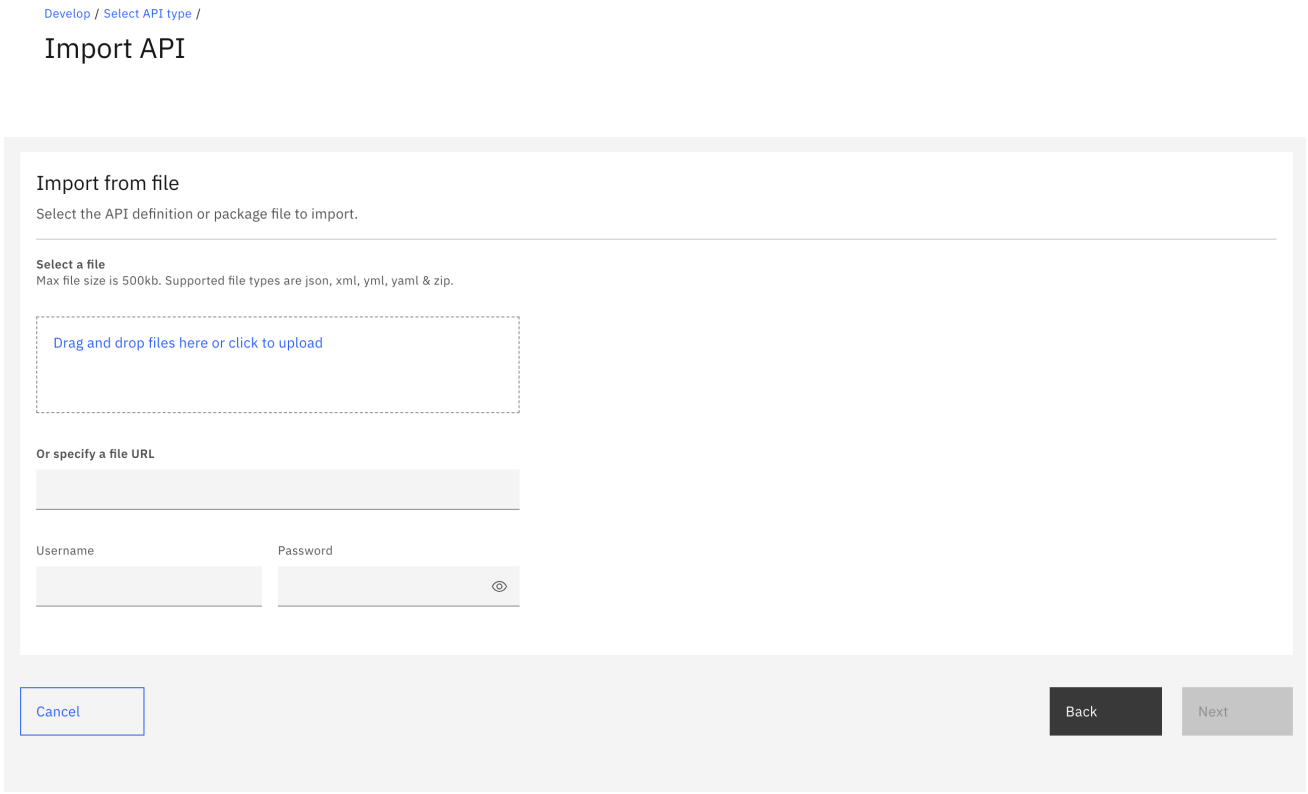


Importing an API

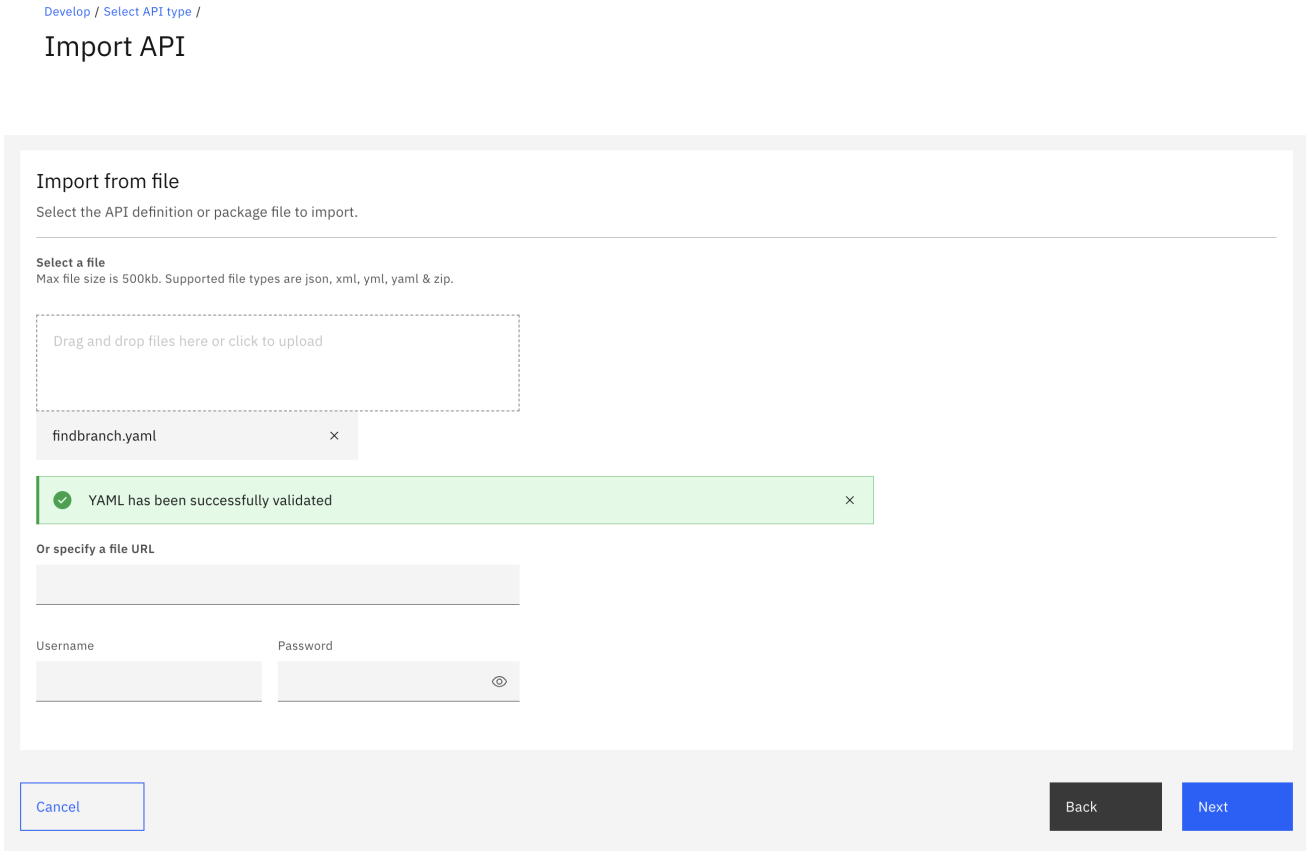
To import an API, complete the following steps:



1. Log in to the API Manager UI.
2. On the home page, click the Develop APIs and Products tile.

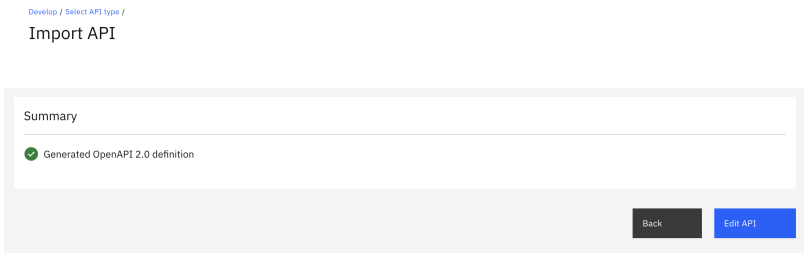


3. On the Develop page, click Add > API.



4. Select OpenAPI 2.0.
5. In the Import section, select Existing OpenAPI and click Next.

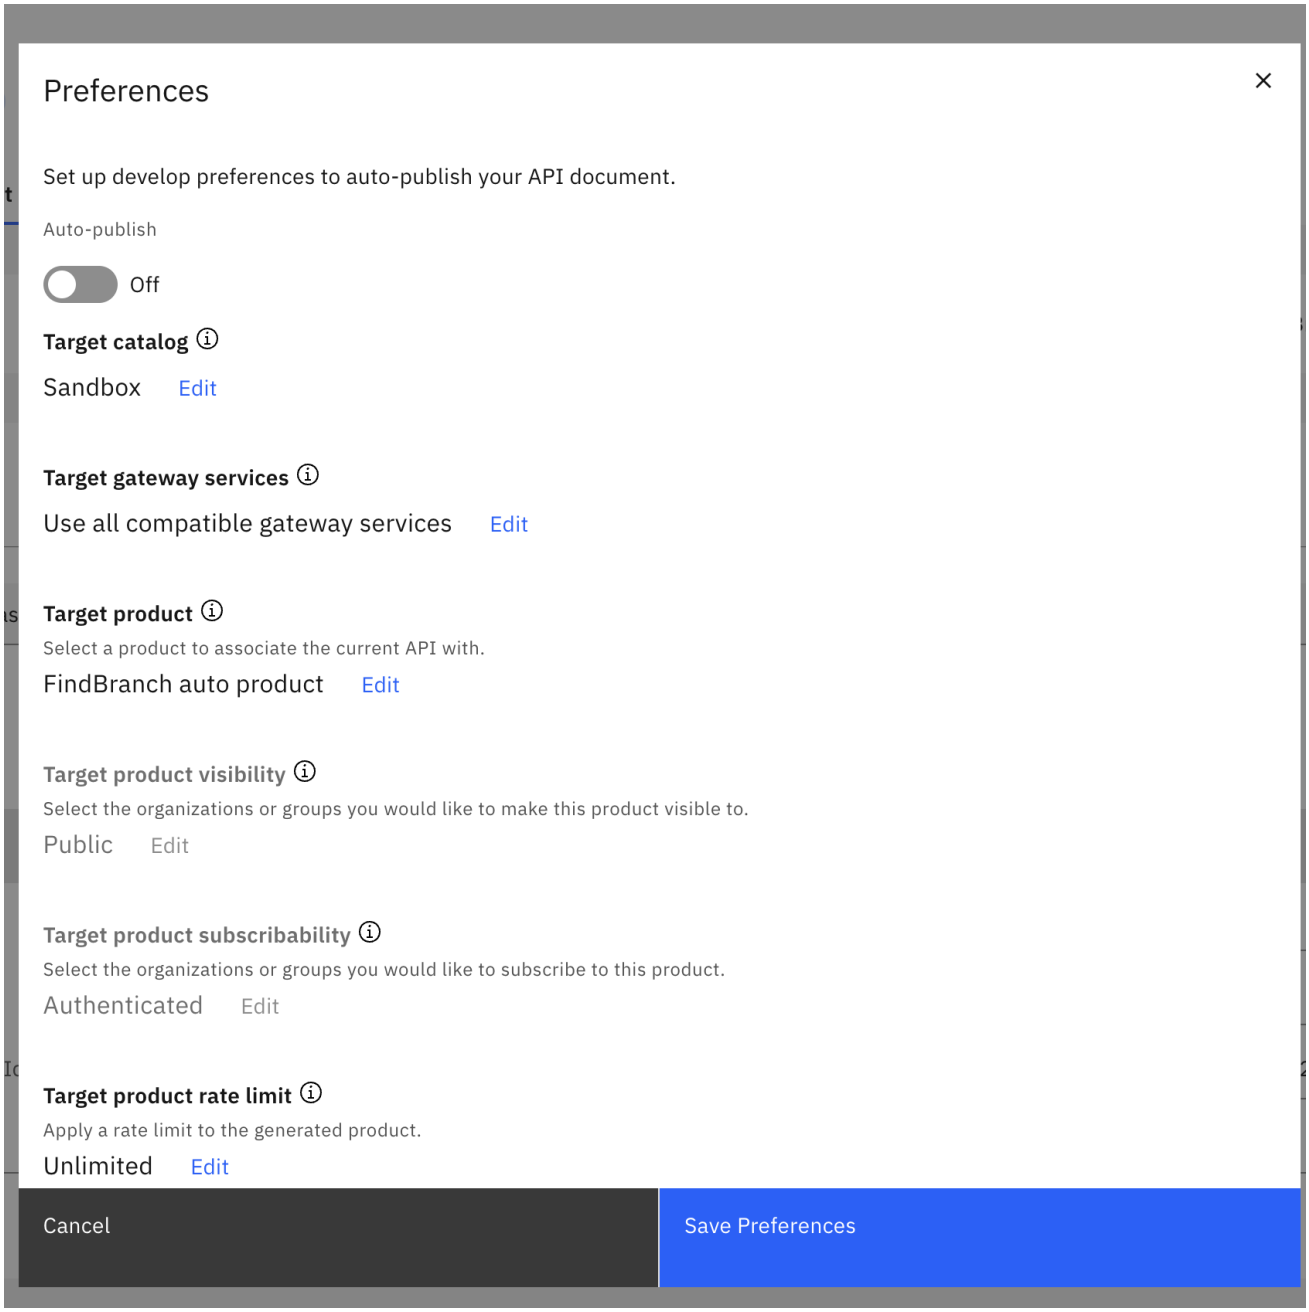
6. Click Drag and drop files here or click to upload.



7. Select the `findbranch.yaml` file on your local file system and upload it. Then click Next.

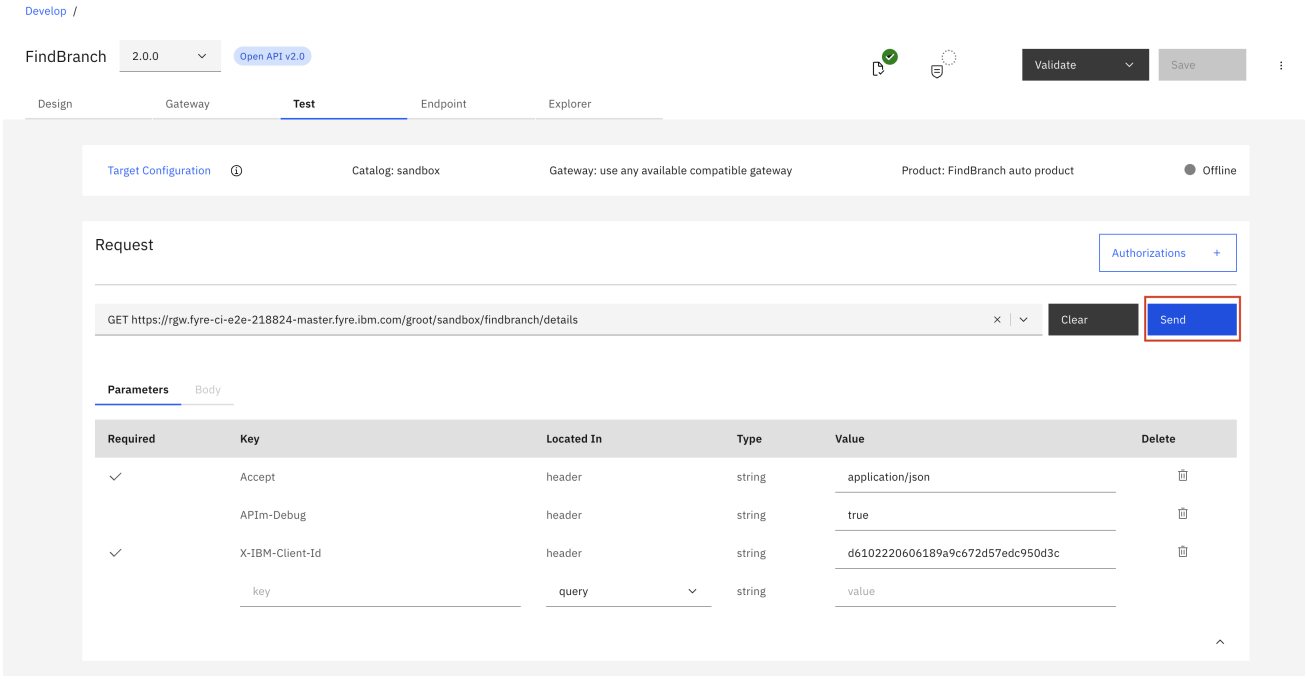
8. The Summary page appears.
   The new API is created. Leave the Summary page open for the next step.

   Note: The API cannot be executed unless it is active.

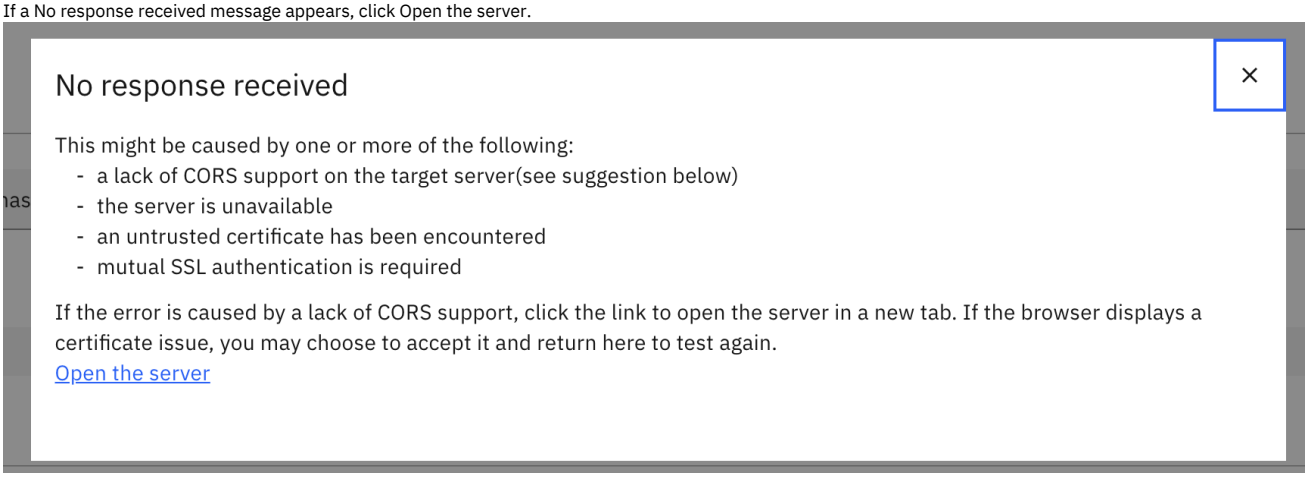


Testing the imported API

To test the imported API, complete the following steps:



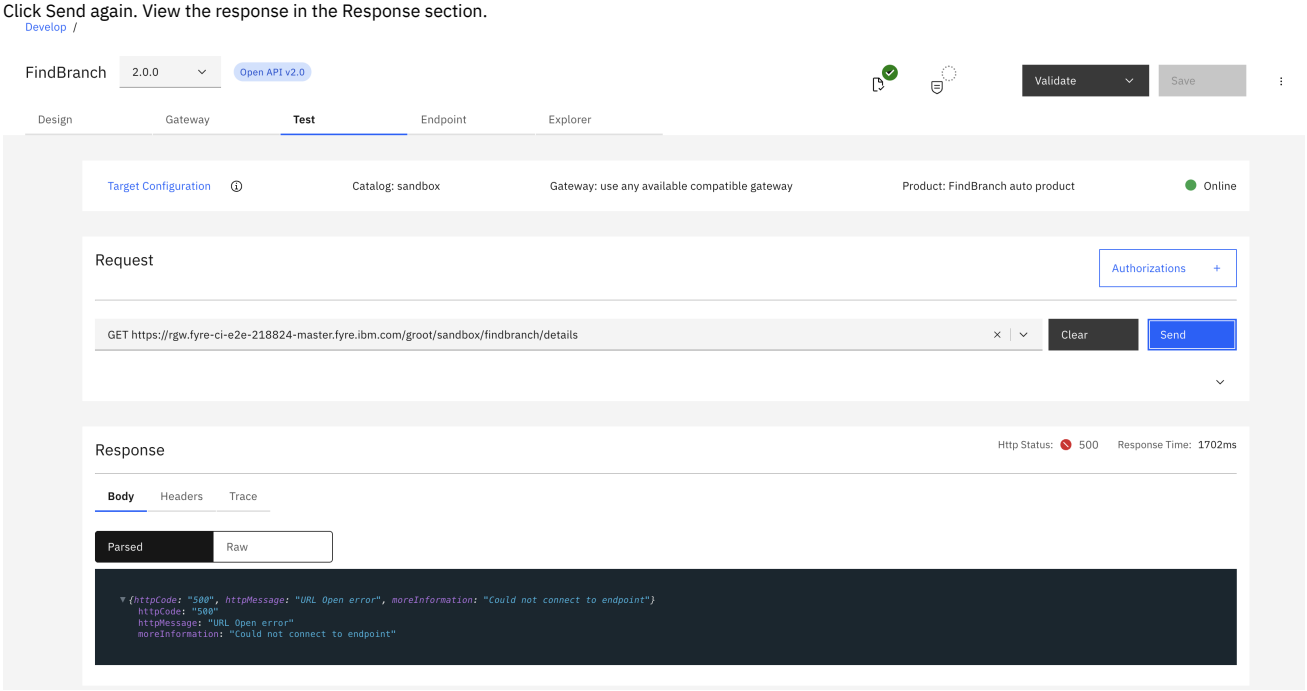
1. In the Summary page, click Edit API
2. On the Develop / findbranch page, click the Test tab in the page header.
   The imported FindBranch API already has a definition, which uses a single policy called **`Invoke`** to execute the API. This API is ready to test.
3. To activate the API, click Target Configuration.



4. On the Preferences window, toggle Auto-publish to set the API status to online.

Preferences
Set up develop preferences to auto-publish your API document.
Auto-publish
Off
Target catalog
Sandbox Edit
Target gateway services
Use all compatible gateway services Edit
Target product
Select a product to associate the current API with.
FindBranch auto product Edit
Target product visibility
Select the organizations or groups you would like to make this product visible to.
Public Edit
Target product subscribability
Select the organizations or groups you would like to subscribe to this product.
Authenticated Edit
Target product rate limit
Apply a rate limit to the generated product.
Unlimited Edit
Cancel
Save Preferences

5. Click Send.



6. If a No response received message appears, click Open the server.

A new browser tab opens. If an error message appears, ignore it. Close the new tab and return to the Test tab.

7. Click Send again. View the response in the Response section.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Imported an API definition.
- Tested an API.

Tutorial: Supersede a Product

This tutorial shows you how to supersede a published product with another product.

Before You Begin

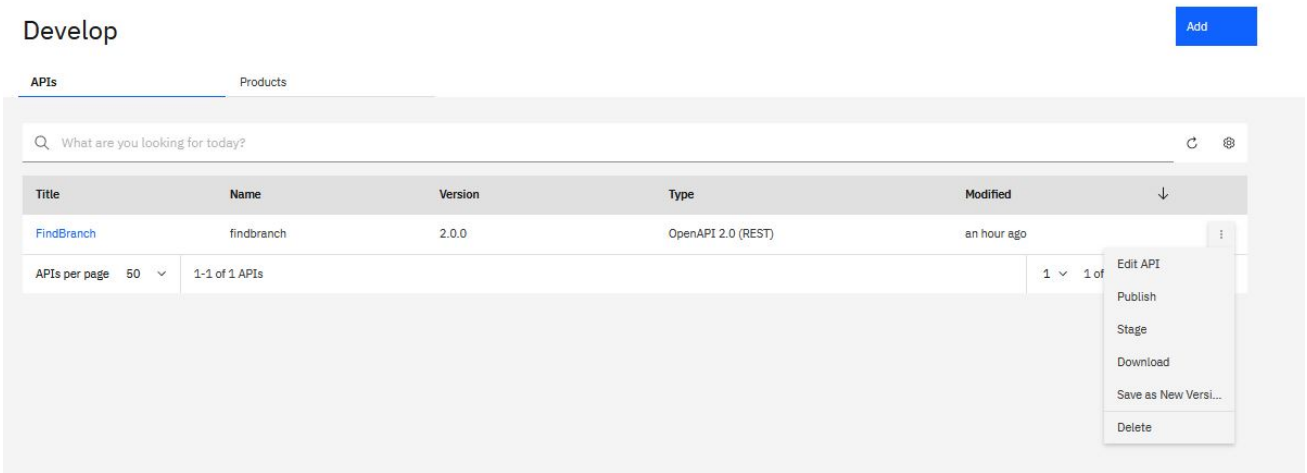
This task can be completed by users who are assigned one of the following roles:

- Catalog Owner
- Catalog Administrator
- Portal User

You must also do the following steps.

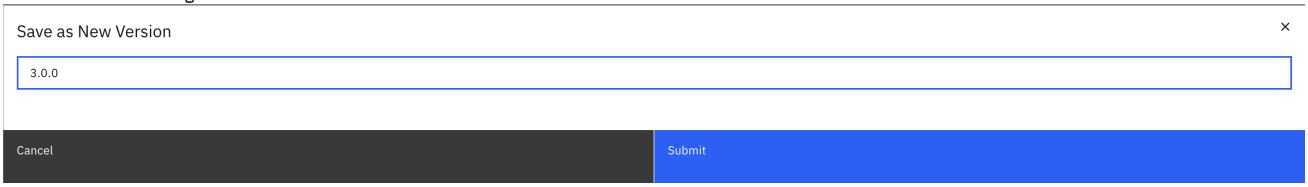
- Complete the Tutorial: Importing an API tutorial.
- You must have a Developer Portal that is activated for the Sandbox catalog. If you do not, complete the Tutorial: Creating the Developer Portal tutorial.
- You must have created an application in the Developer Portal and subscribed it to a product. If you do not, complete the Tutorial: Creating Accounts and Applications on the Developer Portal tutorial.

About this tutorial



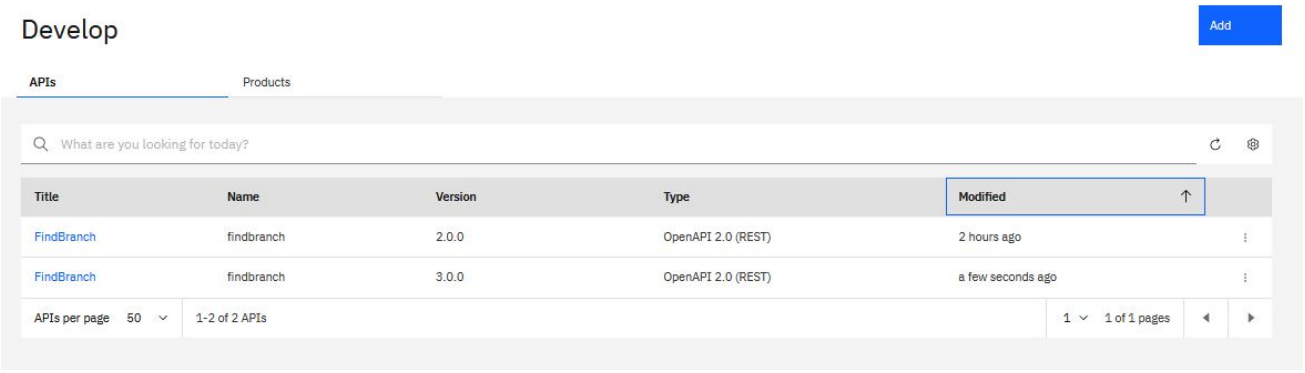
In this tutorial, you are going to complete the following lessons:

- Modify an Existing API
- Duplicate and Change a Product
- Supersede a Product
- Migrate a Product

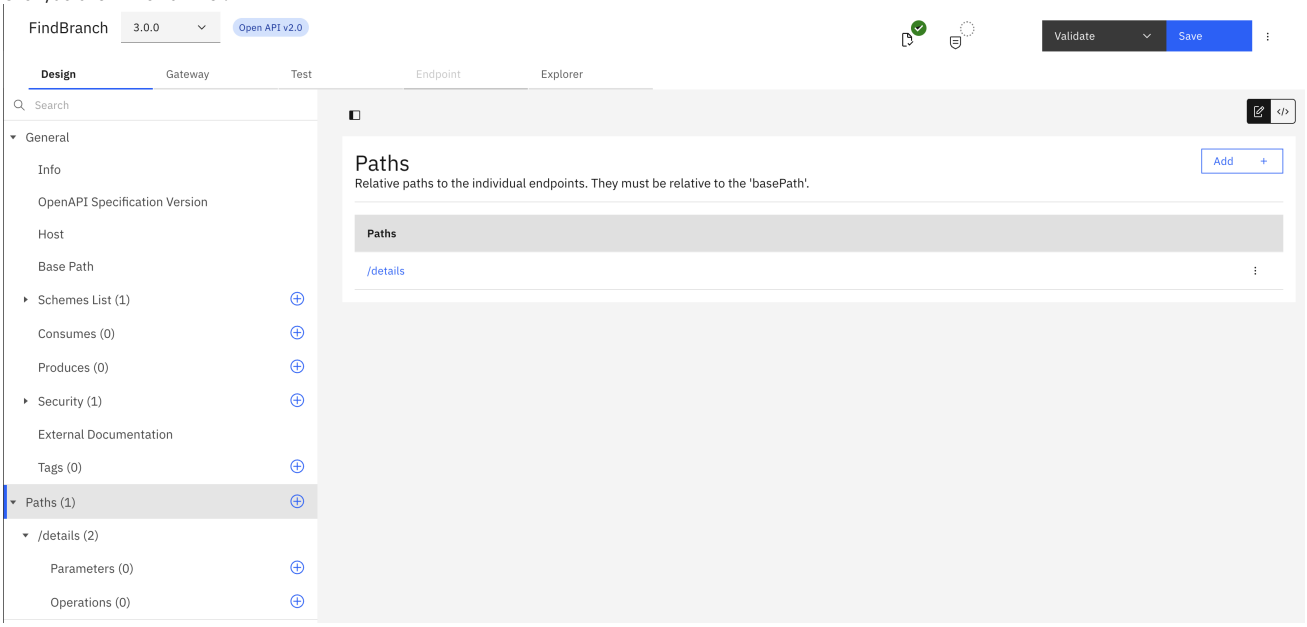


Modify an Existing API

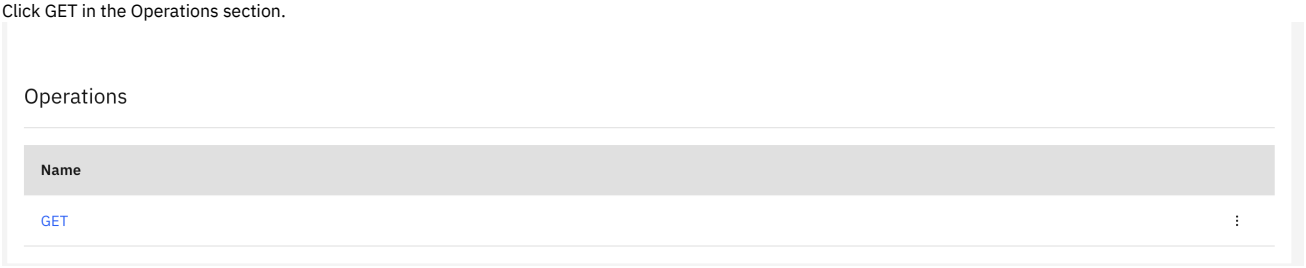
Take the following steps to modify an existing API.



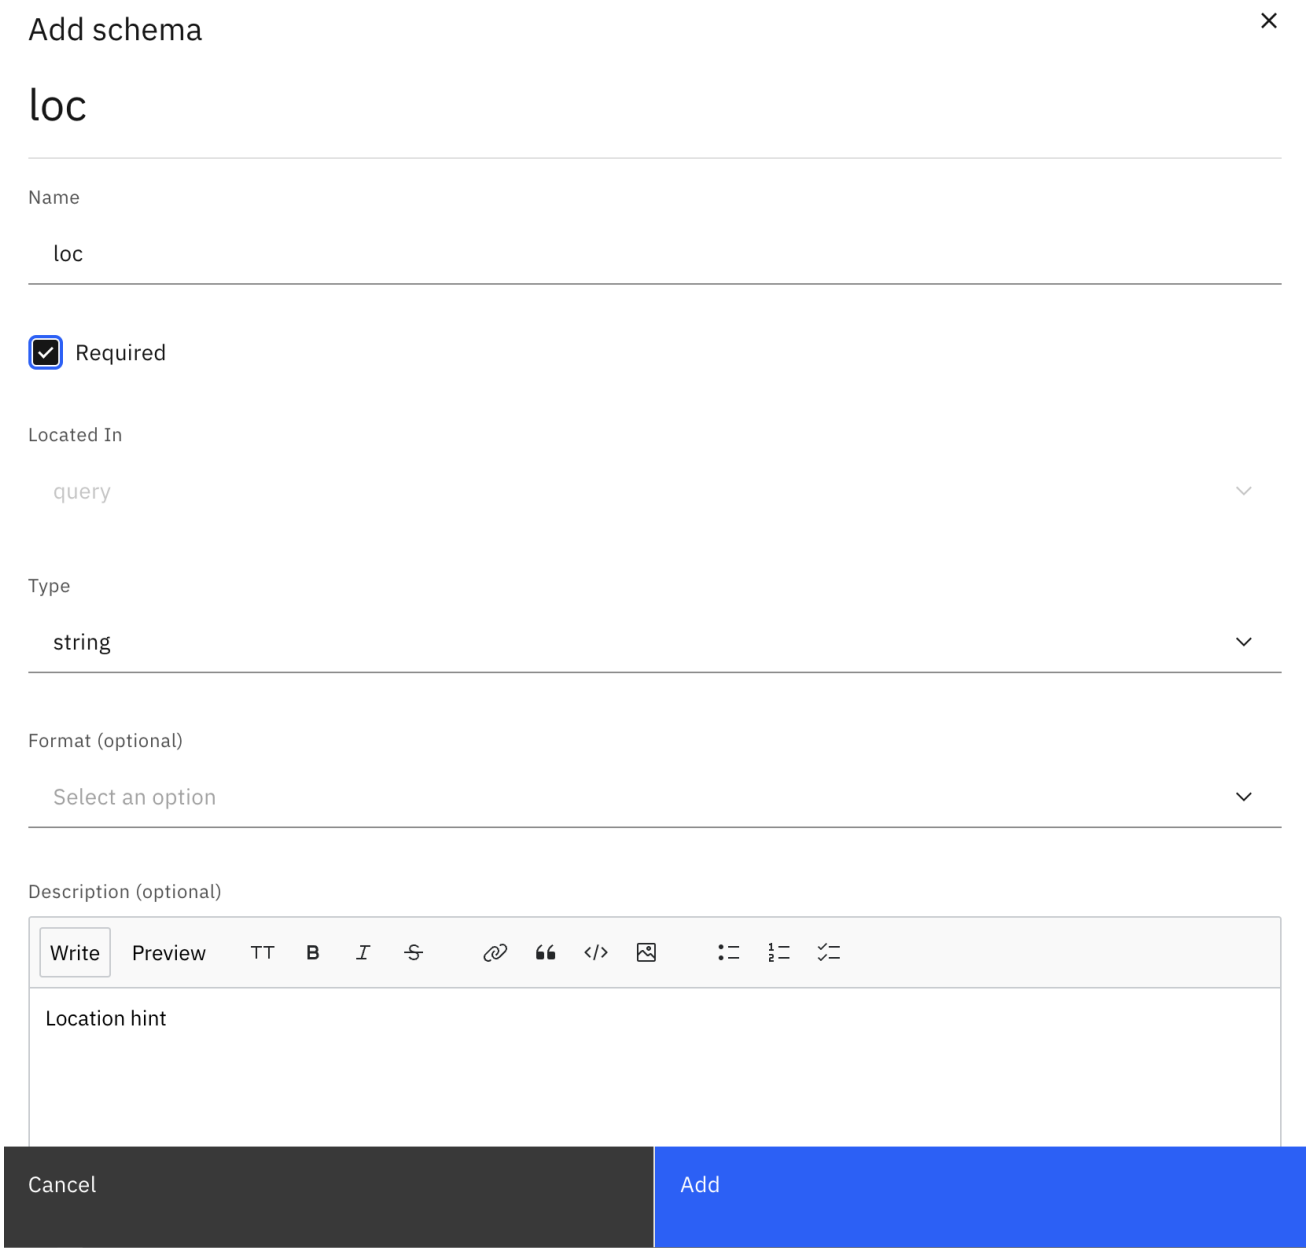
1. Log in to API Manager.
2. In the Welcome page, click the Develop icon in the navigation bar.
3. In APIs tab, click the ellipsis button for existing API FindBranch x.0.0 and select Save as a new version.



4. In the Version field, enter `3.0.0`.
5. Click Submit. The dialog box closes.



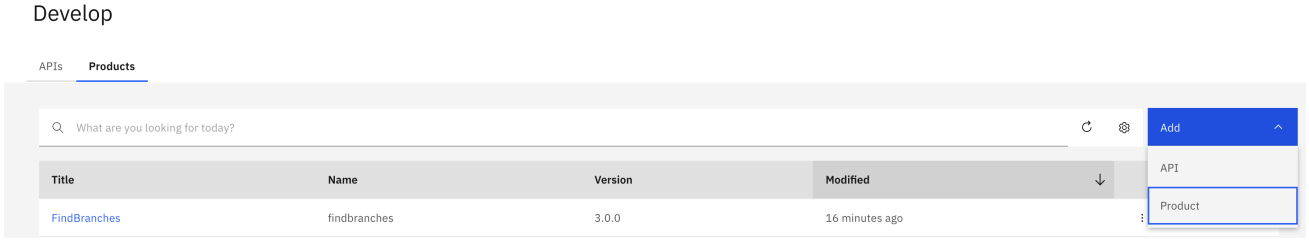
6. Click FindBranch 3.0.0 to edit the new API.



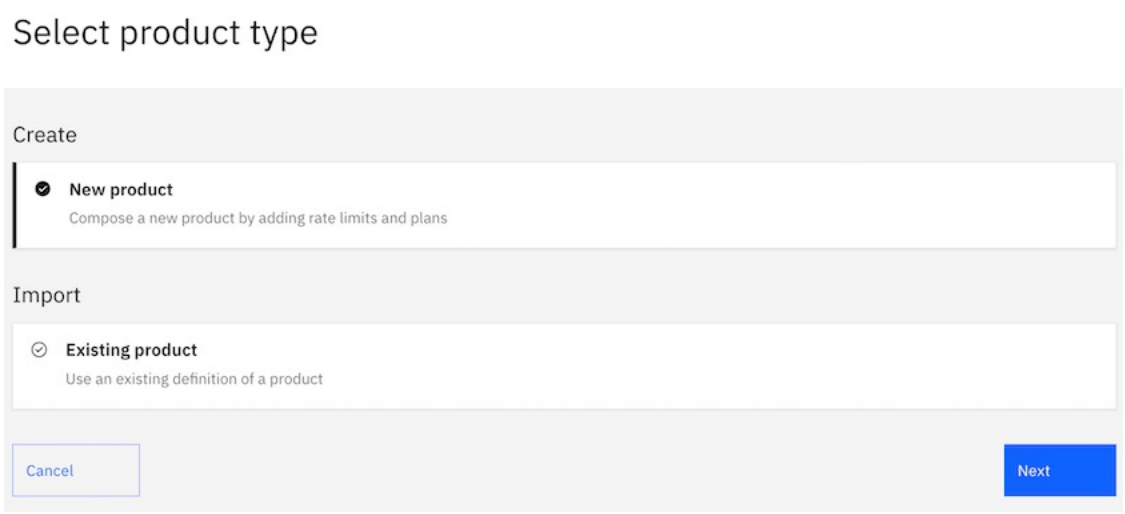
7. Click Paths in the navigation bar.
8. Click /details in the Path list.

9. Click GET in the Operations section.

10. Scroll down. Click Add in the Parameters section.
11. Take the following actions.
    a. Enter `loc` in the NAME field and select Required.
    b. Select `query` in the LOCATED IN field.
    c. Select `string` in the TYPE field.
    d. Enter `Location hint` in the DESCRIPTION field.
    e. Click Add.



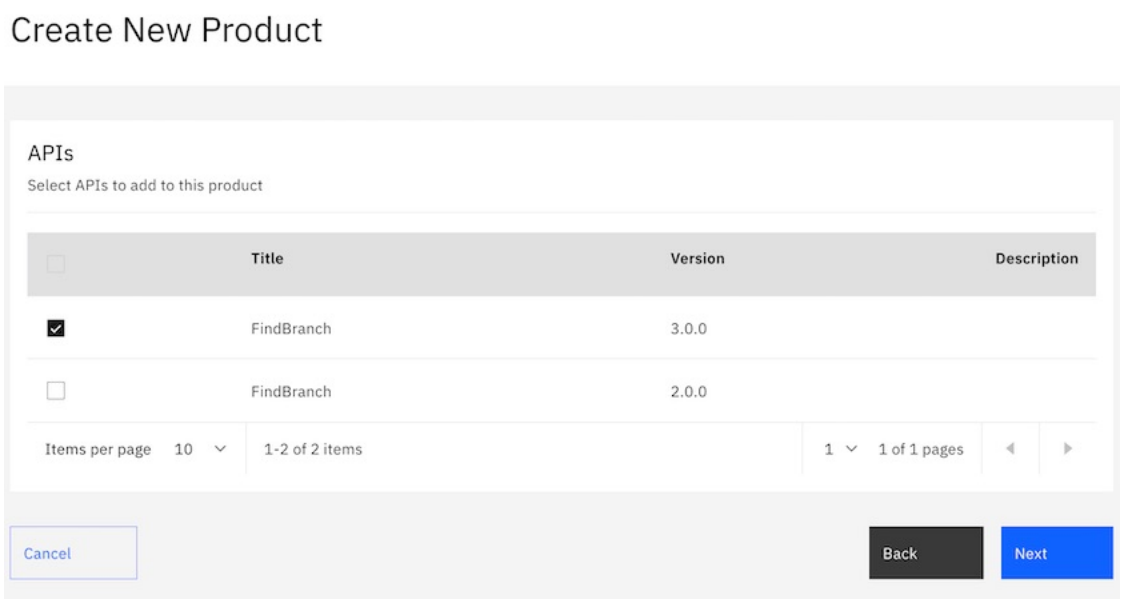
12. Click Save.



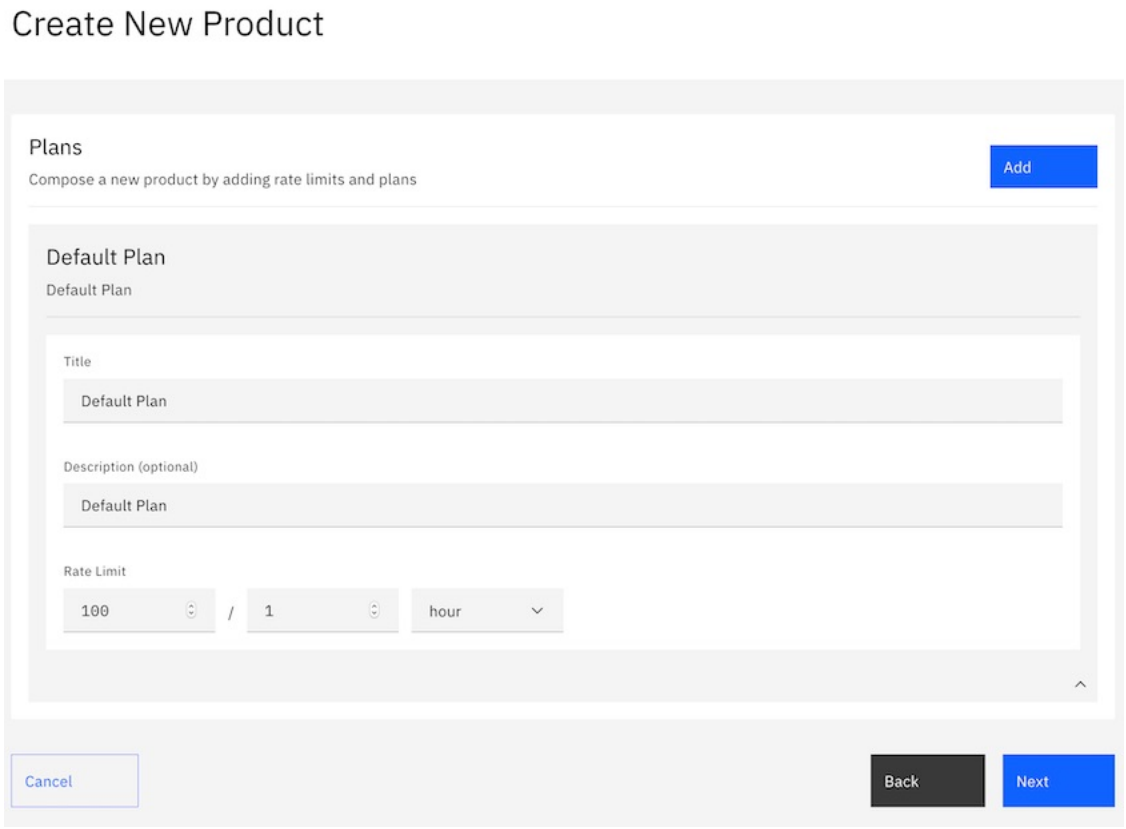
Duplicate and Change a Product

Take the following steps to duplicate and then modify an existing product.

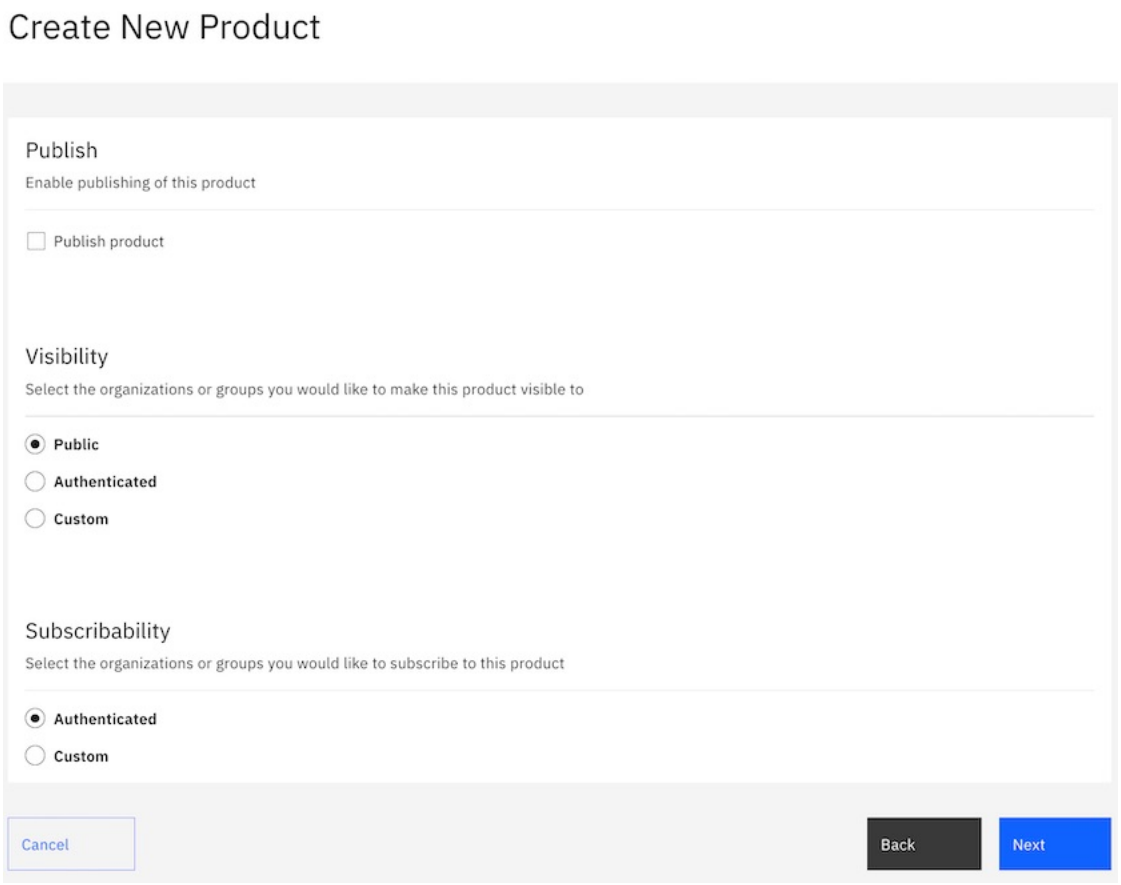
1. Click the Develop icon in the navigation bar.
2. Click Add > Product.



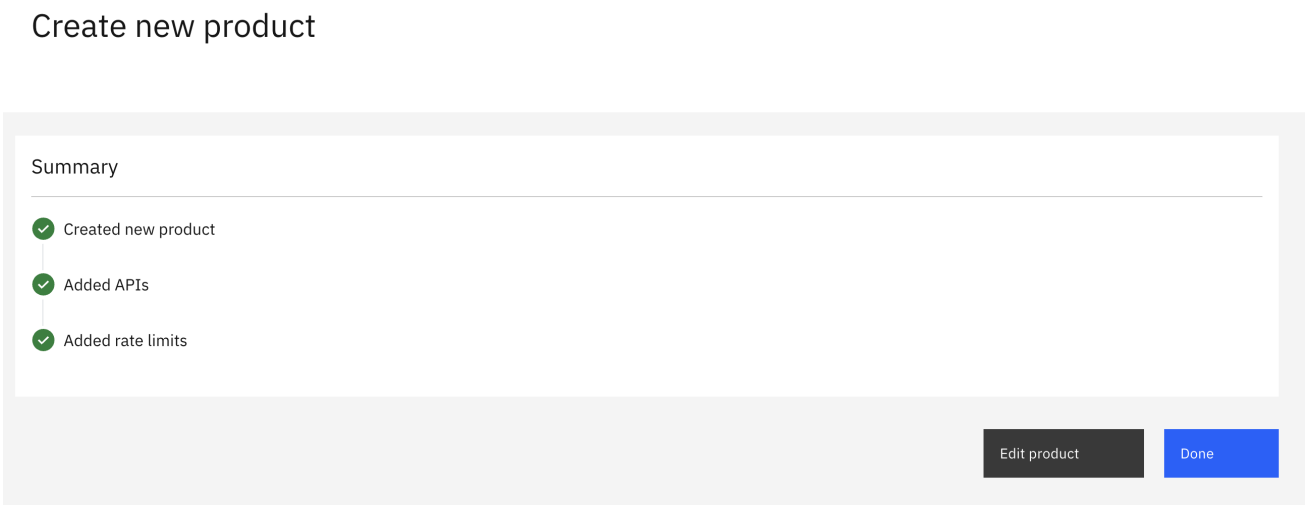
3. Select New product and click Next.



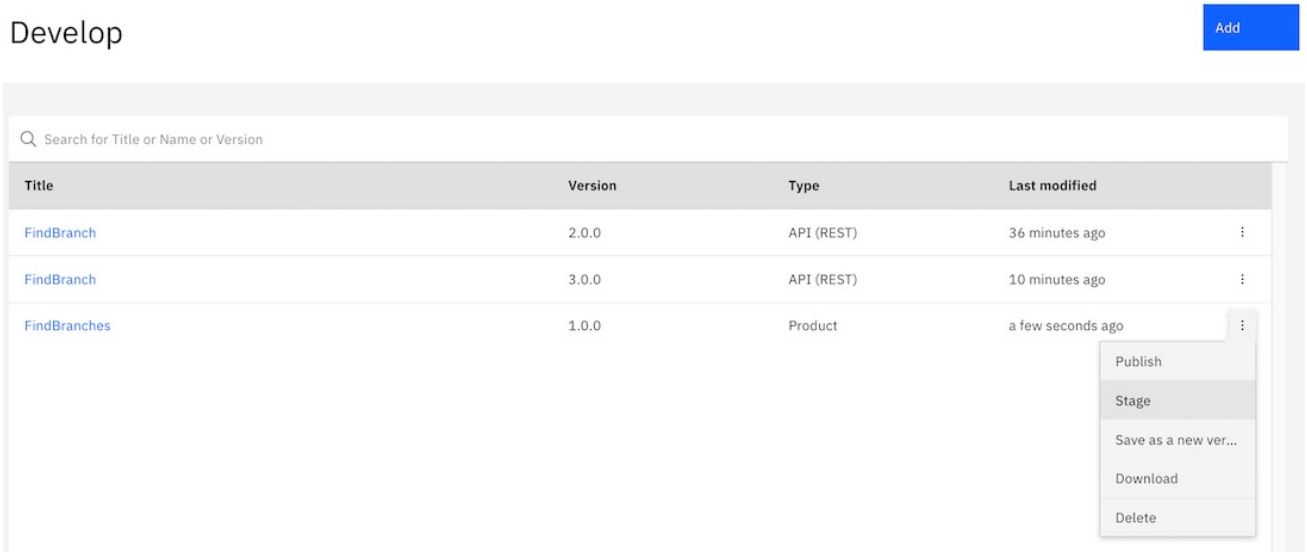
4. Enter `FindBranches` in the Title field.
5. Enter `2.0.0` in the Version field and click Next.



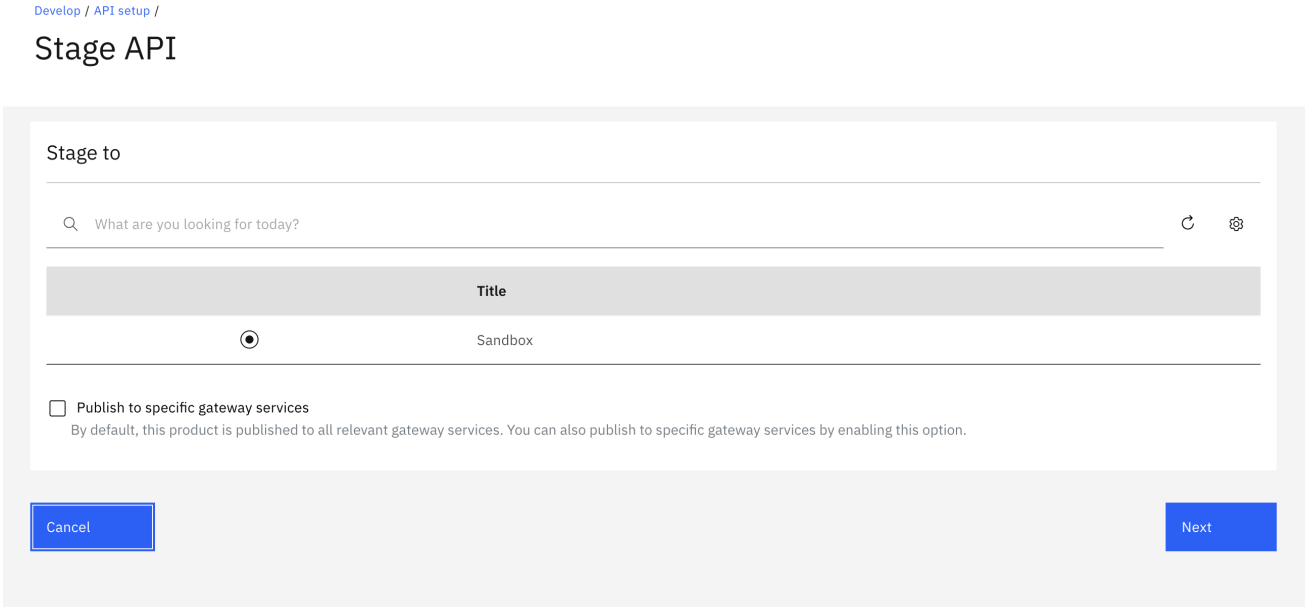
6. Select `FindBranch 3.0.0` and click Next.



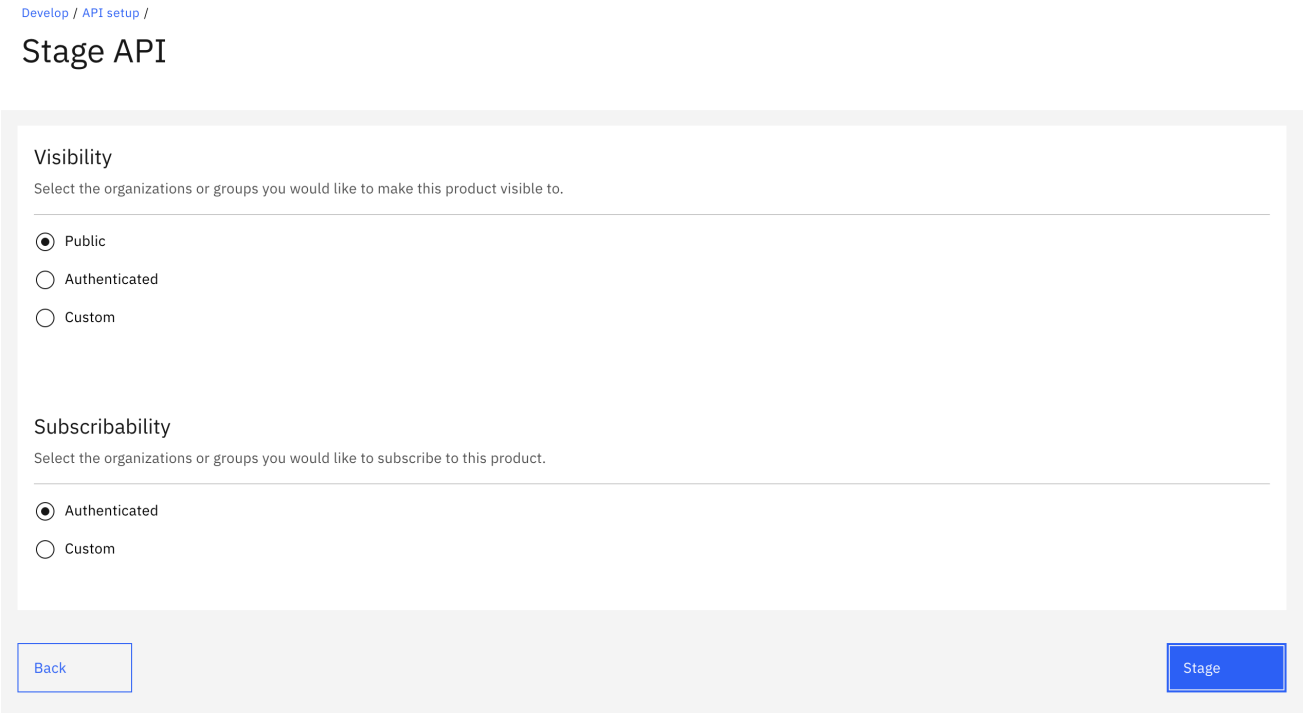
7. Accept the defaults for Plans and click Next.



8. Accept the defaults for Publish, Visibility, and Subscribability. Click Next.

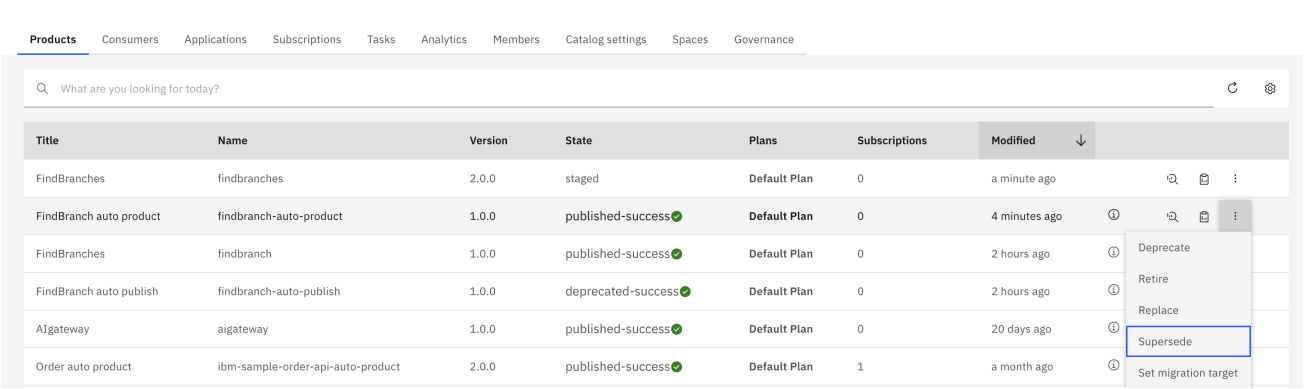


9. Summary page opens. Click Done.

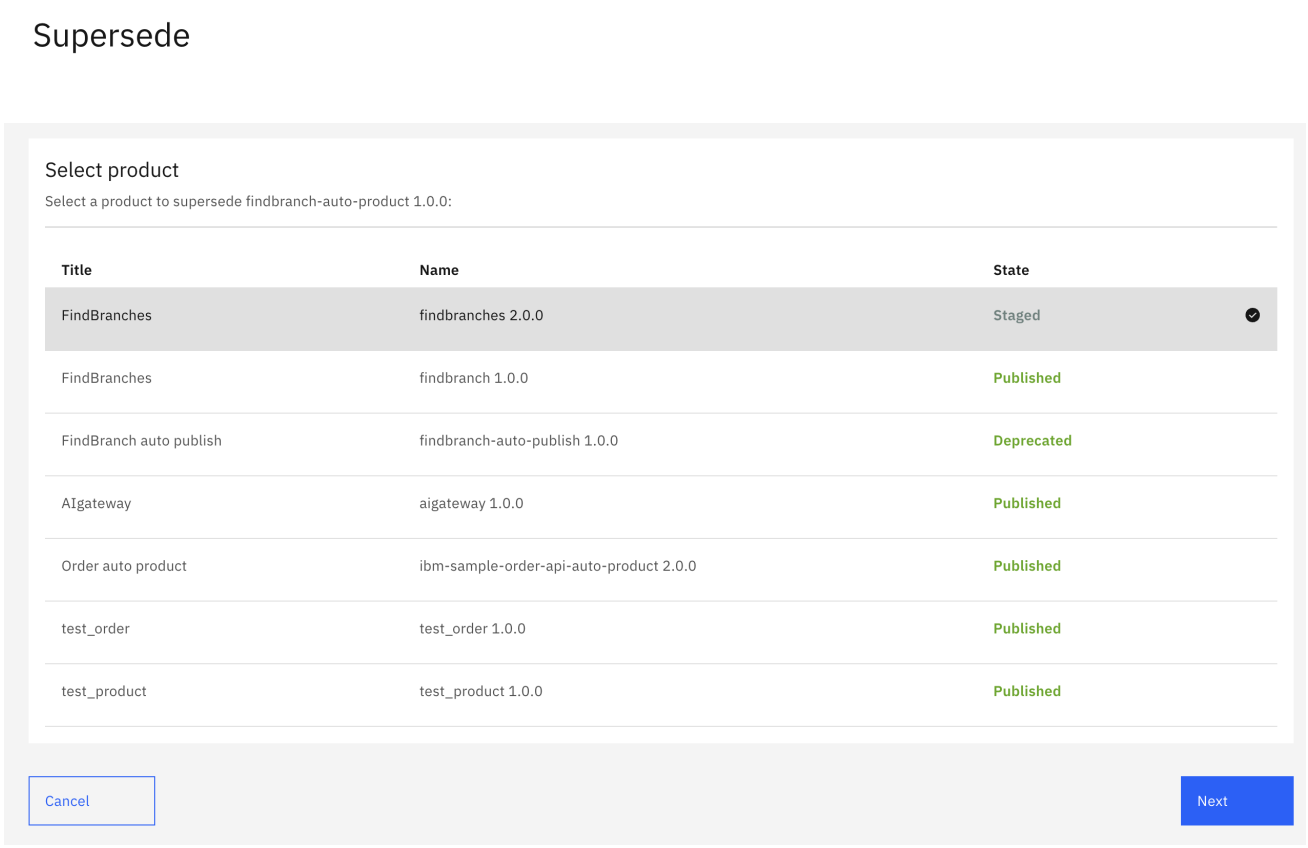


10. Click the ellipsis button ⋮ alongside FindBranches 1.0.0 product and select Stage.

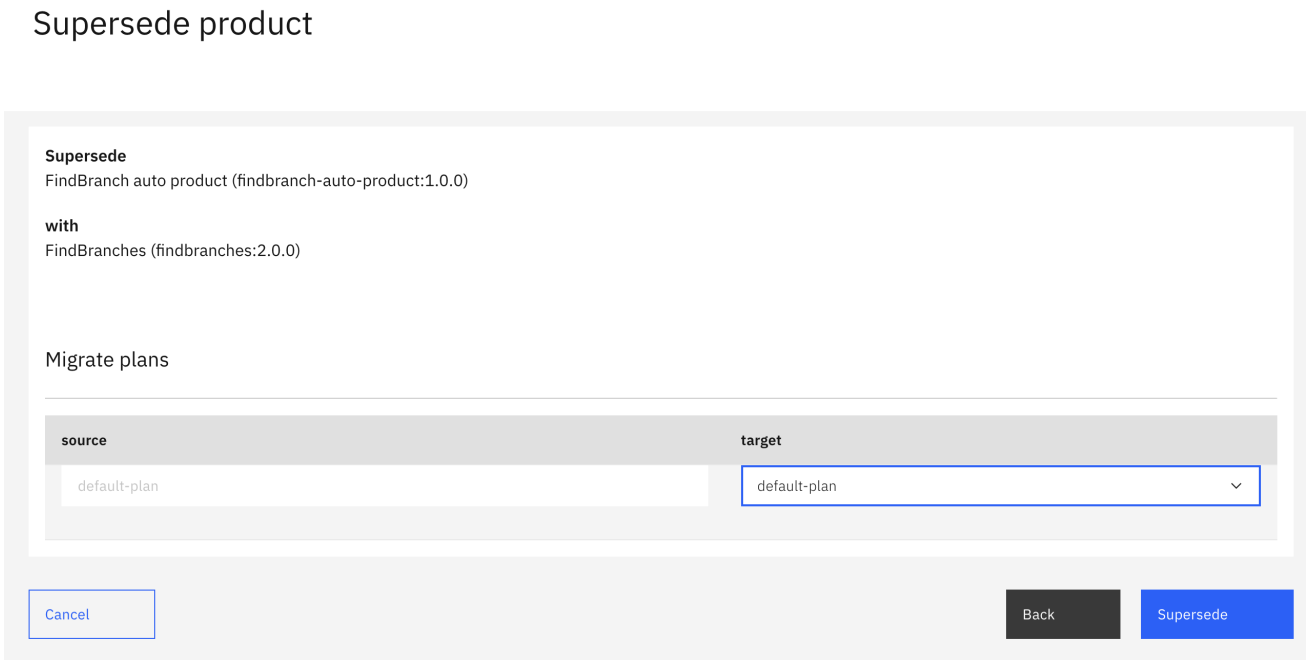
11. Select Sandbox, then click Next.



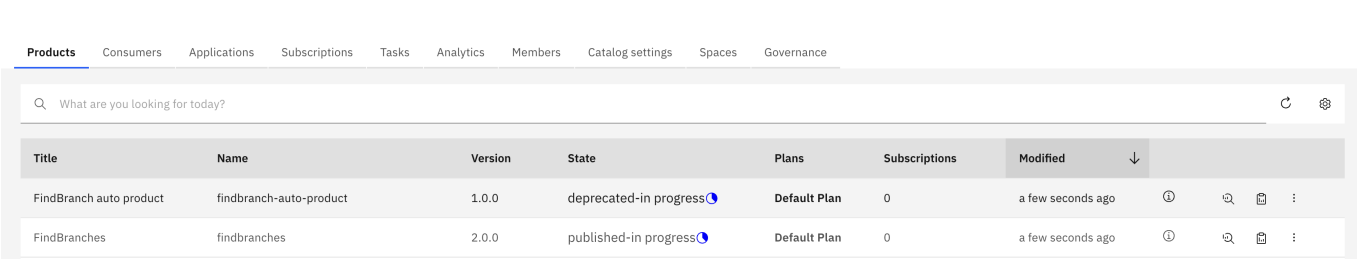
12. Select Public and Authenticated. Then click Stage to add the product to the Sandbox catalog.



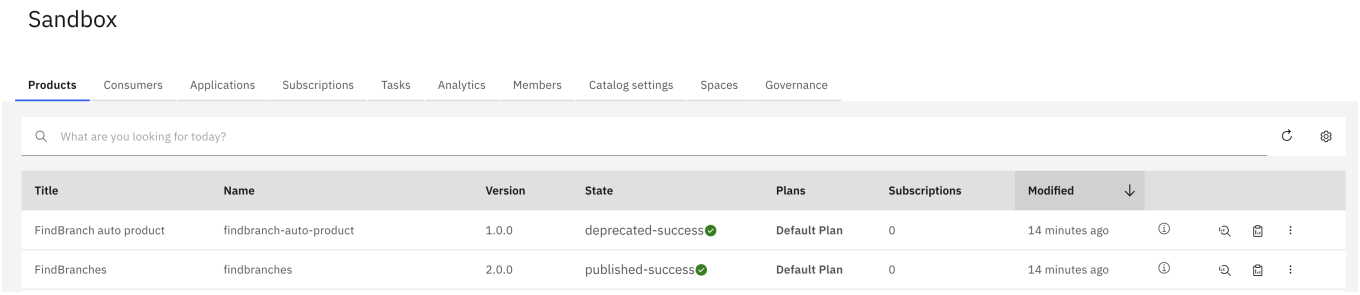
Supersede a Product



1. Click the Manage icon in the navigation bar.
2. Click the Sandbox catalog.
3. Click the ellipsis button alongside the product FindBranch auto product x.0.0 and select Supersede.

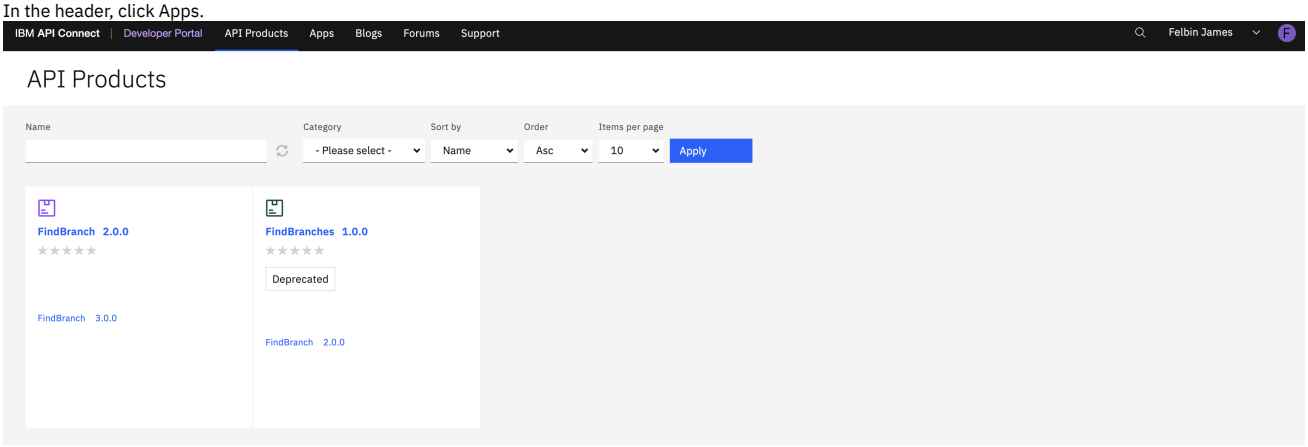


4. Select FindBranches.
5. Click Next.

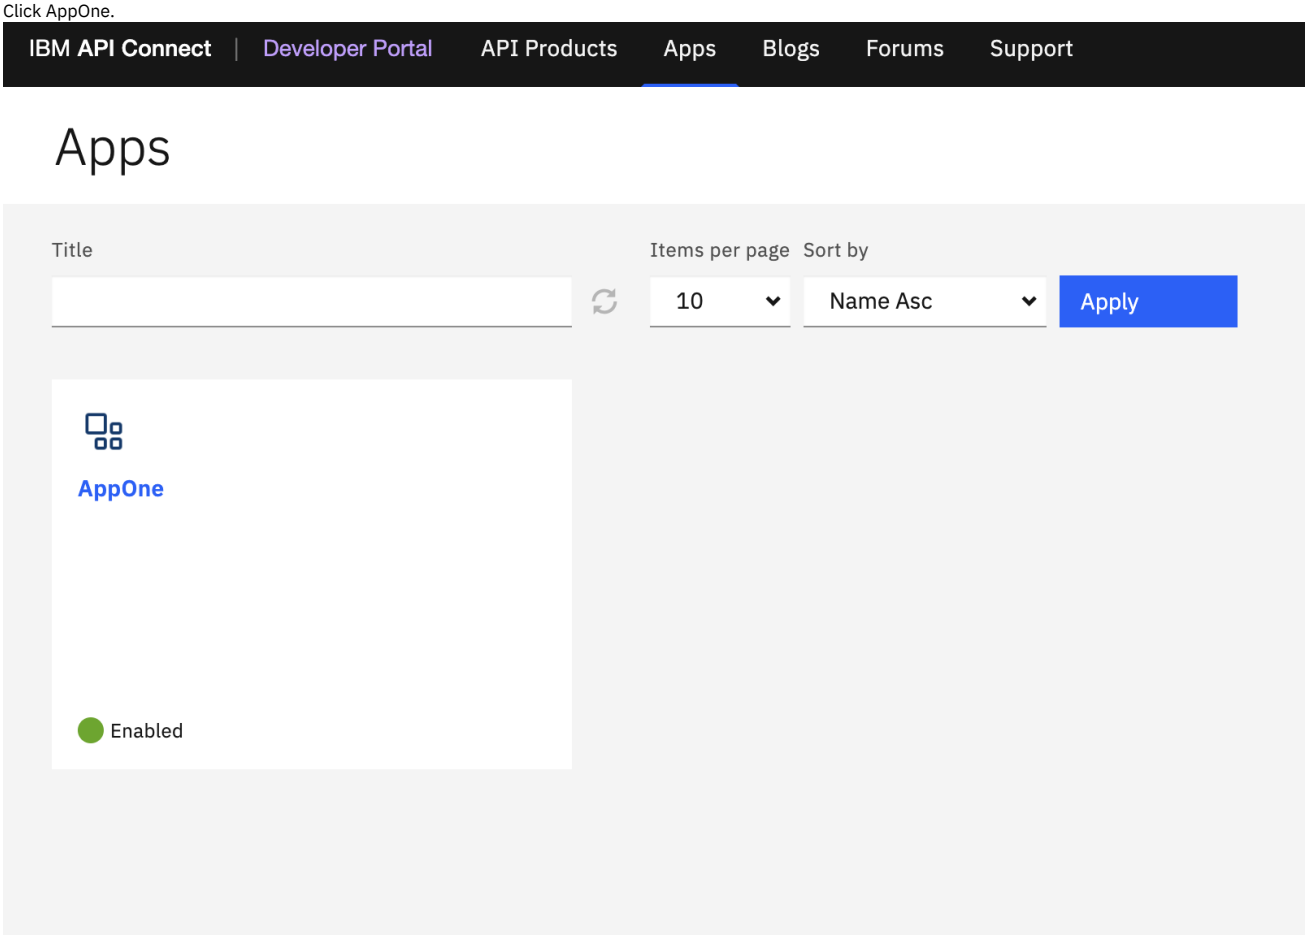


6. Select default-plan plan in the target column.
7. Click Supersede.

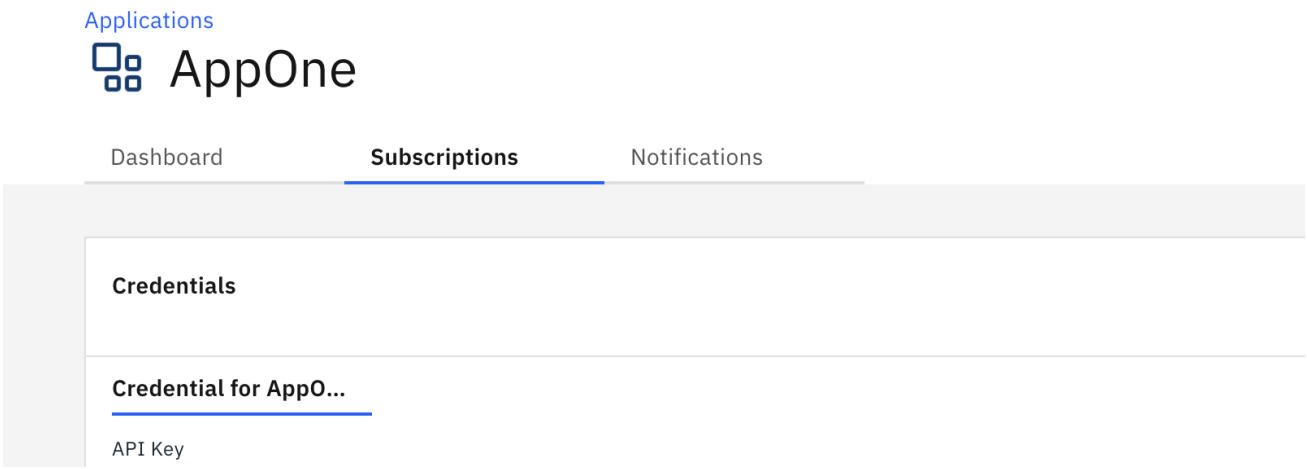
The deprecation process starts immediately. You can see the state as in progress.



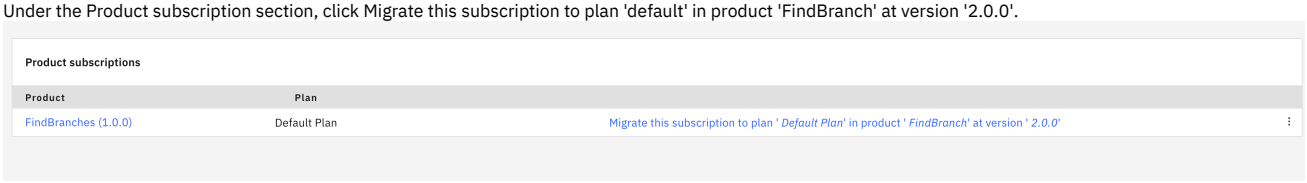
Observe that the state of both products changes over time. FindBranch auto product x.0.0 is now deprecated, and FindBranches 1.0.0 is published. All external applications subscribed to FindBranch auto product x.0.0 remain subscribed but should migrate to FindBranches 1.0.0. The external application developer completes the migration in the Developer Portal.



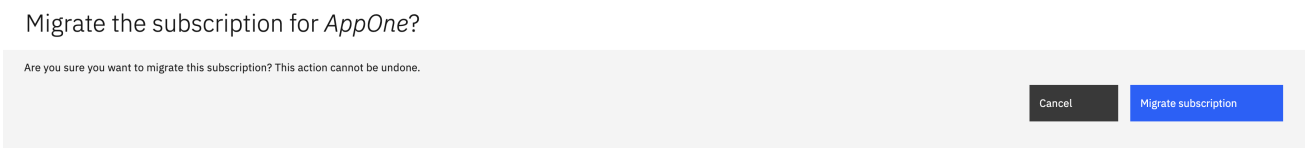
Migrate a Product



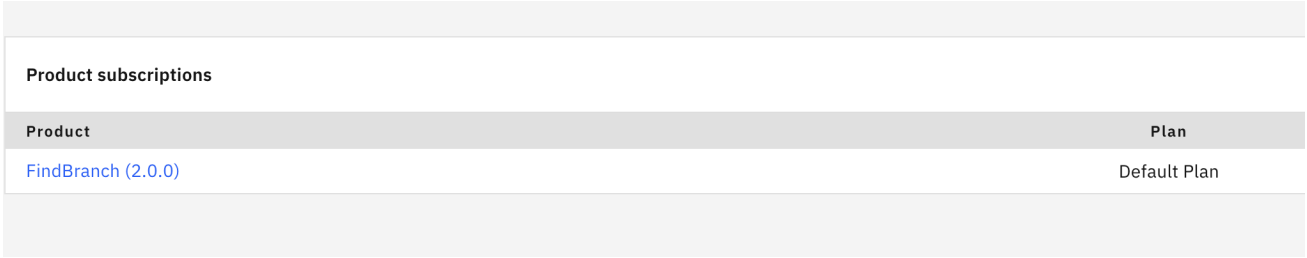
1. In a new browser window, sign in to the Developer Portal using the account you created in Tutorial: Creating Accounts and Applications on the Developer Portal.
2. In the header, click Apps.



3. Click AppOne.



4. Click Subscriptions.



5. Under the Product subscription section, click Migrate this subscription to plan 'default' in product 'FindBranch' at version '2.0.0'.

6. Click Migrate subscription.

7. Notice that the subscription changed to the target product. The subscription is now changed to the target product.

What you did in this tutorial

- Created a new API
- Created a new Product
- Superseded an existing published product with the new product
- Migrated a subscribed external application to the new product

Tutorial: Implementing OAuth Security

This tutorial shows you how to create a native OAuth provider using the API Manager user interface.

About this tutorial

Creating a native OAuth provider lets API Connect perform OAuth authorization tasks internally instead of requiring a third-party application to complete them. When you create a native OAuth Provider, you apply it to an API, which is then updated to include the OAuth configuration. Then you publish the API. Whenever the published API is invoked, API Connect ensures that the calling application is authorized to access the API resources, and then makes the API available.

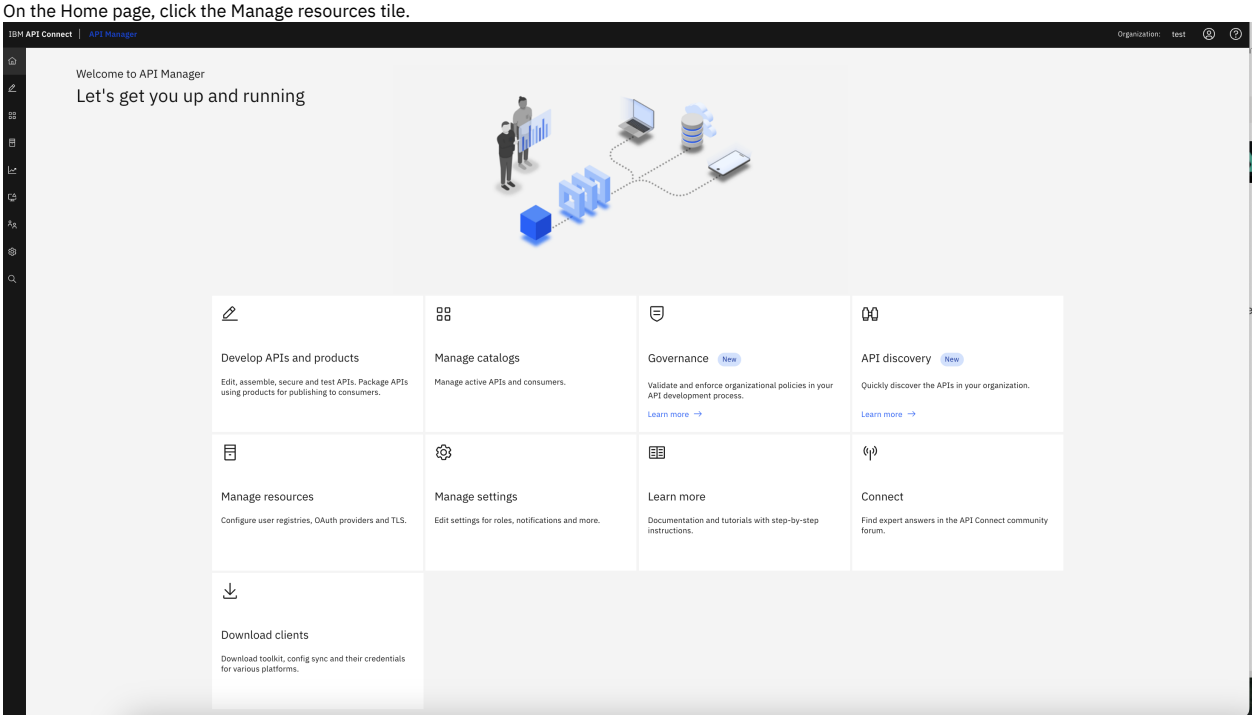
Implementing OAuth security requires you to create a provider, and then update your API to use the provider. In this tutorial you will complete the following lessons:

1. Create a native OAuth provider

2. Add OAuth security to an API
3. Add an OAuth redirect URL to the default Sandbox test application
4. Test the OAuth security implementation

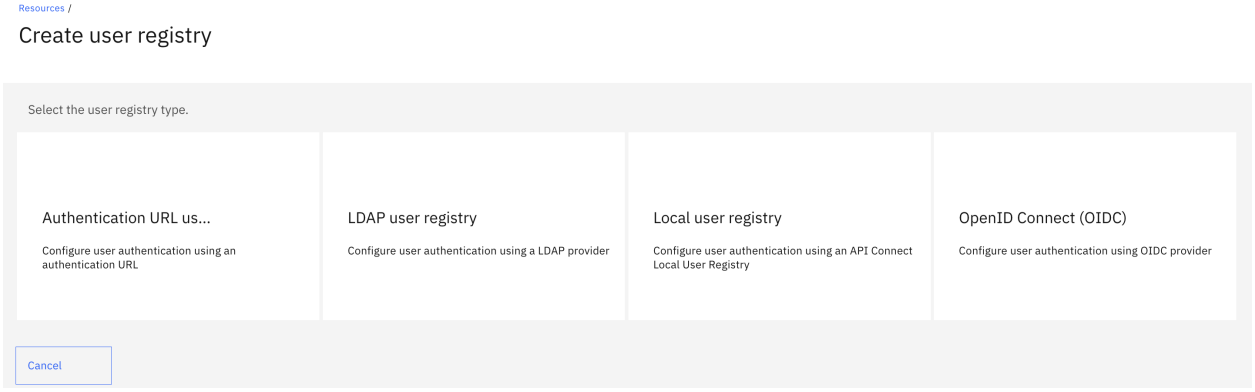
Before you begin

This tutorial uses the predefined FindBranch API. To prepare your environment for this tutorial, complete the following tasks:



1. Add the DataPower® API Gateway service to the Sandbox catalog as explained in Creating and configuring catalogs.
   The Sandbox catalog must be configured to use at least one gateway. For this tutorial, you must use the same gateway that the FindBranch API uses.

2. Import the FindBranch API and activate it as explained in the tutorial, Tutorial: Importing an API.



Create a native OAuth provider

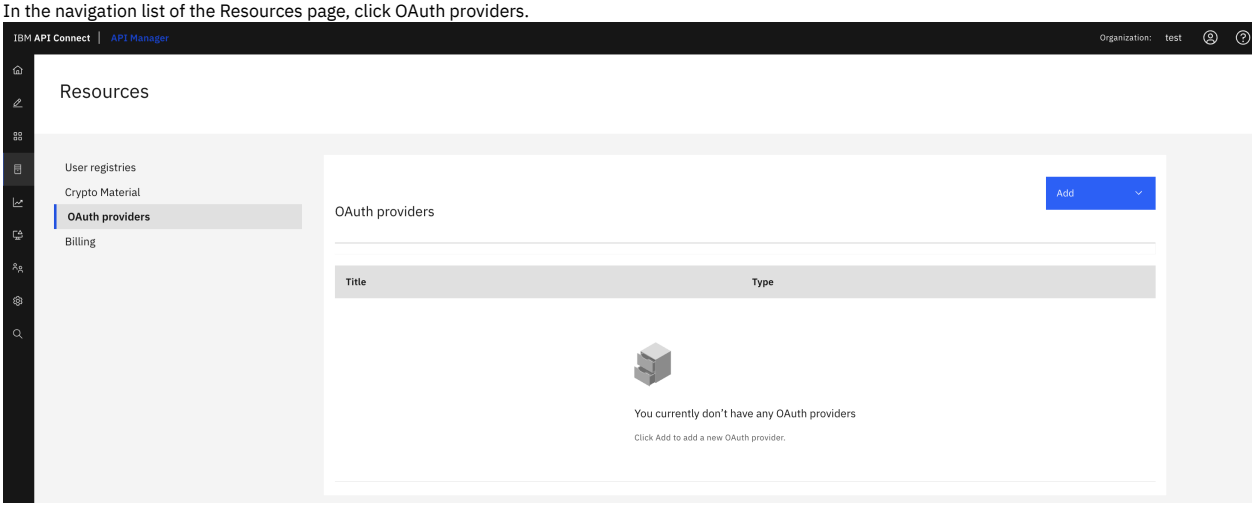
To create a native OAuth provider in API Manager, set up a user registry that uses an external authentication URL to verify users, and then create a provider to authenticate users who log in with that registry.

1. Create a user registry that can be used for authenticating users with OAuth:
   a. Log in to API Manager.
   b. On the Home page, click the Manage resources tile.

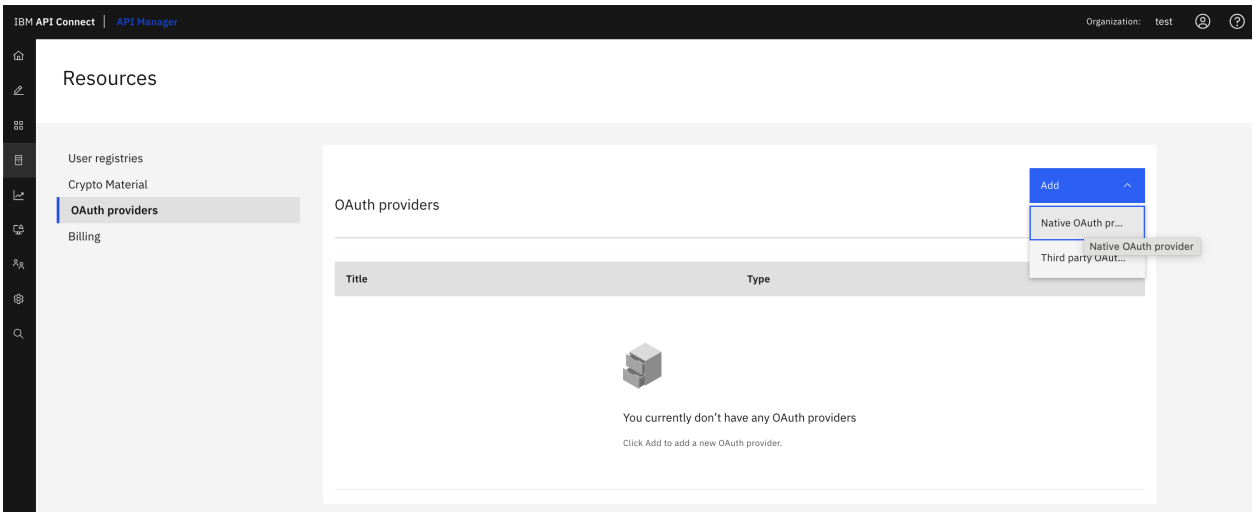
   c. On the Resources page, in the left pane, select User registries.
   d. In the User registries section, click Create.
   e. On the Create user registry page, select the Authentication URL user registry tile. On the Create User Registry page, click Authentication URL User Registry as the selected user registry type.

   f. On the Create authentication URL user registry page, enter the following information.
      i. In the Title and Display Name fields, enter `AuthURL`.
         By entering `AuthURL` in the Title and Display Name fields, you can easily determine that this registry is configured with an authentication URL.

      ii. In the URL field, enter `https://httpbin.org/basic-auth/user/password`.
         Note: The URL provided here is for testing purposes only. The httpbin.org endpoint provides a sandbox where you can simulate a login with basic authentication by passing credentials in the authorization header that match the {user} and {password} path parameters.
      iii. From the TLS client profile (optional) drop down list, select `No TLS profile`.



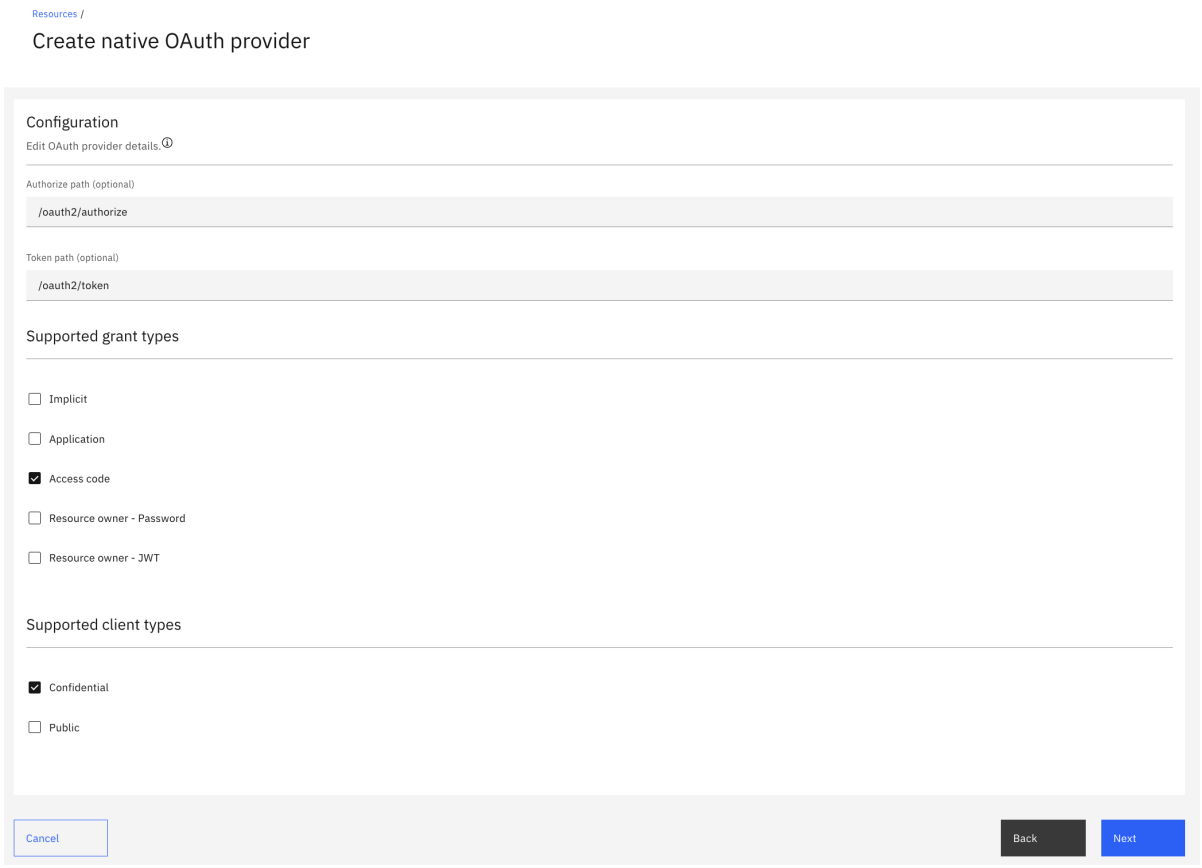
iv. Click Save.



The Resources page displays with the new registry included in the list.

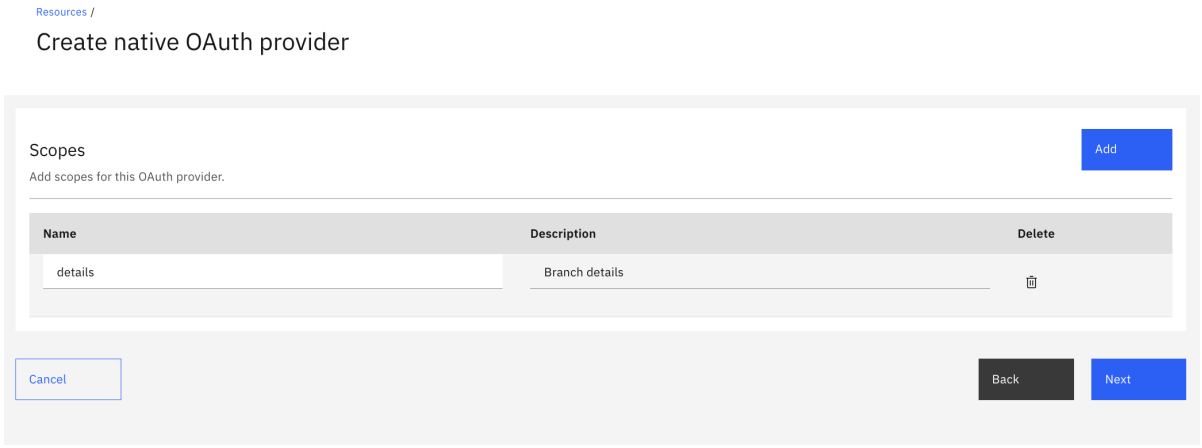
2. To create an OAuth provider to authenticate users who log in with the AuthURL registry, perform the following tasks.
   a. In the navigation list of the Resources page, click OAuth providers.

   b. In the OAuth providers section, click Add > Native OAuth provider.



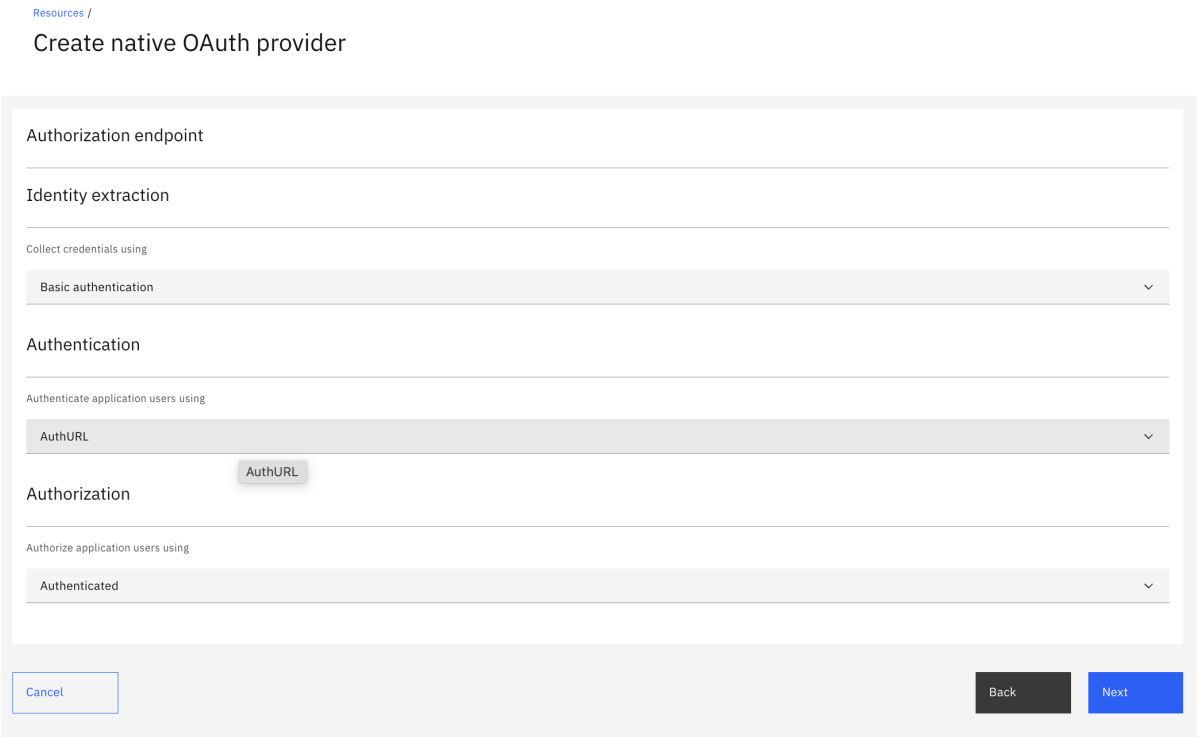
The Create Native OAuth Provider page is displayed.

c. Under the Native OAuth provider section, enter the following information.
   i. In the Title field, enter `MyNativeOAuthProvider`.
   ii. Under the Gateway type section, select the DataPower API Gateway radio button (the same gateway used by the FindBranch API).
   Note: Each native OAuth provider applies to one gateway type. The gateway type that you select here must match the gateway type used by the API that will be secured with this new provider.
   iii. Click Next.



d. Under the Supported grant types section, perform the following tasks.
   i. Select the Access code check box and deselect all the other grant types.
   Note that, this tutorial uses a single grant type to illustrate how the native OAuth provider functions.

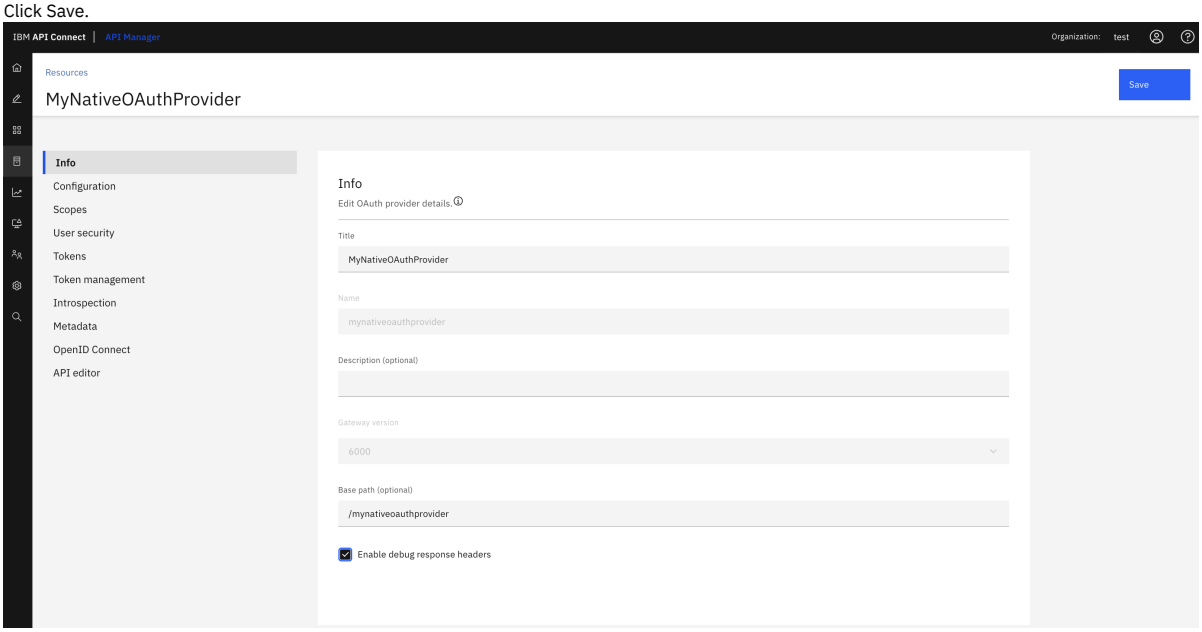
   ii. Click Next.



e. Under the Scopes section, perform the following tasks.

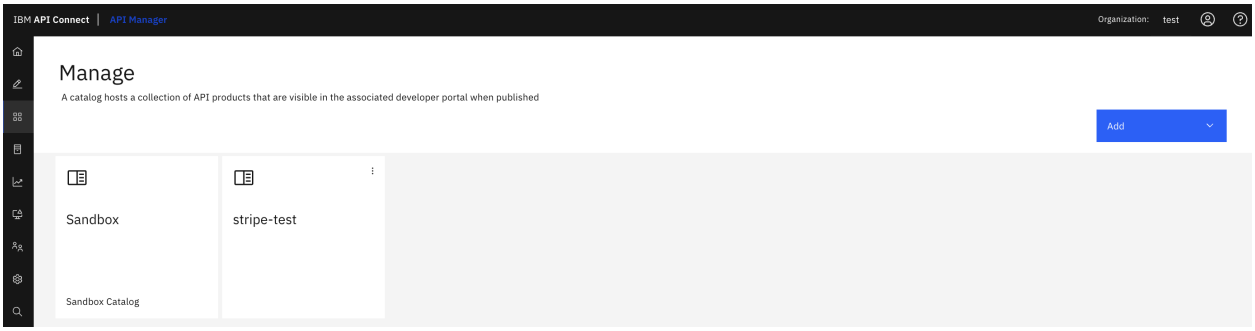
i. Click to delete the default scope.
ii. Click Add to define the scope of the API that will be secured by the native OAuth provider.
iii. In the Name field, enter `details`.
iv. In the Description field, enter `Branch details`
v. Click Next.

f. Under the Authorization Endpoint section, perform the following tasks.



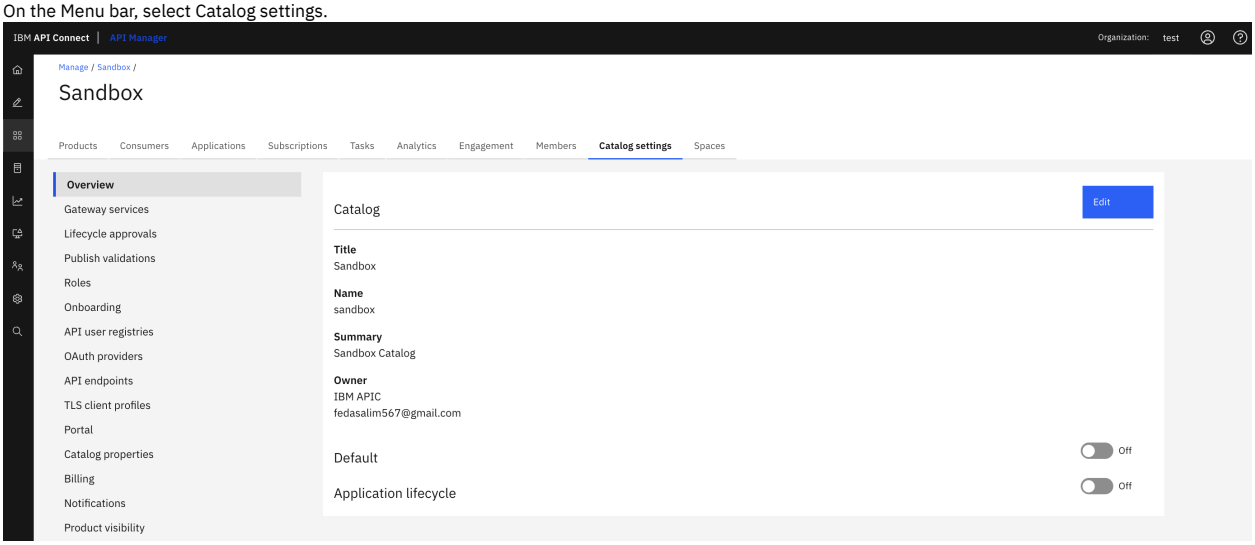
i. Under the Authentication section, from the Authenticate application users using drop down list, select `AuthURL`.
ii. Click Next.

g. Under the Native OAuth provider summary section, review the settings and then click Finish.
Once the new provider is saved, their information becomes available for editing and is displayed on the Info page.



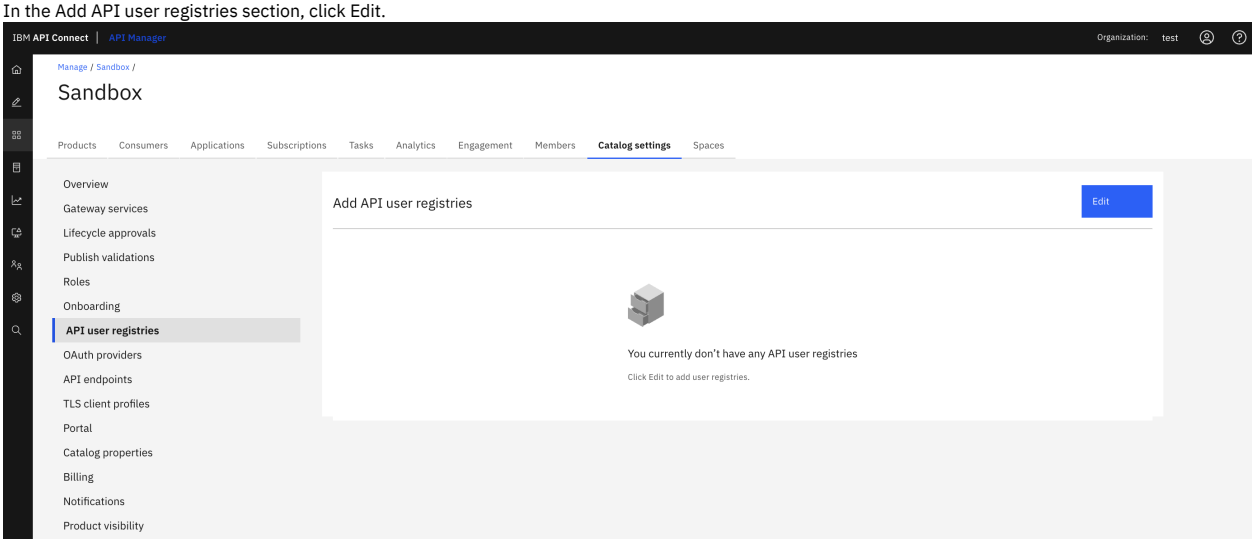
h. On the Info page, perform the following tasks.
   i. Select the Enable debug response headers checkbox.
   Selecting this checkbox includes error details in the response headers when issues occur.

   ii. Click Save.



The new native OAuth provider is now complete.

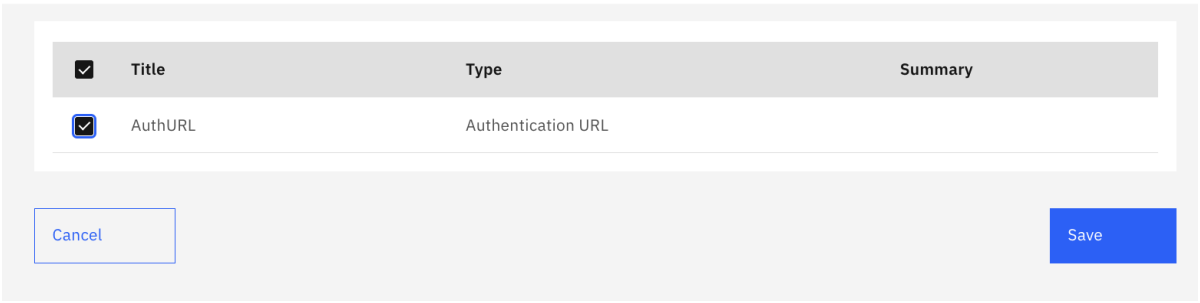
3. To configure the AuthURL registry so that it functions as an API user registry in the Sandbox catalog, perform the following tasks.
   a. In the navigation pane, click the Manage icon .
   b. On the Manage page, click the Sandbox catalog tile.



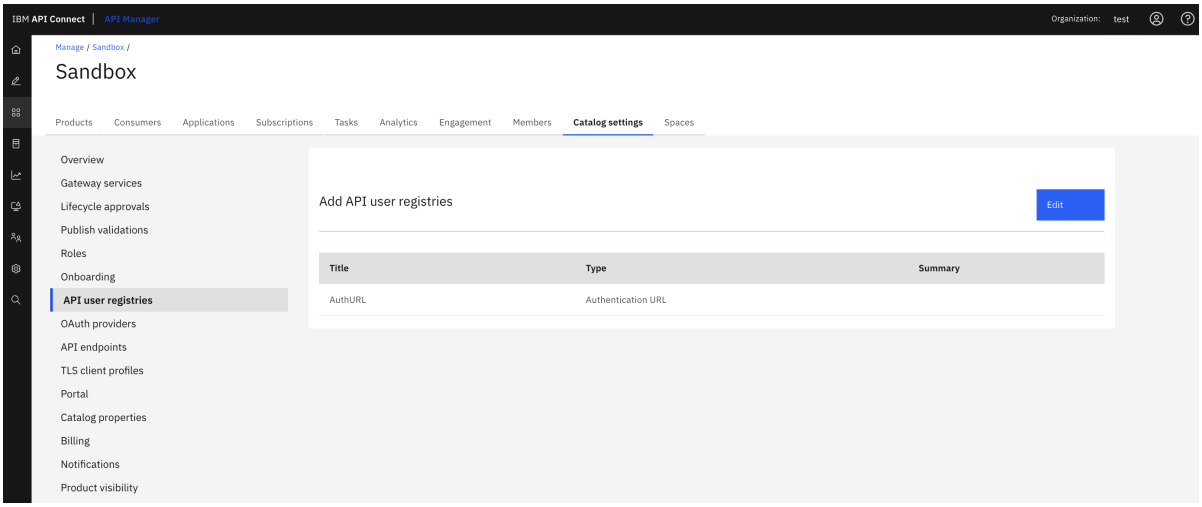
The Products page is displayed.

c. On the Menu bar, select Catalog settings.

d. In the left pane, click API user registries.



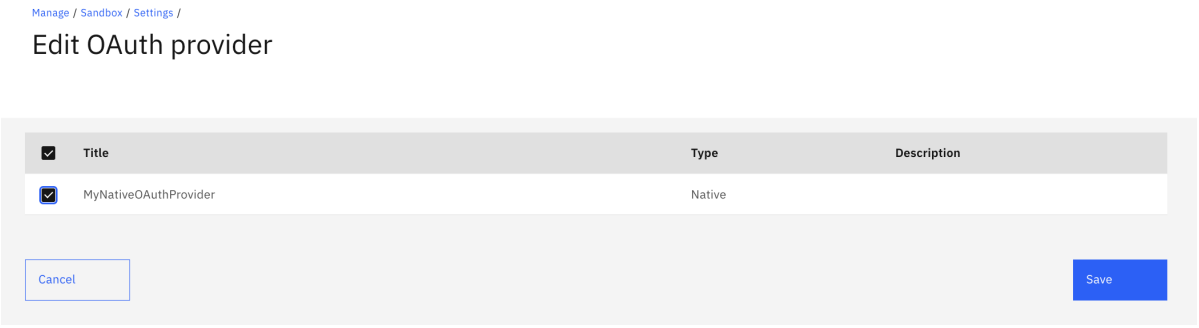
e. In the Add API user registries section, click Edit.



f. On the Edit API user registries page, perform the following tasks.

   i. Select the AuthURL check box.

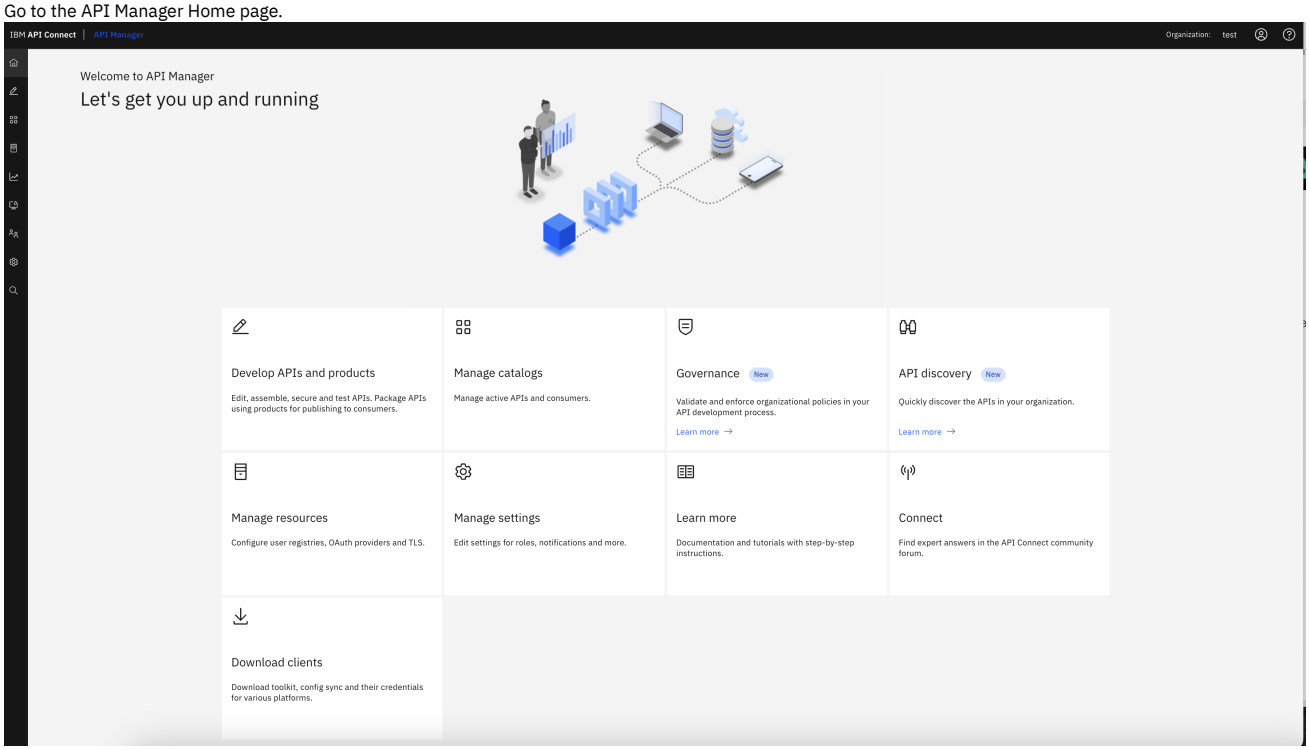
   ii. Click Save.



The new registry displays in the list of API user registries as depicted in the following image.

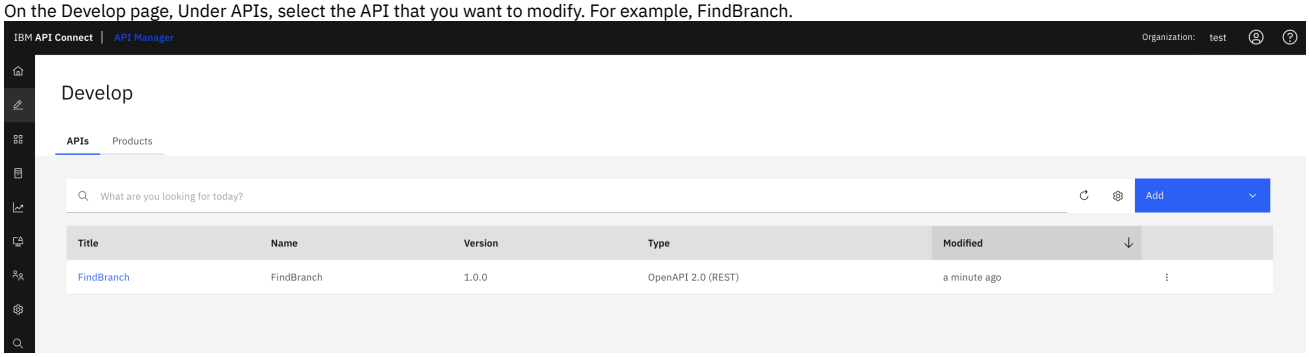
4. To configure your native OAuth provider and make it available in the API Manager interface, perform the following tasks.
   a. Select Manage > Sandbox > Catalog settings.
   b. In the left pane, click OAuth providers.
   c. In the OAuth Providers section, click Edit.

   d. On the Edit OAuth provider page, perform the following task.
      i. Select the MyNativeOAuthProvider checkbox.
      ii. Click Save.



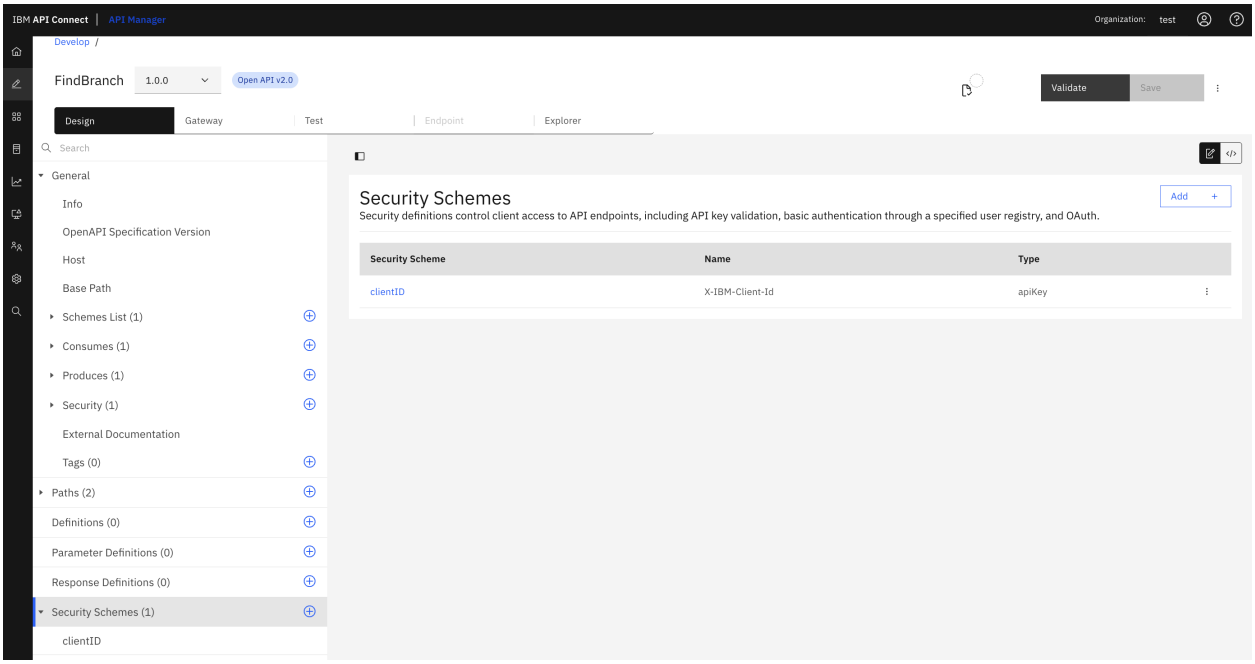
MyNativeOAuthProvider displays in the list of providers that are configured that you can use with API Manager.

Add OAuth security to an API

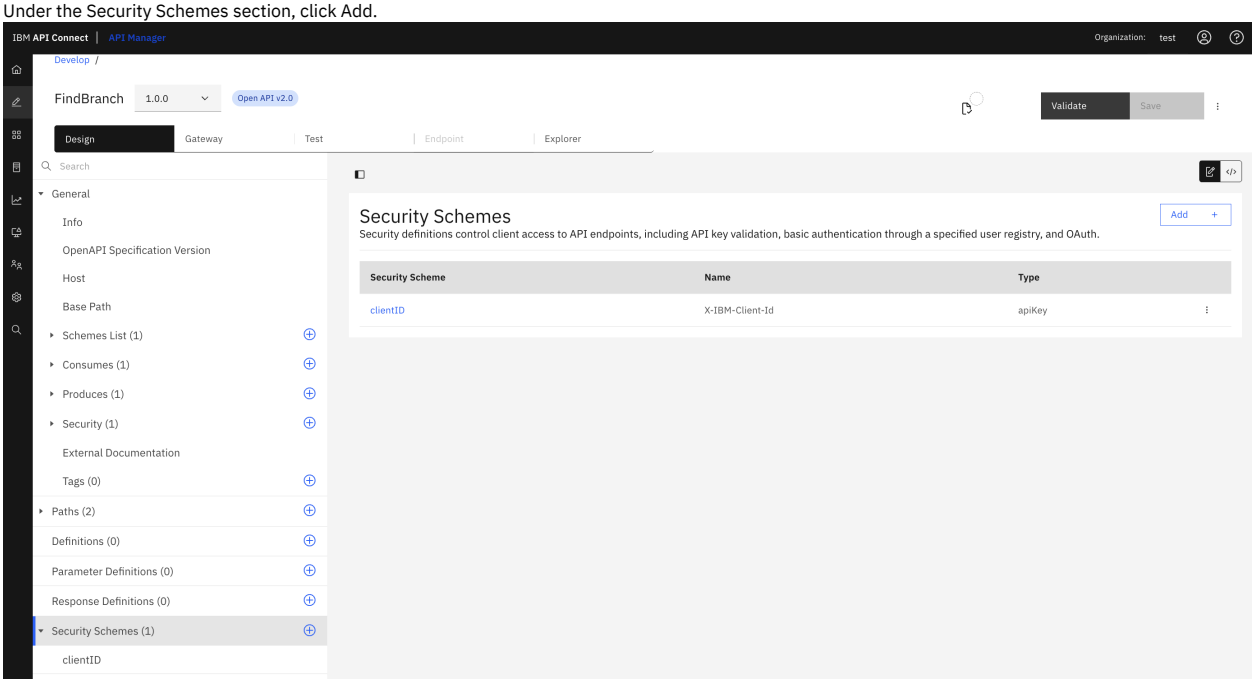


Create a security definition for the FindBranch API and include your native OAuth provider information.

1. Go to the API Manager Home page.

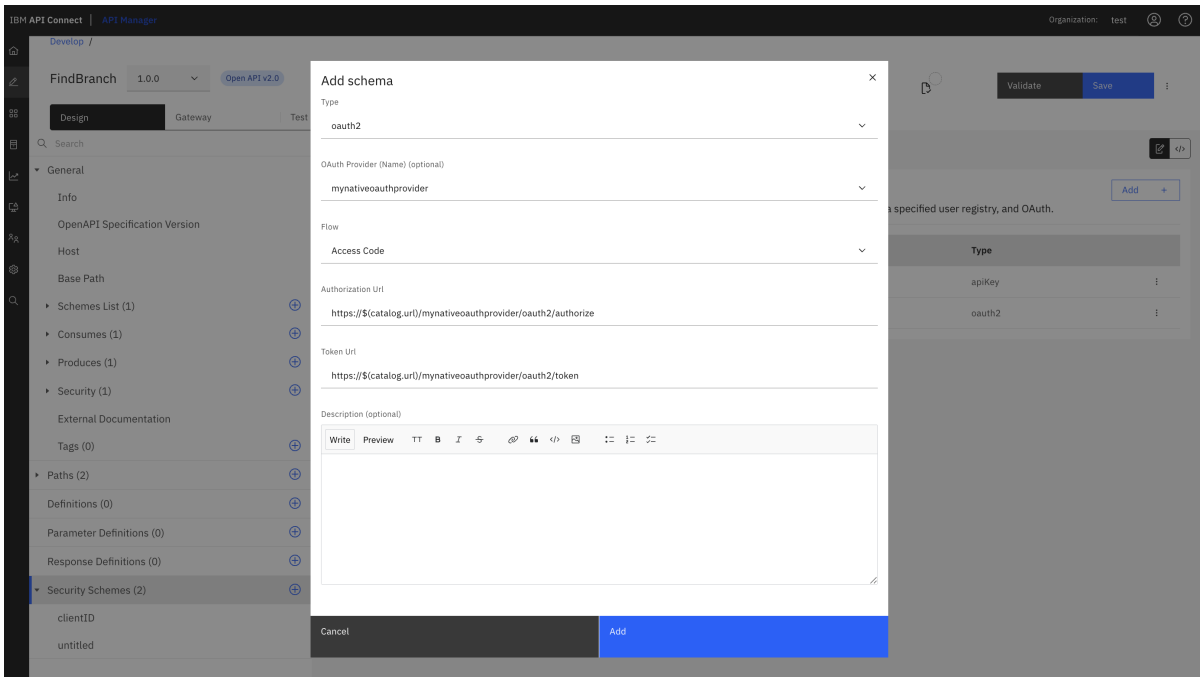


2. On the Home page, click the Develop icon.
   Alternatively, select the Develop APIs and products tile.

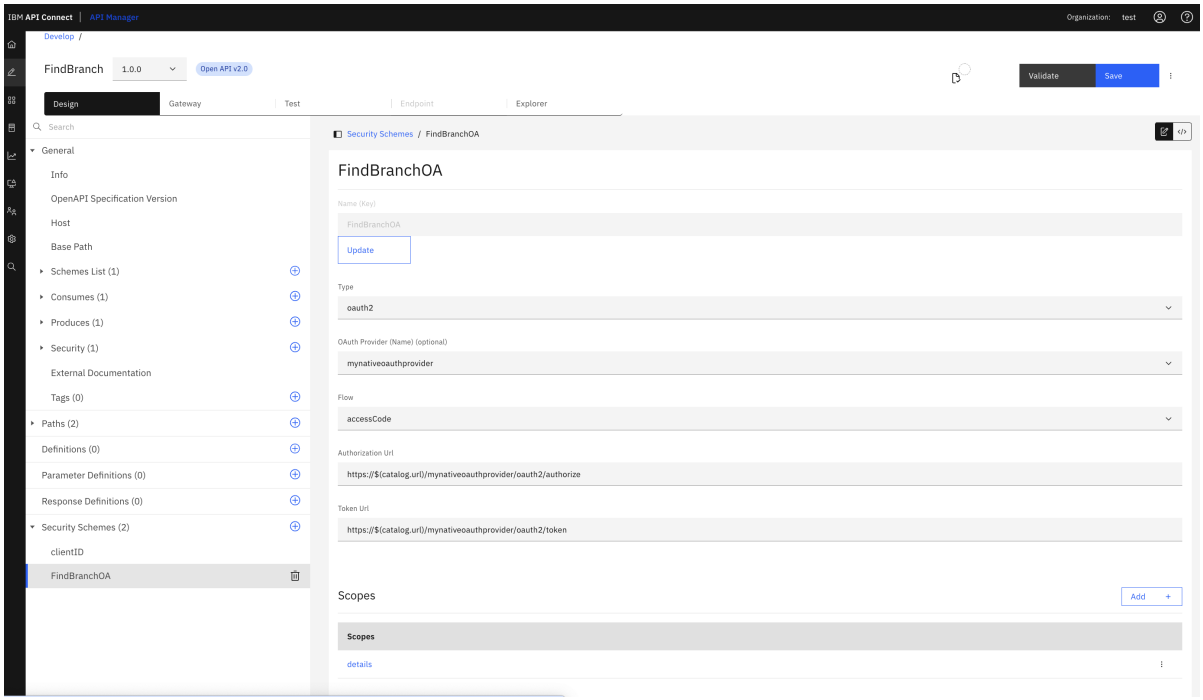


3. On the Develop page, Under APIs, select the API that you want to modify. For example, FindBranch.

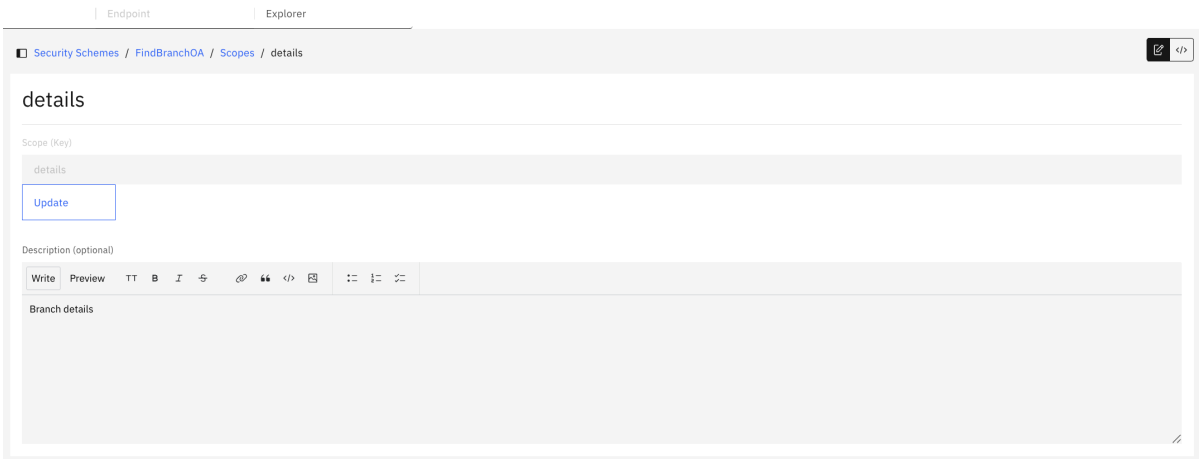
4. On the FindBranch API's Design page, perform the following tasks.
   a. In the left navigation pane, select Security Schemes.



b. Under the Security Schemes section, click Add.

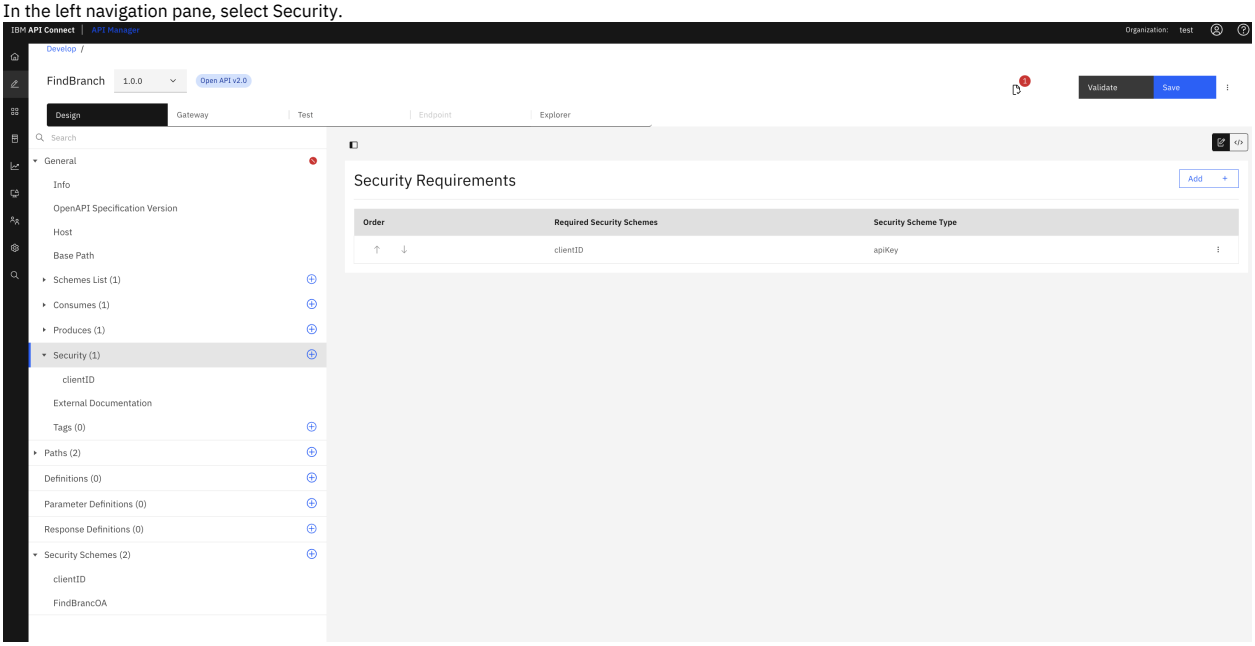


c. In the Add schema pop up window, perform the following tasks.



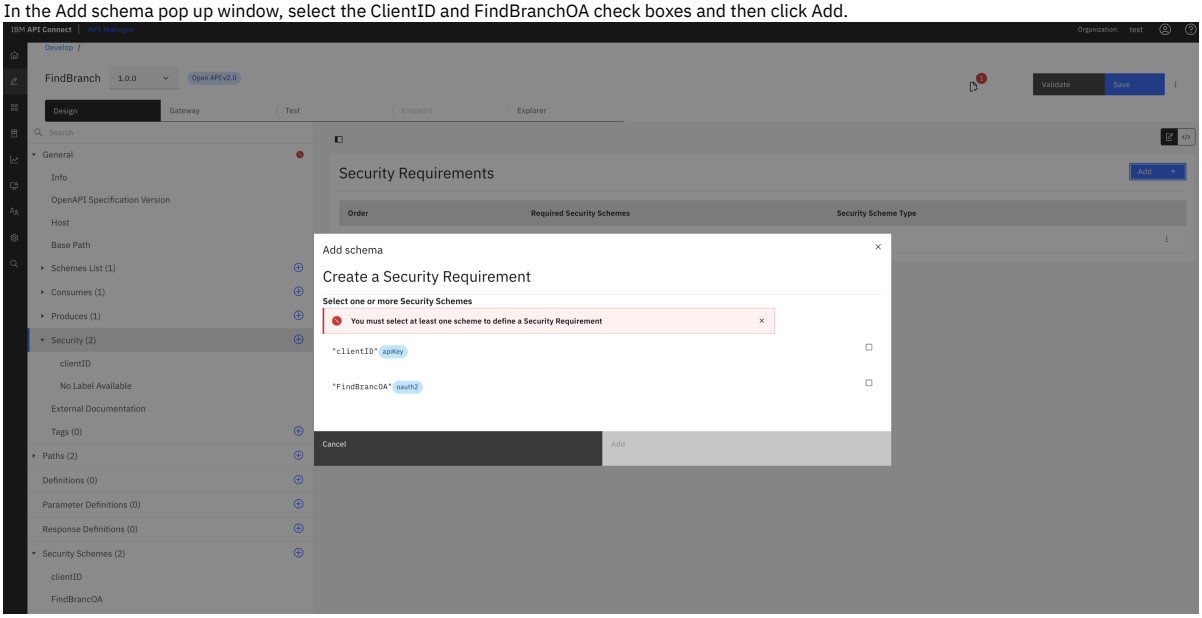
i. In the Security Definition Name (Key) field, enter `FindBranchOA`.
ii. From the Type drop down list, select `oauth2`.
iii. From the OAuth Provider (Name) (optional) drop down list, select MyNativeOAuthProvider.
iv. From the Flow drop down list, select `Access Code`.
v. Retain the pre-filled values in the Authorization Url and the Token Url fields.
vi. Click Add.

FindBranchOA is now displayed under Security Schemes.



vii. In the right pane, under the FindBranchOA section, click the details link and verify that the scope you defined for the native OAuth provider displays.

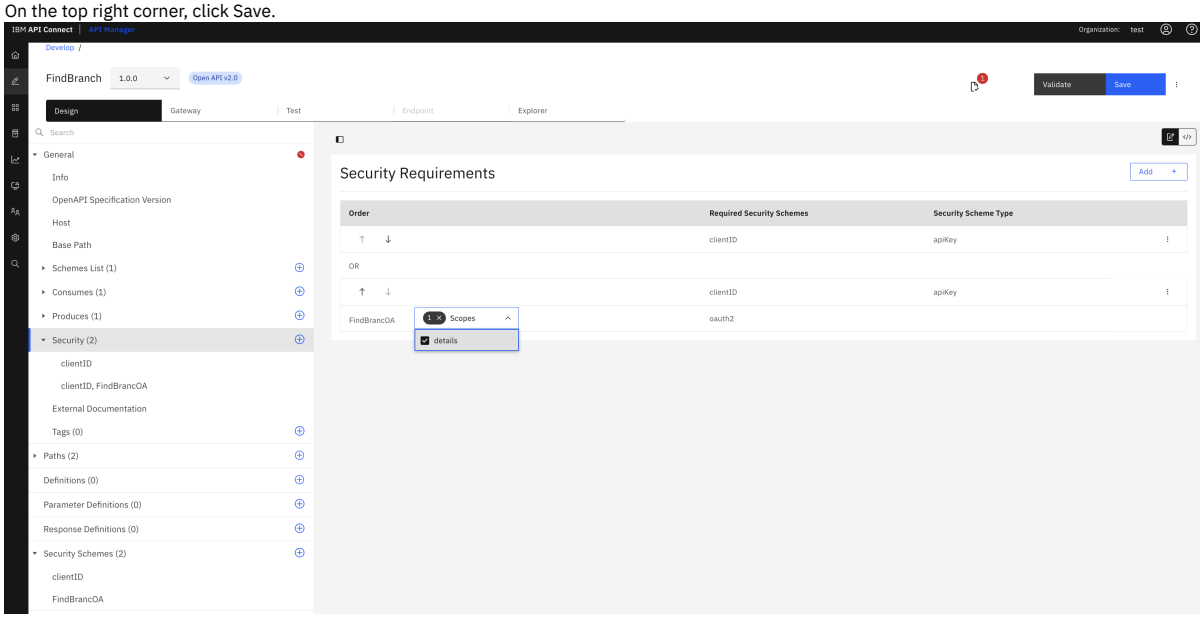
viii. On the top right corner of the page, click Save.



d. In the left navigation pane, select Security.

e. In the Security Requirements section, perform the following tasks.

i. Click Add.

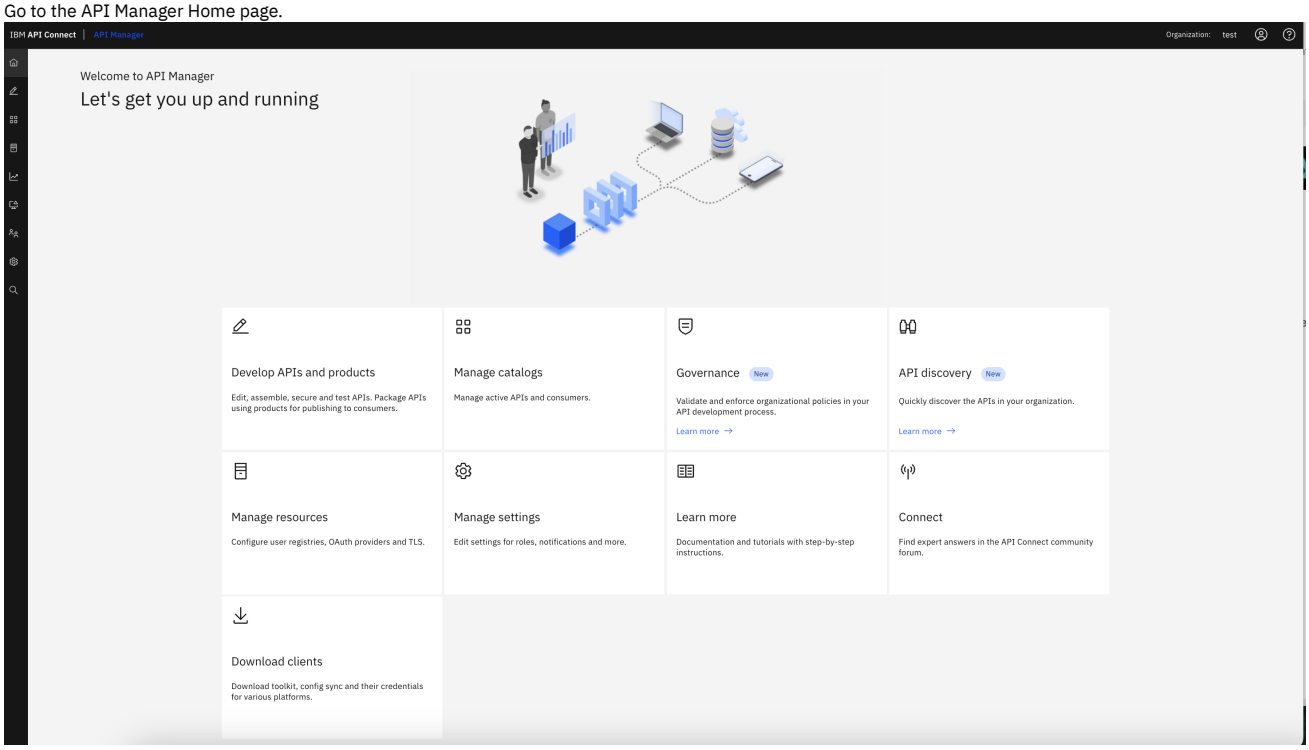


ii. In the Add schema pop up window, select the ClientID and FindBranchOA check boxes and then click Add.

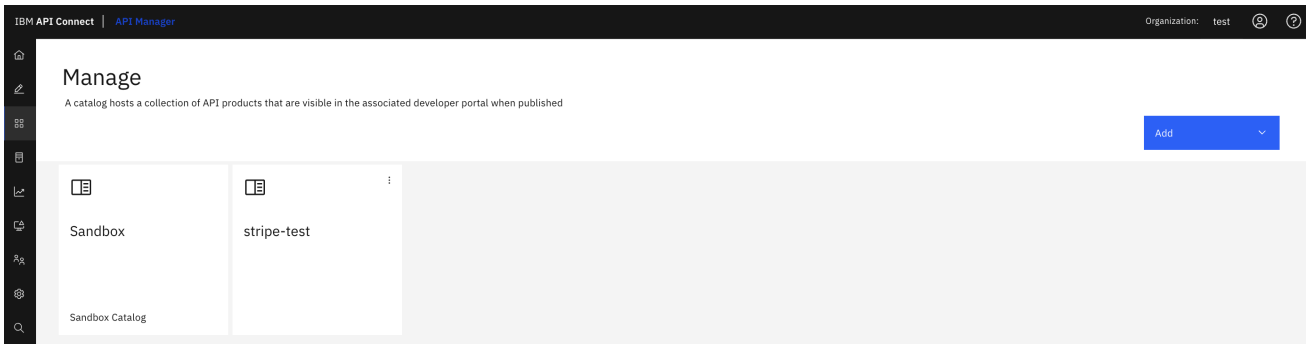
FindBranchOA is now displayed in the Security Requirements section.

iii. Adjacent to FindBranchOA, from the Scopes drop down list, select details.

iv. On the top right corner, click Save.



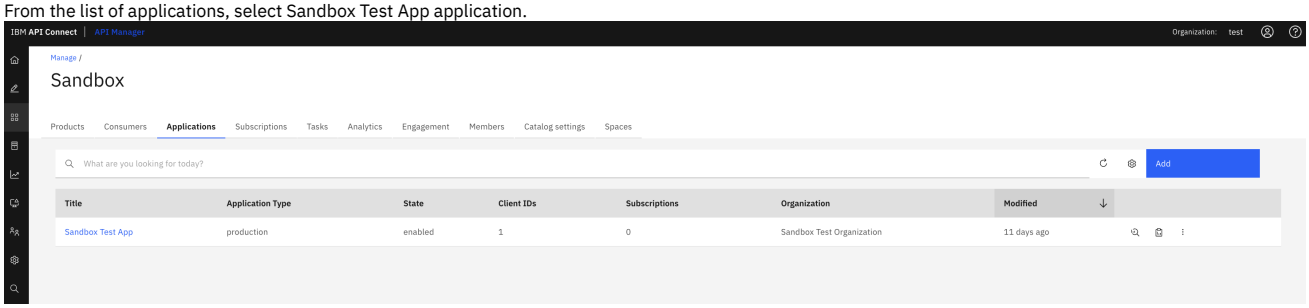
Adding an OAuth redirect to the Sandbox Test App



To test the OAuth functionality within API Manager, use the Sandbox Test App application. The Sandbox Test App is included with the Sandbox catalog, and is automatically subscribed to the default product for every API that you create within the catalog, so it's always available for testing APIs in API Manager.

Note: Before using the application for OAuth testing, you must update it to include an OAuth redirect URL.

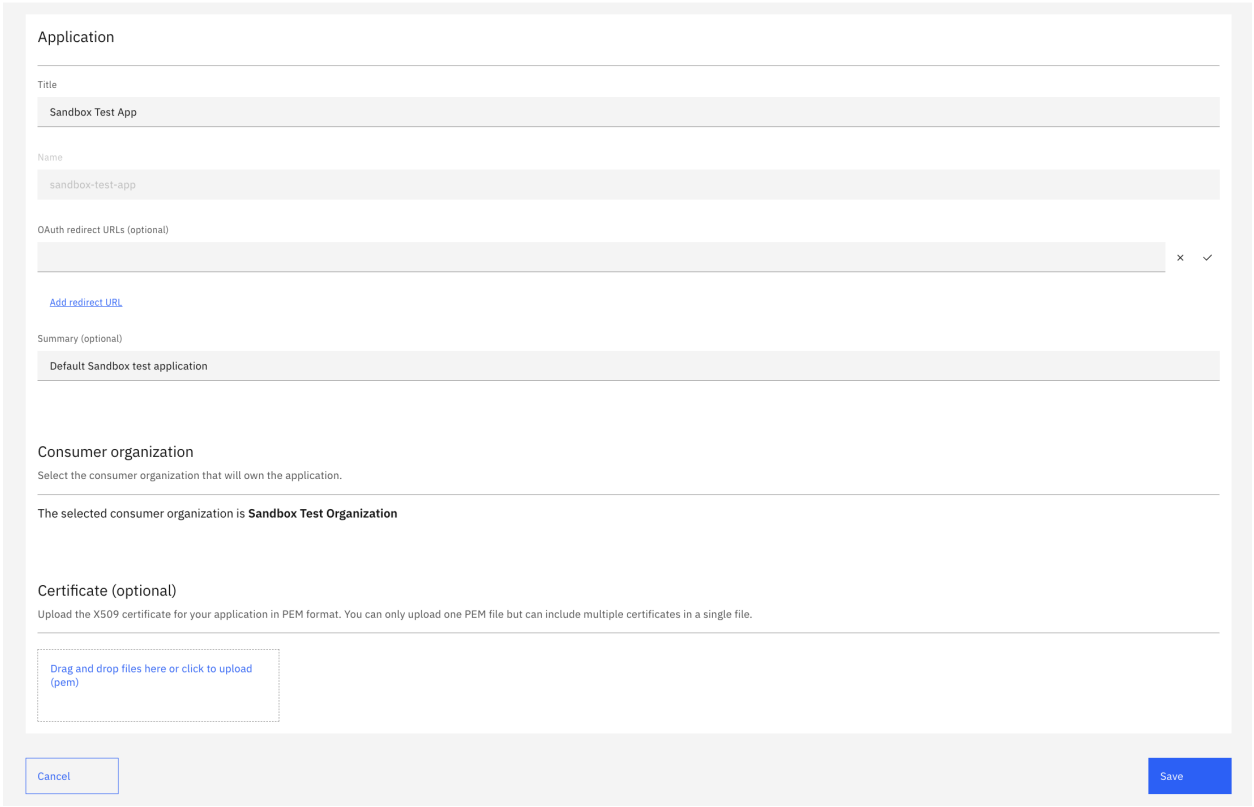
1. Go to the API Manager Home page.



2. On the Home, in the navigation pane, click Manage.
3. On the Manage page, click the Sandbox catalog tile.

The Products page is displayed.

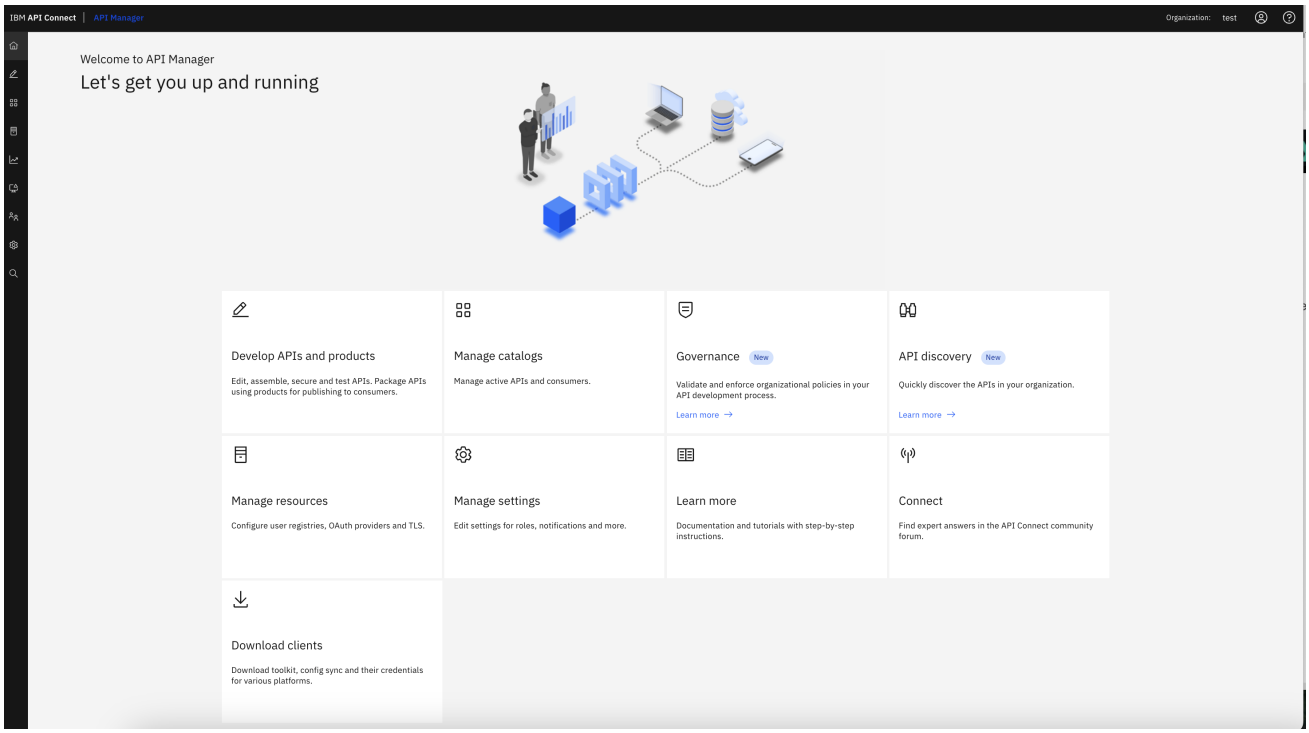
4. On the menu bar, click Applications.
5. From the list of applications, select Sandbox Test App application.



The Edit application page is displayed.

6. On the Edit application page, perform the following tasks.
   a. Under the OAuth redirect URLs (optional) section, click the Add redirect URL.
   b. In the OAuth redirect URLs (optional) field, enter `https://example.com/redirect`
      Although this field is optional, you must enter the value for the authorization flow in your OAuth provider. For testing OAuth within API Manager, the URL can be any value that is formatted as a proper URL, but you must use the same value when you provide the redirect URL during testing.
   c. After entering the value in the OAuth redirect URLs (optional) field, click the Complete icon to save the value.

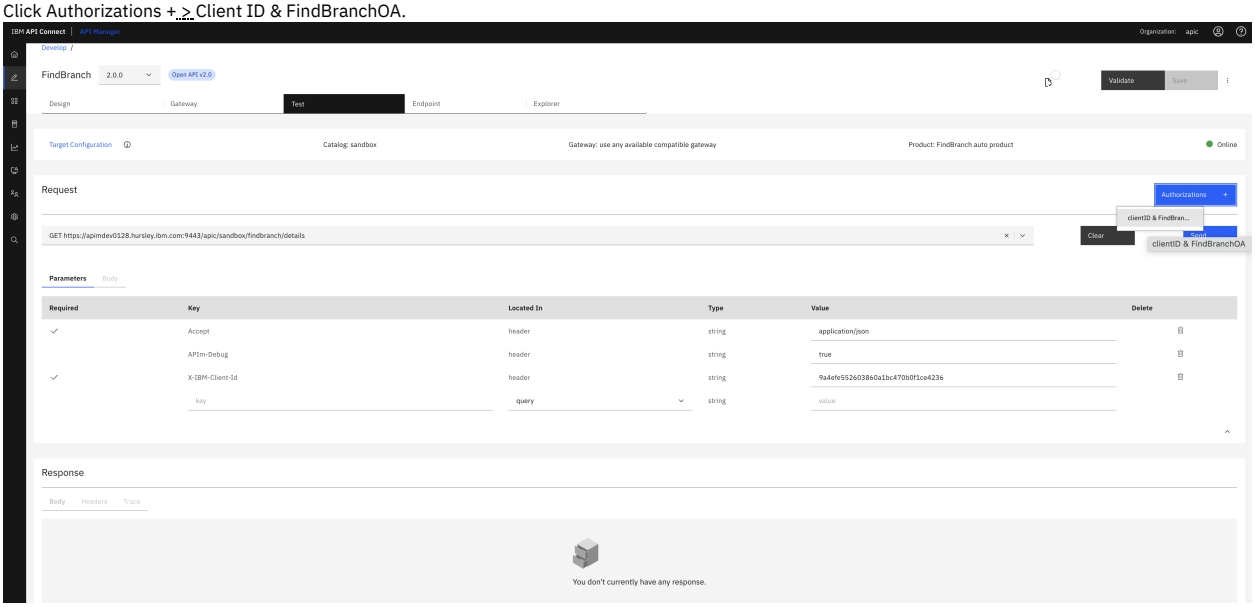
   d. Click Save to update the application.



Test the OAuth security implementation

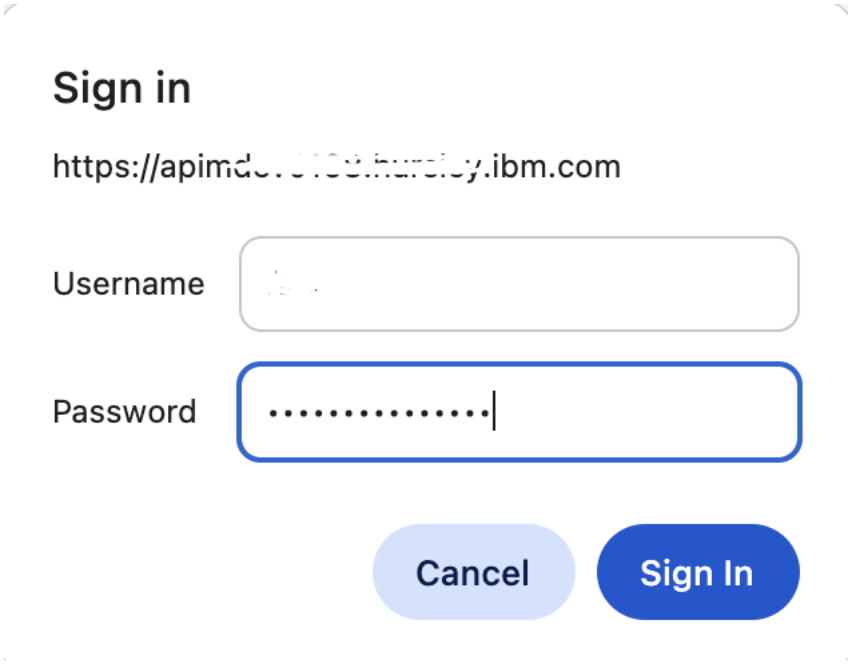
Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test your OAuth implementation, run an API from within API Manager using the Sandbox Test App.

Note: Before running the API,



- You must publish the product to ensure that the latest update is online and available for testing.
- You must obtain an authorization code and then use it to obtain an access token that allows you to execute the API.

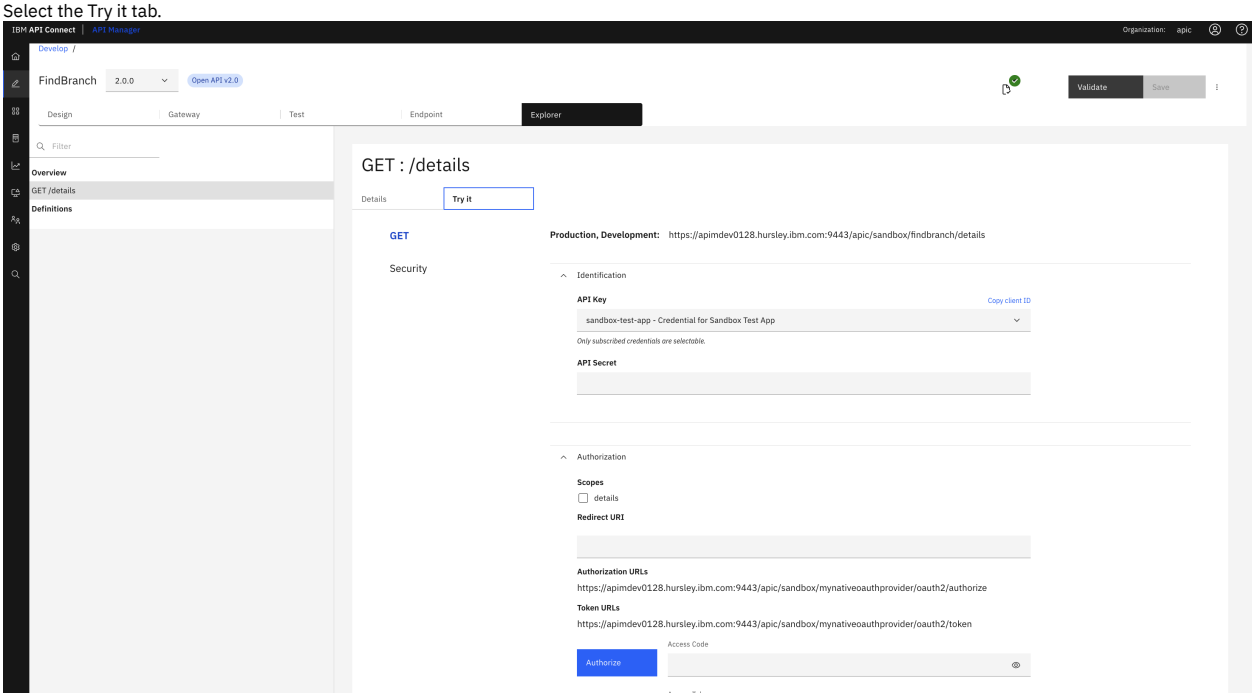
1. Go to the API Manager Home page.



2. On the Home page, click the  Develop icon.
   Alternatively, select the Develop APIs and products tile.

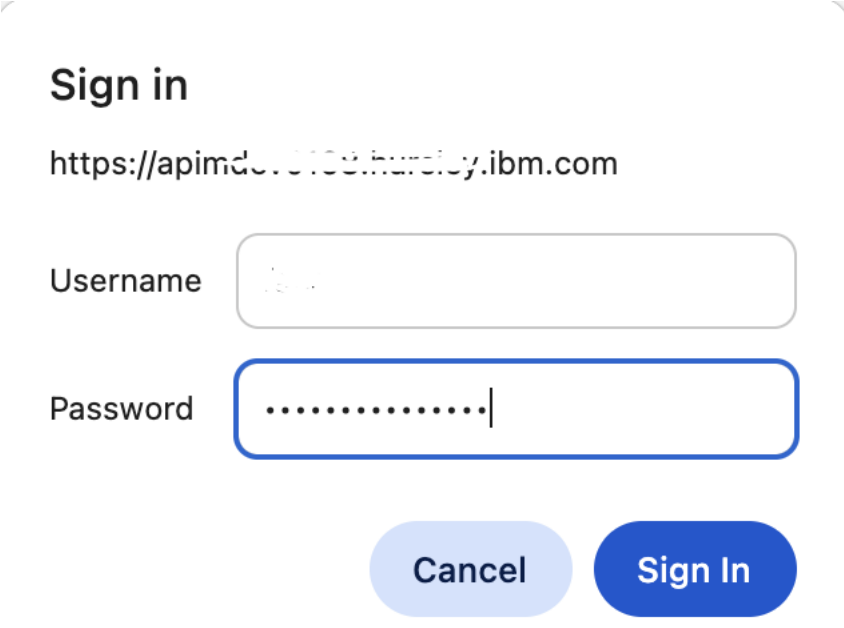
3. On the Develop page, select the API that you want to test. For example, FindBranch.
4. On the Menu bar, select Test.
5. On the Test page, perform the following tasks.
   a. Click Authorizations +. > Client ID & FindBranchOA.

   b. On the Authorize pop up window, perform the following tasks.
      i. Select the Oauth2 tab.
      ii. In the Client ID field, enter your client ID.
      iii. In the Client Secret field, enter your client secret.
      iv. Under Scopes, select the details checkbox.
      v. In the Username field, enter `user`.
      vi. In the Password field, enter `password`.
      vii. Click the Get Token tab.
      viii. In the pop up dialog box, enter the API Manager login credentials and then click Sign In or press ENTER.



The Access Token is generated and displayed on the Authorize pop up window.

ix. Under the Access Token section, copy the token.



x. Click Apply.

6. On the Menu bar, select Explorer.
7. On the Explorer page, in the left pane, select GET/details.
8. In the right pane, under the GET : /details section, perform the following tasks.
   a. Select the Try it tab.

   b. In the API Secret field, enter your client secret.
   c. Under the Authorization section, perform the following tasks.
      i. Select the details checkbox.
      ii. In the Redirect URI field, enter `https://example.com/redirect`.
      iii. To obtain the Authorization code, scroll down and click Authorize.
      iv. In the pop up dialog box, in the User ID field, enter `user`, in the Password field, enter `password`, and then click Sign In or press ENTER.

When you successfully authenticate, your browser redirects to a window that displays the page from the redirect URL. Your authorization code is included in the address bar as a parameter to the URL.

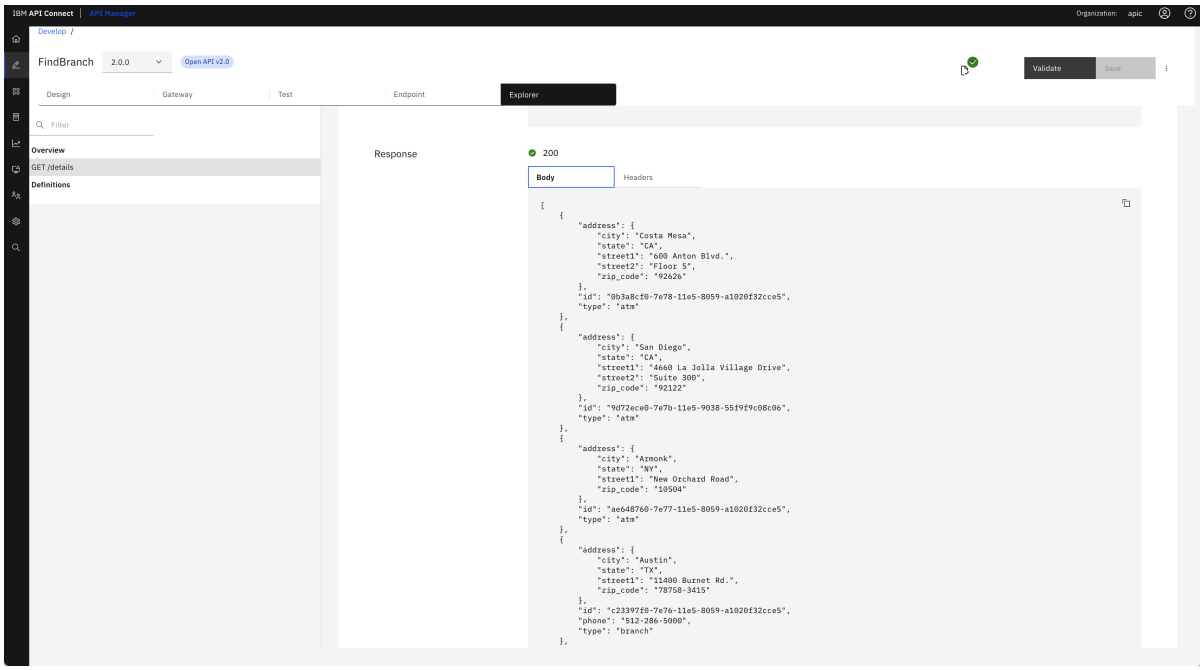
Your authorization code is included in the address bar as a parameter to the URL as displayed the following image. If the URL is **`https://example.com/redirect?code=AAPl-yX6XVtdROcU4_WJhETLPLjLOJoJIpAYSFf7-4FxcNJ2XfXbMWpu8LnruLtcgmkdjNeDstRi0aO-d8bZX888iQYrtyhfrYSgADZgWy84nw`**, your Authorization code is, **`AAPl-yX6XVtdROcU4_WJhETLPLjLOJoJIpAYSFf7-4FxcNJ2XfXbMWpu8LnruLtcgmkdjNeDstRi0aO-d8bZX888iQYrtyhfrYSgADZgWy84nw`**.

v. Copy the authorization code from the URL in the window's address bar, capturing everything after "code=".

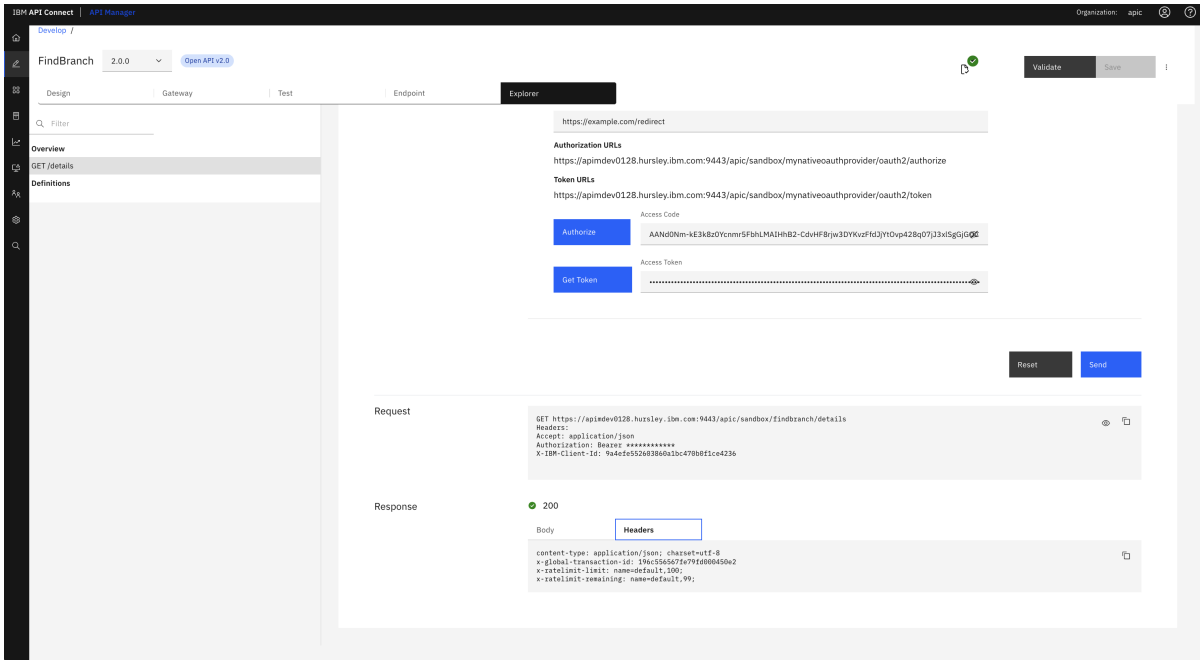
https://example.com/redirect?code=**AALEn_1uXA3u6IoHKeJeLUX8tqilKD9W7VGkmoI8UgrN97ZvMR9IkczQ1Bffxk-PVLyfCVII5ZYo9wTmxGwgyqwC1ktIZ3beYYDw7OWAbBkQhg**

For example:

```
https://example.com/redirect?
code= AALMmZCyKnhY1HpZGfpHkFH7wDdsNh9R2hgDfGwMVgdEzBOTlnq5LPZ3x6RFPa3V7CzsGacH8LLGlafnqa3ntbh921n5rJE7W0_jC1cAtzcZEg
```



vi. In the Authorize field, enter the authorization code.



vii. Click Get Token to obtain the access token.
If the authorization is successful, the Get Token is now filled with the access code.

Tip: If the access token does not appear and you see a message about your authorization code expiring, return to the previous step to request a new Authorization code, and use it to generate the access token.

viii. Click Send.
The FindBranch API's response displays the Status code `200`. You can view the response Headers information, and the Body information that contains each bank branch's data.

You can scroll down and view the information under the Response section.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a user registry for use with an OAuth provider.
- Created a native OAuth provider and made it available within the catalog.
- Added OAuth security to an API.
- Updated the Sandbox Test App (client application) to provide an OAuth redirect for testing.
- Tested the OAuth security by obtaining an authorization code, exchanging it for an access token, and invoking the secured API.

Tutorial: Implementing OIDC Security

This tutorial shows you how to add OIDC (OpenID Connect) capability to an existing native OAuth provider using API Manager.

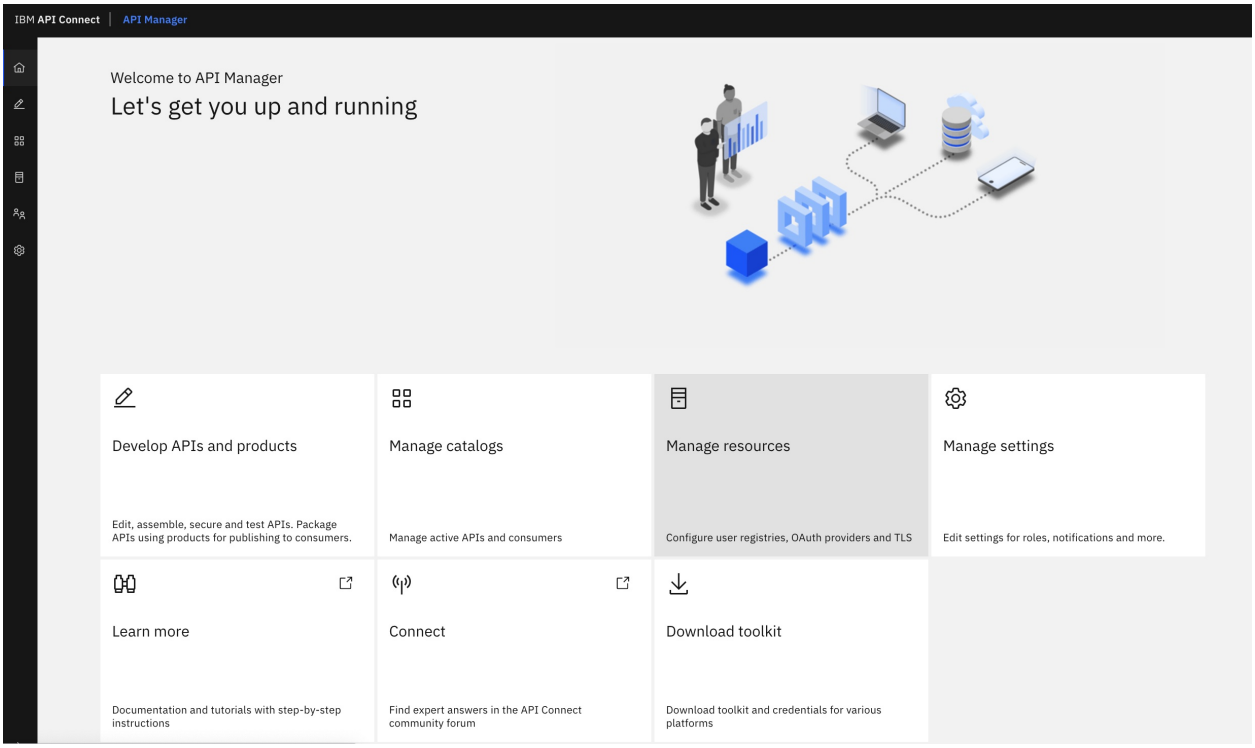
About this tutorial

OpenID Connect is an authentication protocol that works with OAuth to control user access to resources. When you use OAuth to determine a user's authorizations, you can additionally use OIDC to authenticate the user through the use of JSON Web Tokens (JWT).

In this tutorial you will complete the following lessons:

1. Add OIDC capability to an OAuth native provider
2. Test OIDC Security

Before you begin

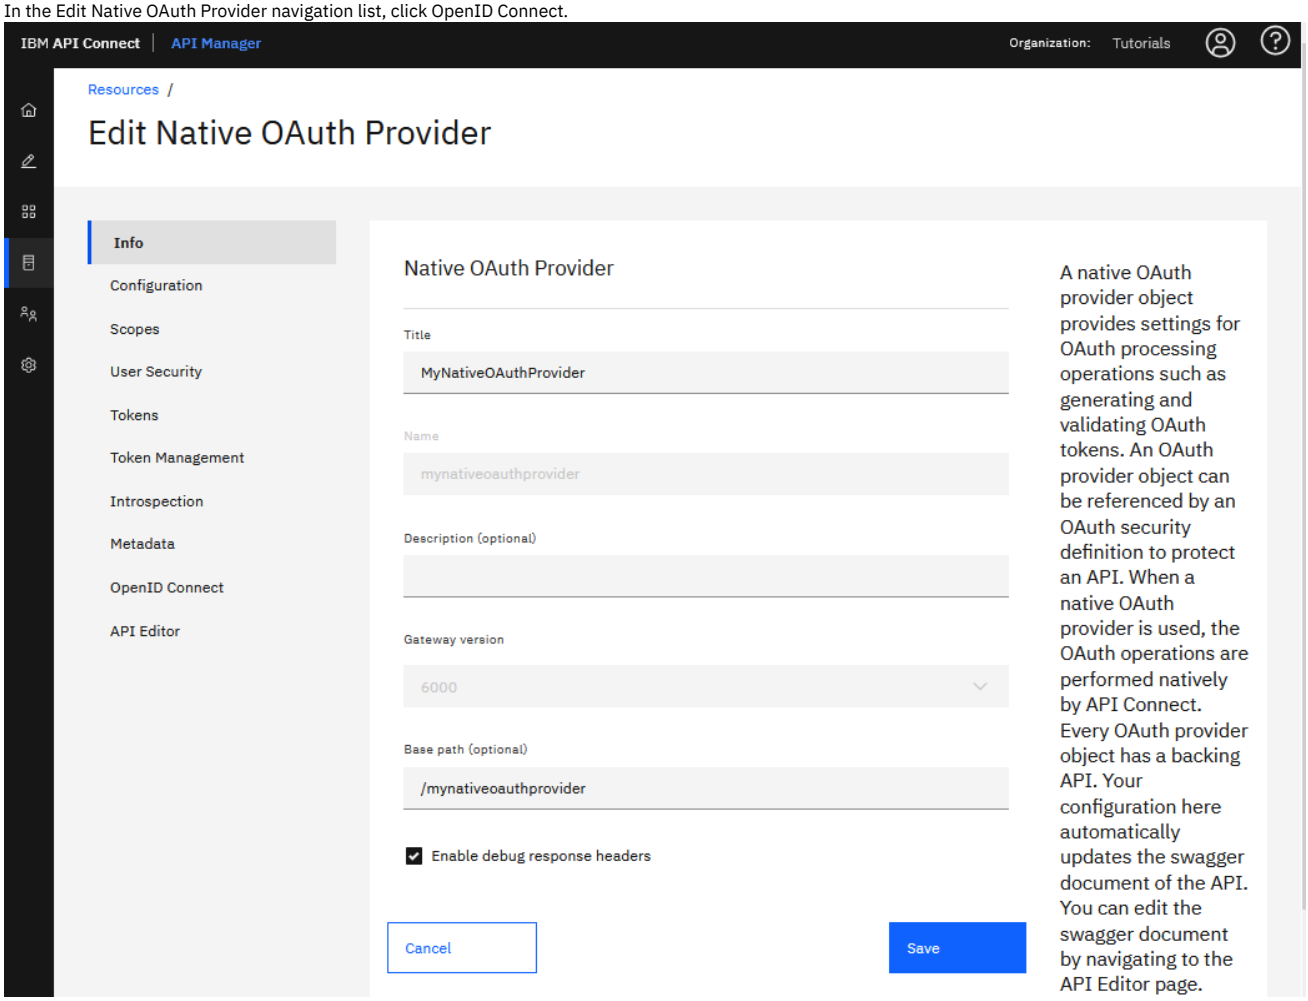


This tutorial uses the predefined FindBranch API and an existing native OAuth provider configured with the "Access code" grant type. To prepare your environment for this tutorial, complete the following tasks:

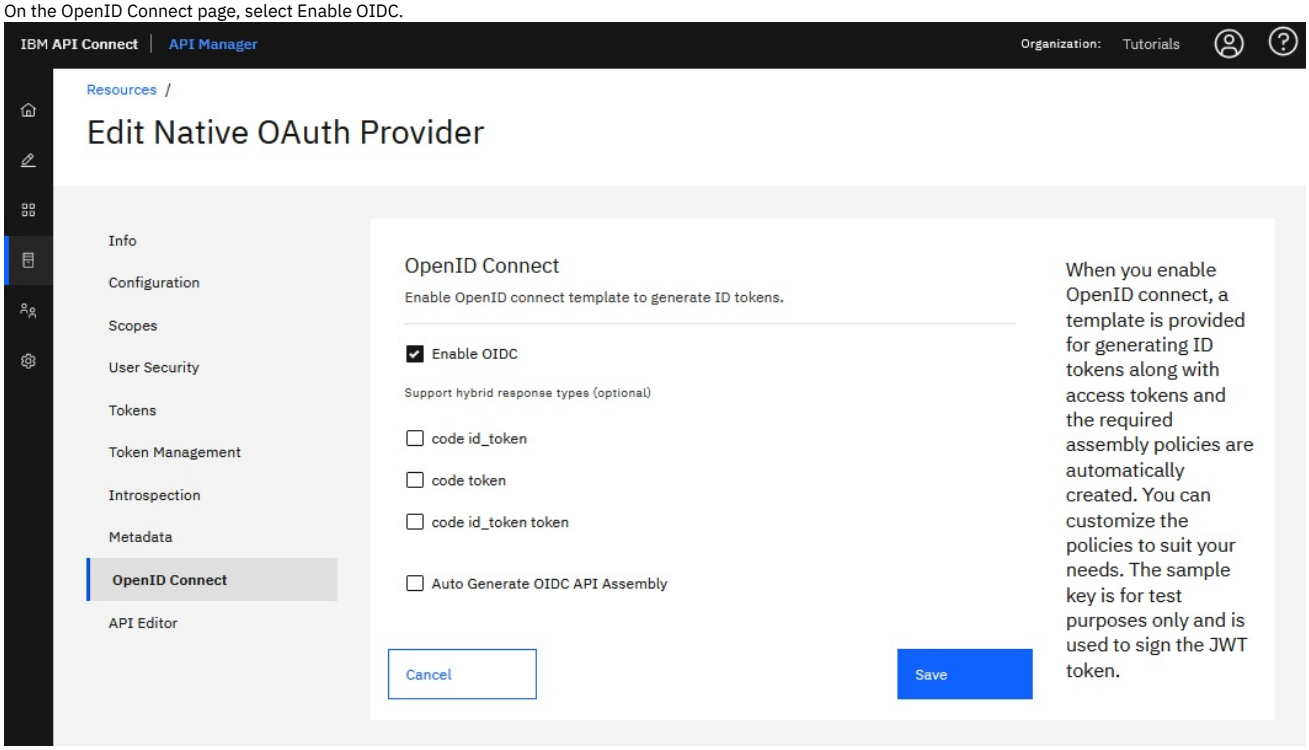
1. Add the DataPower® API Gateway gateway service to the Sandbox catalog as explained in Creating and configuring catalogs.
   The Sandbox catalog must be configured to use at least one gateway. For this tutorial, you must use the same gateway that the FindBranch API uses.
2. Import the FindBranch API and activate it as explained in Tutorial: Importing an API.
3. Create the MyNativeOAuthProvider native OAuth provider as explained in Tutorial: Implementing OAuth Security.

Add OIDC capability to an OAuth native provider

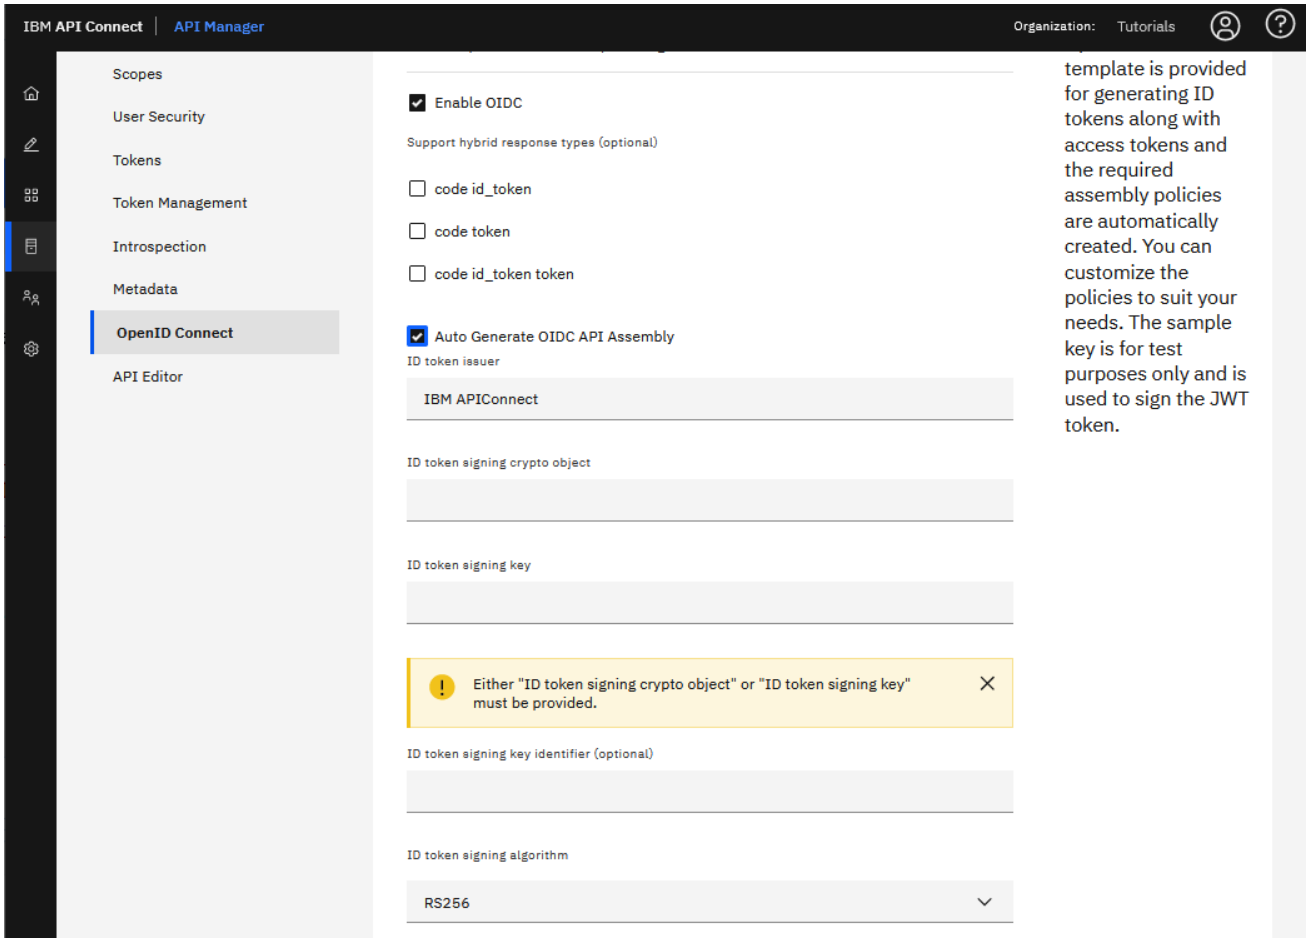
To add OIDC security to a native OAuth provider, complete the following steps:



1. Open the OAuth provider for editing:
   a. Log in to API Manager.
   b. On the Home page, click the Manage resources tile.



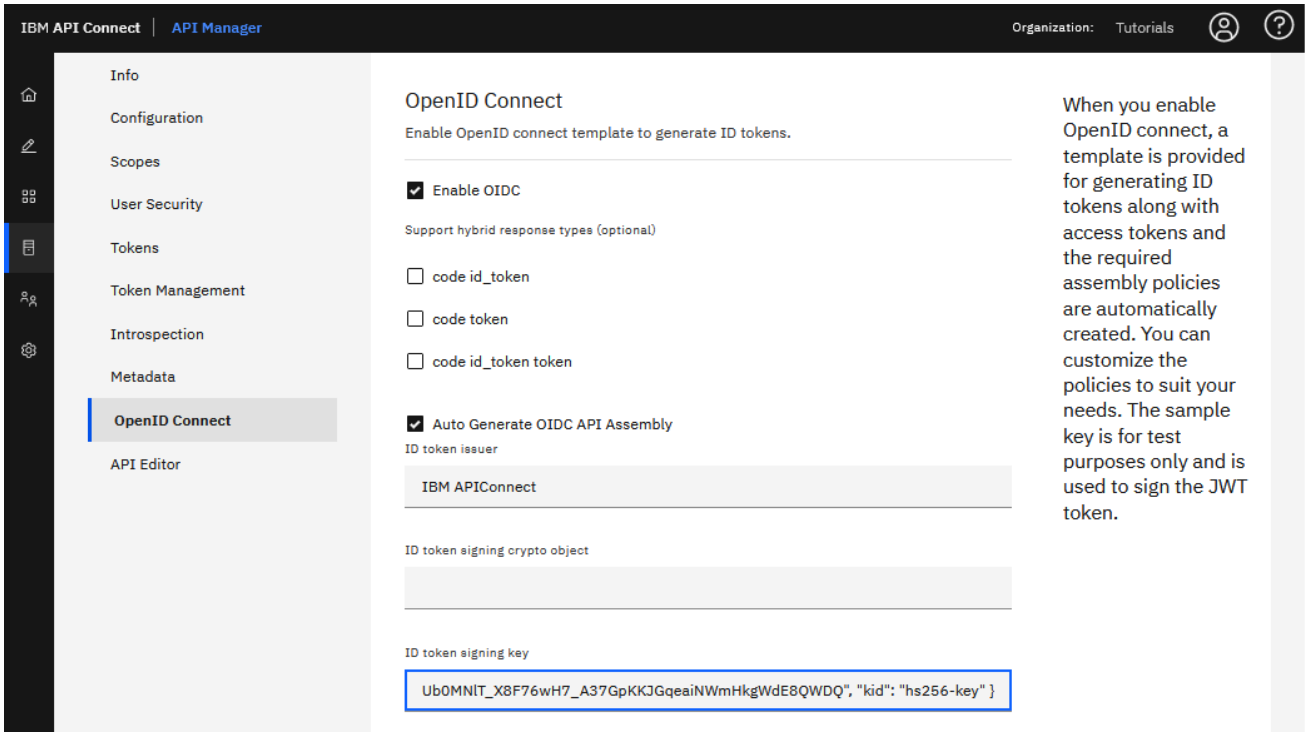
c. In the Resources navigation list, click OAuth Providers.
d. In the list of OAuth providers, click MyNativeOAuthProvider to open it.



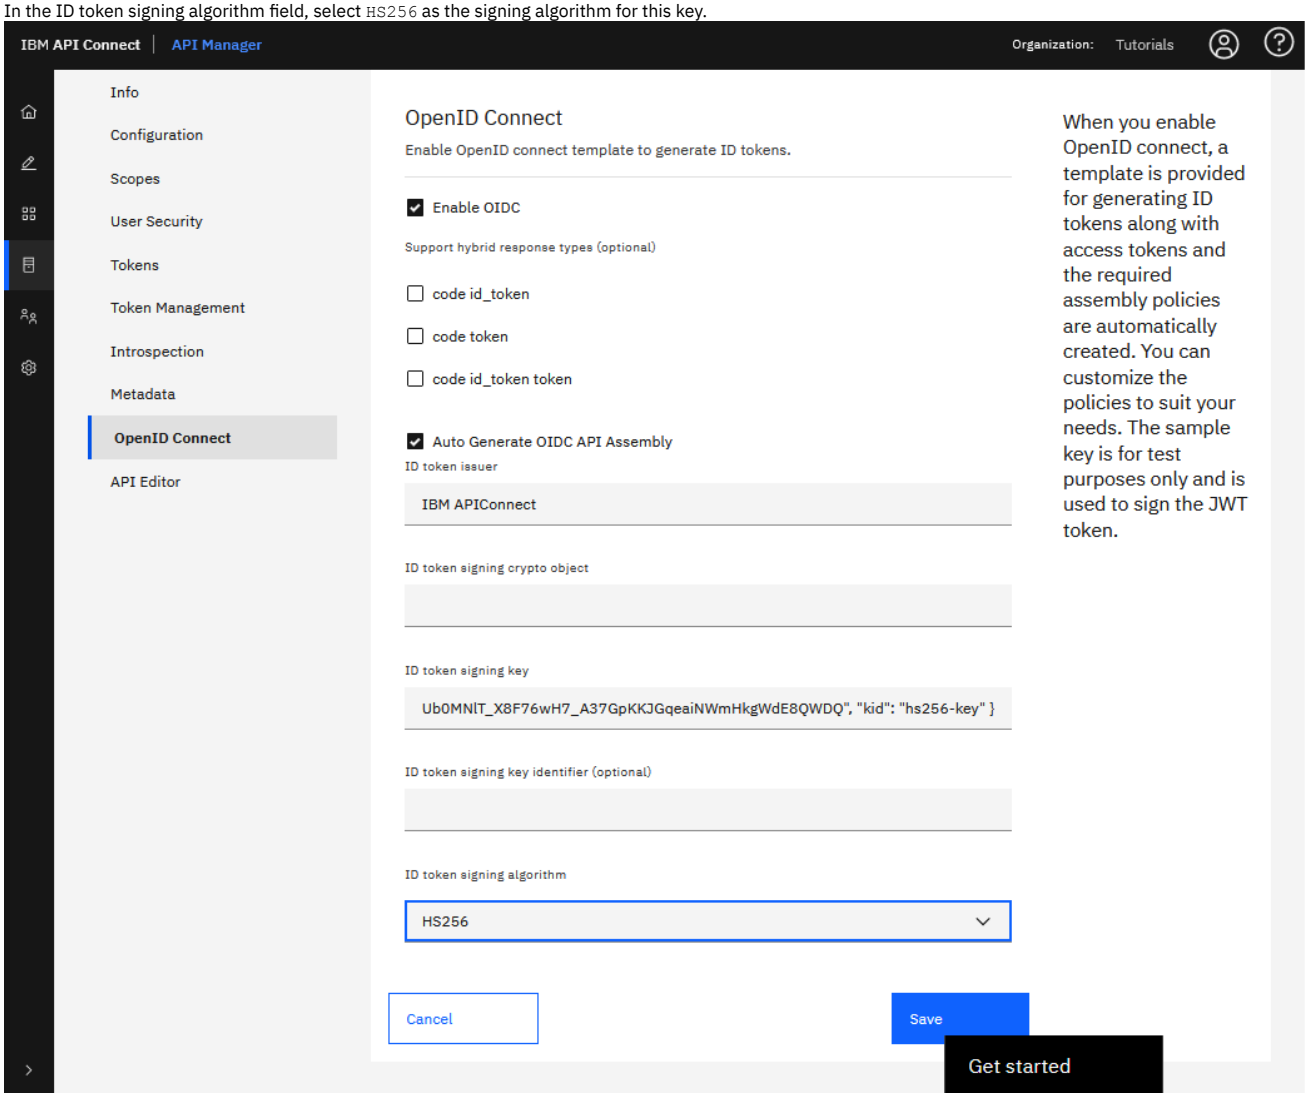
2. In the Edit Native OAuth Provider navigation list, click OpenID Connect.

3. On the OpenID Connect page, select Enable OIDC.

4. If any settings are selected in the Support hybrid response types list on the page, clear the selections.
5. Select Auto Generate OIDC API Assembly.
   This option updates your API with the flow for OIDC.



A message displays to warn that you must provide either an ID token signing crypto object or an ID token signing key. In this tutorial, you provide a JWK key (in the next step).

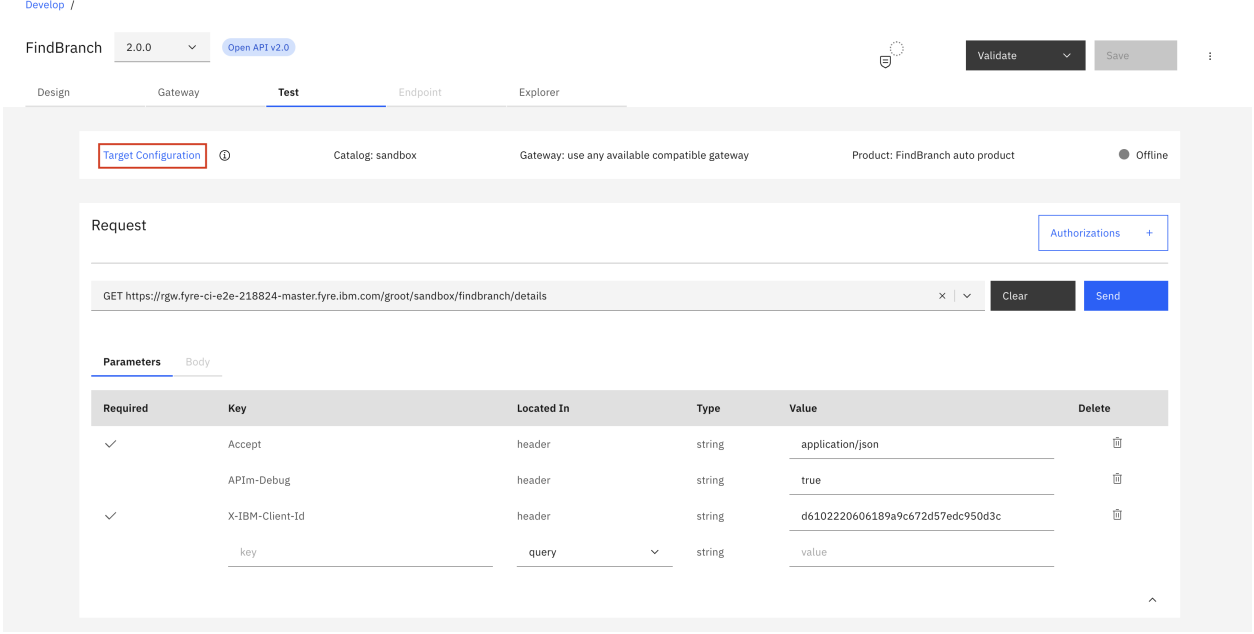


6. Click to copy the following key, and then paste it in the ID token signing key field:

```
{ "alg": "HS256", "kty": "oct", "use": "sig", "k": "o5yErLaE-dbgVpSw65Rq57OA9dHyaF66Q_Et5azPa-
XUjbyP0w9iRWhR4kru09aFfQLXeIODIN4uhjElYKXt8n76jt0Pjkd2pqk4t9abRF6tnL19GV4pflfL6uvVKkP4weOh39tqHt4TmkBgF2P-
gFhgssZpjwq6l82fz3dUhQ2nkzoLA_CnyDGLZLd7SZ1yv73uzfE2Ot813zmig8KTMEMWVcWSDvy61F06vs_6LURcq_IEEevUiubBxG5S2akNnWigfpbhWYjMI5
M22FOCpdcDBt4L7K1-yHt95Siz0QUb0MNlT_X8F76wH7_A37GpKKJGqeaiNWmHkgWdE8QWDQ", "kid": "hs256-key" }
```

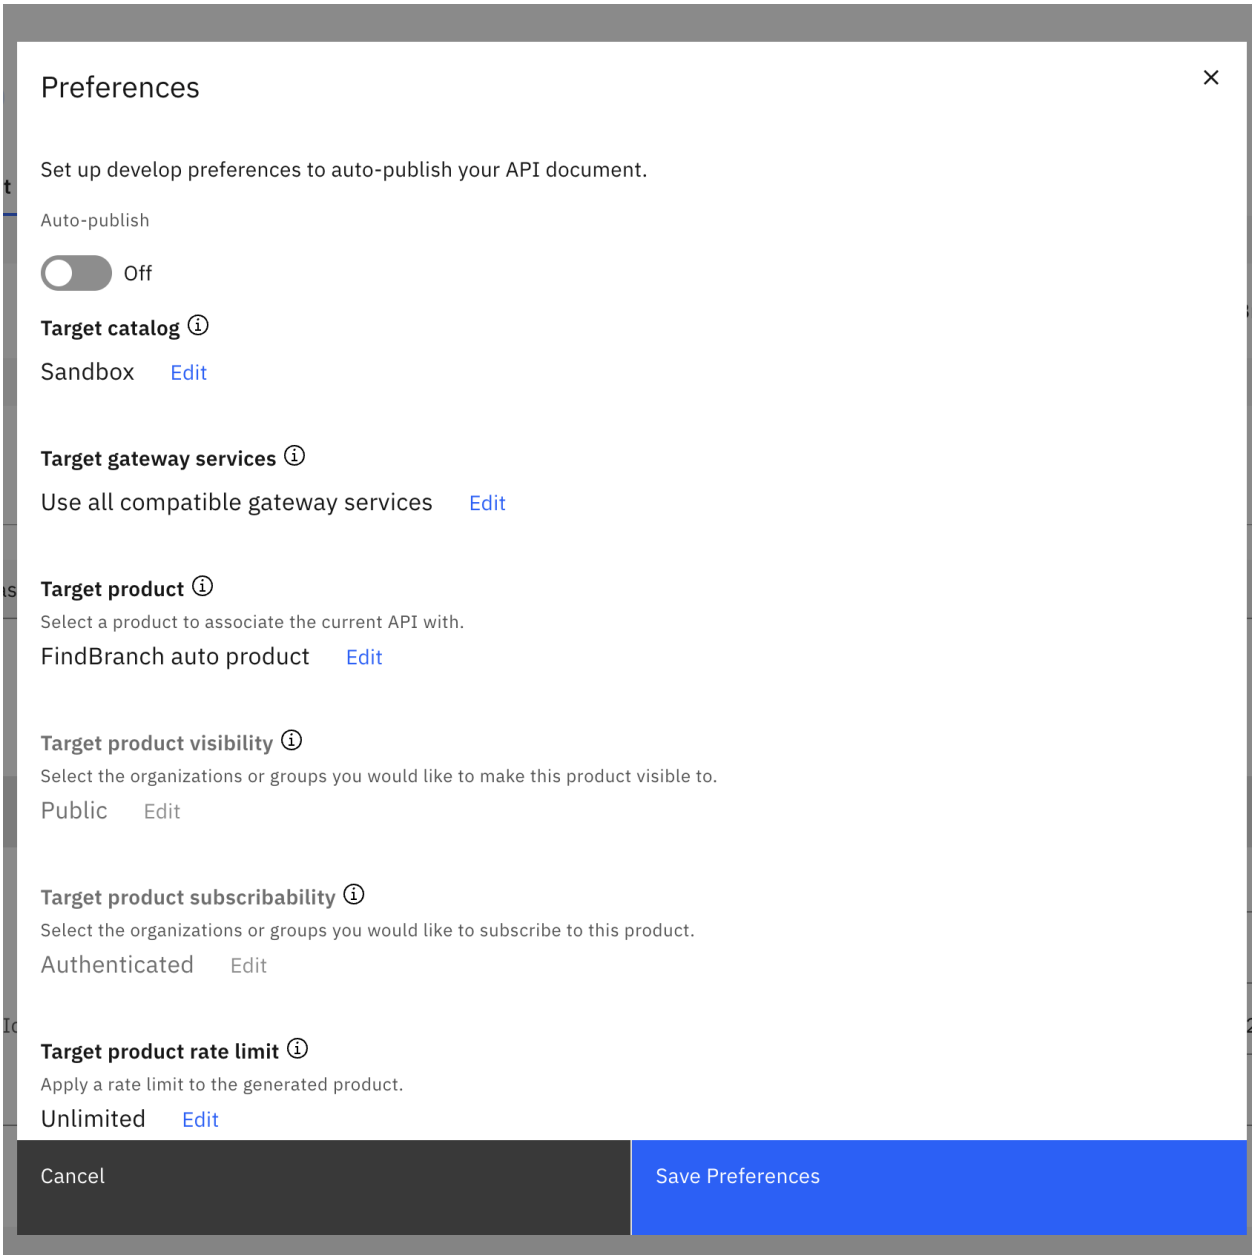
This key is not secure and is only intended for use in this tutorial.

7. In the ID token signing algorithm field, select `HS256` as the signing algorithm for this key.



8. Click Save.

Test OIDC Security



Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
When you test the new OIDC security in the API Manager Test panel, you complete the same steps that you used for testing the native OAuth provider. The Test panel does not display the JWT token that is received with the access token, so in this tutorial you will obtain the JWT token using cURL commands so that you can verify that the token is returned.

1. Set up the Test panel to invoke your API:
   a. On the Develop / findbranch page, click the Test tab in the page header.
   The imported FindBranch API already has a definition, which uses a single policy called **`Invoke`** to execute the API. This API is ready to test.

   b. To activate the API, click Target Configuration.

   c. On the Preferences window, toggle Auto-publish to set the API status to online.

Preferences
Set up develop preferences to auto-publish your API document.

d. Click Send.

e. If a No response received message appears, click Open the server.

A new browser tab opens. If an error message appears, ignore it.

2. Switch to a command window and use cURL commands to obtain the access token and JWT token that allow you to use the API:
   Note: The authorization code that you receive from the OAuth provider expires after a few minutes. To avoid having to repeat the request, prepare both of the commands for this step as much as possible before executing the first command.
   a. Run the following cURL command to request an authorization code for the API:

```
curl -k -i --header "Authorization: Basic dXNlcjpwYXNz"\
 --request GET "Authorization_URL\
?redirect_uri=https://example.com/redirect\
&scope=openid+details\
&response_type=code\
&client_id=Client_ID"
```

Where:

- The cURL parameter `-k` allows cURL to execute your operation even for insecure server connections.
- The cURL parameter `-i` includes protocol response headers in the output so that you can view the response in the command window.
- The authorization header specifies that you will authenticate with the user registry (the AuthURL user registry that you created) using Basic authentication, and provides the password ("pass") encoded in base64.
- The *`Authorization_URL`* is copied from the Test panel.
- The `redirect_uri` is the OAuth redirect URL that you configured in the Sandbox Test App.
- The `scope` specifies two scopes, concatenated with "+": the API's `details` scope that you will access, and the OIDC scope that authorizes you.
- The `response_type` is `code` because you want to receive an authorization code.
- The *`Client_ID`* is copied from the Test panel's "Identification" section and ensures that you can access your Sandbox Test App.

Example:

```
curl -k -i --header "Authorization: Basic dXNlcjpwYXNz"\
 --request GET "https://example.com/eb-org/sandbox/mynativeoauthprovider/oauth2/authorize\
?redirect_uri=https://example.com/redirect\
&scope=openid+details\
&response_type=code\
&client_id=01c43d1620e0c4e6ded0dec20b5655d9"
```

The response looks like the following example:

```
HTTP/1.1 302 Found
Connection: Keep-Alive
Transfer-Encoding: chunked
X-RateLimit-Limit: name=default,100;
X-RateLimit-Remaining: name=default,93;
User-Agent: curl/7.55.1
Accept: */*
X-Client-IP: IP_address
X-Global-Transaction-ID: 12df8d855e7e18ee00000681
Location:
https://example.com/redirect? code=AALxLnKixp9VIy3PvVKBwfbuTgNbwnZtHB6iS9b_BUw39UZZjUi2CeFdPYJZW0mgqNMtzFUhrsfu3FFiC9
aGfHnJ3CqdIANqlo-v-DkQv7ELWw
Content-Type: text/xml
Date: Fri, 27 Mar 2020 15:17:02 GMT
```

b. Copy the authorization code (returned in the **code** parameter) so you can use in the next step.
c. Run the following cURL command to exchange the authorization code for an access token and a JWT token:

```
curl -k -i --header "Content-Type: application/x-www-form-urlencoded"\
 --request POST "Token_URL"\
 --data-urlencode "code=Authorization_code"\
 --data-urlencode "client_secret=Client_Secret"\
 --data-urlencode "grant_type=authorization_code"\
 --data-urlencode "scope=openid details"\
 --data-urlencode "client_id=Client_ID"
```

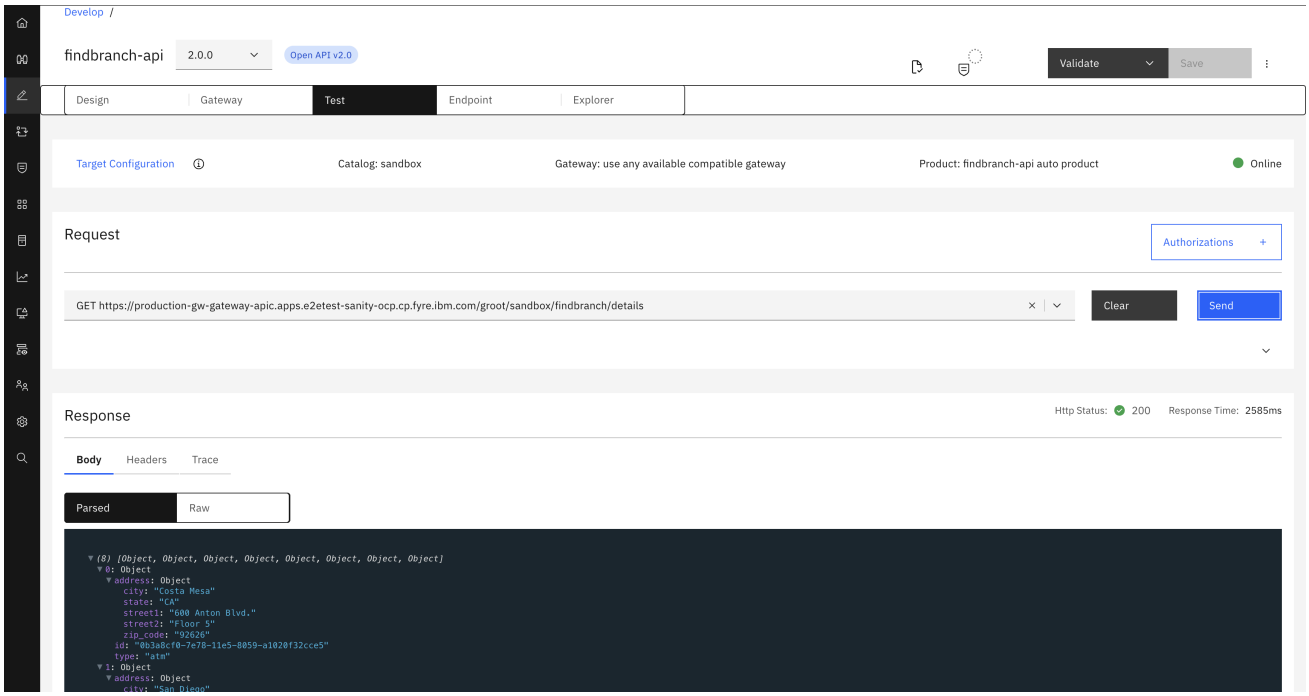
Where:

- The ***Token_URL*** is copied from the Test panel.
- The ***Authorization_code*** is copied from the response to the previous command.
- The ***Client_Secret*** is copied from the Test panel's "Identification" section.
- The **grant_type** is "authorization_code".
- The **scope** again specifies two scopes (separated with a space in this command because the values are enclosed in quotation marks).
- The ***Client_ID*** is copied from the Test panel's "Identification" section.

Example:

```
curl -k -i --header "Content-Type: application/x-www-form-urlencoded"\
 --request POST "https://example.com/eb-org/sandbox/mynativeoauthprovider/oauth2/token"\
 --data-urlencode "code=AAJ8zz5SvYgxFw0zY0fOxAOiDeaw_PLR6dAFh-ojXVjv-
80TB25VGfj28J4Jf7jzgaWVVfLQuVTRSfUbp2hDjYsX9QmZHJOg5p_bfHFWBlQlLg"\
 --data-urlencode "client_secret=d6634763de6c612ae69636d0fc948650"\
 --data-urlencode "grant_type=authorization_code"\
 --data-urlencode "scope=openid details"\
 --data-urlencode "client_id=01c43d1620e0c4e6ded0dec20b5655d9"
```

The response looks like the following example:



```
{"token_type":"Bearer", "access_token":"AAIgMDFjNDNkMTYyMGUwYzRlNmRlZDBkZWMyMGI1NjU1ZDkm4gPMmFjgv2XXhI7t6LZ8BcIRaO_Lv
WirsNDlirJWi_7qqKGp_fr5py7yE_fHoD17ajAUJPPuUjsV5xj7go25JQjk_smS-AYvmPXRi99IxQ" ,"scope":"openid
details","expires_in":3600,"consented_on":1585322249, "id_token":"eyJraWQiOiJoczI1Ni1rZXkiLCJhbGciOiJIUzI1NiJ9.eyJqdG
kiOiI3NjE2OTRiYS1iYjYzLTRlNWQtOTc1ZS04NThkZGYxMmI2ZTkiLCJpc3MiOiJQk0gQVBJQ29ubmVjdCIsInN1YiI6InVzZXIiLCJhdWQiOiIwMWM
0M2QxNjIwZTBjNGU2ZGVkMGRlYzIwYjU2NTVkOSIsImV4cCI6MTU4NTMyNTg1MiwiaWF0IjoxNTg1MzIyMjUyLCJhdF9oYXNoIjoibDZYRDV5SjVuMTU1
MkZSV19pR2k2USJ9.IO1RVPWV5zOhYGmCXUvG0_-9OO0guURPwaEbGOqCpCg" }
```

The response includes two tokens: the access token and the JWT (labeled "id_token"). Receiving these tokens verifies that you are authenticated using OIDC and your native OAuth provider.

Note: If you receive an `Invalid request` response with an error about an expired code, it means the authorization code expired. Return to substep a and repeat the process to obtain a new authorization code, and then quickly exchange it for the access token and JWT token.

3. Return to the Test panel and click Send to execute the API.
You don't need to paste any codes into the Test panel because you used cURL to exchange tokens with API Connect.

The FindBranch API's response displays the Status code `200 OK` and response header information, and the body contains the data for each bank branch.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Added OIDC security to an existing API.
- Tested the security by manually requesting an authorization code and exchanging it for an access token plus a JWT token before invoking the API.

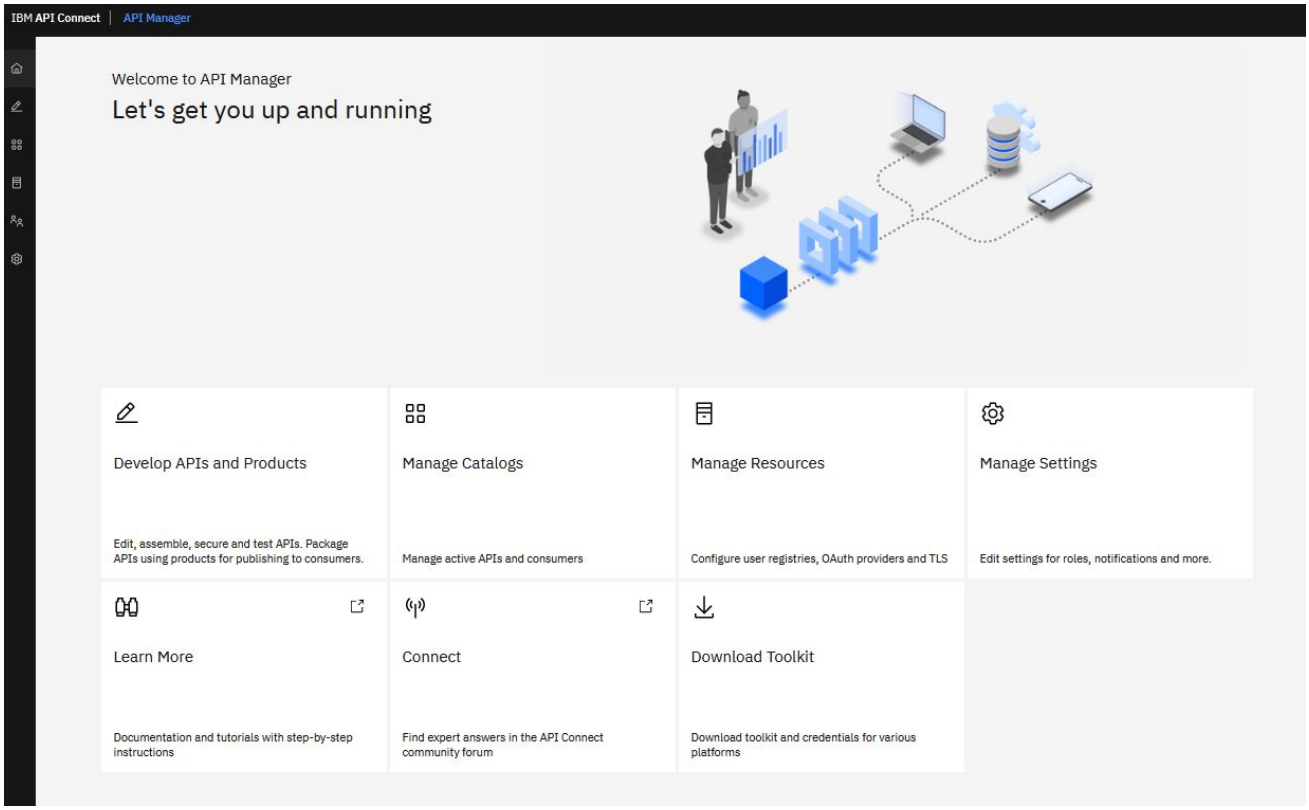
Tutorial: Generate a JSON Web Token (JWT)

This tutorial shows you how to define and implement a REST API definition that generates a JSON Web Token (JWT).

About this tutorial

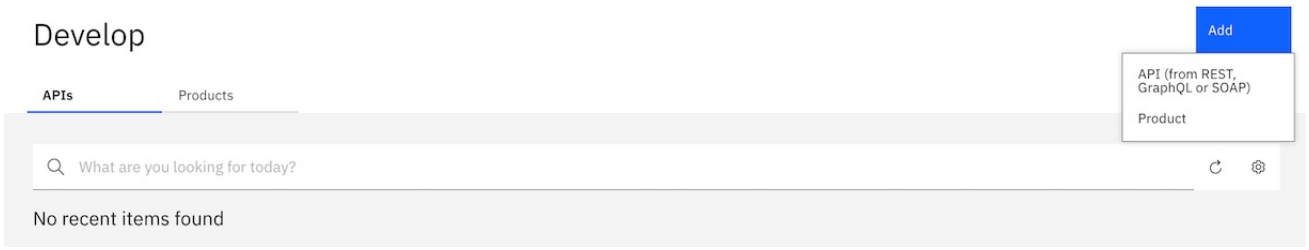
In this tutorial, you complete the following lessons:

1. Generate a JWT
2. Testing the REST API



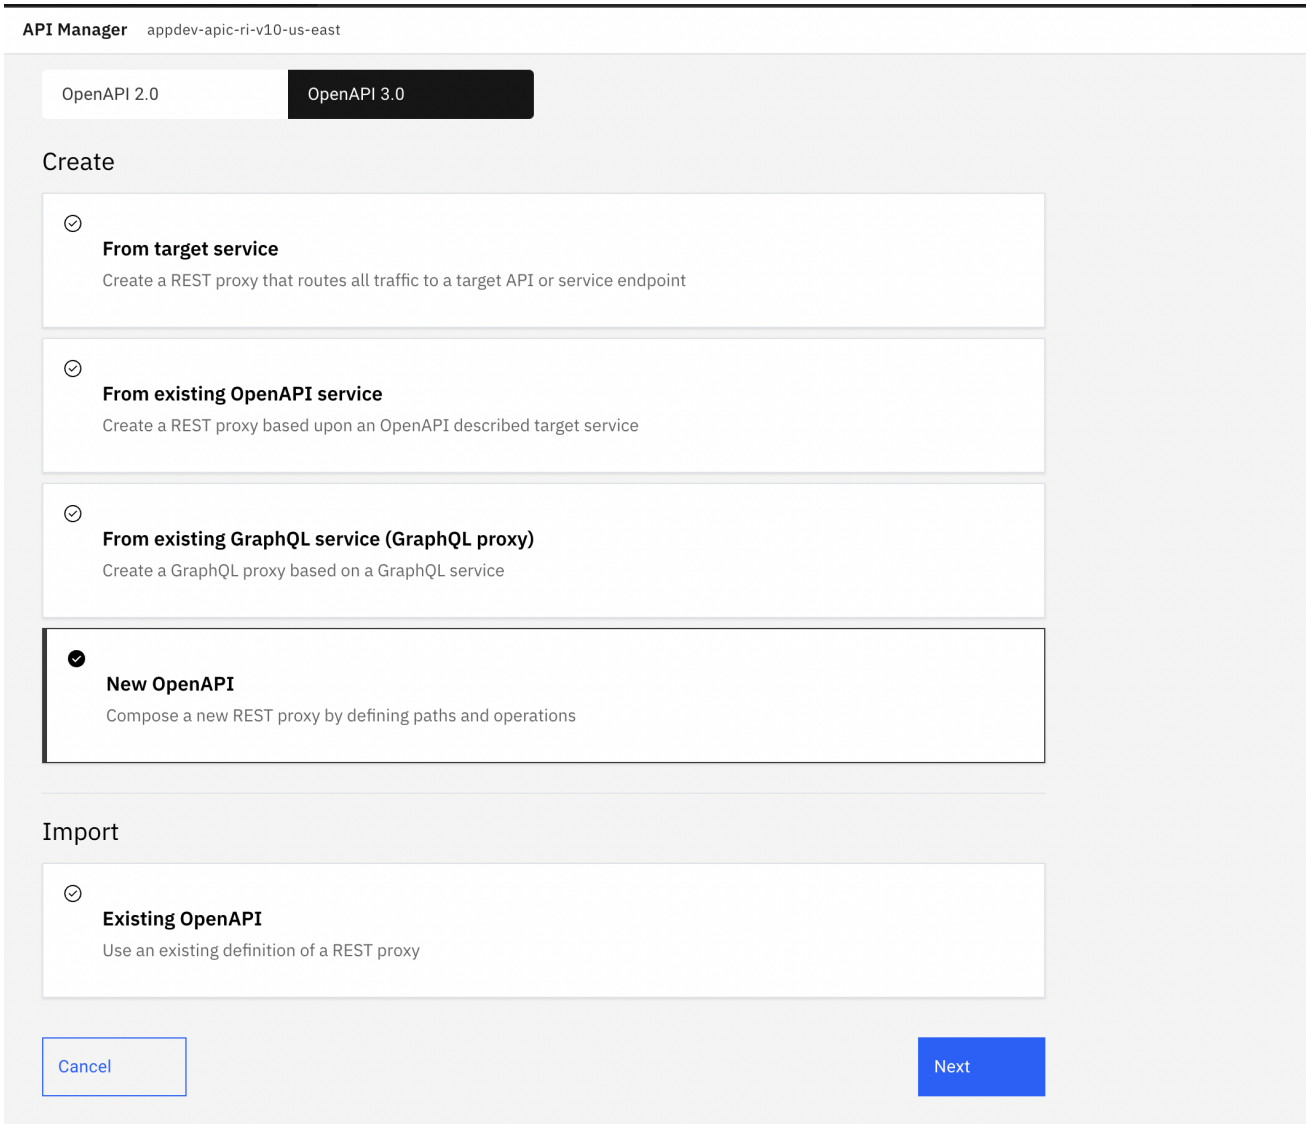
Note: The Sandbox catalog must be configured to use either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway or both. See Creating and configuring catalogs.

Generate a JWT

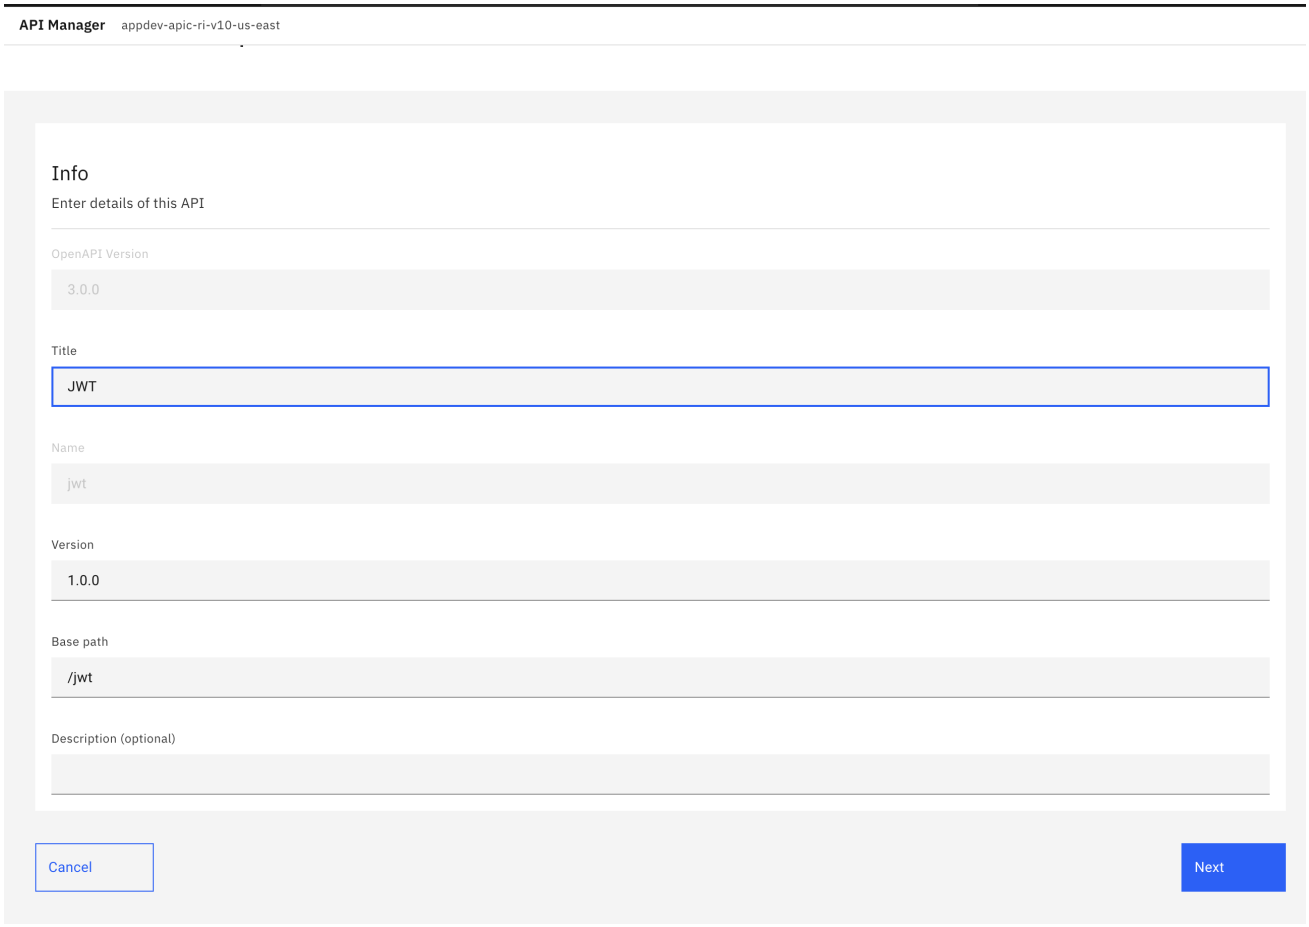


Create a REST API to generate and return a JSON Web Token (JWT).

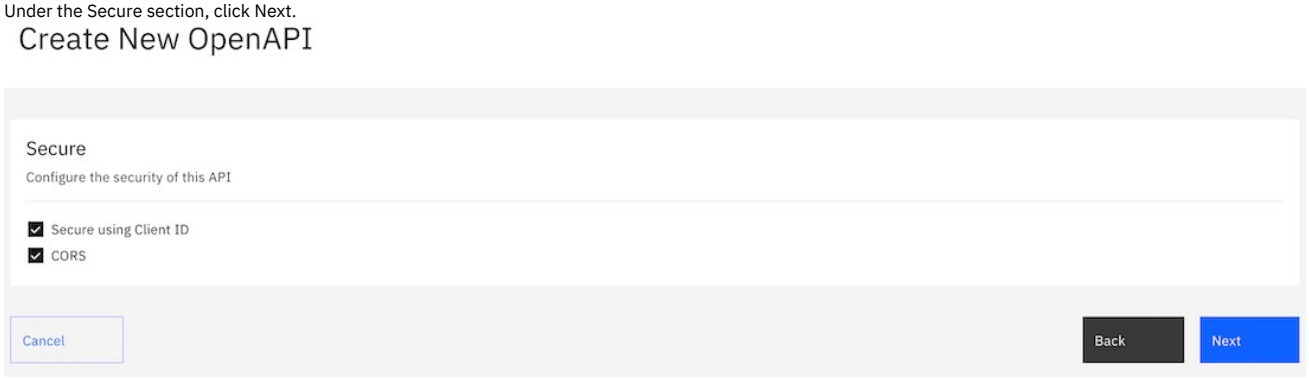
To add and define this REST API, complete the following steps:



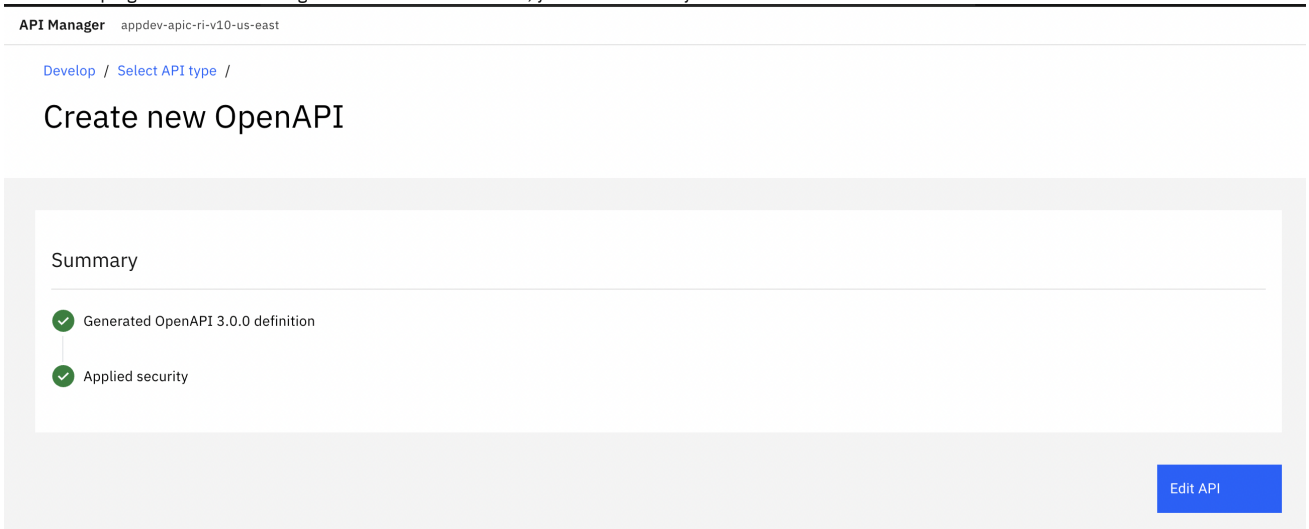
1. Log in to API Manager.
2. In the Welcome page, click the Develop APIs and Products tile.



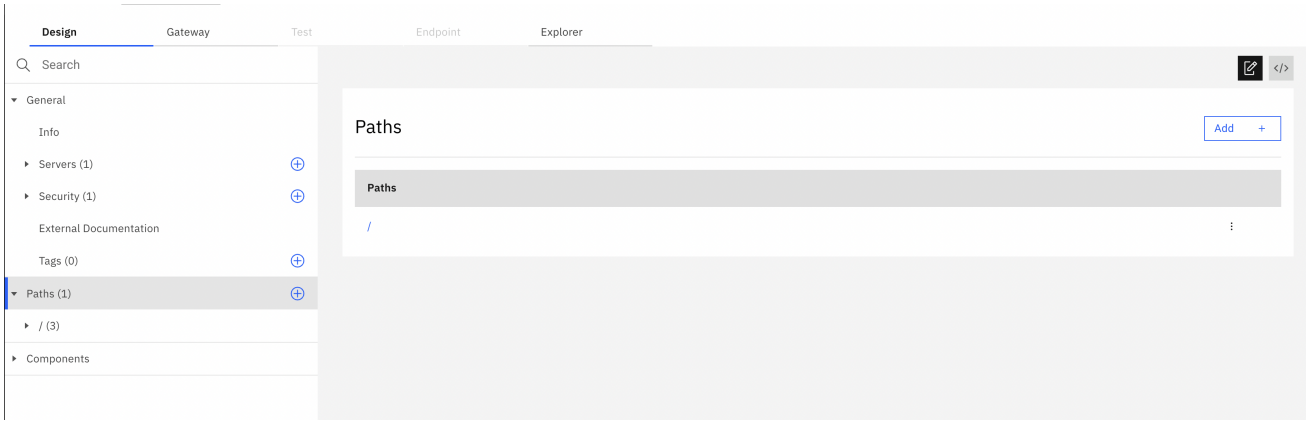
3. Click Add > API .



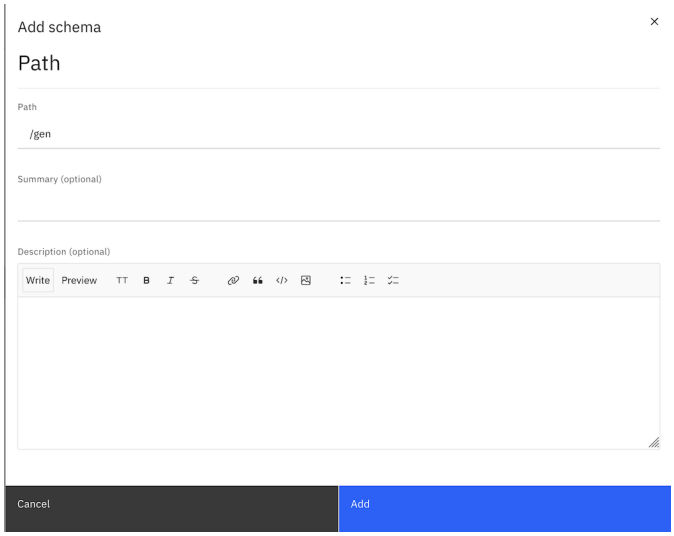
4. Ensure that OpenAPI 3.0 is selected.
5. Select New OpenAPI and click Next.



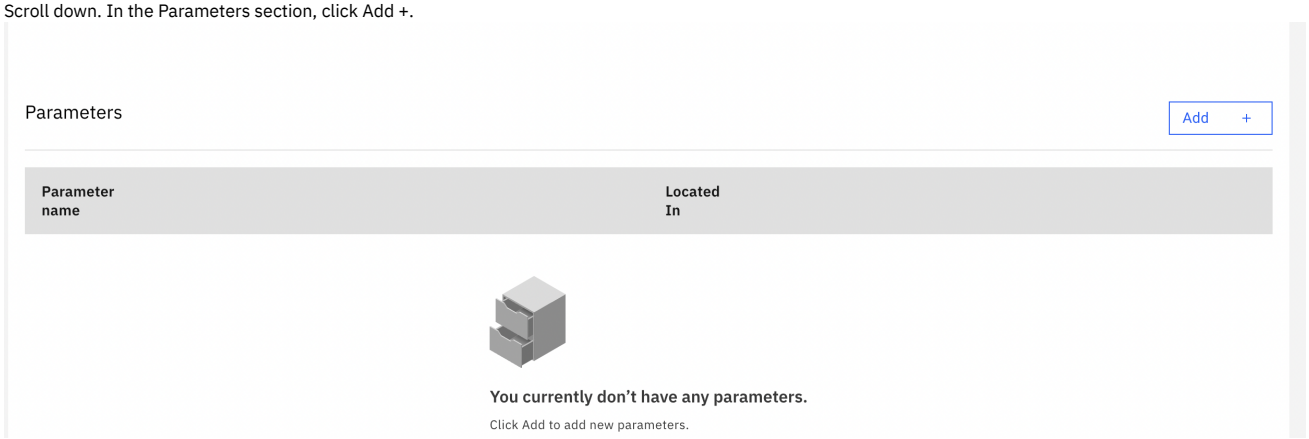
6. Enter the appropriate information to create a REST API definition.
   a. In the Title field, enter `JWT`.
   b. The Name and Base Path fields auto-populate with the terms `jwt` and `/jwt` respectively.
   c. The Version field auto-populates with `1.0.0`.



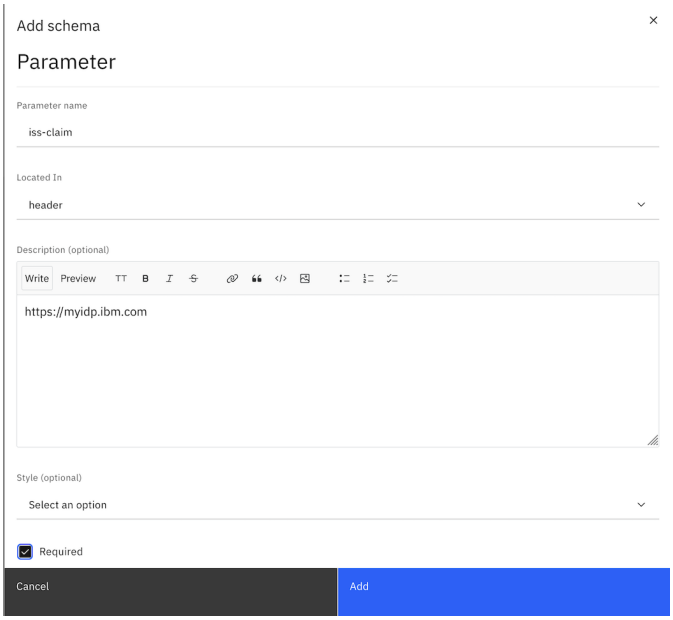
7. Click Next.
8. Under the Secure section, click Next.



9. You see the progress as the new API gets created. When it is done, you see a Summary. Click Edit API.



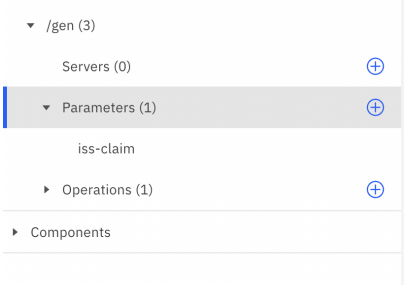
10. In the side bar of the Design page, select Paths to display the Paths panel.
11. Click Add +.



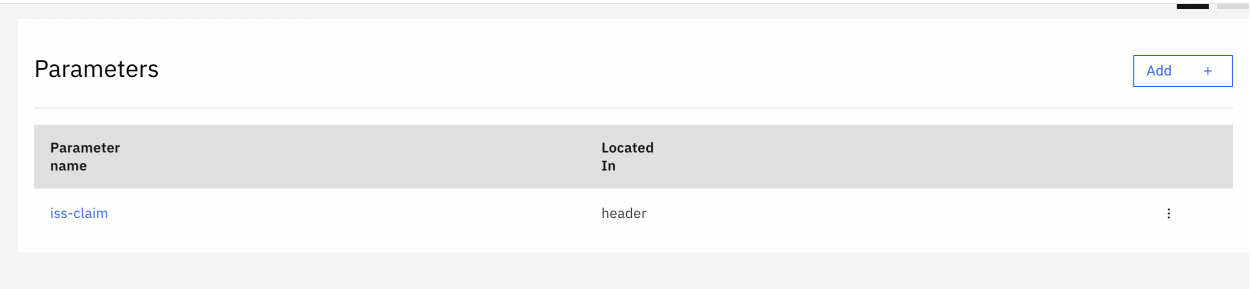
12. In the Path field, enter /gen.
13. Click Add.

14. Scroll down. In the Parameters section, click Add +.

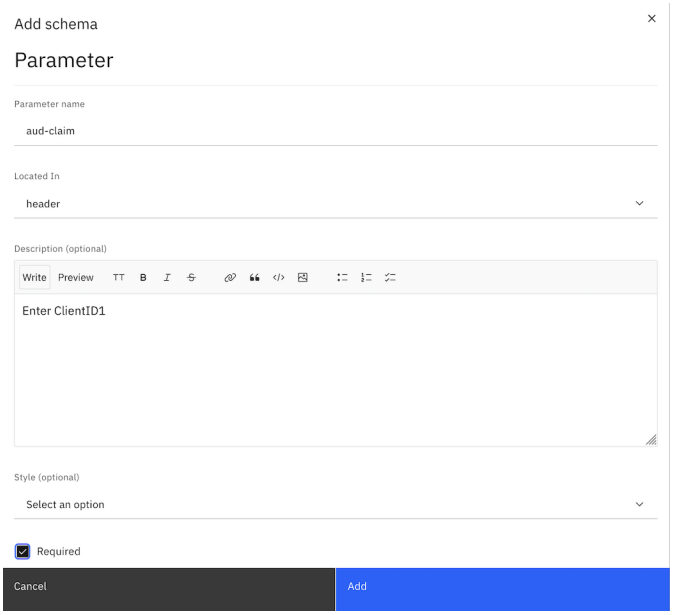
    a. Enter `iss-claim` in the Parameter name field.
    b. Select the `header` from the Located In list.
    c. Enter `https://myidp.ibm.com` to match in the Description field.
    d. Select the Required checkbox.
    e. Click Add.



f. Scroll down. In the Schema section, click Create

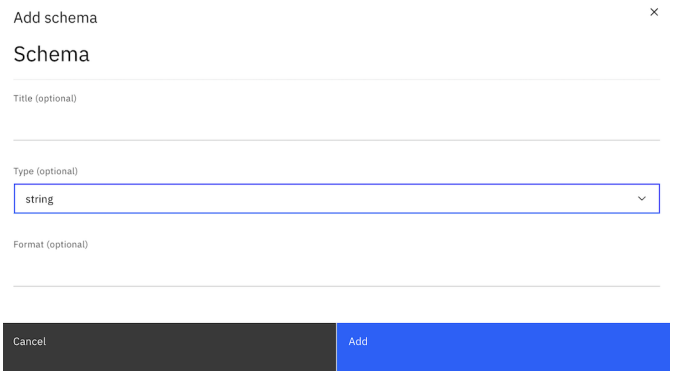


g. Select string in the Type list.
h. Click Add.

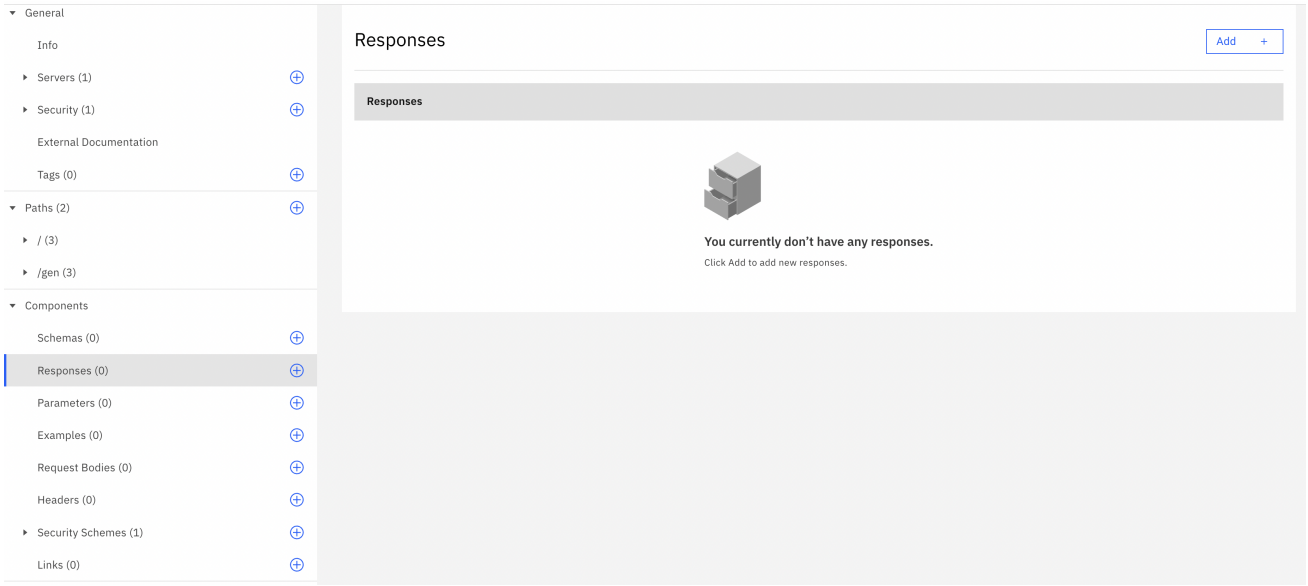


15. After you create the parameter, click Save.
16. To add a second parameter. Complete the following steps:
    a. In the side bar of the Design page, select Parameters under the newly created /gen path.

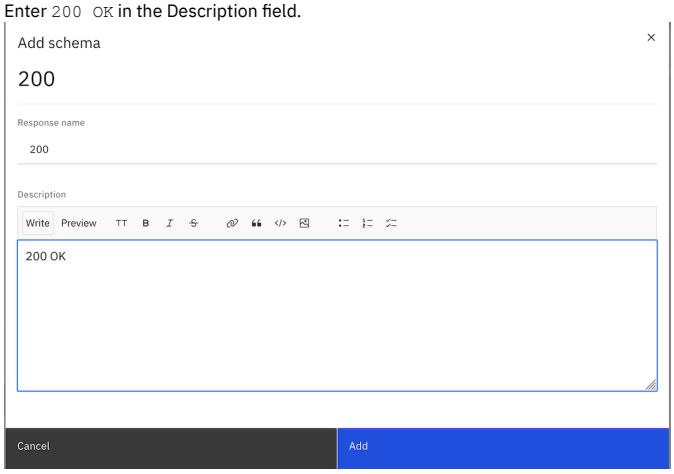
b. Click Add +.



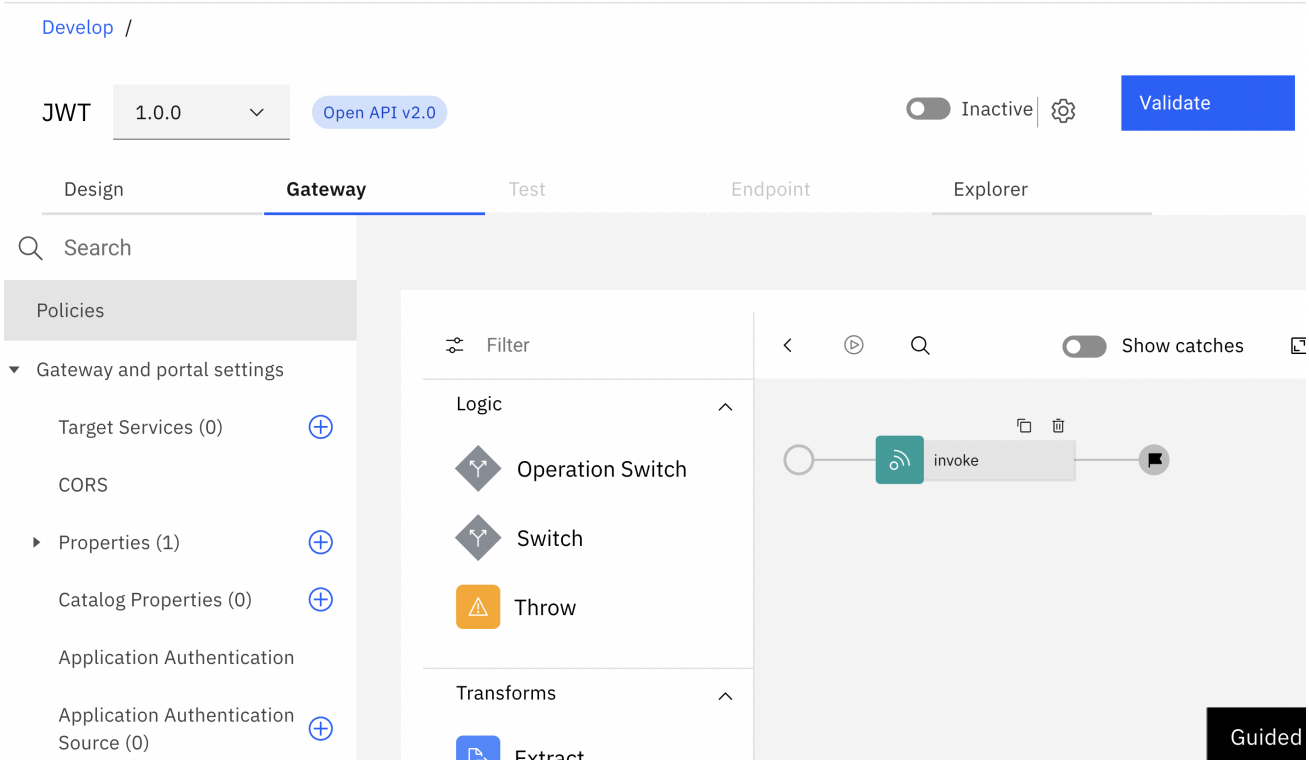
c. Enter `aud-claim` in the Parameter name field.
d. Select `header` from the Located In list.
e. Enter `Enter ClientID1` to match in the Description field.
f. Select the Required checkbox.
g. Click Add.



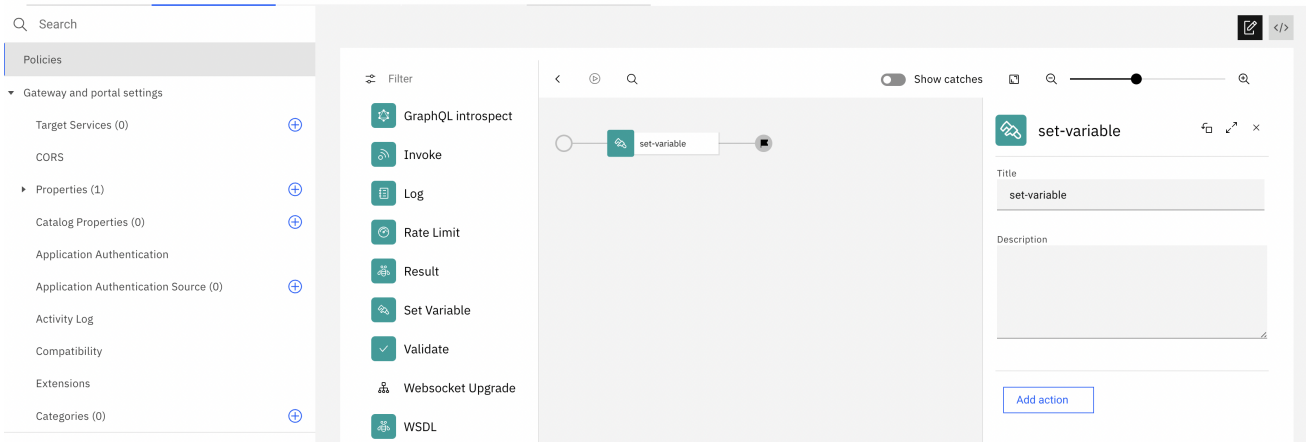
h. Scroll down. In the Schema section, click Create.



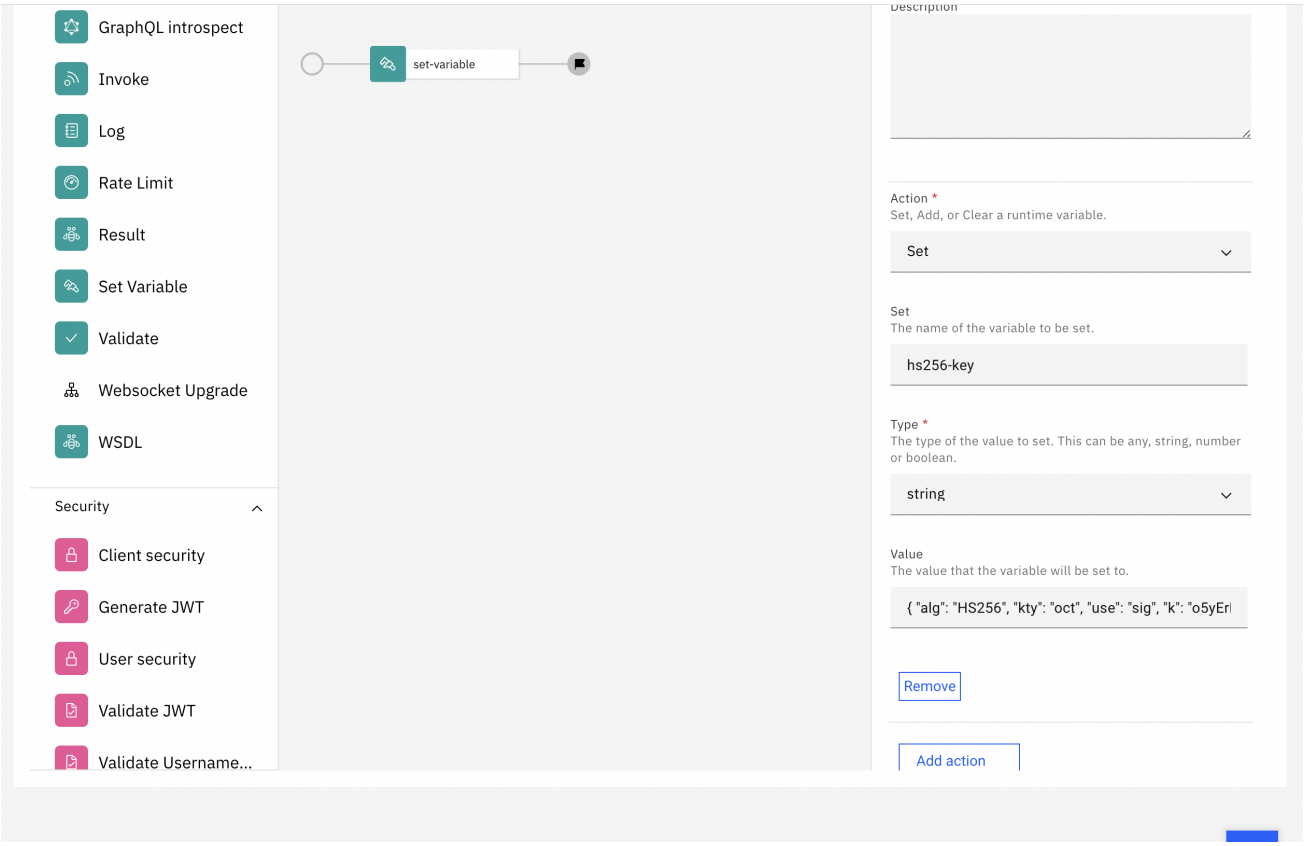
i. Select `string` from the Type list.
j. Click Add.



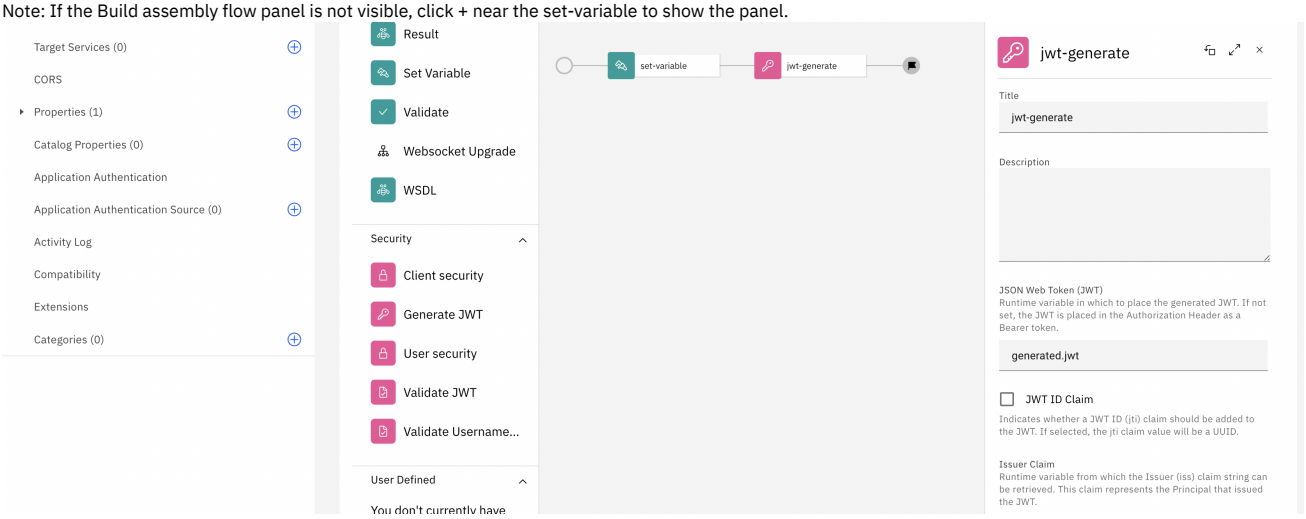
17. After you create the second parameter, click Save.
18. Click Components > Responses.
19. Click Add.



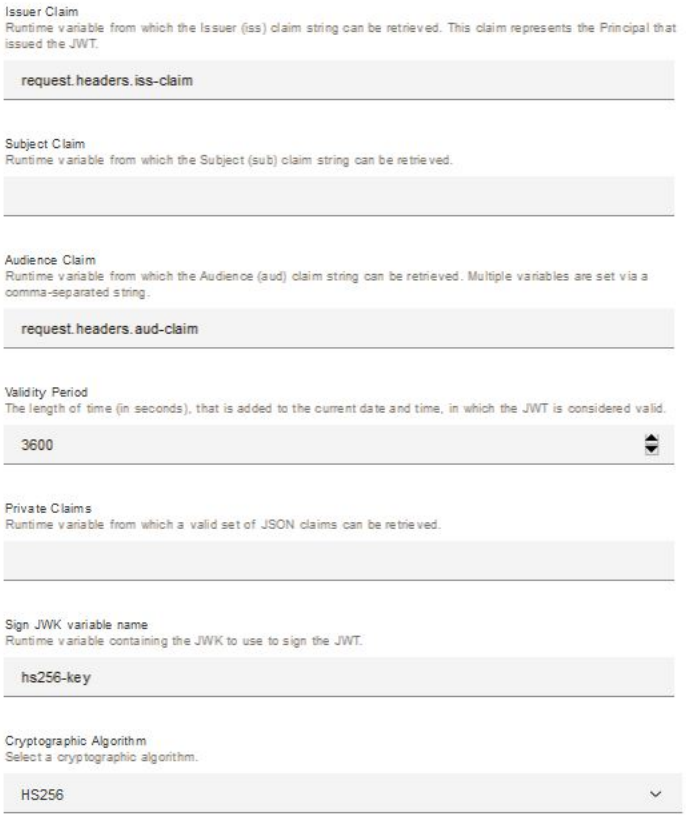
20. The Response name field auto-populates with `200`.
21. Enter `200 OK` in the Description field.



22. Click Add.
23. After you create the response, click Save.
24. Select the Gateway tab.
25. Hover the mouse over the existing policy node and click the trash can icon to delete it.

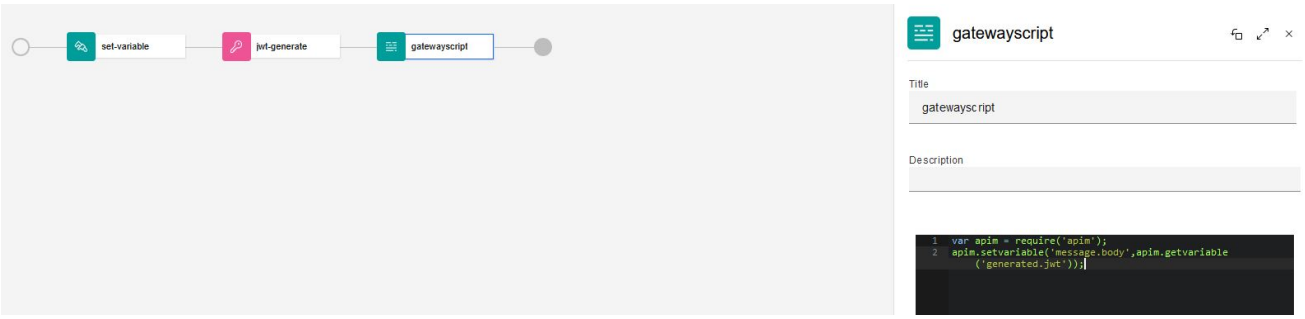


26. From Actions, click Set Variable to add the action onto the processing flow line. A configuration panel automatically opens.
27. Click Add action.



28. Enter `hs256-key` in the Set field.
29. Select `string` from the Type list.
30. Enter a JWK in the Value field. The following is an example. `{ "alg": "HS256", "kty": "oct", "use": "sig", "k": "o5yErLaE-dbgVpSw65Rq57OA9dHyaF66Q_Et5azPa-XUjbyP0w9iRWhR4kru09aFfQLXeIODIN4uhjElYKXt8n76jt0Pjkd2pqk4t9abRF6tnL19GV4pflfL6uvVKkP4weOh39tqHt4TmkBgF2P-gFhgssZpjwq6l82fz3dUhQ2nkzoLA_CnyDGLZLd7SZ1yv73uzfE2Ot813zmig8KTMEMWVcWSDvy61F06vs_6LURcq_IEEevUiubBxG5S2akNnWigfpbhWYjMI5M22FOCpdcDBt4L7K1-yHt95Siz0QUb0MNlT_X8F76wH7_A37GpKKJGqeaiNWmHkgWdE8QWDQ", "kid": "hs256-key" }`

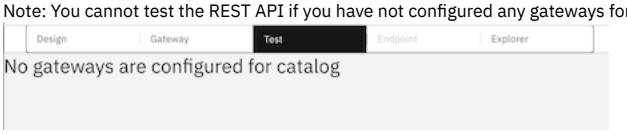
31. Close the property panel. Click Save.
32. From Actions, click Generate JWT to add the action onto the processing flow line after the set-variable icon. A configuration panel automatically opens.
    Note: If the Build assembly flow panel is not visible, click + near the set-variable to show the panel.



33. Enter `request.headers.iss-claim` in the Issuer Claim field.
34. Enter `request.headers.aud-claim` in the Audience Claim field.
35. Enter `hs256-key` in the Sign JWK variable name field.
36. Select `HS256` from the Cryptogrpahic Algorithm list.

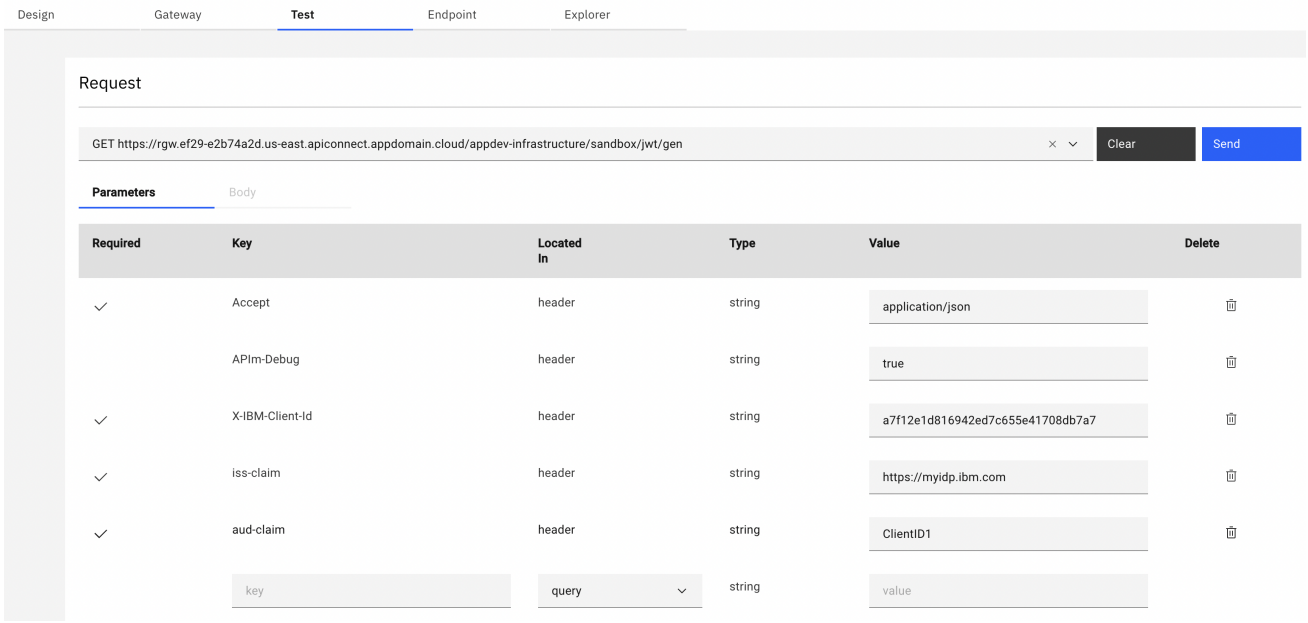
37. Close the property panel. Click Save.
38. From Actions, click GatewayScript to add the action onto the processing flow line after the Generate JWT icon. A configuration panel automatically opens.
39. Enter the following code:

```
var apim = require('apim');
apim.setvariable('message.body',apim.getvariable('generated.jwt'));
```



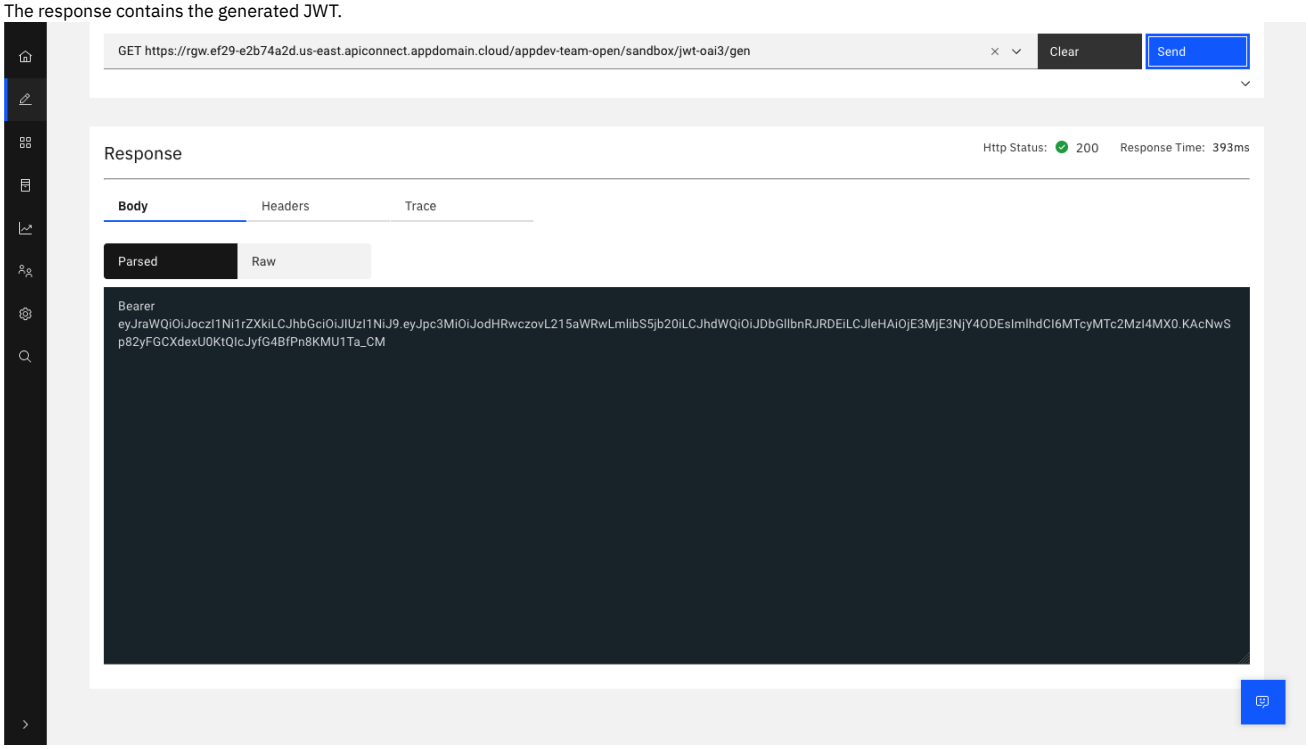
Note: You might see the following warning when you add the GatewayScript action: **`This gatewayscript policy should not use the apim module which is only for migrating old APIs`**. You can ignore this warning and proceed.

40. Close the property panel. Click Save.



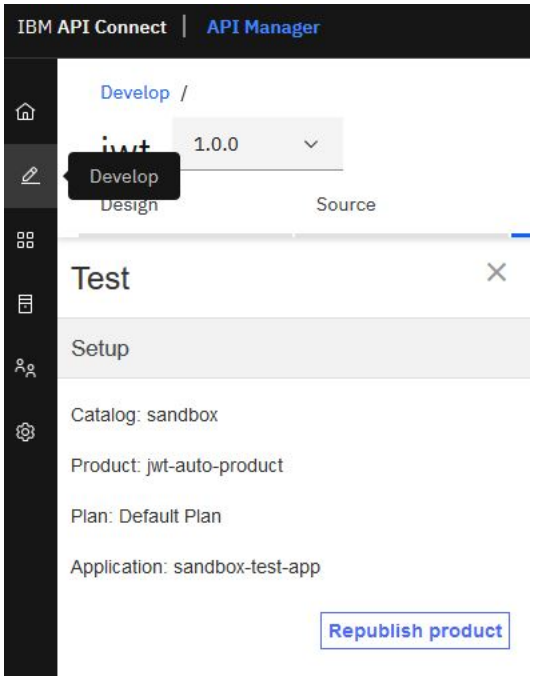
Testing the REST API

Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test the REST API, complete the following steps:

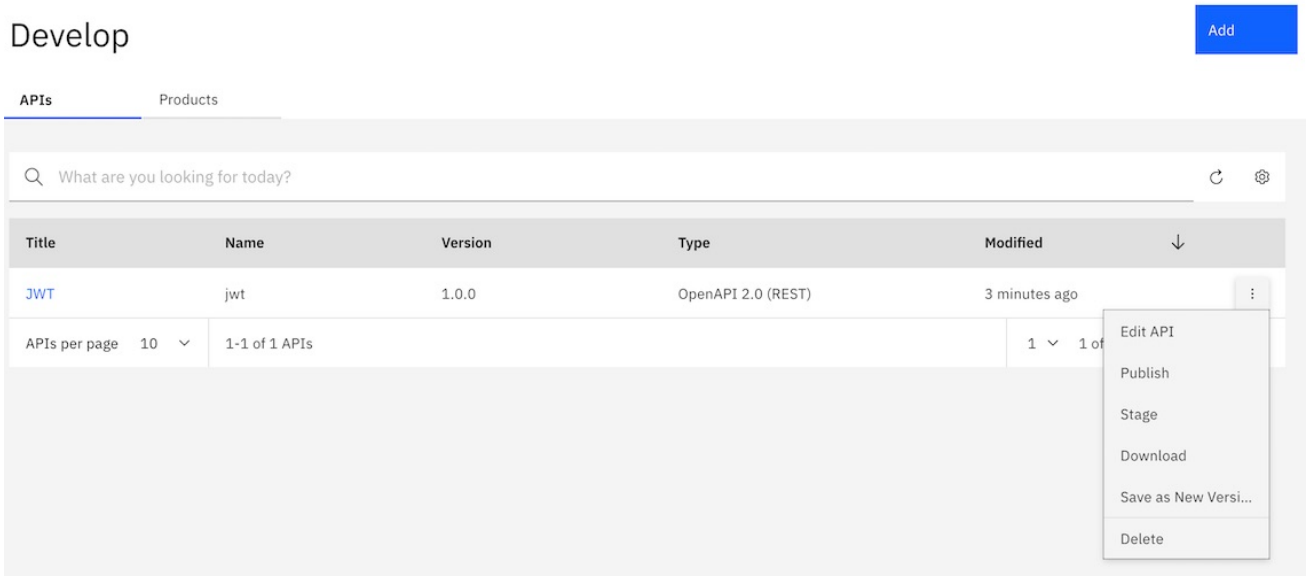


1. Click Test.
   Note: You cannot test the REST API if you have not configured any gateways for the catalog and an error message is displayed under the Test tab.

2. Click Target configuration and set Auto-publish to On.
3. Click Save preferences. The API status is shown as Online in the Test tab.
4. Enter `https://myidp.ibm.com` in the Value field corresponding to the iss-claim parameter.
5. Enter `ClientID1` in the Value field corresponding to the aud-claim parameter.
6. Click Send.



7. The response contains the generated JWT.



Manage your API definition

Now, that your new API works correctly, you can manage this API. To see your immediate options, take the following steps.

1. Click the Develop icon on the navigation bar.

2. Click the Options icon ⋮ alongside the JWT API.

3. Select Download.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a new API definition that generates a JSON Web Token (JWT).
- Tested the new API.

Tutorial: Validate a JSON Web Token (JWT)

This tutorial shows you how to define and implement a REST API definition that validates a JSON Web Token (JWT).

About this tutorial

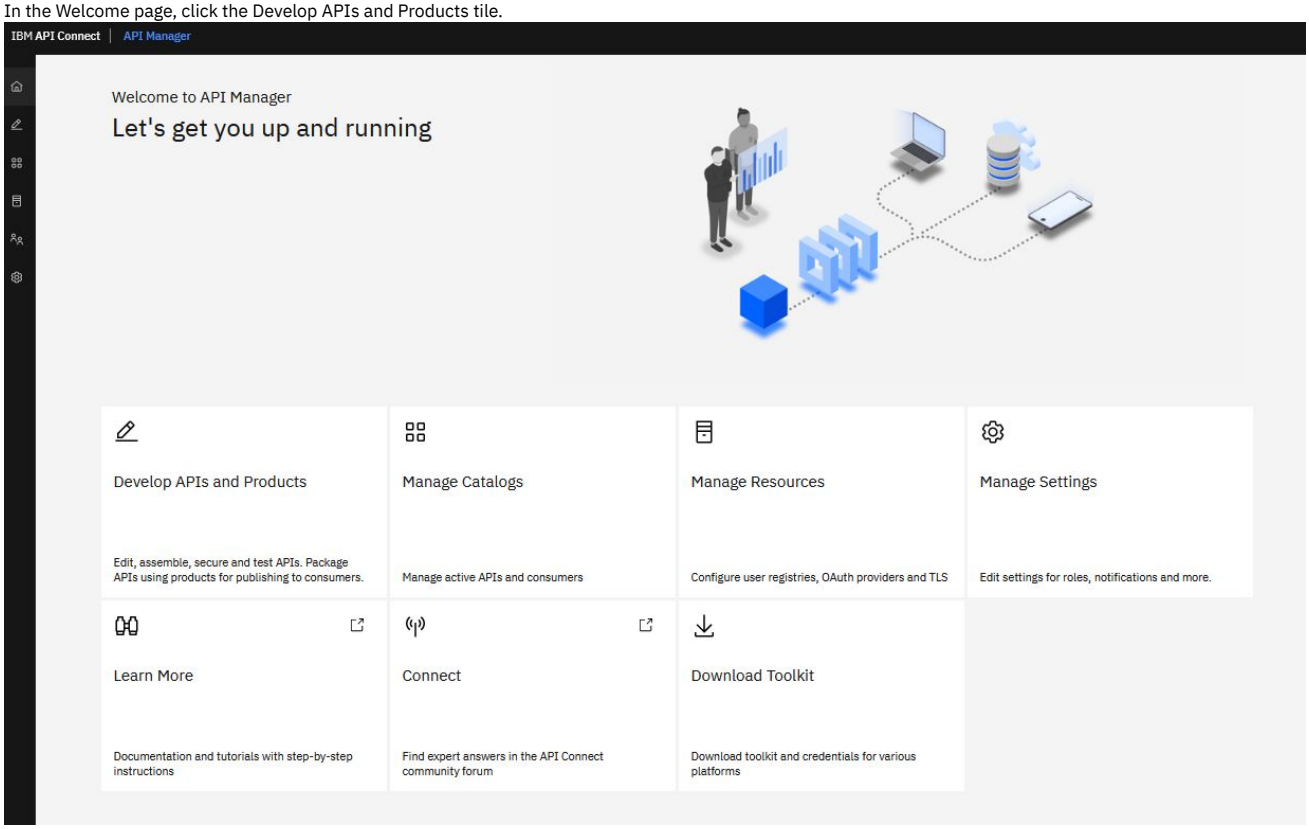
In this tutorial, you complete the following lessons:

1. Validate a JWT
2. Testing the REST API

Note: The Sandbox catalog must be configured to use either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway or both. See Creating and configuring catalogs.

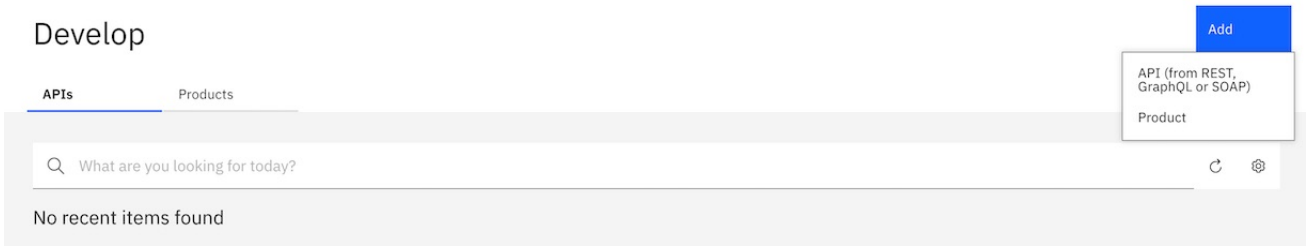
Before You Begin

Also do the following steps.



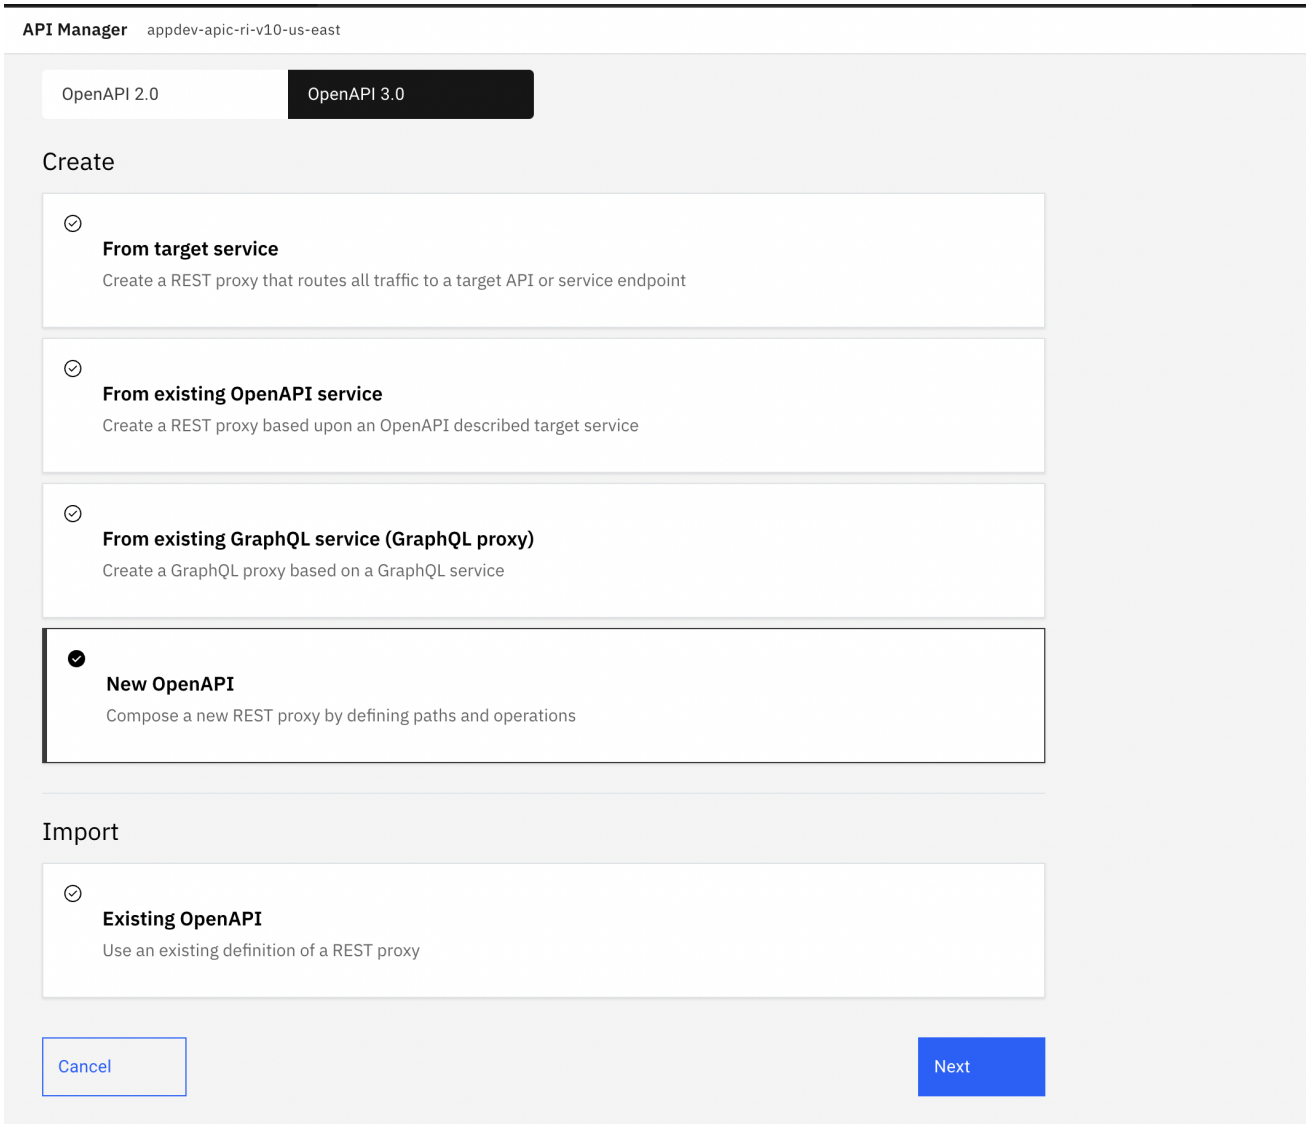
- Complete the Tutorial: Generate a JSON Web Token (JWT) tutorial. This tutorial generates a JSON Web Token that can be validated by this tutorial. You need this JWT to test this validation API.

Validate a JWT

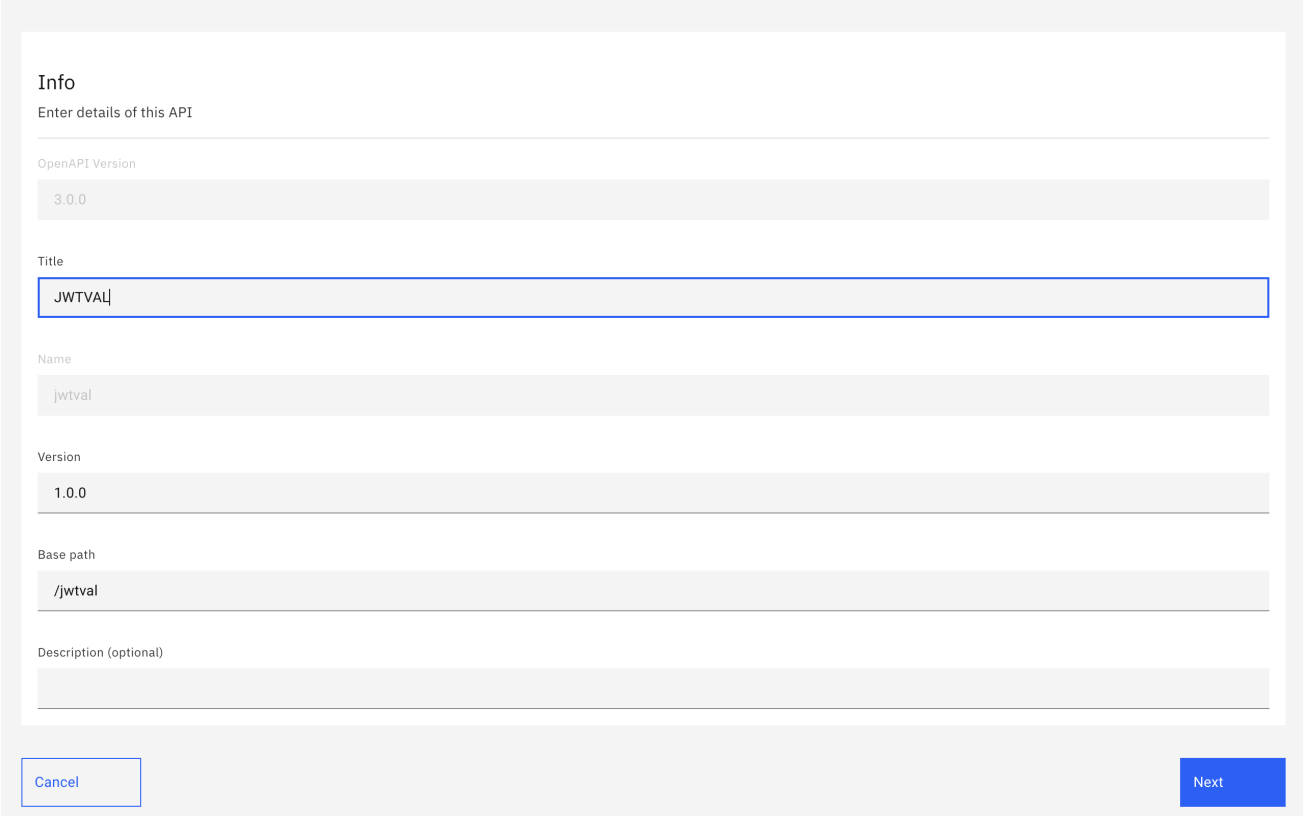


Create a REST API to validate a JSON Web Token (JWT).

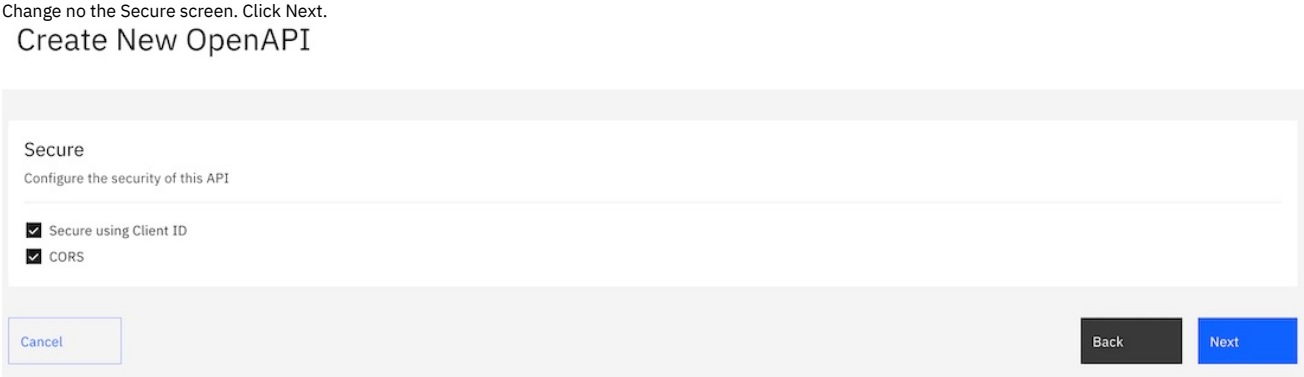
To add and define this REST API, complete the following steps:



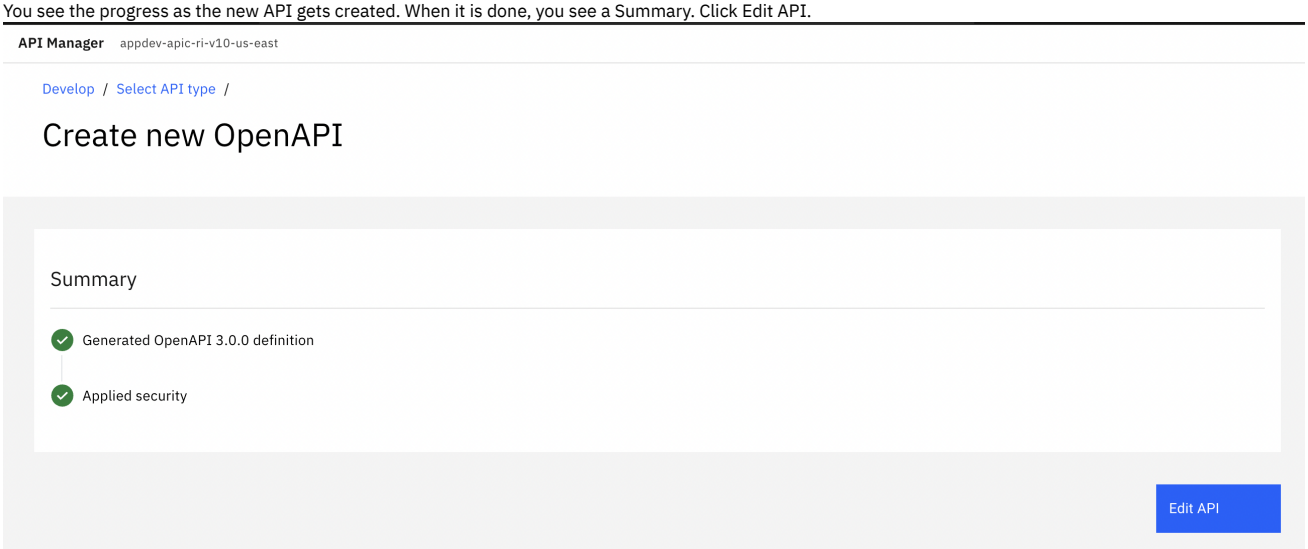
1. Log in to API Manager.
2. In the Welcome page, click the Develop APIs and Products tile.



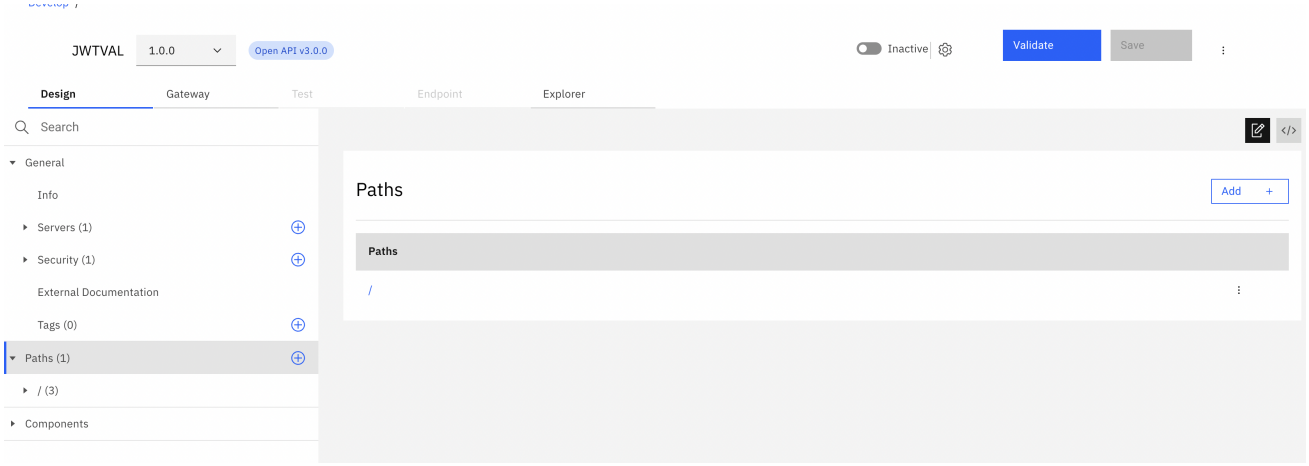
3. Click Add > API (from REST, GraphQL or SOAP).



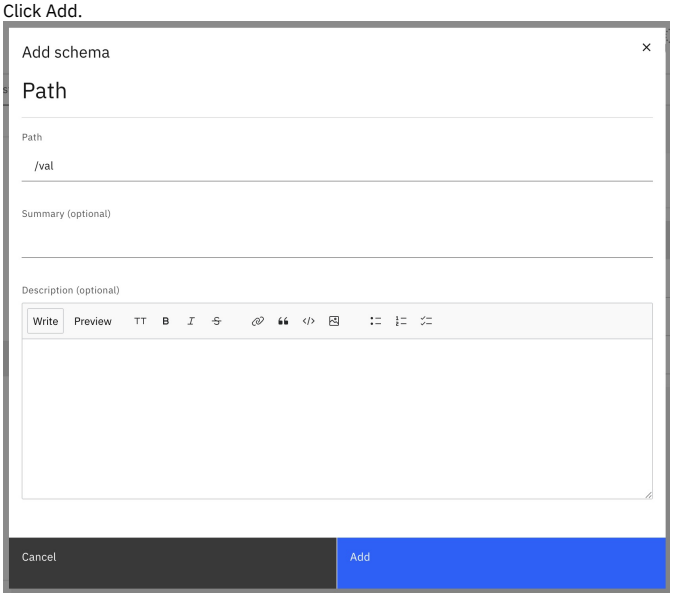
4. Ensure that OpenAPI 3.0 is selected.
5. Select New OpenAPI. Click Next.



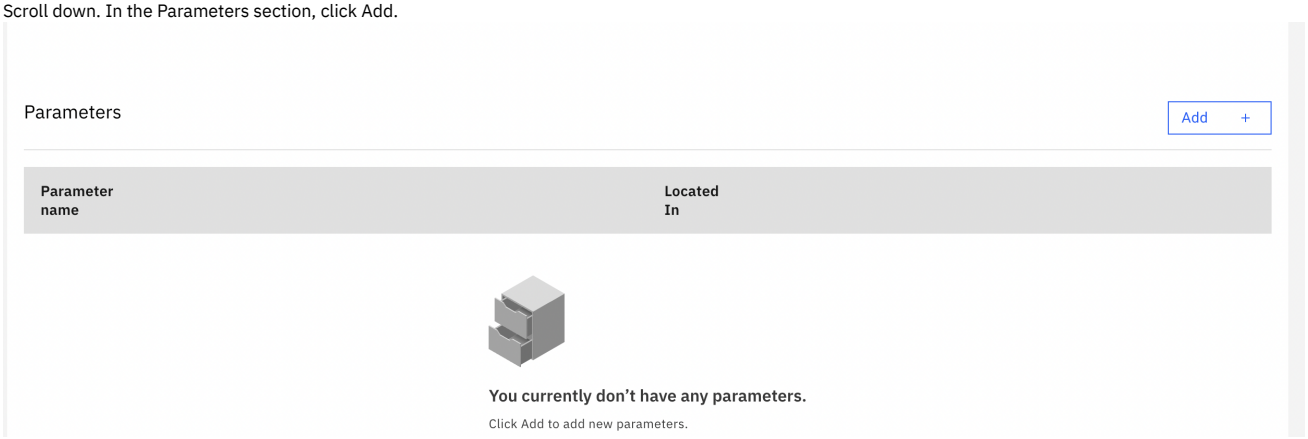
6. Enter the appropriate information to create a REST API definition.
   a. In the Title field, enter `JWTVAL`.
   b. The Name and Base Path fields auto-populate with the terms `jwtval` and `/jwtval` respectively.
   c. The Version field auto-populates with `1.0.0`.



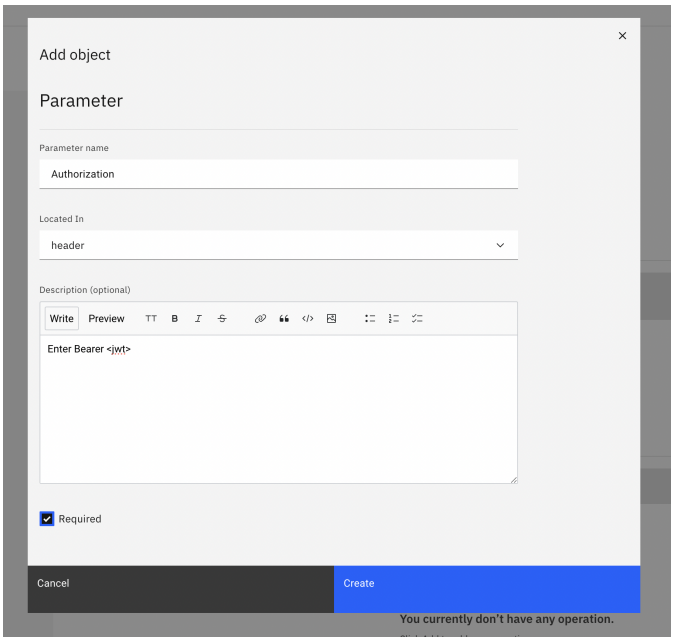
7. Click Next.
8. Change no the Secure screen. Click Next.



9. You see the progress as the new API gets created. When it is done, you see a Summary. Click Edit API.

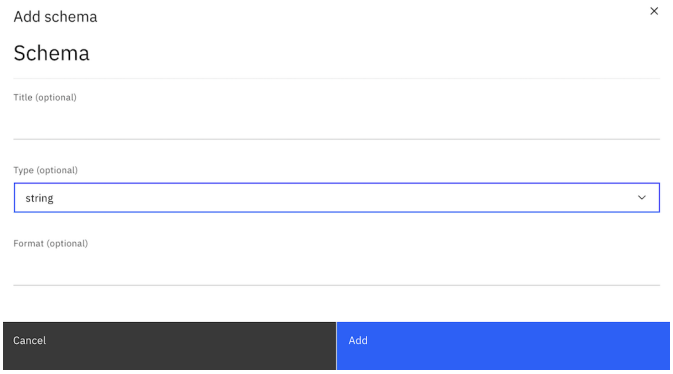


10. In the side bar of the Design page, select Paths to display the Paths panel.
11. Click Add.

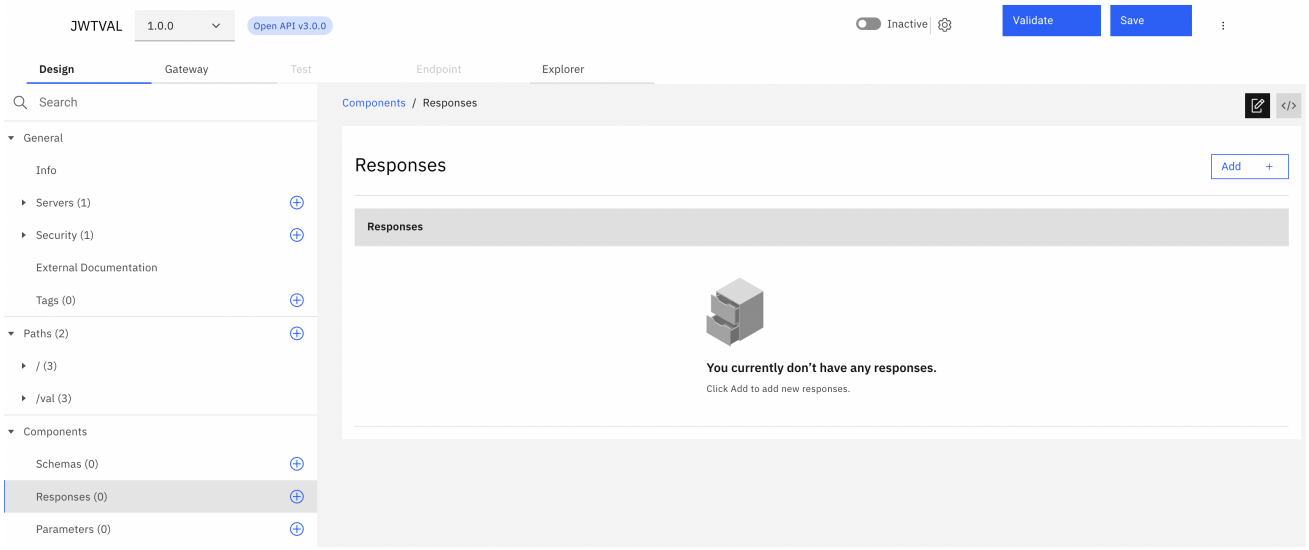


12. In the path field, enter /val.
13. Click Add.

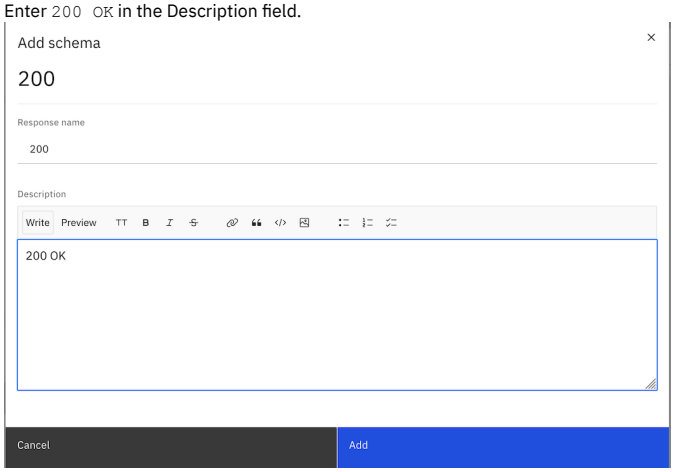
14. Scroll down. In the Parameters section, click Add.



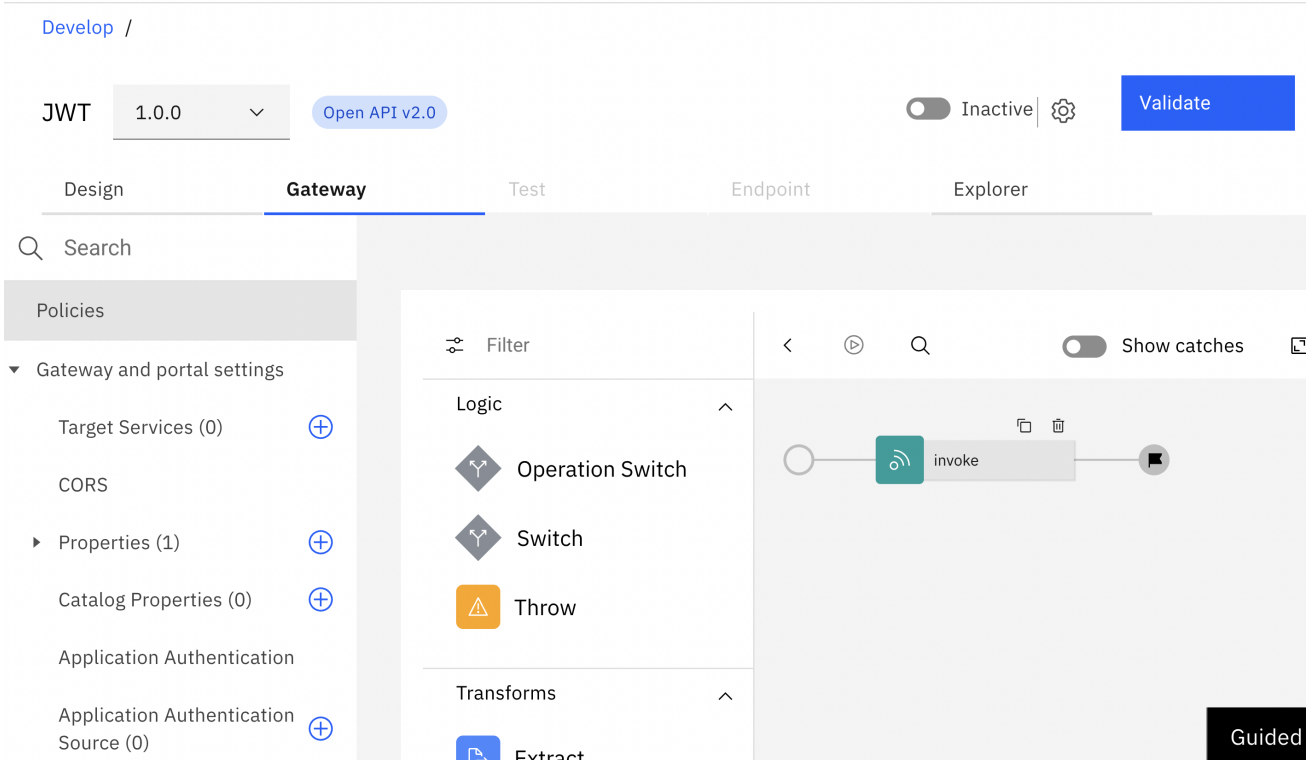
a. Enter `Authorization` in the Parameter name field.
b. Select the `header` in the Located In field.
c. Enter `Enter Bearer <jwt>` to match in the Description field.
d. Select Required.
e. Click Create.



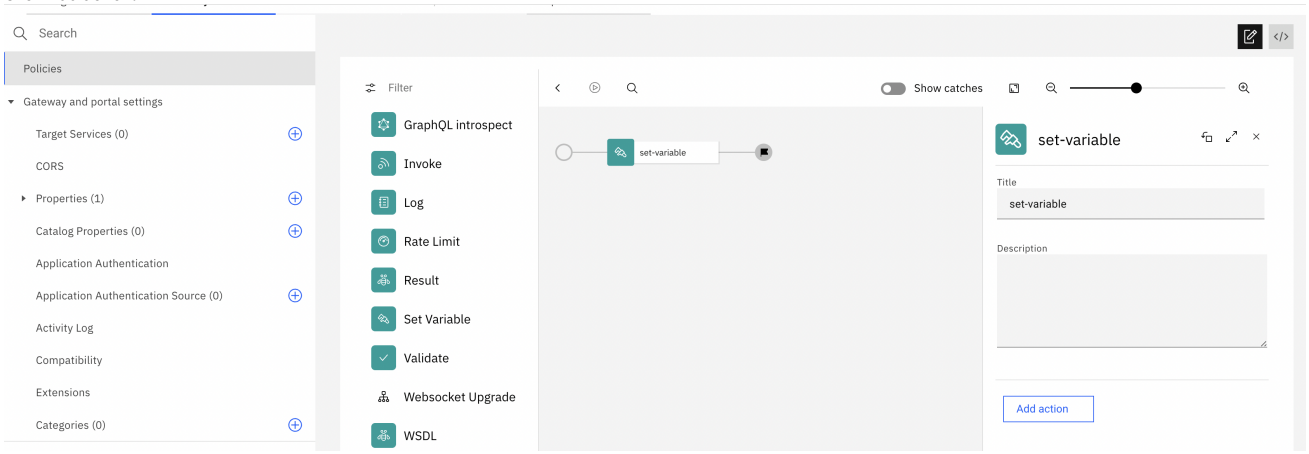
f. Scroll down. In the Schema section, click Create



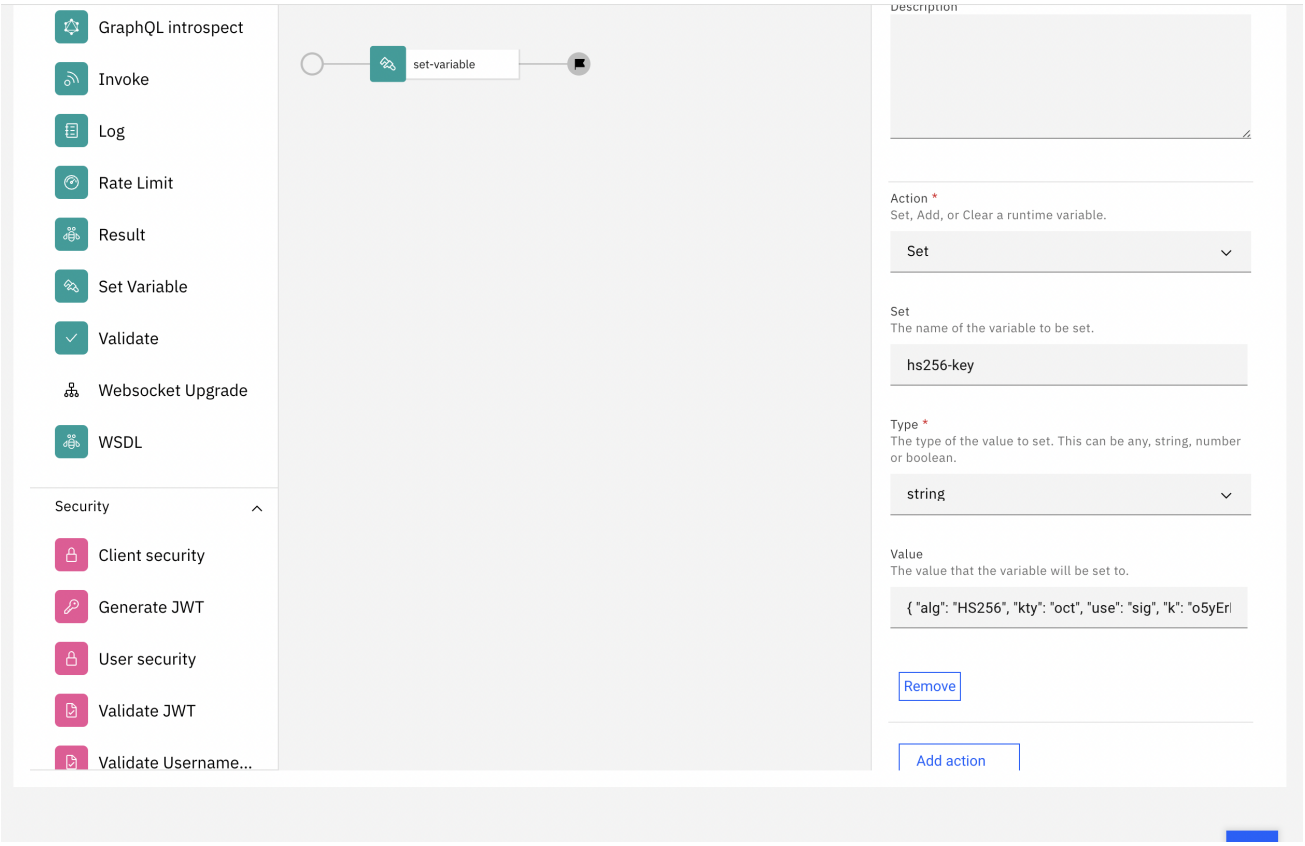
g. Select the `string` in the Type field.
h. Click Create.



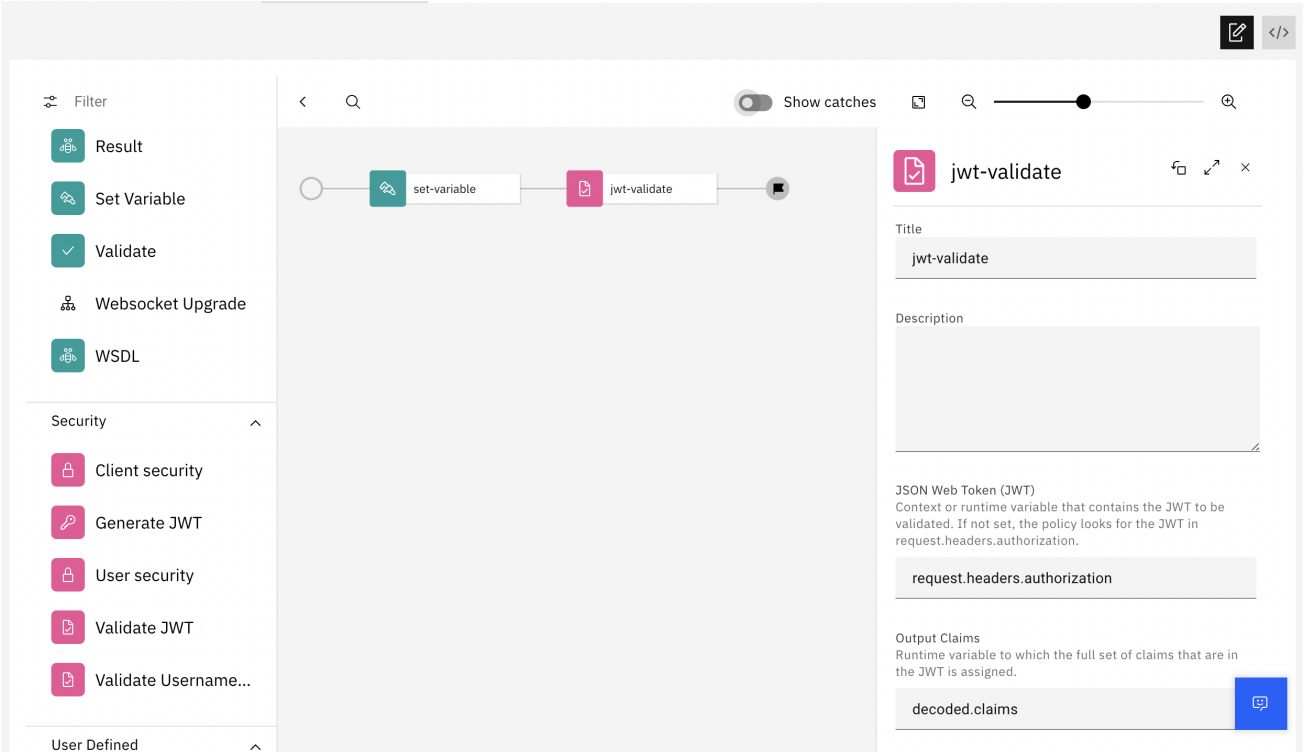
15. After you create the parameter, click Save.
16. Click Components > Responses.
17. Click Add.



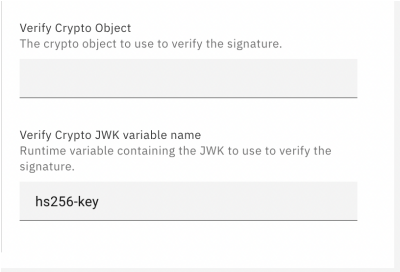
18. The Response name field auto-populates with `200`.
19. Enter `200 OK` in the Description field.



20. After you create the response, click Save.
21. Click Gateway.
22. Hover the mouse over the existing Proxy or start action and click the trash can icon to delete it.

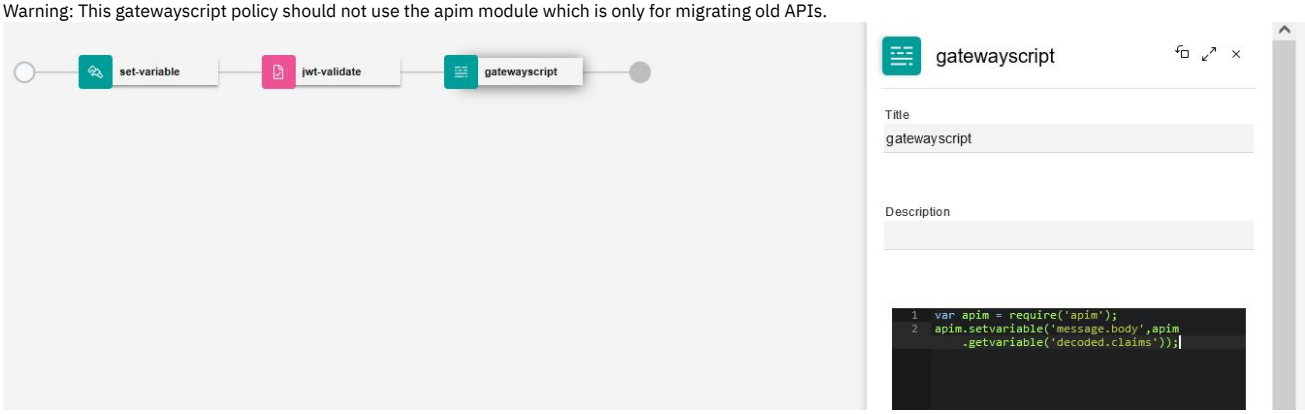


23. Drag the Set Variable action onto the processing flow line. A configuration panel automatically opens.
24. Click Add action.

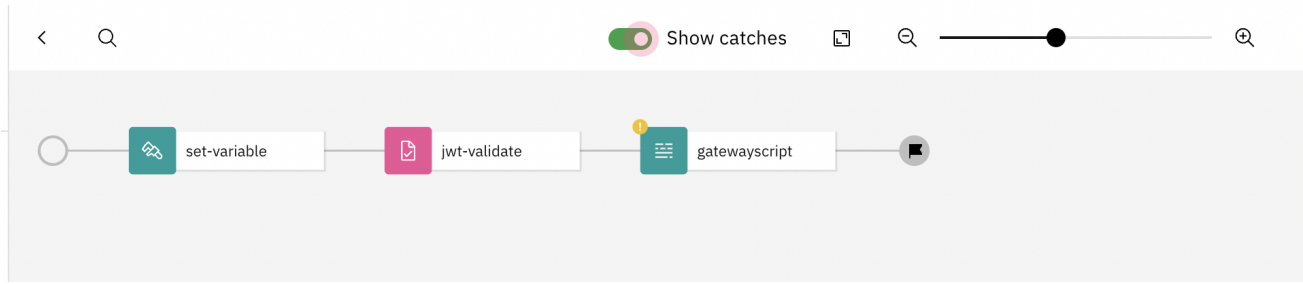


25. Enter `hs256-key` in the Set field.
26. Select the `string` in the Type field.
27. Enter a JWK in the Value field. The following is an example. `{ "alg": "HS256", "kty": "oct", "use": "sig", "k": "o5yErLaE-dbgVpSw65Rq57OA9dHyaF66Q_Et5azPa-XUjbyP0w9iRWhR4kru09aFfQLXeIODIN4uhjElYKXt8n76jt0Pjkd2pqk4t9abRF6tnL19GV4pflfL6uvVKkP4weOh39tqHt4TmkBgF2P-gFhgssZpjwq6l82fz3dUhQ2nkzoLA_CnyDGLZLd7SZ1yv73uzfE2Ot813zmig8KTMEMWVcWSDvy61F06vs_6LURcq_IEEevUiubBxG5S2akNnWigfpbhWYjMI5M22FOCpdcDBt4L7K1-yHt95Siz0QUb0MNlT_X8F76wH7_A37GpKKJGqeaiNWmHkgWdE8QWDQ", "kid": "hs256-key" }`

28. Close the property panel. Click Save.
29. Drag the Validate JWT action onto the processing flow line after the set-variable icon. A configuration panel automatically opens.

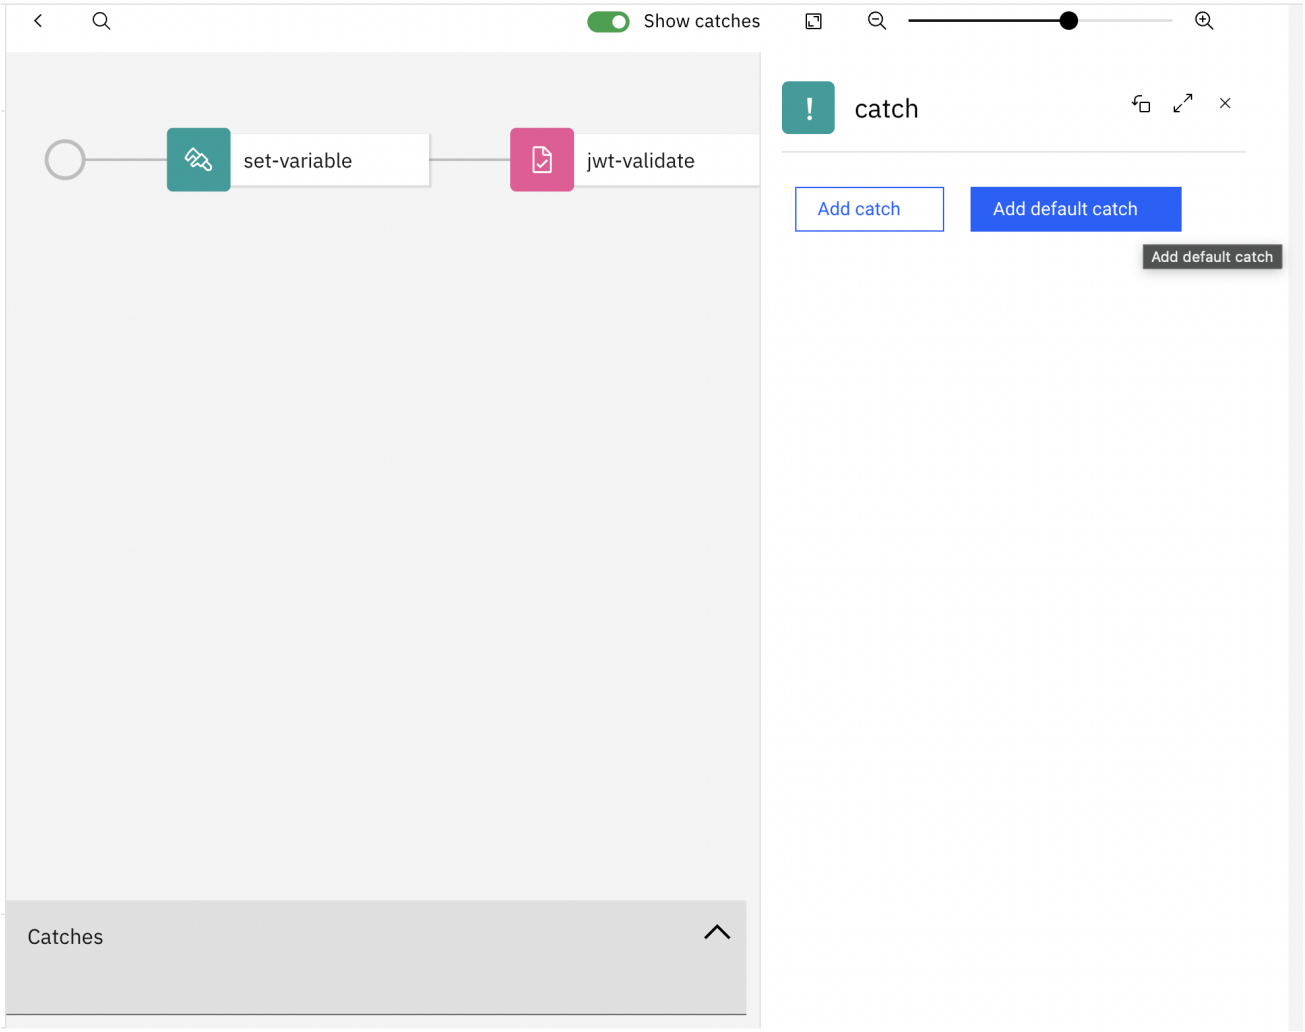


30. Enter `hs256-key` in the Verify Crypto JWK variable name field.



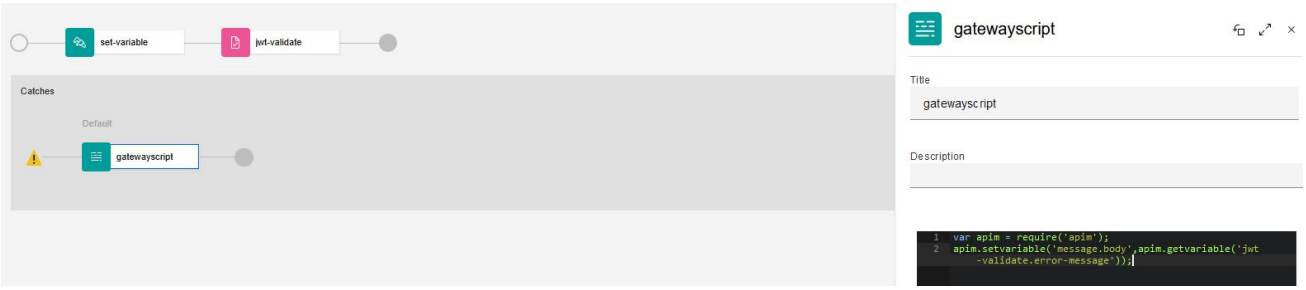
31. Close the property panel. Click Save.
32. Drag the GatewayScript action onto the processing flow line after the Validate JWT icon. A configuration panel automatically opens.
33. Enter the following code:

```
var apim = require('apim');
apim.setvariable('message.body',apim.getvariable('decoded.claims'));
```



Note: The response might include the following warning, which can be ignored:
Warning: This gatewayscript policy should not use the apim module which is only for migrating old APIs.

34. Close the property panel. Click Save.
35. Ensure that the Show catches option is enabled so that the catch area is displayed.



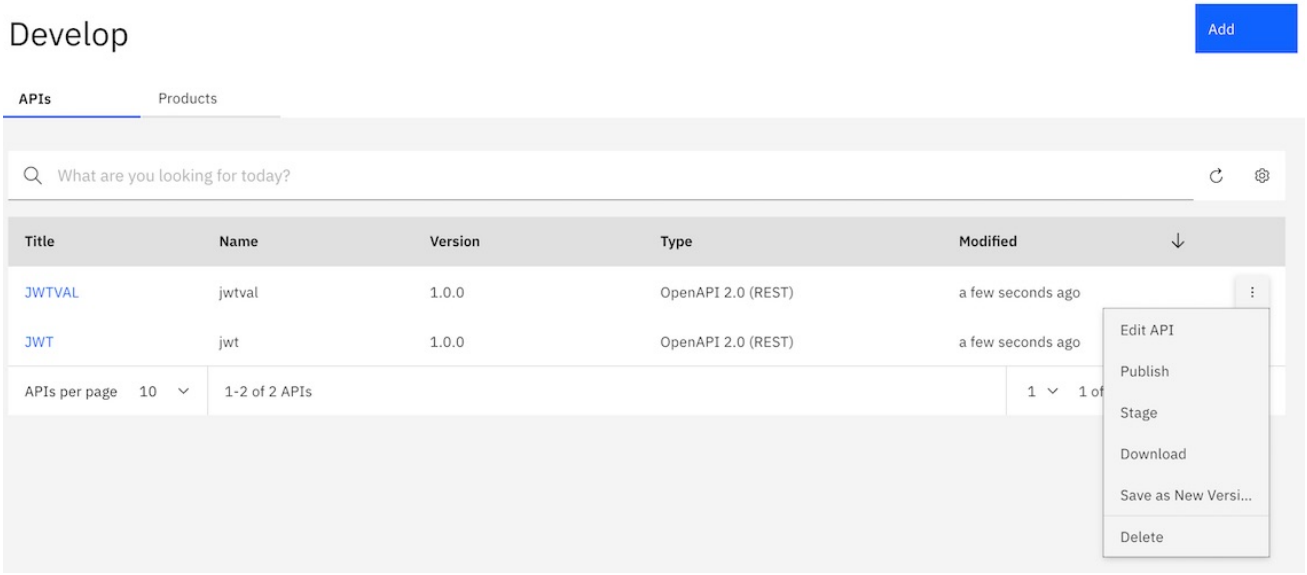
36. Click Catches. A property panel opens.
37. Click Add default catch.

38. Drag the GatewayScript policy action onto the catch flow line.
39. Enter the following code:

```
var apim = require('apim');
apim.setvariable('message.body',apim.getvariable('jwt-validate.error-message'));
```

40. Close the property panel. Click Save.

Testing the REST API



Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test the REST API, you need a valid JWT. You can obtain such a JWT by starting the API created in the Tutorial: Generate a JSON Web Token (JWT). To test the REST API, complete the following steps:

1. Turn on the activation toggle to activate the API you created.
2. Click Test.
3. Enter `Bearer` followed by a space followed by a valid JWT generated with the same sign key in the Value field corresponding to the Authorization parameter.
   Note: If the Authorization key is missing from the parameters, confirm that the correct request path is selected. Select a request path that ends with **`/val`**, or manually append **`/val`** to the GET request.
4. Click Send.
5. The response contains branch data.

Manage your API definition

Now, that your new API works correctly, you can manage this API. To see your immediate options, take the following steps.

1. Click the Develop icon on the navigation bar.
2. Click the Options icon alongside the Mapper API.

3. Select Download.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a new API definition that validates a JSON Web Token (JWT).
- Tested the new API.

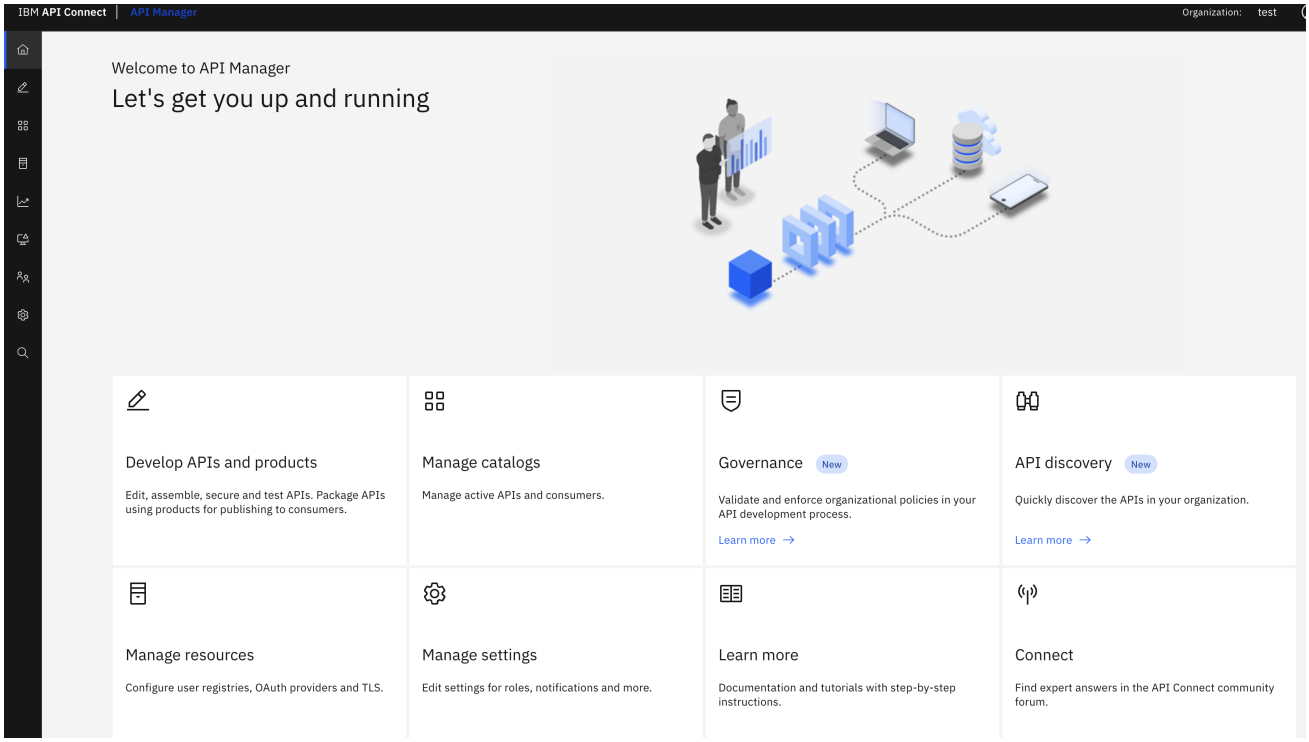
Tutorial: Creating a Client Application

This tutorial shows you how to create a client application using the API Manager. The ability to create a new application using the API Manager allows members of a provider organization, such as API developers or testers, to create the environment needed to complete an API.

About this tutorial

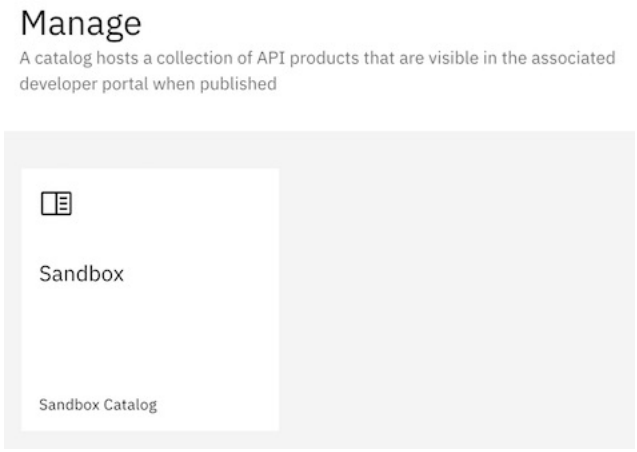
In this tutorial you will complete the following lessons:

1. Create a Client Application
2. Subscribing to Products and APIs



Before you begin

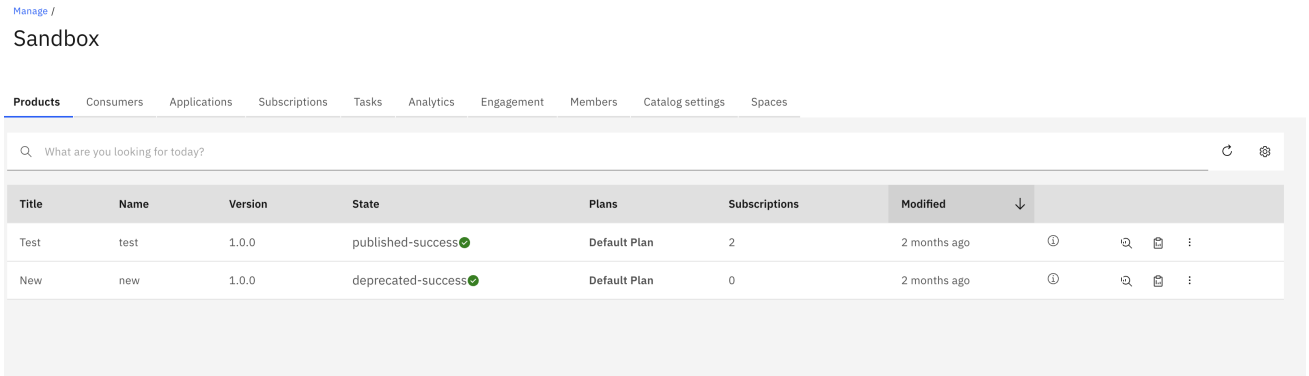
In this tutorial you will create a new client application. You can then subscribe this new application to a product if one exists in your catalog. If you do not have an existing product, complete Tutorial: Importing an API before beginning this tutorial. When you import the API, a product is created for it automatically.



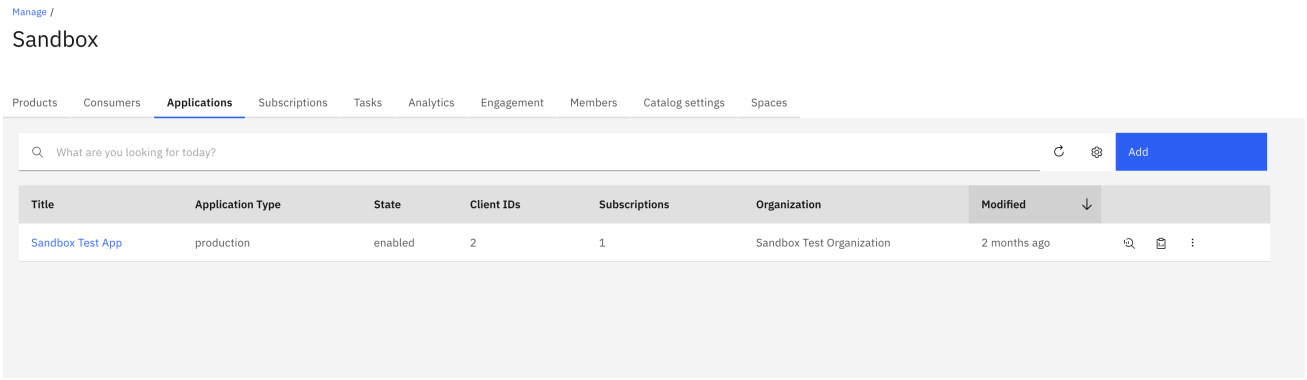
Create a Client Application

To create a client application using the API Manager, complete the following steps:

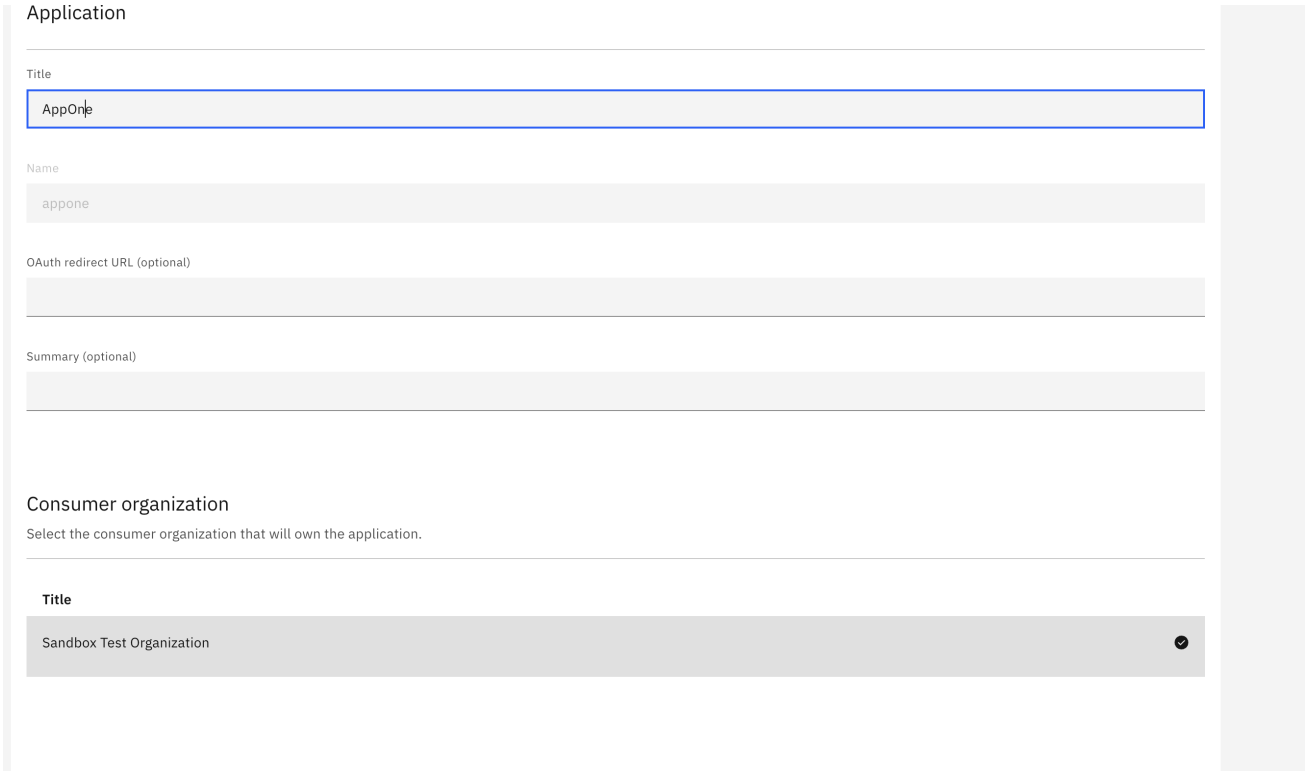
1. Log in to API Manager.
2. In the Home page, click the Manage Catalogs tile.



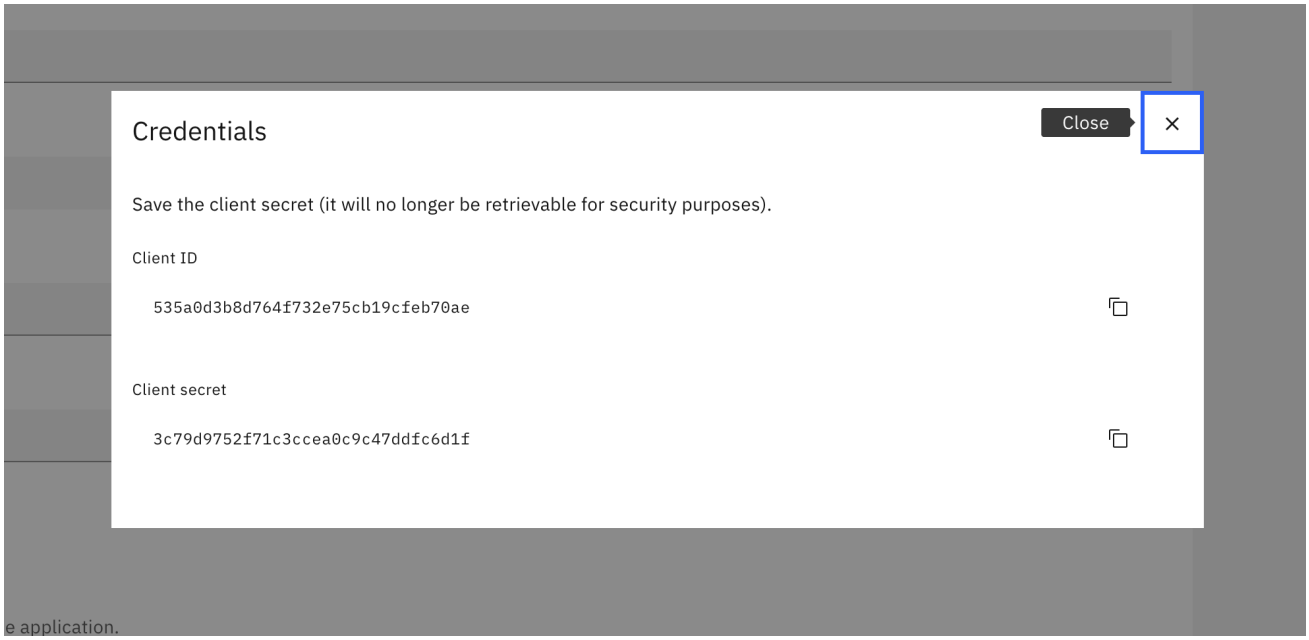
3. Click the Sandbox Catalog to open it.



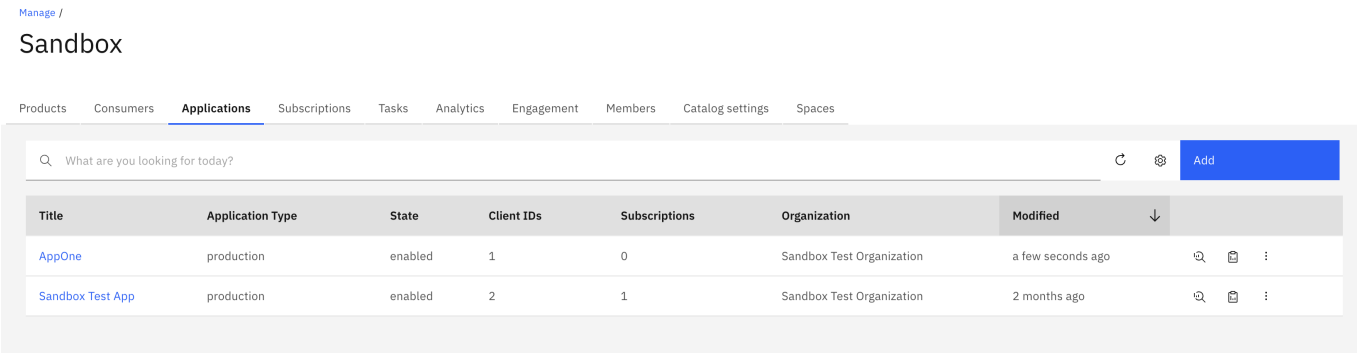
The catalog opens to the Products page.



4. Click the Applications tab.



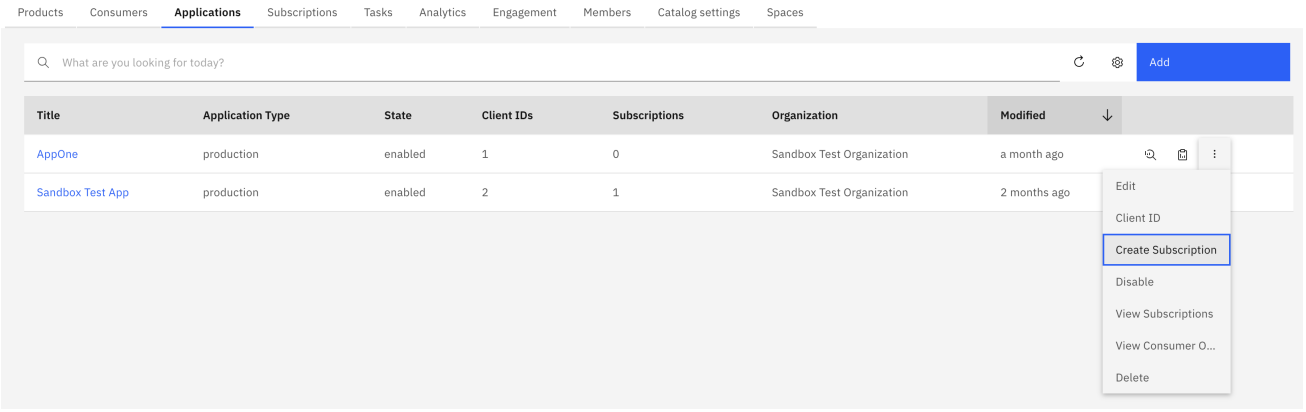
5. On the Applications page, click Add.



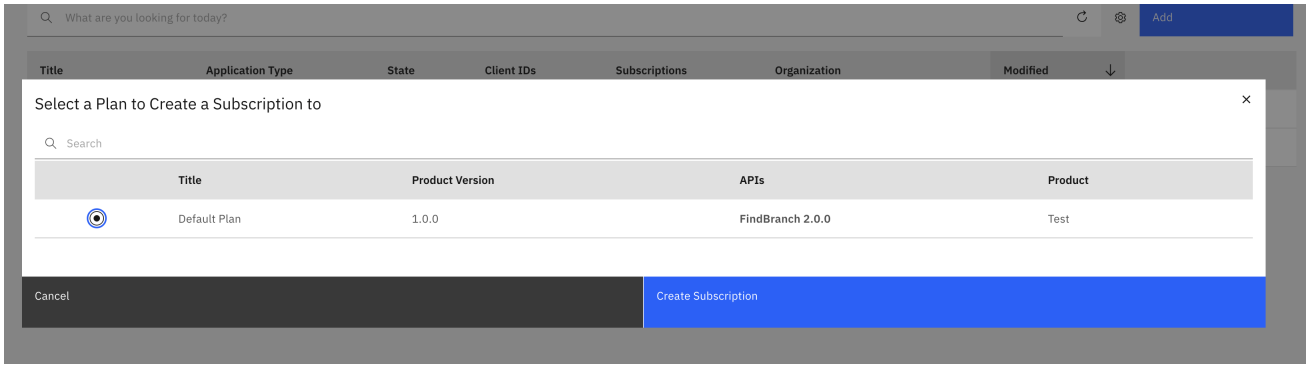
6. On the Create Application page, type (or copy and paste) `AppOne` in the Title field.
7. In the Consumer Organization field, select the Sandbox Test Organization.
   The Sandbox Catalog includes one consumer organization, which is selected by default.

8. Click Create.
9. When the Credentials panel presents the application's credentials, use the Copy button to copy each value in turn and paste it into a file. Then click the x to dismiss the panel.
   You will need these values later for testing purposes and you don't copy the secret now, you will have to generate a new one later.

The new "AppOne" application displays in the list on the Applications page. By default, the application is enabled and is ready for use.



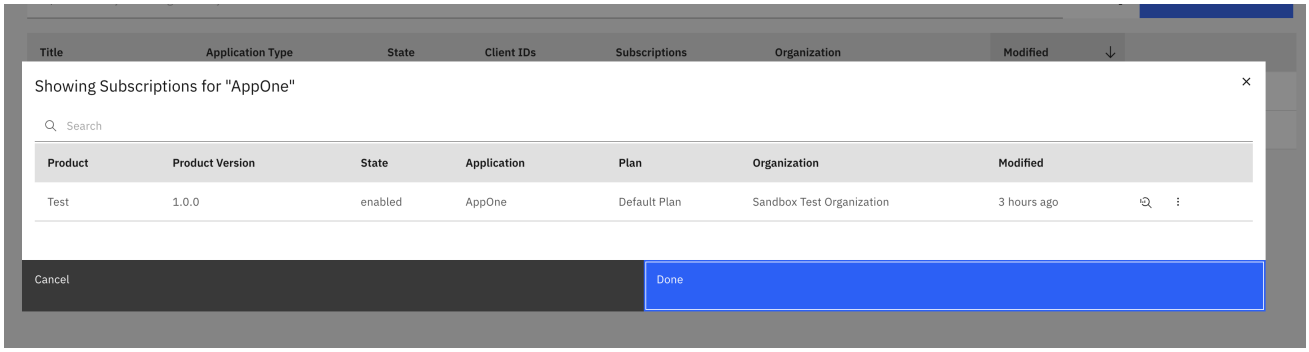
Proceed to the next section to subscribe the application to a Product and an API, so that you can use the application to test them.



Subscribing to Products and APIs

You can subscribe the new client application to an existing published product, which gives the app permission to execute the APIs contained in the product. Complete the following steps to subscribe the client app to a product.

1. On the Applications page, click the options icon ⋮ next to the "AppOne" application, and then click Create subscription.



2. On the Create Subscription page, select the Product/Plan combination for the API.
   A Product can contain multiple APIs, and a *Plan* can contain multiple Products. Be sure to subscribe your app to the correct Product and Plan.

This tutorial uses the FindBranch auto product that was created by importing the FindBranch API in a previous tutorial.

3. Click Create Subscription.
4. On the Applications page, click ⋮ > View Subscriptions next to the AppOne application.
The Subscriptions page now lists the new subscription for the "AppOne" application.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a client application.
- Subscribed the client to a product that contains an API.

Tutorial: How to monetize an API Product

This tutorial shows you how to define a pricing plan for an API Product, and how API consumers can then subscribe to that monetized Product in the Developer Portal.

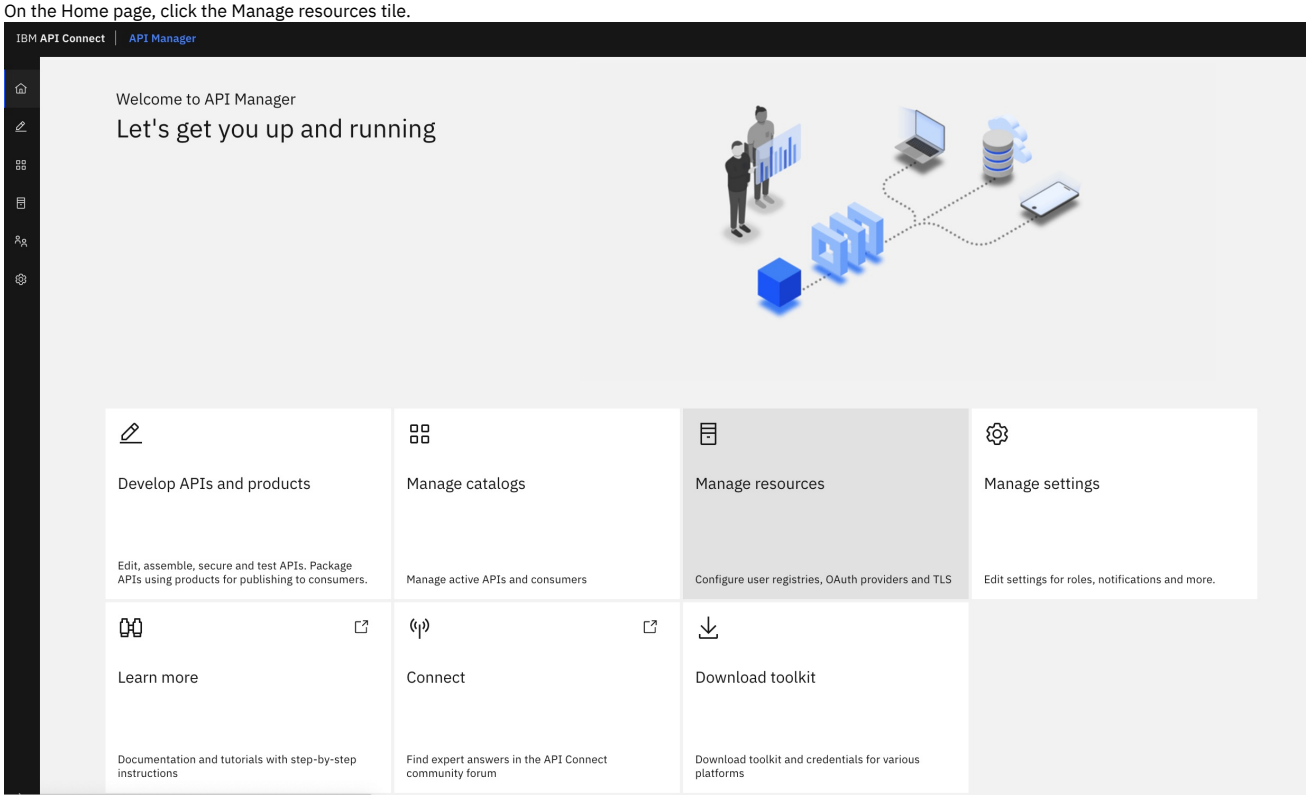
Before you begin

To complete this tutorial, you must have the following prerequisites:

- Either be the provider organization owner, or have `Settings: Manage` permissions, for your API Manager account.
- The billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on Kubernetes and Configuring monetization on VMware for more information.
- Have internet access that allows your API Connect management server to communicate with your Stripe account. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.
- Have a Stripe test account. If you don't have a Stripe account, you can create one during this tutorial. Stripe accounts (including test accounts) can be created at https://dashboard.stripe.com/register.

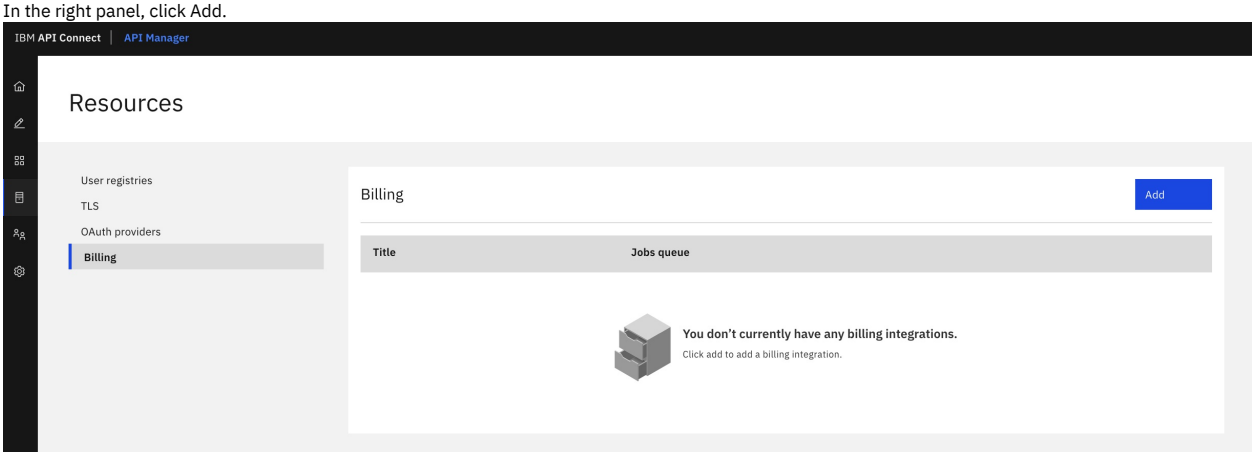
About this tutorial

IBM® API Connect includes a subscription billing feature that allows API providers to define pricing Plans in their API Products, and monetize their API offerings. If a Product contains a pricing Plan, API consumers must enter their payment information into the Developer Portal before they can subscribe to that Plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.



In this tutorial you will complete the following activities:

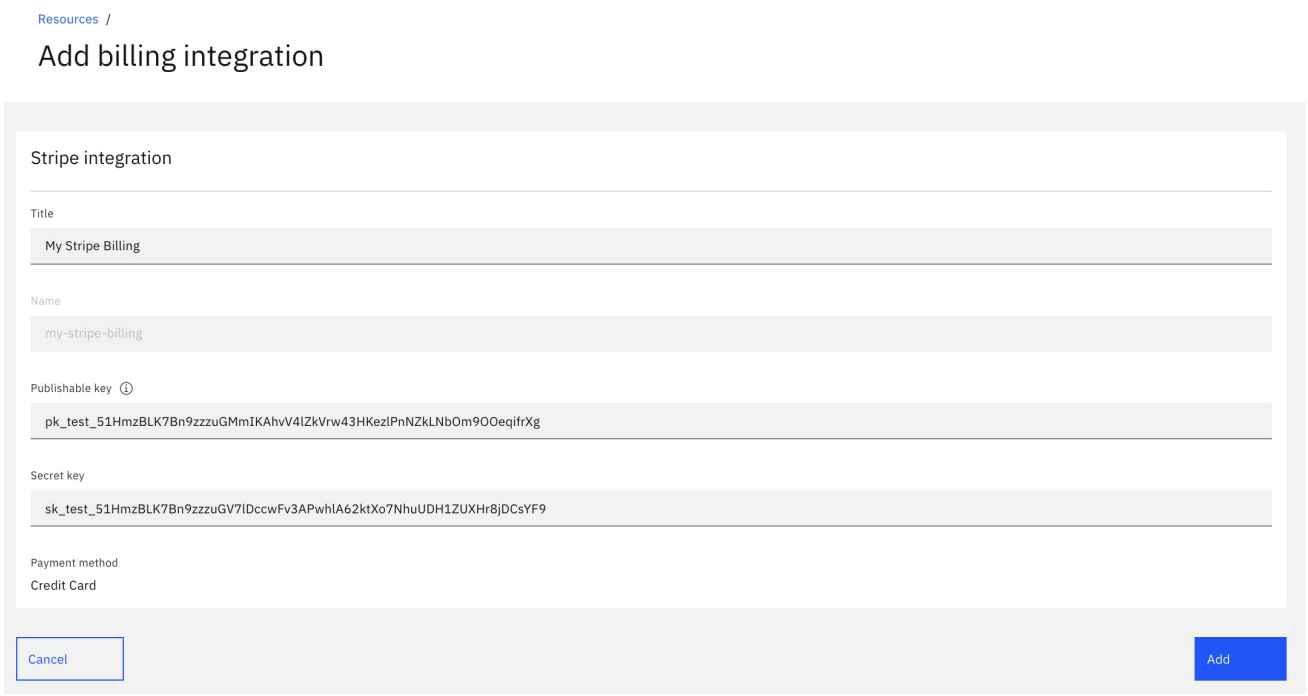
1. Set up your billing resource
2. Configure a stripe-test catalog
3. Enable the Stripe payment method in the Developer Portal
4. Create and publish a monetized Product
5. Verify the publish in your Stripe account
6. View the monetized Product in the Developer Portal



Set up your billing resource

Create a Stripe billing integration resource for your provider organization by completing the following steps.

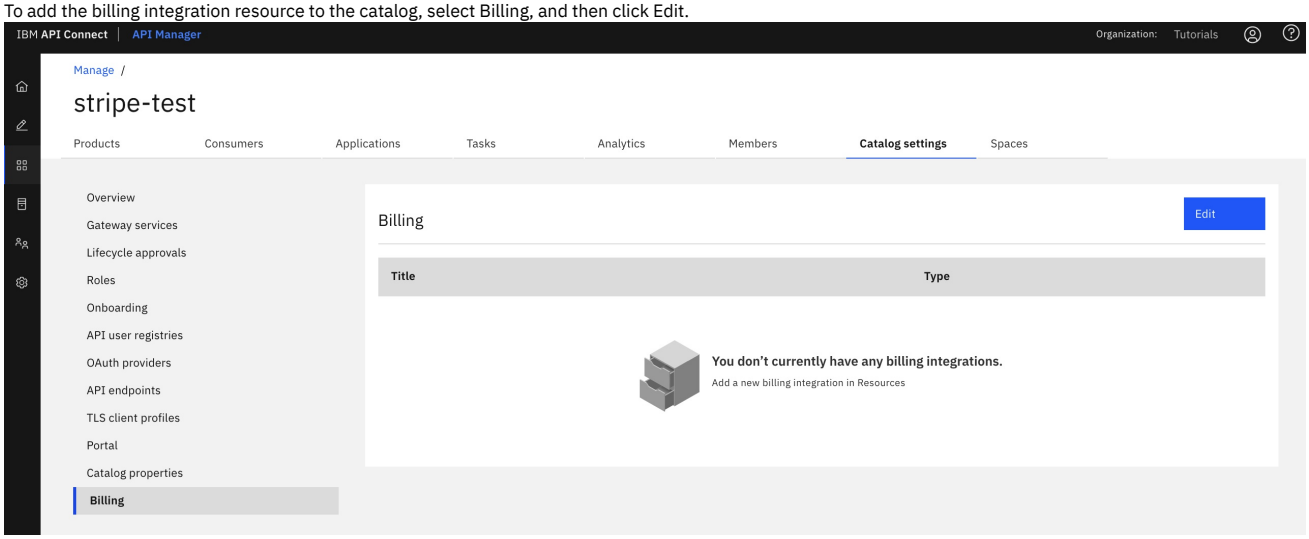
1. Log in to API Manager.
2. On the Home page, click the Manage resources tile.



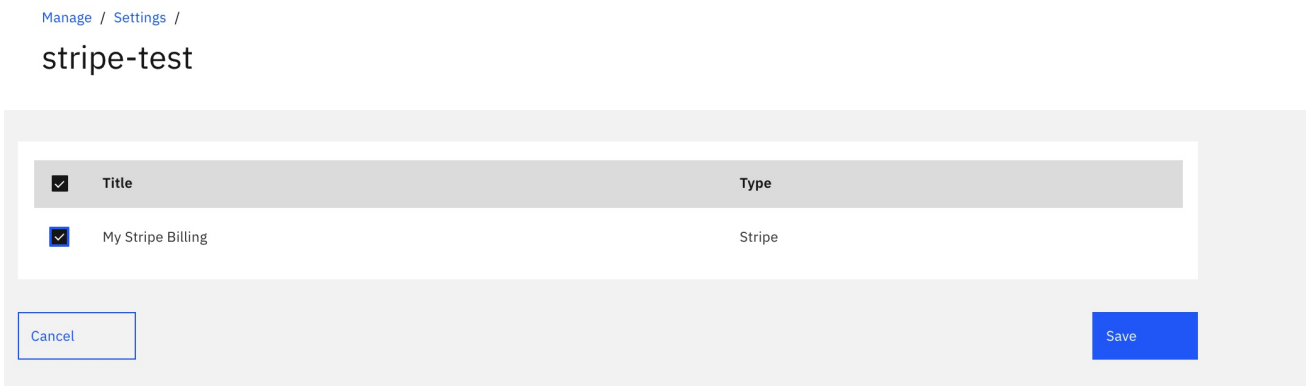
3. On the Resources page, perform the following tasks.
   a. In the left panel, select Billing.
   b. In the right panel, click Add.

   The Add billing integration page for Stripe integration is displayed.

4. On the Add billing integration page, perform the following tasks.
   a. In the Title field, enter your billing integration title. For example, `My Stripe Billing`.
      Note: The Name field is auto-filled based on the Title that you entered.
   b. In the Publishable key field, enter the test key for your Stripe account.
   c. In the Secret key field, enter the test key for your Stripe account.
      Tip: If you don't have a Stripe account, you can create one here: https://dashboard.stripe.com/register. Refer to your Stripe dashboard to get your test API keys. For more information, see https://dashboard.stripe.com/apikeys.
      Note: Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. For this tutorial you should use your Stripe test API keys.

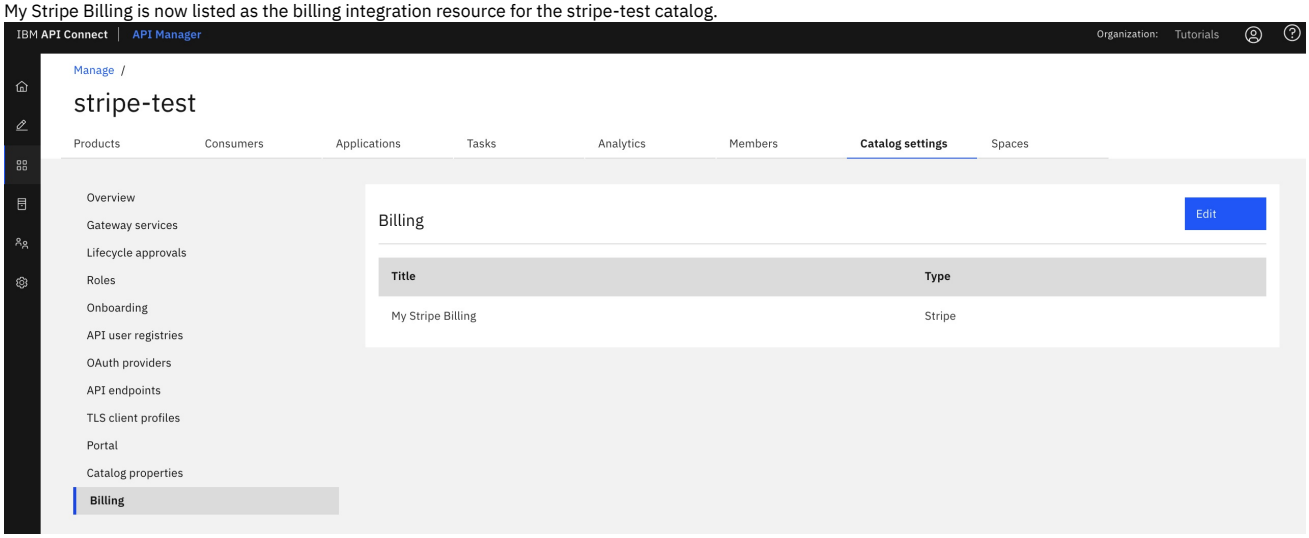


5. Click Add to create your Stripe billing integration resource. The My Stripe Billing integration is now displayed as the billing resource.



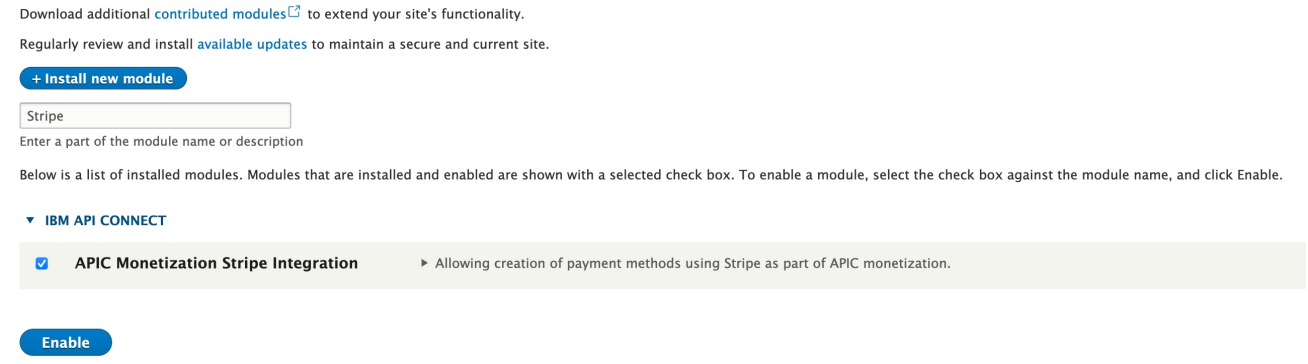
Configure a stripe-test catalog

To be able to publish monetized Product Plans, you must add your billing integration resource to a catalog. During this activity you will create a new catalog called stripe-test, so you can delete the catalog at the end of the tutorial if you wish.



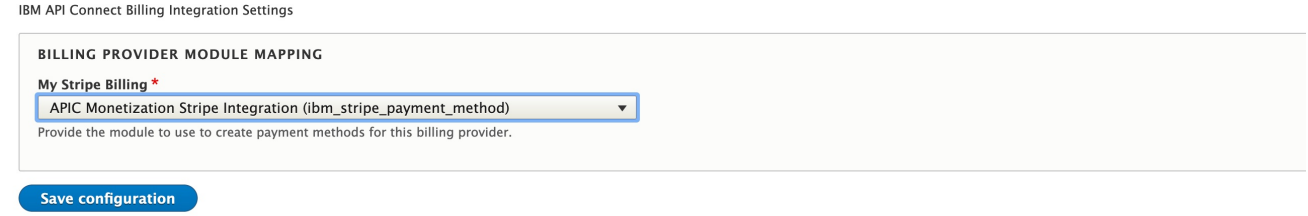
1. In the API Manager, click the Manage icon in the side navigation bar.
2. Click Add > Create catalog, and create a new catalog called `stripe-test`.
3. Click the stripe-test catalog tile, and then click the Catalog settings tab. Select Gateway services and ensure that the catalog is configured to use either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway, or both. Then select Portal, and create a Developer Portal. If you're not sure how to configure these settings, see Creating and configuring catalogs.
4. To add the billing integration resource to the catalog, select Billing, and then click Edit.

5. Select the My Stripe Billing resource that you created earlier, and click Save.



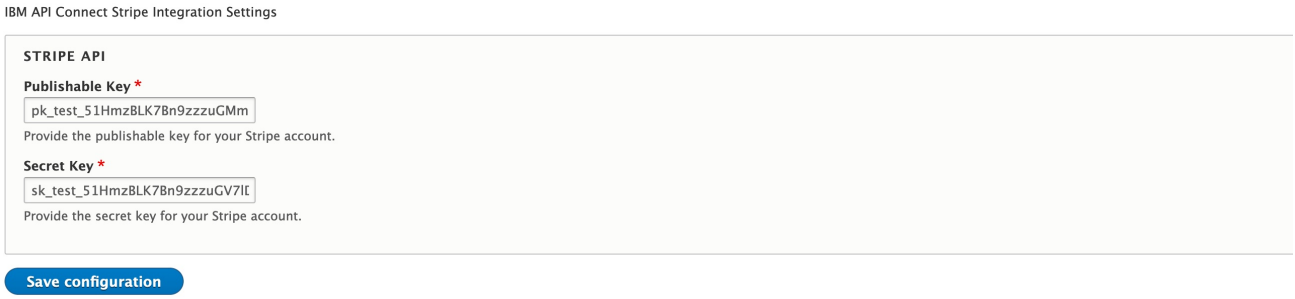
My Stripe Billing is now listed as the billing integration resource for the stripe-test catalog.

Enable the Stripe payment method in the Developer Portal



To enable API consumers to subscribe to Products with paid Plans, you must configure the Stripe payment method in the Developer Portal for the stripe-test catalog.

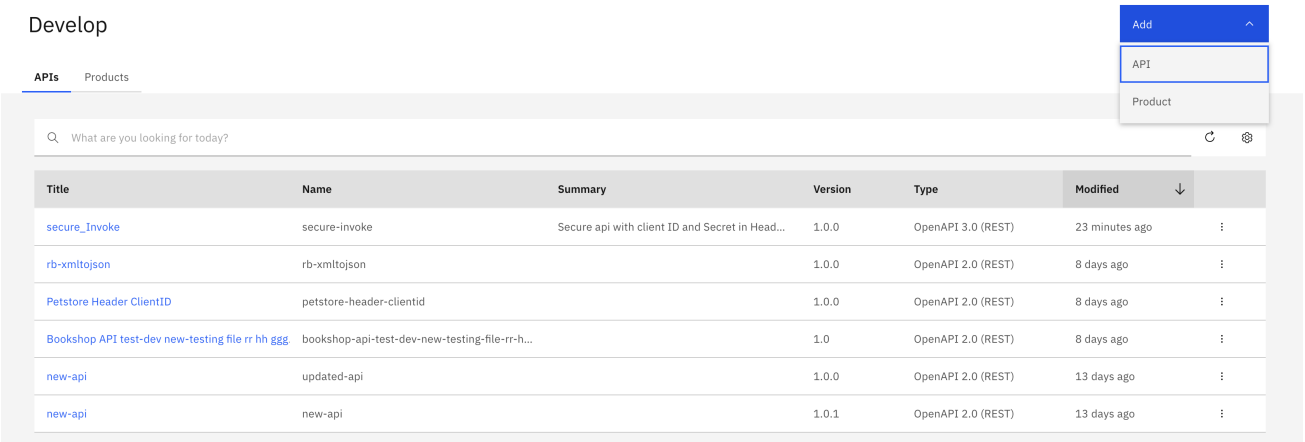
1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Extend. The List tab for the Extend page opens, and the list of installed modules is displayed.
4. Enter `Stripe` into the search filter, select APIC Monetization Stripe Integration, and click Enable.



The default settings for the APIC Monetization Stripe Integration module are now enabled, and you now need to edit those settings.

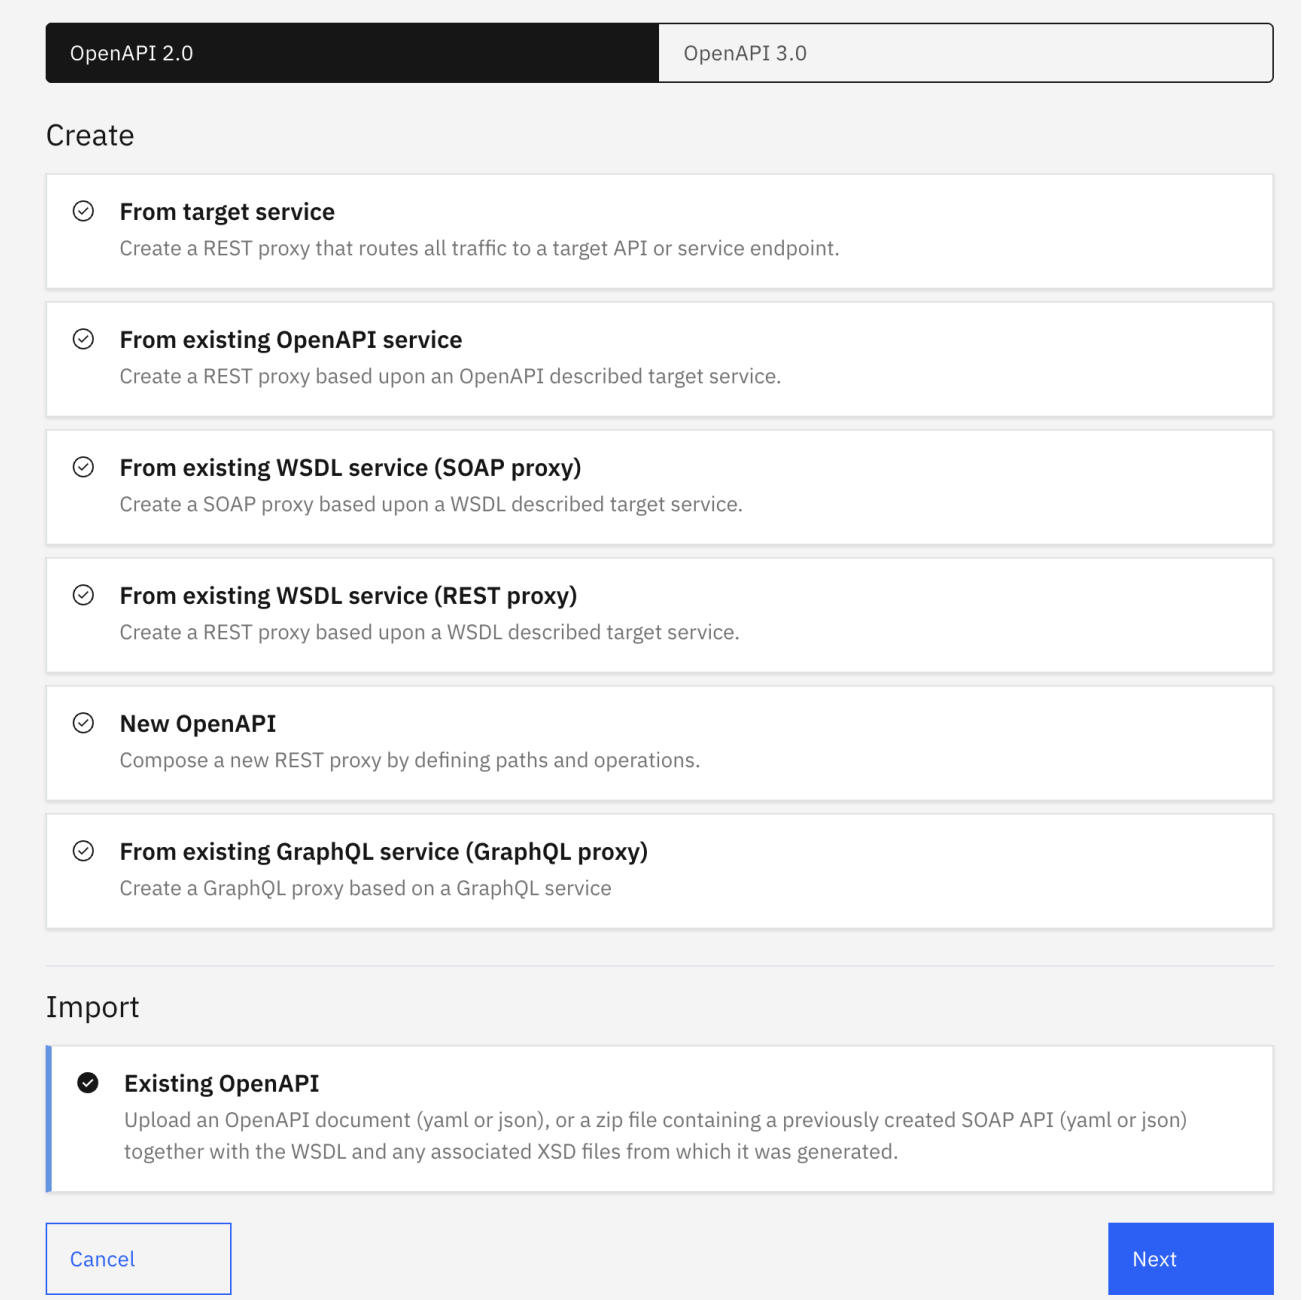
5. Click Configuration > System > IBM API Connect Billing.
6. Change the billing provider module mapping drop-down option to be the newly enabled APIC Monetization Stripe Integration (ibm_stripe_payment_method), and click Save configuration.

7. Click Configuration > System > IBM APIC Stripe Integration, and enter the same Stripe test API credentials that you entered for the My Stripe Billing integration resource in Step 4 of Set up your billing resource. Then click Save configuration.



The Stripe payment method is now configured in the Developer Portal.

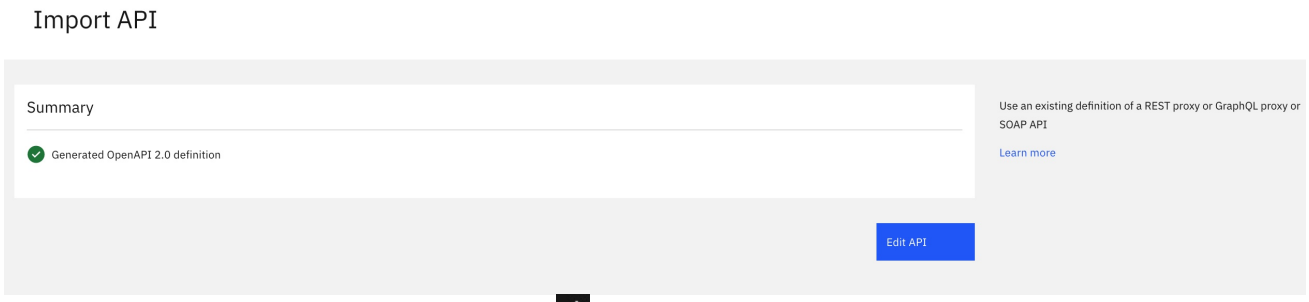
Create and publish a monetized Product



Create a Product that includes a pricing Plan, and publish the Product to the Developer Portal.

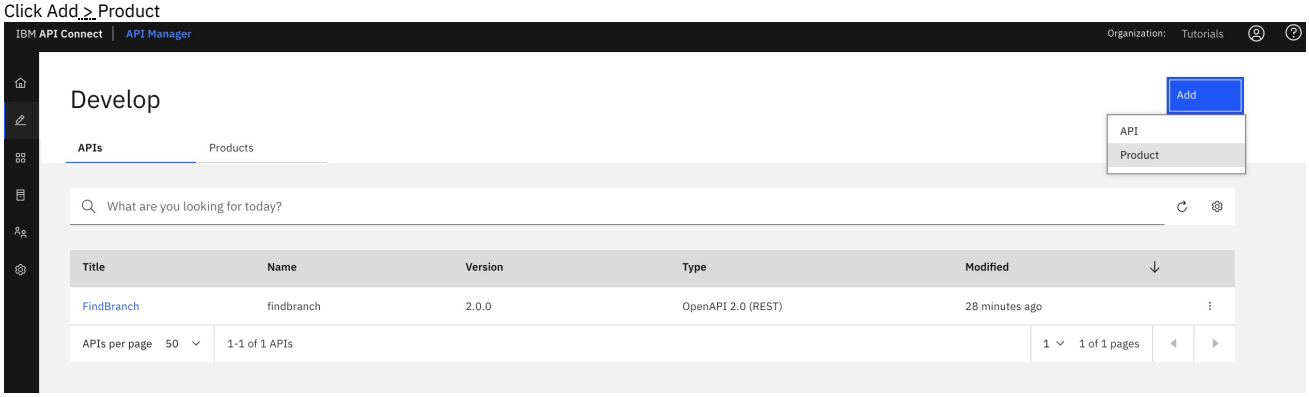
1. First you need to download a test API to use with your Product:
   - If your stripe-test catalog uses a DataPower Gateway (v5 compatible), download the findbranch.txt file to your local filesystem. Rename this file to `findbranch.yaml`.
   - If your stripe-test catalog uses a DataPower API Gateway, download the findbranch_v6.txt file to your local filesystem. Rename this file to `findbranch.yaml`.

   Or if you prefer, you can use one of your own APIs.
2. To import the API into API Manager, click the Develop icon in the side navigation bar, and then click Add > API (from REST, GraphQL or SOAP).

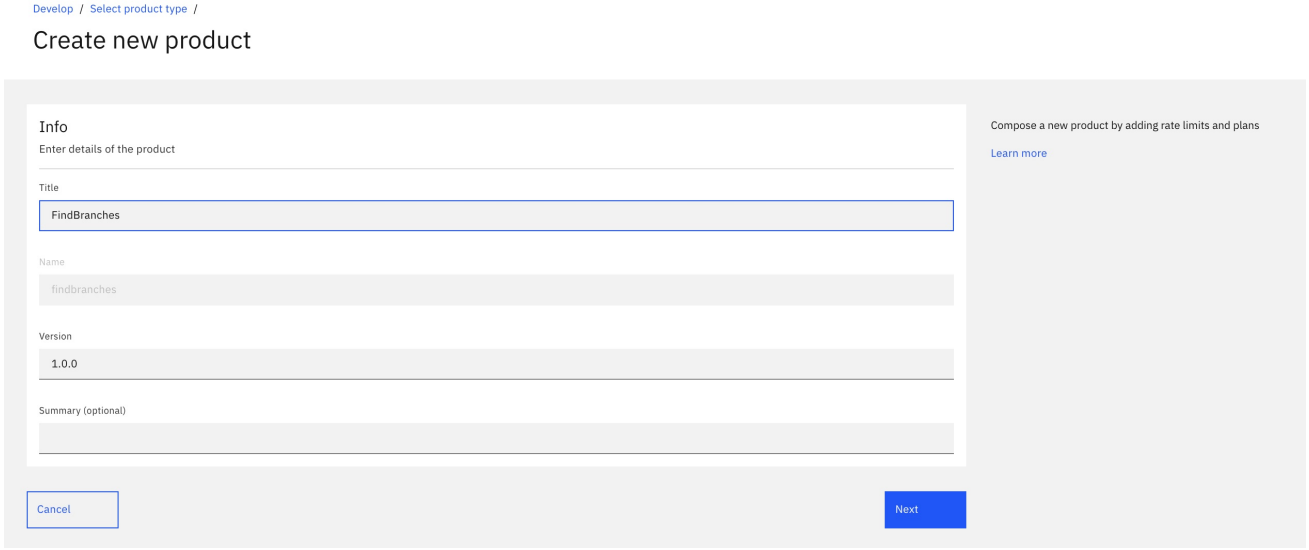


3. Ensure that OpenAPI 2.0 is selected, and then select Existing OpenAPI from the Import section, and click Next.

4. Click Drag and drop files here or click to upload, and select the `findbranch.yaml` file on your local file system to upload it. Then click Next.

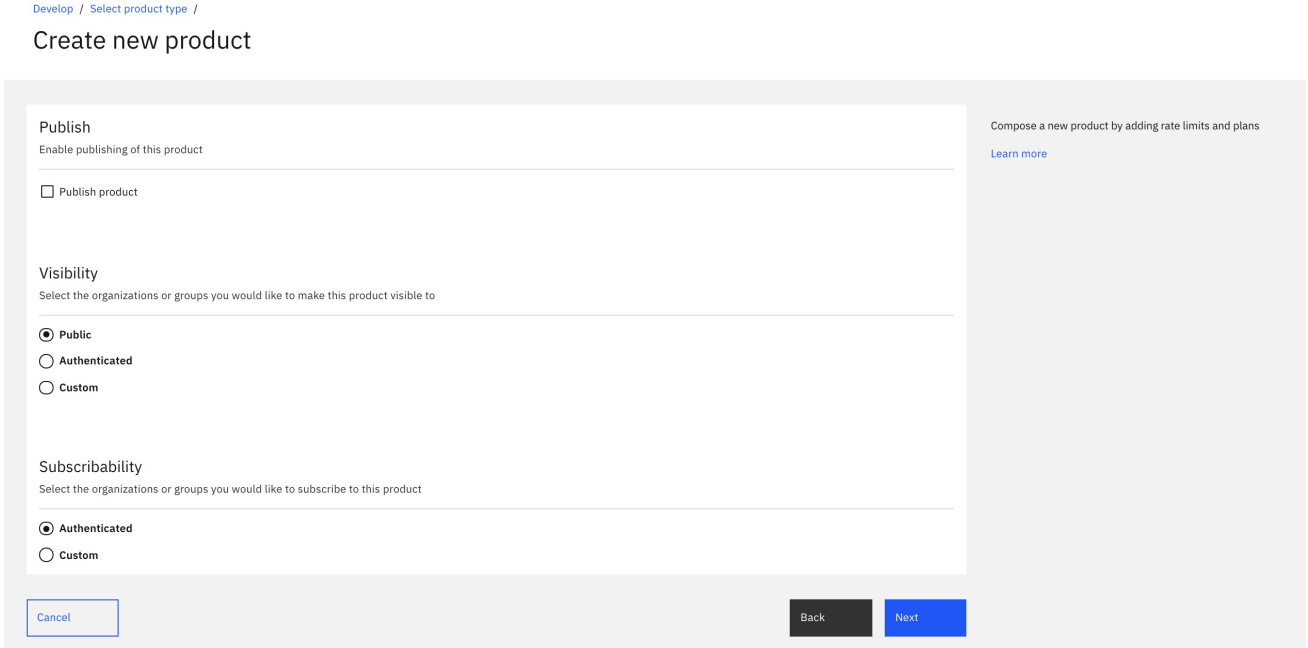


5. Leave Activate API unchecked, as you will activate the API when you publish the monetized Product later in this section. Click Next to continue.
6. The Summary page displays, showing that the API definition has been generated.

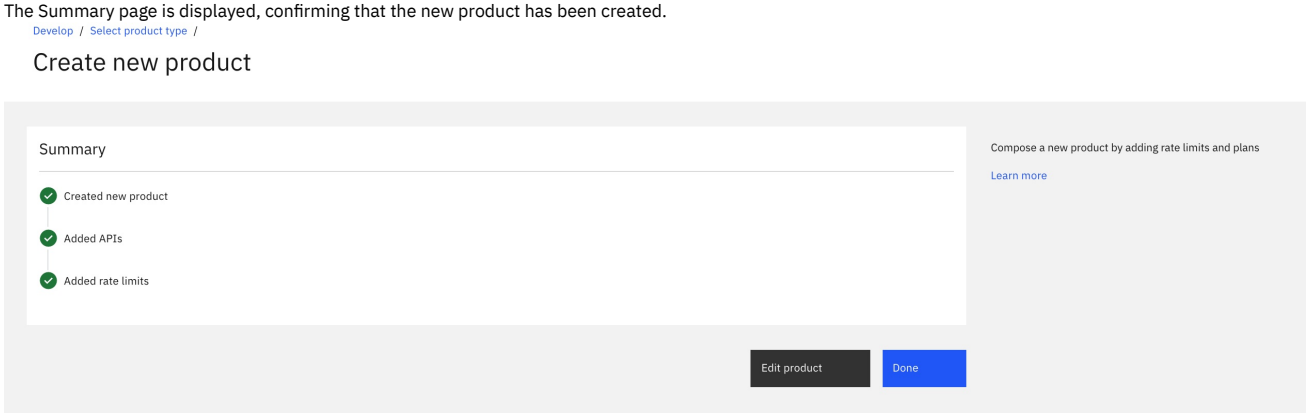


7. Click Edit API to see your generated API definition, and then click the Develop icon in the side navigation bar to continue with creating a monetized Product.

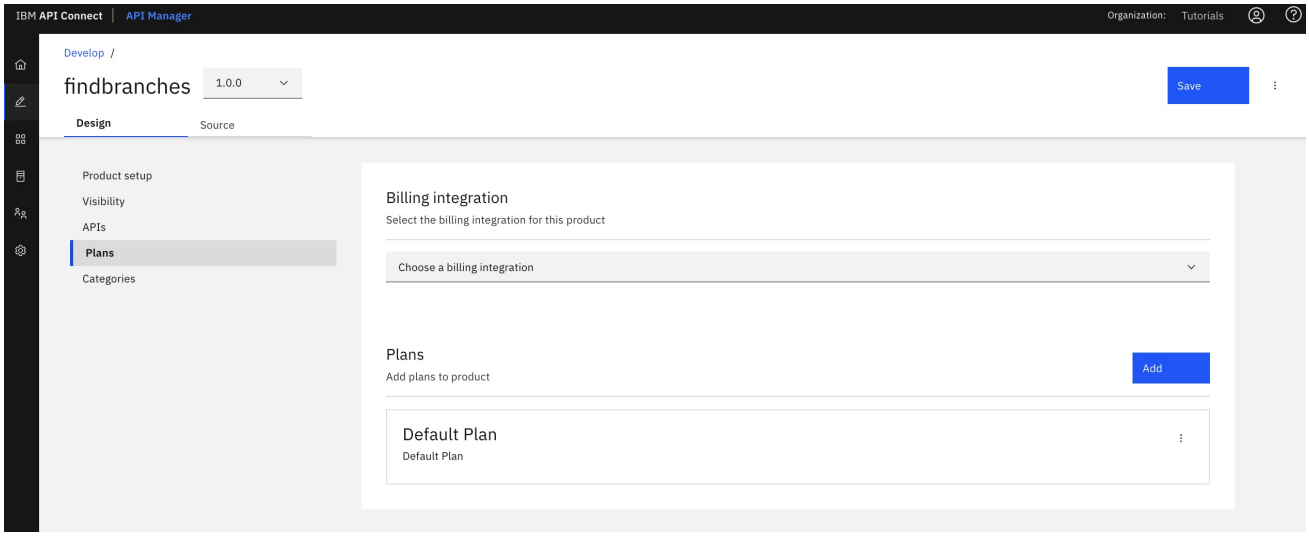
   The FindBranch API should now be shown in your list of APIs - if it isn't, just click the Refresh icon to refresh your browser.
8. Click Add > Product



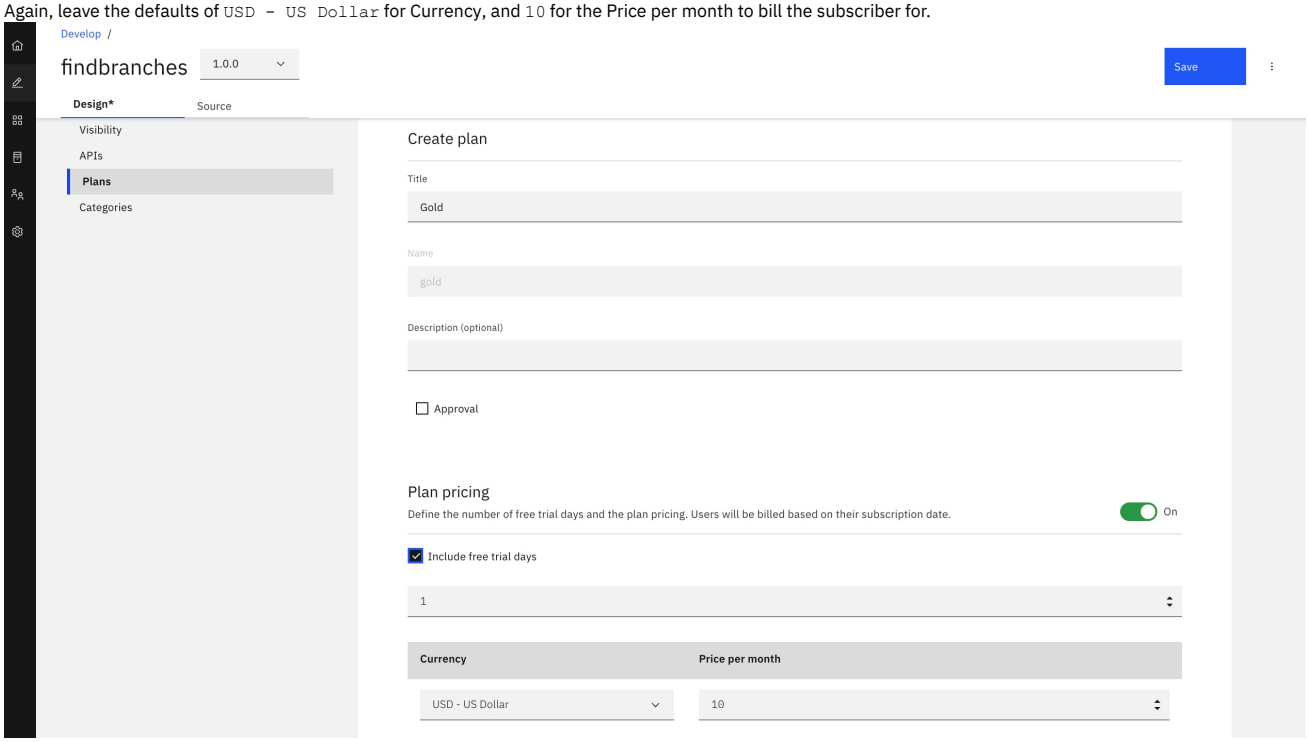
9. Select New product, and click Next.
10. Enter `FindBranches` in the Title field, and click Next.



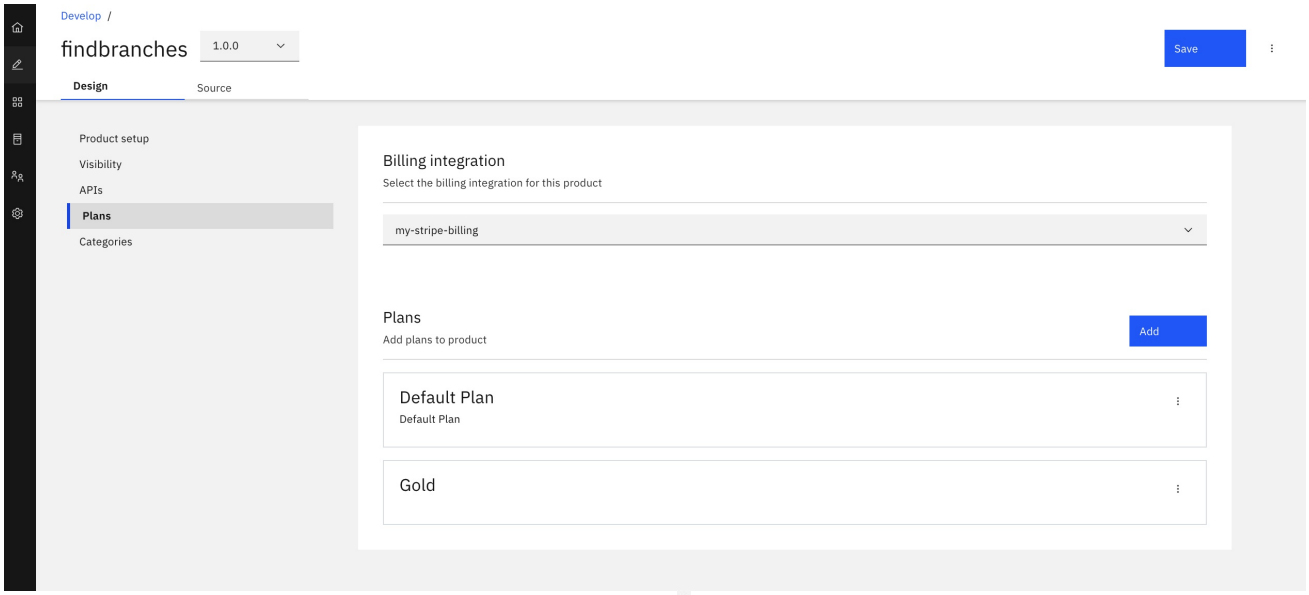
11. Select the `FindBranch` API that you imported, or your own API, and click Next.
12. Accept the defaults for Plans, and click Next. You'll add a priced Plan later.



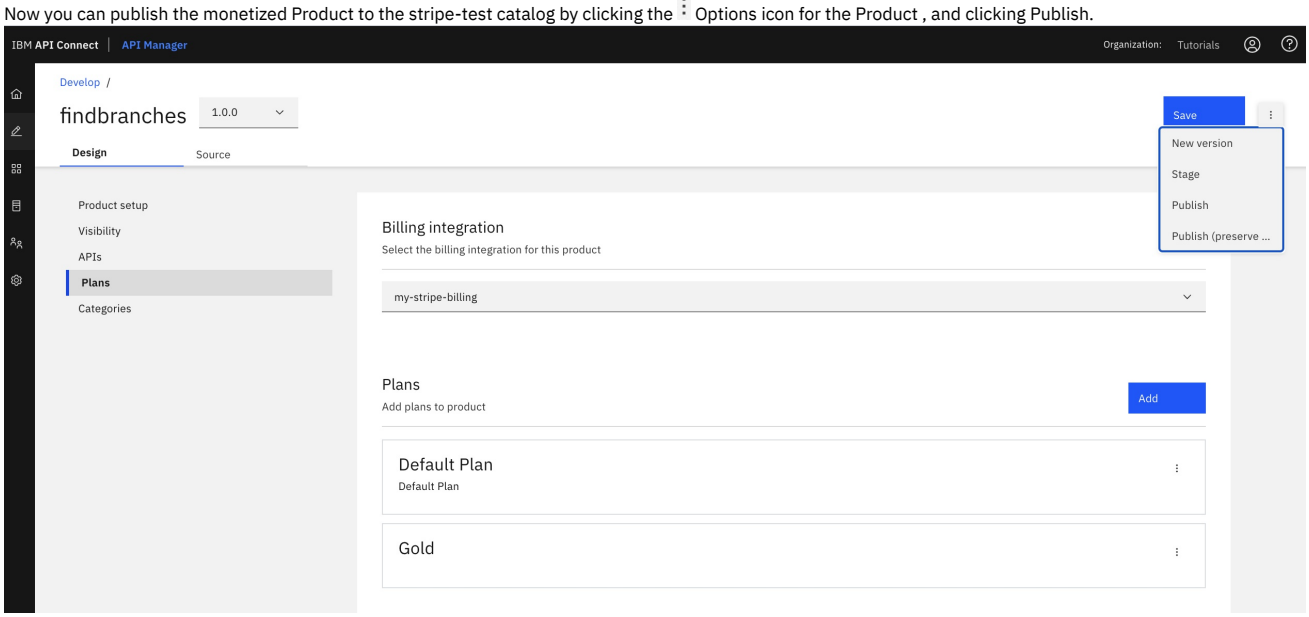
13. Accept the defaults for Publish, Visibility, and Subscribability as well, and click Next.



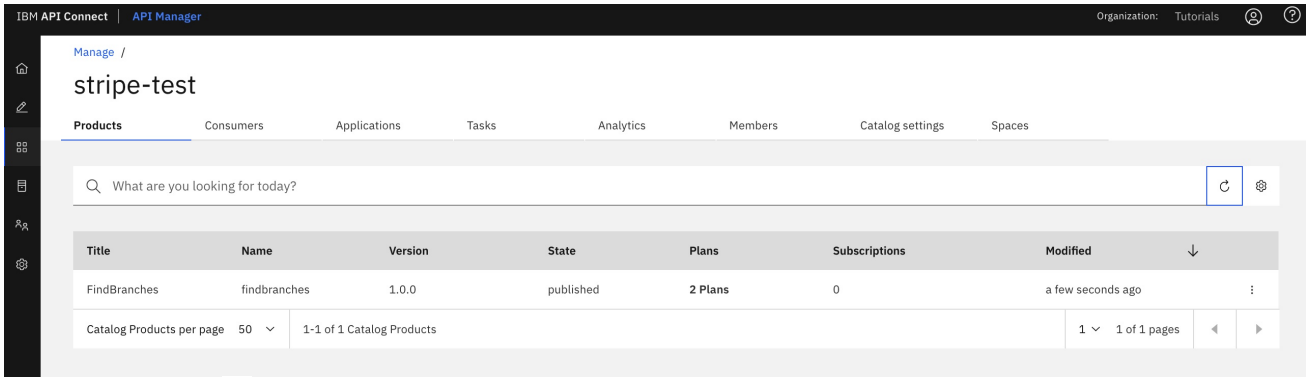
14. The Summary page is displayed, confirming that the new product has been created.



15. Click Edit product to continue with the configuration.
16. With the Design tab selected, click Plans in the navigation menu.



17. In the Billing integration section, select my-stripe-billing as the billing integration resource.
18. In the Plans section, click Add to create a new Plan with pricing.
19. Enter a Title for the new Plan, for example `Gold`, but leave the Approval checkbox unchecked.
20. Change the toggle to On for Plan pricing, and the Plan pricing definition section is displayed.
21. Select Include free trial days, and leave the default of `1` for the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.
22. Again, leave the defaults of `USD - US Dollar` for Currency, and `10` for the Price per month to bill the subscriber for.



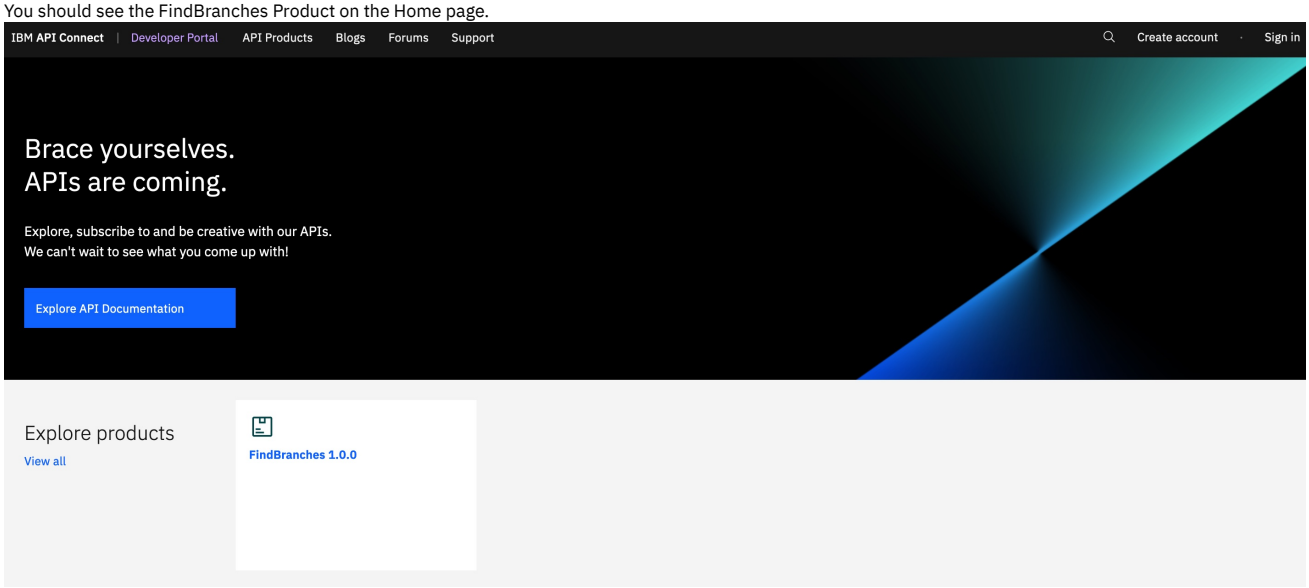
23. In the Plan rate limits section, change the Calls to be `1000` per hour, to differentiate this Plan from the Default Plan. Click Save to save the new pricing Plan.

24. Now you can publish the monetized Product to the stripe-test catalog by clicking the ⋮ Options icon for the Product , and clicking Publish.

25. Ensure that the stripe-test catalog is selected, and then click Publish.
26. You can verify that the FindBranches Product is now published by clicking the Manage icon in the side navigation bar, and selecting the stripe-test tile. The FindBranches Product is now listed under the Products tab.

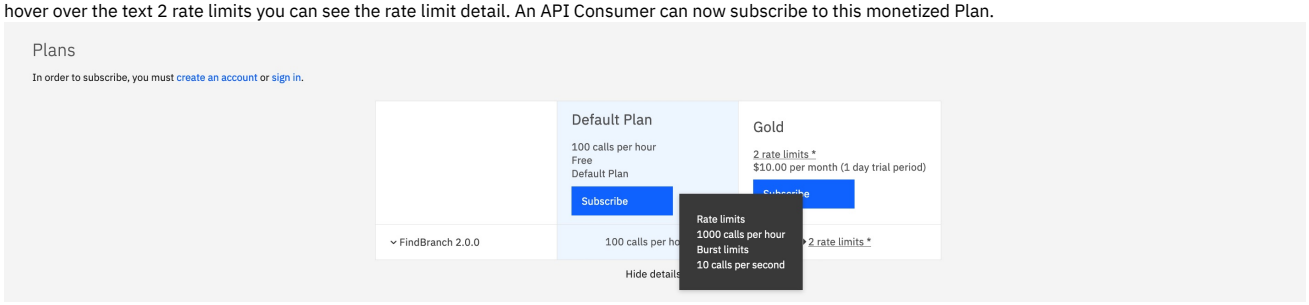
Tip: Remember to click the Refresh icon if the Product isn't displayed.

Verify the publish in your Stripe account



You can verify that the Product Plans were published into your Stripe account by completing the following steps.

1. Log in to your Stripe test account.
2. Select Events in the Developer navigation.
3. Check that events were created when you published the Product plans.



View the monetized Product in the Developer Portal

You can check that the monetized Product is now visible in the Developer Portal by completing the following steps.

1. Open the Developer Portal for the stripe-test catalog in your web browser. You don't need to log in.
2. You should see the FindBranches Product on the Home page.

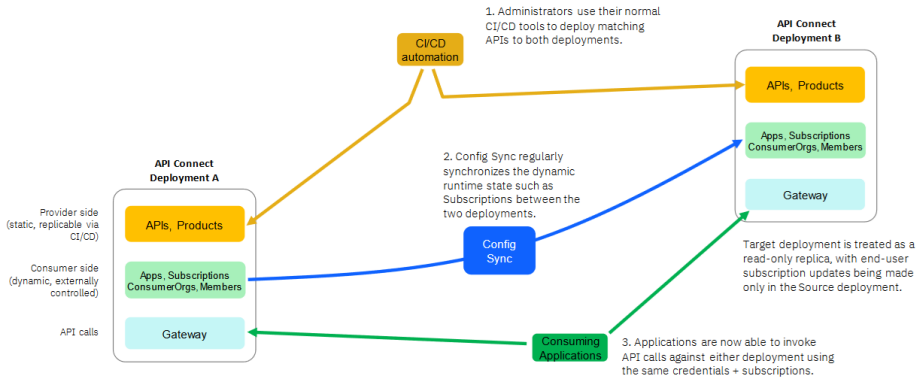
3. Click the FindBranches tile, and the Plans are displayed, showing both the Default and Gold Plans. You can see the pricing information for the Gold Plan, and if you hover over the text 2 rate limits you can see the rate limit detail. An API Consumer can now subscribe to this monetized Plan.

What you did in this tutorial

In this tutorial, you successfully created and published a monetized Product ready for API Consumer subscriptions. You completed the following activities:

- Created a Stripe billing integration resource.
- Configured a stripe-test catalog.
- Enabled Stripe in the Developer Portal.
- Created and published a monetized Product.
- Verified the publish in your Stripe account.
- Viewed the monetized Product in the Developer Portal.

Related concepts



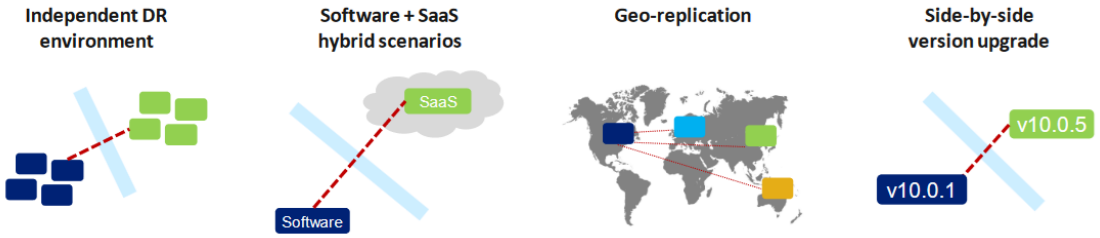
- Monetizing your products

Using Config Sync to replicate catalog data

Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

API Connect Config Sync (apic-configsync) can be run either as a stand-alone binary with a Kubernetes cronjob, to facilitate the unidirectional replication of consumer-side data (consumer organizations, members, apps, subscriptions, credentials) and Product and API from a catalog in a source API Connect cluster to a corresponding catalog in a separate, target API Connect cluster.

The following image shows how you can use Config Sync to replicate consumer-side data from a source deployment to a target deployment:



Config Sync can be run as frequently as required, and detects the differences between the replicated resource types in the source and target catalogs so that it efficiently replicates only the new changes that have been made in the source instance.

Changes that are made in a target catalog can be synced back to the source by swapping the configuration, so that the original source catalog is the designated target and the original target is the designated source. This process is known as a *reverse sync*.

As shown in the following image, Config Sync helps to enable a range of hybrid cloud API topologies such as:

- Independent disaster recovery instances
- Software and SaaS hybrid scenarios
- Geo-replication
- Side-by-side version upgrade

Requirements

For API Connect Config Sync to run successfully, the following requirements that must be satisfied:

Target cluster configuration
: The target API Connect cluster must be configured correctly, including:

  - Topology setup
  - Provider organization creation
  - Catalog creation

Replicating APIs and Products
: If you disable the product and API syncing using the **`SyncProductsAndAPIs`** environment variable, then you must manually replicate the APIs and products from the source catalog to the target catalog, either through manual procedures or CI/CD pipelines. For more information about disabling API and Product syncing, see the SyncProductsAndAPIs section.

  Note: If you need to use Product and API sync feature, ensure that both the source and target API Connect clusters run version 10.0.8.3 or later.

Target catalog settings
: The target catalog settings must be configured to match the configuration of the source catalog, including:

  - User registries
  - OAuth providers
  - TLS client profiles
  - Lifecycle approvals
  - Application lifecycle
  - Other relevant catalog settings

  If products and APIs syncing is enabled, you must set the **`catalog_settings.config_sync_target_catalog`** property to **`true`** on the target catalog. This can be done using the toolkit or REST API.

  To update the catalog settings using the toolkit, run the following command:

  ```
  ./apic catalog-settings:update -s <server_url> -o <org_name> -c <catalog_name> <catalog_setting_file>
  ```

  For example:

  ```
  ./apic catalog-settings:update -s https://api.example.com -o test_org -c test_catalog catalog_setting_file.txt
  ```

  The `catalog_setting_file.txt` should contain the following JSON:

```
{
  "config_sync_target_catalog": true
}
```

Note: Login to the `target cluster` and run the command there, not in the source.

User registries and OAuth Providers

- Compatible onboarding user registries must be configured in the target catalog with the same name and type as in the source catalog. Ensure that the target configured must be same as the source.
- If this is not possible, use the USER_REGISTRY_NAME_MAPPING variable.
- All OAuth providers must be configured on the target catalog and spaces.
- All API user registries must be configured on the target catalog and spaces.
- All TLS client profiles must be configured on the target catalog and spaces.

Connectivity and permissions
: The Config Sync utility uses the API Connect Provider REST API, so you must have connectivity to both the source and target clusters with sufficient provider organization user permissions.

Reserved metadata key
: The `metadata.source_id` key is reserved for use by Config Sync

Resource mapping
: Config Sync uses the `metadata` field of a resource to track which resources in the source catalog map to which resources in the target catalog. In addition to using the `metadata` field, API Connect Config Sync also uses the `name` field of some resources to determine a match. This is typically done for resources that are not synchronized by the utility but are needed in the target catalog for the synchronization to be successful. Examples of such resources include:

  - User Registries
  - Consumer Org Groups
  - Roles
  - Published Products (where both the `name` and `version` fields are used for product matching)

  By using a combination of the `metadata` and `name` fields, Config Sync can accurately map resources between the source and target catalogs, ensuring a successful synchronization.

Tracking resource mappings
: To track which resources in the source catalog map to which resources in the target catalog, Config Sync uses the `metadata` field of a particular resource. Specifically, when a new resource is created in the target catalog, the `metadata` field of that resource is set to contain a key named `source_id` with a value equal to the ID of the corresponding resource in the source catalog that is being synchronized.

  This process enables Config Sync to maintain a record of the relationships between resources in the source and target catalogs, ensuring that changes are accurately propagated and that resources are correctly matched across catalogs.

Note: The first time Config Sync runs, it might take longer to complete than subsequent runs require (depending on the number of resources to synchronize). The first run of the utility creates all new resources in the target cluster; subsequent runs perform only synchronization of any data that was added, updated, or deleted since the last run of the utility.

Limitations

API Connect Config Sync has the following limitations:

- Config Sync does not back up data; it merely replicates the contents of a source catalog to a target catalog. You must still take periodic backups to ensure the safety of your data.
- A reverse sync can be performed only if the original source cluster and the original target cluster are at the same VRM (Version.Release.Milestone) level. For example, API Connect 10.0.8.1 and API Connect 10.0.8.0 are at the same VRM level even though they are at different fix pack levels. A reverse sync to a different version, release, or milestone is not supported.
- Source and target deployments operate independently of each other:
  - API rate limiting on Plans is counted independently in the source catalog and the target catalog.
  - OIDC tokens are not replicated. OIDC tokens that are generated in the source cluster are not valid within the target cluster.
  - Analytics data is tracked independently in the source cluster and the target cluster. Analytics data is not replicated or aggregated across clusters.
  - Developer Portal configuration is not replicated. If you want to enable consumer organization access in the target catalog, you must replicate your Developer Portal site for consistency (restore the site with UUID/URL update where needed).
- Config Sync operates on a single source-target catalog pair at a time.
  If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

Supported versions of API Connect

Config Sync can synchronize consumer-side resources across different versions of API Connect clusters. The target cluster version must always be greater or equal to the source cluster version.

Table 1 shows the supported version combinations of API Connect:

Table 1. Supported source and target version combinations of API Connect

Source version	Target Version	Release Stream
10.0.5+	10.0.5+	Previous LTS -> Previous LTS
10.0.5+	10.0.8+	Previous LTS -> Current SC2
10.0.8+	10.0.8+	Current SC2 -> Current SC2
10.0.8+	10.0.10.0	Current SC2 -> Current CD
10.0.10.0	10.0.10.0	Current CD -> Current CD

Consumption reporting

The analytics subsystem records the number of resources that are processed during a config sync. You can see the total number of resources that were processed for a config sync at provider organization and catalog scope in the consumption dashboard of the API Manager UI. To see the number of resources processed at the cloud scope, see the consumption dashboard in the Cloud Manager UI.

For users on call volume licensing, the amount of data that is synchronized is converted to API calls and is included in your call volume license.

- **Downloading and extracting the API Connect Config Sync utility**
  Download and extract the API Connect Config Sync utility.
- **Setting environment variables for Config Sync**
  Configure environment variables that can be used by the API Connect Config Sync utility.
- **Enabling encrypted LUR user data sync**
  Enable sensitive data (passwords) of members belonging to a LUR configured for a catalog to be synced between the source cluster and the target cluster.
- **Running Config Sync as a stand-alone binary**
  The prebuilt binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.
- **Running Config Sync as a cronjob on OpenShift**
  Running the apic-configsync utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.
- **Running Config Sync as a cronjob on Kubernetes**
  Running the apic-configsync utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.

Downloading and extracting the API Connect Config Sync utility

Download and extract the API Connect Config Sync utility.

About this task

You can download Config Sync from one of the following locations:

- IBM Fix Central.
- The Cloud Manager or API Manager UI.

The Config Sync download is a compressed file called configsync.tgz that contains the following artifacts:

- A binaries directory with subdirectories that contain the apic-configsync utility for each of the supported client platforms (Mac, Windows, Linux x86, and ppc64).
- A helper_files directory that contains YAML files for configuring cronjobs if you want to run the utility on a schedule.
- An ibm-apic-configsync-image.tar.gz file that contains the docker image for running the utility on a schedule in a Kubernetes cluster with a cronjob.

Procedure

1. Download the Config Sync compressed file and credentials.
   - Download from the Cloud Manager or API Manager UI:
     - On the Welcome page, click the Download clients tile.
     - Select the Config Sync tab.
     - Click the Download link under Step 1: Download Config Sync.
     - Click the Download link under Step 2: Download credentials.
   - Download **`configsync`** from IBM Fix Central, and download the credentials from the API Manager UI:
     - Search for a file called **`configsync`** under the IBM API Connect product.
       Note: Fix Central returns the product files that you can upgrade to based on what you set in API Connect **`Installed Version`**. To find files for your current version, select a previous release. For example, if you want the **`configsync`** file from V10.0.9.0, set **`Installed Version`** to V10.0.8.1.
     - From the API Manager UI Welcome page, click the Download clients tile.
     - Click the Config Sync tab.
     - Click the Download link under Step 2: Download credentials.
2. Extract the apic-configsync package by running the following command:

   ```
   tar xzf configsync.tgz
   ```

Setting environment variables for Config Sync

Configure environment variables that can be used by the API Connect Config Sync utility.

API Connect Config Sync consumes a set of configuration properties required to connect to and perform REST calls against the source and target API Connect clusters. The configuration properties are passed to the utility with environment variables.

The following environment variables must be set to the appropriate values for the source and target API Connect cluster:

```
# Properties for source catalog
export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
export SOURCE_ORG=sourceporg
export SOURCE_REALM=provider/default-idp-2
export SOURCE_ADMIN_USER=sourceadmin
export SOURCE_ADMIN_PASSWORD=sourceadminpassword
#export SOURCE_ADMIN_APIKEY=1010101010101010
export SOURCE_CATALOG=sourcecatalog
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111
```

```
# Properties for target catalog
export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
export TARGET_ORG=targetporg
export TARGET_REALM=provider/default-idp-2
export TARGET_ADMIN_USER=targetadmin
export TARGET_ADMIN_PASSWORD=targetadminpassword
#export TARGET_ADMIN_APIKEY=2020202020202020
export TARGET_CATALOG=targetcatalog
export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
```

Locating information for the environment variables

The following list explains how to obtain the setting for each of the environment variables.

`*_MGMT_SERVER`

This property specifies the hostname and path that provides access to the REST API endpoint for your catalog. Locate **`toolkit.endpoint`** property in the toolkit **`credentials.json`** file that you downloaded in Downloading and extracting the API Connect Config Sync utility, and set the **`*_MGMT_SERVER`** variable to the value of the **`toolkit.endpoint`** property.
The value might look like the following example:

`https://platform-api.`*`hostname`*`.com/api`

`*_TOOLKIT_CREDENTIALS_CLIENTID, *_TOOLKIT_CREDENTIALS_CLIENTSECRET`

The toolkit credentials **`clientID`** and **`clientSecret`** are used to authenticate the utility to be able to make REST API calls against the API Connect cluster. Locate following properties in the toolkit **`credentials.json`** file that you downloaded in Downloading and extracting the API Connect Config Sync utility, and set the environment variables as shown:

- Set the **`*_TOOLKIT_CREDENTIALS_CLIENTID`** variable to the value of the **`toolkit.client_id`** property
- Set the **`*_TOOLKIT_CREDENTIALS_CLIENTSECRET`** variable to the value of the **`toolkit.client_secret`** property

`*_ORG`

This is the short name of the provider organization in which your catalog is hosted. Set the **`*_ORG`** variable to the value of the provider organization's **`Name`** property.
To locate the provider organization name, complete the following steps:

1. Log in to the API Manager.
2. From the Home tab, select Manage settings.
3. On the Settings page, click the Overview tab and locate the value of the **`Name`** property (not the **`Title`**).

`*_REALM`

This property specifies the identity provider realm of the API Manager registry for your instance of API Connect. Set the **`*_REALM`** variable to the value of the realm name. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see **`*_API_KEY`** for details).
To obtain the realm name, run the following toolkit CLI command:

`apic identity-providers:list --scope provider --server <`*`mgmt_endpoint_url`*`> --fields title,realm`

where **`<`*`mgmt_endpoint_url`*`>`** is the API Manager URL with any segments (for example, **`/manage`**) removed from the end of the URL. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints.

The following example shows a response listing the available realms for a deployment:

`apic identity-providers:list --scope provider --server <`*`mgmt_endpoint_url`*`> --fields title,realm`

```
total_results: 2
results:
  - title: 'API Manager User Registry'
    realm: 'provider/default-idp-2'
  - title: 'Common Services User Registry'
    realm: 'provider/common-services'
```

In the example, the realm for the API Manager registry is **`provider/default-idp-2`**.

For more information on obtaining the realm name, see How to determine the identity provider.

`*_CATALOG`

This property indicates the name of the Catalog that you want to synchronize. Set the **`*_CATALOG`** variable to the value of the catalog's **`Name`** property.
To locate the catalog name, complete the following steps:

1. Log in to the API Manager UI.
2. From the Home tab, select Manage catalogs.
3. Select the tile for the catalog you want to synchronize.
4. Click the Catalog settings tab.
5. On the Settings page, locate the value of the catalog's **`Name`** property (not the **`Title`**).

`*_ADMIN_USER`

This property is the name of the user account under which you will authenticate to the catalog. Set the **`*_ADMIN_USER`** variable to the value of the username that the utility will log in with to perform the synchronization task. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see **`*_API_KEY`** for details).
In the source catalog, the user must be a Catalog Administrator or Organization Administrator with the ability to create consumer objects on behalf of the end users.
In the target catalog, the user must have authorization to update catalog settings and enable or disable the **`hash_client_secret`** property.

To confirm the username, complete the following steps:

1. Log in to the API Manager UI with the user account you will use to synchronize the catalog.
2. Click the username in the page header.
3. Select My account.

4. Locate the value of the Username property.

`*_ADMIN_PASSWORD`
In most cases you will authenticate to the API Manager with the password associated to your username. Set the **`*_ADMIN_PASSWORD`** property to your password, being careful with any non-alphanumeric characters that may be in your password. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see **`*_API_KEY`** for details).
Attention: If you set the **`*_ADMIN_PASSWORD`** variable, then skip the **`*_ADMIN_APIKEY`** variable. Do not set both variables when synchronizing a particular catalog.

`*_ADMIN_APIKEY`
In API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example API Connect Enterprise as a Service), you must authenticate using an API key instead of your password.
To locate your API key, complete the following steps:

1. Log in to the API Manager UI using your IBM ID.
2. In the page header, click  and select My API Keys.
3. On the My API Keys page, click Add.
4. Set a title and description for your new API key and click Create.
5. Copy the new API key from the dialog box.

Attention: If you set the **`*_ADMIN_APIKEY`** variable, then skip the **`*_ADMIN_PASSWORD`** variable. Do not set both variables when synchronizing a particular catalog.

Setting the environment variables

- Mac and Linux x86:
  On Mac or Linux x86, you can either export the environment variables individually on the command line directly or create a script to export the environment variables and source that file from the command line, as in the following example:

```
# Properties for source catalog
export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
export SOURCE_ORG=sourceporg
export SOURCE_REALM=provider/default-idp-2
export SOURCE_ADMIN_USER=sourceadmin
export SOURCE_ADMIN_PASSWORD=sourceadminpassword
#export SOURCE_ADMIN_APIKEY=1010101010101010
export SOURCE_CATALOG=sourcecatalog
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111

# Properties for target catalog
export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
export TARGET_ORG=targetporg
export TARGET_REALM=provider/default-idp-2
export TARGET_ADMIN_USER=targetadmin
export TARGET_ADMIN_PASSWORD=targetadminpassword
#export TARGET_ADMIN_APIKEY=2020202020202020
export TARGET_CATALOG=targetcatalog
export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
```

  In the example, notice that the command to set the **`*_ADMIN_APIKEY`** variable is commented out because the **`*_ADMIN_PASSWORD`** is used instead.

- Windows:
  On Windows, you can set each environment variable individually by opening a command window and running the following command for each variable:

```
setx <variable_name> "<variable_value>"
```

  where:
  - ***`<variable_name>`*** is the name of the environment variable to set
  - ***`<variable_value>`*** is the value to set for the specified variable name

  Alternatively, you can create a batch file that uses the **`setx`** command to set the environment variables, as in the following example:

```
REM Properties for source catalog
setx SOURCE_MGMT_SERVER "https://yoursourcehostname.com/path"
setx SOURCE_ORG "sourceporg"
setx SOURCE_REALM "provider/default-idp-2"
setx SOURCE_ADMIN_USER "sourceadmin"
setx SOURCE_ADMIN_PASSWORD "sourceadminpassword"
REM setx SOURCE_ADMIN_APIKEY "1010101010101010"
setx SOURCE_CATALOG "sourcecatalog"
setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTID "00000000-0000-0000-0000-000000000000"
setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET "11111111-1111-1111-1111-111111111111"

REM Properties for target catalog
setx TARGET_MGMT_SERVER "https://yourtargethostname.com/path"
setx TARGET_ORG "targetporg"
setx TARGET_REALM "provider/default-idp-2"
setx TARGET_ADMIN_USER "targetadmin"
setx TARGET_ADMIN_PASSWORD "targetadminpassword"
REM setx TARGET_ADMIN_APIKEY "2020202020202020"
setx TARGET_CATALOG "targetcatalog"
setx TARGET_TOOLKIT_CREDENTIALS_CLIENTID "22222222-2222-2222-2222-222222222222"
setx TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET "33333333-3333-3333-3333-333333333333"
```

  In the example batch file, notice that the command to set the **`*_ADMIN_APIKEY`** variable is commented out because the **`*_ADMIN_PASSWORD`** is used instead.

Optional environment variables

USER_REGISTRY_NAME_MAPPING
: By default config sync requires that user registries in the target catalog have the same name and type as the user registries in the source catalog.

  If your source user registries have different names on your target, then you can use the **USER_REGISTRY_NAME_MAPPING** variable to map each source registry name to a target registry name.

  The format of **USER_REGISTRY_NAME_MAPPING** is as follows:

  ```
  USER_REGISTRY_NAME_MAPPING="source-ur1,target-ur1;source-ur2,target-ur2"
  ```

  Use a comma to separate source and target registry names.

  If you have multiple user registries to map, then use a semi-colon as a separator.

API_CACHE_REQUEST_PAGE_SIZE
: Use the environment variable to specify the number of APIs you want to fetch and cache in a single GET request . If you do not set this variable, the default page size of 100 is used.

SyncProductsAndAPIs
: Set the environment variable **SyncProductsAndAPIs** to `False`, if you want to disable the Product and API sync feature. By default, the Product and API sync feature is enabled.
  Note: Product and API is synced only when the target API Connect cluster are deployed on 10.0.8.2 or later.

Enabling encrypted LUR user data sync

Enable sensitive data (passwords) of members belonging to a LUR configured for a catalog to be synced between the source cluster and the target cluster.

About this task

An LUR (Local User Registry) can be configured with a JWKS (JSON Web Key Set) to enable the encryption and decryption of sensitive user data. The JWKS is added to the organization in the target API Connect cluster, which contains the LUR that is configured with the target catalog. The JWKS is then added to the LUR that is configured with the target catalog. Next, the public key of the JWKS is added to the corresponding LUR in the source cluster. Once configured, subsequent runs of the Config Sync retrieves the encrypted user data from the source and sync it with the target.

Note: Encrypted user data is synced only when both the the source and target API Connect clusters are deployed on 10.0.8.0 or later.

Procedure

Configure a JWKS for the target LUR:

1. In the target deployment, log in to API Manager that uses the API Connect provider organization that owns the target catalog (where the LUR is defined).
2. Click  > Crypto Material.
3. On the crypto page, look in the JWK Set section and click Create.
4. On the Create JWK Set page, either provide an existing JWK Set or generate a new one:
   - To use an existing set, complete the following steps:
     - Provide a name for the JWKS in the Key set title field.
     - Enter the values into the JWK private key and JWK public key fields.
       Note: Ensure that both the public and private keys include a **kid** property with the same **uuid** value; for example, :

       ```
       "kid":"1facd4b7-4dac-409f-949c-9f0cb2f98689",
       ```

     - Save a copy of the keys:
       - You use the JWK public key later in this task.
       - If you plan to perform a reverse sync (see What to do next) between the target catalog and the source catalog, you use the JWK private key to complete that task.
     - Click Save.
   - To generate a JWKS, complete the following steps:
     - Provide a name for the JWKS in the Key set title field.
     - Click Generate to populate the JWK private key and JWK public key fields.
     - Save a copy of the keys:
       - You will use the JWK public key later in this task.
       - If you plan to perform a reverse sync (see What to do next) between the target catalog and the source catalog, you use the JWK private key to complete that task.
     - Click Save.
5. On the Resources page, navigate to the Local User Registry that is configured with the target catalog by clicking User registries and then selecting the appropriate registry.
6. On the Edit local user registry page, locate the Additional Support section.
7. In the Key set for data import field, select the JWKS that you created for this LUR.
8. In the JWK public key for data export field, paste the JWK public key that you used for creating the JWK Set.
9. Click Save.

Provide the target LUR's JWK public key to the corresponding LUR in the source deployment:

10. In the source deployment, log in to API Manager that uses the API Connect provider organization that owns the source catalog (where the LUR is defined).
11. Click  > User registries and then select the LUR that corresponds to the LUR you worked with in the target deployment.
12. In the JWK public key for data export field, paste the JWK public key that you used for creating the JWK Set.
13. Click Save.

Results

The LUR in your source catalog is now configured to encrypt sensitive user data, and the LUR in your target catalog is configured to both encrypt and decrypt the sensitive data.

The next time that you run Config Sync, the sensitive data (passwords) of users in the LUR will be synced from the source to the target to enable consumer org members to log in to the target cluster using the same password.

What to do next

(Optional) Configure support for sensitive data with a reverse sync:

Changes made in a target catalog can be synced back to the source by swapping the configuration so that the original source catalog is the designated target and the original target is the designated source. This process is known as a *reverse sync*. If you want to enable the sensitive user data to be synced as part of a reverse sync scenario, create a new JWKS in the source API Connect deployment and use the same public or private key pair as the JWKS in the target deployment. Then, edit the LUR that is configured with the source catalog and select the JWKS in the Key set for data import field.

Running Config Sync as a stand-alone binary

The prebuilt binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

About this task

Running a stand-alone invocation of apic-configsync that uses one of the prebuilt binaries is the most flexible option. For optimal performance, apic-configsync should run as close to the target cluster as possible.

Complete the following steps to configure environment variables and run the stand-alone binary.

Procedure

1. Download and extract the API Connect Config Sync package.
2. In the extracted package, navigate to the /binaries/*<platform>* directory that contains the appropriate version of the apic-configsync utility for your platform.
3. Define the environment variables for the source and target catalogs.
4. Run the utility with the following command:
   - Mac and Linux x86: `./apic-configsync`
   - Windows: `apic-configsync.exe`

Running Config Sync as a cronjob on OpenShift

Running the apic-configsync utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry.
  The examples in this topic use `skopeo` to copy the image to the target registry, but you could use equivalent `docker` or `podman` commands instead.
- Expose the OpenShift registry with `defaultRoute` by running the following command:

  ```
  oc patch configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}' --type=merge
  ```

  For more information, see Exposing the registry in the OpenShift documentation. It is not necessary to perform step 5 (the "podman login" step) in the instructions.
- Set the `REGISTRY_HOST` environment variable to the OpenShift registry by running the following command:

  ```
  REGISTRY_HOST=$(oc get route default-route -n openshift-image-registry --template='{{ .spec.host }}')
  ```

- Set the `APIC_PROJECT` environment variable to the namespace (project) where you intend to run the cronjob. For optimal performance, the cronjob should run within the same OpenShift environment as the target API Connect cluster.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on OpenShift or Cloud Pak for Integration. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same OpenShift environment as the target API Connect cluster.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

   ```
   tar xf ibm-apic-configsync-image.tar.gz
   ```

3. Copy the extracted Config Sync image to the target registry.
   For example, if you use skopeo, run the following command:

   ```
   skopeo copy --dest-tls-verify=false --dest-registry-token=$(oc whoami -t) dir:./ibm-apic-configsync/ibm-apic-configsync-<version>/<tag> docker://$REGISTRY_HOST/$APIC_PROJECT/ibm-apic-configsync-<version>:<tag>
   ```

   Replace ***<version>*** and ***<tag>*** with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

4. Define the environment variables for the source and target catalogs.
5. Create secrets to host configuration details for the source cluster and the target cluster.
   a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

   ```
   oc create secret --namespace $APIC_PROJECT generic source-catalog-details \
       --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
       --from-literal=SOURCE_ORG=$SOURCE_ORG \
       --from-literal=SOURCE_REALM=$SOURCE_REALM \
       --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
       --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
       --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

   b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

   ```
   oc create secret --namespace $APIC_PROJECT generic target-catalog-details \
       --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
       --from-literal=TARGET_ORG=$TARGET_ORG \
       --from-literal=TARGET_REALM=$TARGET_REALM \
       --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
       --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
       --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

6. Create the cronjob:
   a. Open the **helper_files/configsync-cronjob-ocp.yaml** file located in the extracted API Connect Config Sync package.
   b. Modify the **schedule** property to specify how frequently the job will run.
   The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.

   c. Set the **concurrencyPolicy** to **Forbid**.
   Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

   d. In the **image** property, replace the ***<APIC_PROJECT>*** variable with the namespace (project) where you will run the cronjob.
   e. Create the cronjob resource in the cluster by running the following command:

   ```
   oc --namespace $APIC_PROJECT apply -f helper_files/configsync-cronjob-ocp.yaml
   ```

Running Config Sync as a cronjob on Kubernetes

Running the apic-configsync utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry.
  The examples in this topic use **skopeo** to copy the image to the target registry, but you could use equivalent **docker** or **podman** commands instead.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on Kubernetes. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same Kubernetes environment as the target API Connect cluster.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

```
tar xf ibm-apic-configsync-image.tar.gz
```

3. Copy the extracted Config Sync image to the target registry.
   For example, if you use skopeo, run the following command:

   ```
   skopeo copy dir:./ibm-apic-configsync/ibm-apic-configsync-<version>/<tag> docker://<registry>/ibm-apic-configsync/ibm-apic-configsync-<version>:<tag>
   ```

   Replace ***<version>*** and ***<tag>*** with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

   Replace ***<registry>*** with the actual registry value for your image registry. Refer to the skopeo documentation on configuring credentials for your destination registry.

4. Define the environment variables for the source and target catalogs.
5. Create secrets to host configuration details for the source cluster and the target cluster.
   a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

   ```
   kubectl create secret --namespace <namespace> generic source-catalog-details \
       --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
       --from-literal=SOURCE_ORG=$SOURCE_ORG \
       --from-literal=SOURCE_REALM=$SOURCE_REALM \
       --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
       --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
       --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

   b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

   ```
   kubectl create secret --namespace <namespace> generic target-catalog-details \
       --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
       --from-literal=TARGET_ORG=$TARGET_ORG \
       --from-literal=TARGET_REALM=$TARGET_REALM \
       --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
       --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
       --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

6. Create the cronjob:
   a. Open the `helper_files/configsync-cronjob-k8s.yaml` file located in the extracted API Connect Config Sync package.
   b. Modify the `schedule` property to specify how frequently the job will run.
      The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.

   c. Set the `concurrencyPolicy` to `Forbid`.
      Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

   d. In the `image` property, replace the ***<registry>*** variable with the actual registry value for your image registry.
   e. Create the cronjob resource in the cluster by running the following command:

   ```
   kubectl --namespace <namespace> apply -f helper_files/configsync-cronjob-k8s.yaml
   ```

Authoring policies

With the on-premise offering, you can control specific processing features in the Gateway server of IBM® API Connect by creating user-defined policies.

IBM API Connect enables organizations to easily promote business services as APIs to internal and external developer communities. API developers can rapidly create, proxy, assemble, and secure APIs through the API Designer user interface (UI). The API Designer assembly feature allows API developers to create complex REST or SOAP API operations that transform data, perform multiple service calls, aggregate data, and apply policies.

A policy is a piece of configuration that controls a specific aspect of processing in the IBM DataPower® Gateway server during the handling of an API invocation at run time. IBM API Connect provides a number of different types of policies, but you can also create user-defined policies to provide more processing control.

When would you need a user-defined policy?

A user-defined policy enables you to control extra processing features in the Gateway server, such as security, or routing of requests. The user-defined policies feature is available only with the on-premise offering of IBM API Connect.

Create a user-defined policy in IBM API Connect when you need to augment the actions or activities that are performed by the API gateway. For example, you might want to perform the following operations:

- Implement your own proprietary logic for dynamic routing of requests.
- Enforce extra security constraints to your API.
- Make accessible an extra capability that is provided in DataPower that is not yet accessible in the IBM API Connect policy catalog.

Note: For best results, do not try to update your existing user-defined policies, because those are already in use by your APIs. Instead, create a new version of the policy that you want to update, and then modify the API assembly to use the newer version of the policy.
See the following topics for more information about user-defined policies, and how to create and import them into IBM API Connect:

- **Authoring policies for the DataPower Gateway (v5 compatible)**
  A user-defined policy for the DataPower Gateway (v5 compatible) consists of a package that contains a YAML definition file that describes the policy, together with

the policy implementation files. You import the package into one or more Catalogs in your IBM API Connect environment to make the policy available to APIs that are published to those Catalogs.

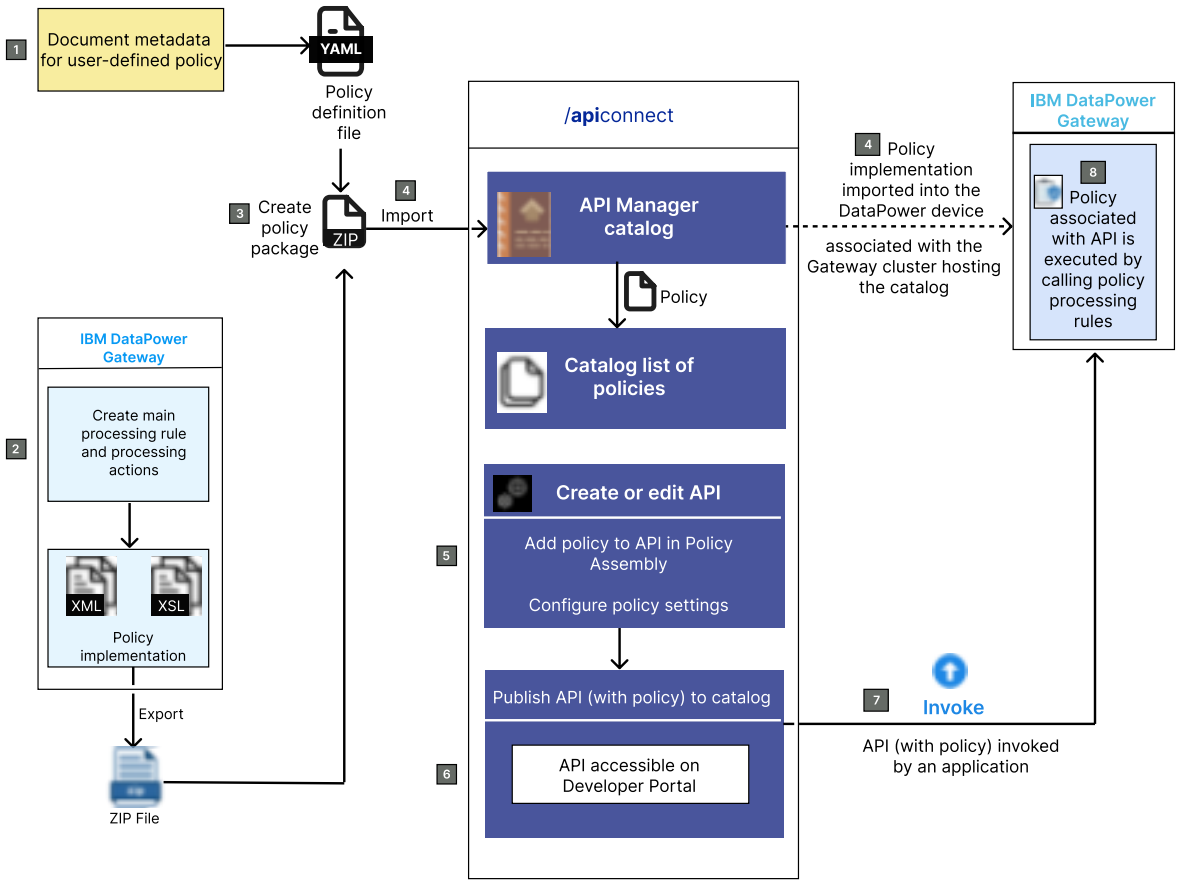
DataPower Gateway (v5 compatible) only

Authoring policies for the DataPower Gateway (v5 compatible)



A user-defined policy for the DataPower® Gateway (v5 compatible) consists of a package that contains a YAML definition file that describes the policy, together with the policy implementation files. You import the package into one or more Catalogs in your IBM® API Connect environment to make the policy available to APIs that are published to those Catalogs.

How do user-defined policies work?

A user-defined policy is implemented as a DataPower processing rule. After a policy is imported into an IBM API Connect Catalog, the policy is available to be placed into an assembly flow of an enforced API. When the API is published, and invoked by an application, the API Gateway executes all policies that are associated with this API. An API Gateway that is running in DataPower calls the IBM DataPower Gateway processing rules that those policies implement.

The following diagram provides an overview of how to create and execute a user-defined policy in IBM API Connect.

Figure 1. The user-defined policy process

For details on how to define and deploy user-defined policies for the DataPower Gateway (v5 compatible), see the following subtopics:

DataPower Gateway (v5 compatible) only

Describing your policy

Describe your user-defined policy by creating a definition file in YAML format to document metadata about the policy.

About this task

A policy YAML file contains the following sections:

- A specification version.
- An information section.
- An attach section.
- A properties section.
- A gateways section.

You can create a policy YAML file by using any editor of your choice. Both .yaml and .yml file extensions are supported, but the use of the .yaml file extension is recommended by yaml.org.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Procedure

The following steps describe how to construct a policy YAML file.

1. Set the specification version by adding the following line to the beginning of the file: `policy: 1.0.0`.
2. Complete the information section with details about the policy by using the following syntax:

```
info:
  title: Title of policy
  name: shortnameofpolicy
  version: 1.0.0
  description: An example policy
  contact:
    name: name1
    url: url1
    email: email1
```

   where:
   - `title` is the title of the policy. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - `name` is the short name for the policy and must contain only alphanumeric characters, the - (dash) character, and the _ (underscore) character (blank spaces are not supported). The name is case-sensitive, and should be 20 characters or less so that it can be displayed in the API Manager user interface. In the example, the name is shown as `<policy-name>`.
     Important: The policy short name must be different from the OpenAPI names of the built-in policies, otherwise it will cause a policy conflict in the API assembly definition. For a list of the OpenAPI built-in policy names, see execute. Also, consider including an appropriate unique prefix or suffix string in the short names of your user-defined policies to prevent possible name conflicts with future built-in policies.
     Note: The `name:` property must be identical to the Node.js module name.
   - `version` is the version number of the policy. This is a reserved property.
     Tip: The *version.release.modification* version numbering scheme is recommended, for example *1.0.0*.
     Note: The `info.version` in policy.yaml must match the `version` indicated in package.json.
   - `description` (optional) is a short description of the policy.
   - `contact` (optional) is the contact information for the policy, where:
     - `name` (string) is the identifying name of the contact person or organization.
     - `url` (string) is the URL that points to the contact information.
     - `email` (string) is the email address of the contact person or organization.
3. Complete the attach section by specifying which type of API flow the policy can be attached to.

```
attach:
 - rest
 - soap
```

   where:
   - `rest` indicates that this policy can be attached to a REST API flow.
   - `soap` indicates that this policy can be attached to a SOAP API flow.

   The attach section must contain at least one API flow type. If a policy can be attached to both API flow types, they must both be indicated in the attach section.

4. Complete the properties section by defining a JSON schema (based on JSON Schema Specification Draft 4, but rendered in YAML format) that contains the list of properties the policy will declare as required input. These properties are presented to the API author at development time, when the properties can be configured or mapped to values as required.
   The JSON schema defines a root object that contains the following JSON properties:
   - `type`
   - `properties`
   - `required`

   The syntax and definition of these properties matches the JSON schema definition. The following code block shows an example of a simple schema that defines one required property (*a_property*):

```
properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    a_property:
    label: a label
    description: a description
    type: a type
  required:
    - a_property
```

The root *type* of the schema must be an **object**, as shown in the example schema. You can define zero or more properties in the schema. Required properties are declared by using the **required** parameter, as shown in the example schema. The policy will not be accessible in the API Manager assembly editor, unless all the required properties have values. Each property is an object with the following items:

- **label** is a short name for the property and is displayed in the Name column of the API Manager assembly editor.
- **description** is a short description for the property and is displayed in the Description column of the API Manager assembly editor.
- **type** must be one of the following primitives that are supported:
  - *integer*
  - *number*
  - *string*
  - *boolean* (this primitive is shown as a check box in the assembly editor)
  - *array*
- **default** (optional) specifies a default value for the property.
- **enum** (for properties with a **type** of *string*) is an array of valid values.

5. In your gateways section, specify that the policy is for the DataPower® Gateway.
   Enter the following code:

```
gateways:
  - datapower-gateway
```

6. Save the new policy as a YAML file using the value of the **name** property (in the **info** section) as the file's name.
   Required: To ensure a successful import, the YAML file must use the name specified in the policy's **name** property.

Results

You have created a user-defined policy definition YAML file that documents metadata about your policy.

Example

The following code block shows an example of a policy definition file that contains all the supported primitives. This policy must be saved as sampleimpl.yaml to ensure that it can be imported into API Connect.

```
policy: 1.0.0

info:
  title: Sample Policy
  name: sampleimpl
  version: 1.0.1
  description: This is a sample policy.
  contact:
    name: Steve Product Manager
    url: http://developer.acme.com/contacturl
    email: steve-product-manager@someemailservice.com

attach:
  - rest
  - soap

properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    samplestring:
      label: String Property
      description: Sample string property
      type: string
    sampleboolean:
      label: Boolean Property
      description: Sample boolean property
      type: boolean
    sampleinteger:
      label: Integer Property
      description: Sample integer property
      type: integer
    samplenumber:
      label: Number Property
      description: Sample number property
      type: number
    samplestringwithenum:
      label: Enum Property
      description: Sample string enum property
      enum:
        - one
        - two
        - three
      default: one
      type: string
    samplearray:
      label: Array of properties
```

```
      description: Sample array of properties
      type: array
      items:
        type: object
        properties:
          string:
            label: String Property
            description: Sample string property in array
            type: string
          boolean:
            label: Boolean Property
            description: Sample boolean property in array
            type: boolean
        required:
          - string
  required:
    - samplestring
    - sampleboolean
    - sampleinteger
    - samplenumber
    - samplearray

gateways:
  - datapower-gateway
```

In the following code block, an example of a policy definition file for modifying message payload is shown.

```
policy: 1.0.0

info:
  title: Run GatewayScript
  name: gatewayscript-policy
  version: 1.0.0
  description: Execute GatewayScript
  contact:
    name: IBM DataPower Samples
    url: https://github.com/ibm-datapower/
    email: steve-product-manager@ibm.com

attach:
  - rest
  - soap

gateways:
  - datapower-gateway

properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    source:
      label: "GatewayScript Source"
      description: "The location of the GatewayScript file to execute"
      type: string
      default: store:///identity.js
    value:
      label: "New Value"
      description: "The value to be added to the payload"
      type: string
      default: "Hello Policy"
required:
    - source
    - value
```

What to do next

Create an implementation for your user-defined policy by using DataPower processing rules and actions. For more information, see Implementing your policy.

DataPower Gateway (v5 compatible) only

Implementing your policy

Create an implementation for your user-defined policy by using DataPower® processing rules and actions.

Before you begin

You must create a policy YAML file before you create an implementation. For more information, see Describing your policy.

You can create an implementation for your policy by using the usual tools available to IBM® DataPower Gateway developers. However, the DataPower user interface is typically the tool that is used to create processing rules and actions.
Note: You must be skilled in DataPower tooling and concepts, before you can create a policy implementation.
In order for your processing actions to work well under the API Gateway configuration, and also to enable the use of contextual information that is relevant to the processing actions, a library of functions and templates is available that you can use to assist you in writing the XSLT or GatewayScript transformations. This library provides the following mechanisms:

- Access to input property values (input from the assembly editor).
- Access to context values (the API Gateway runtime context).
- Access to the runtime payload message and media-type.
- Ability to modify the payload message.
- Ability to end the policy execution with an error.

About this task

You create an implementation for your user-defined policy in the IBM DataPower Gateway. The implementation must adhere to the following conventions:

1. You must create a main processing rule, and this rule will be the starting point for the policy. The rule name must start with the name of the policy (the value of the **`name`** property in the "info" section of the policy YAML file), followed by -main; for example *checkmembership-main*.
2. There are no restrictions on what actions the processing rule can execute, on condition that the rule adheres to the naming convention in point 1. and the instructions that are detailed in this topic.
3. The names of the processing actions and all other objects also must start with the name of the user-defined policy (the value of the **`name`** property in the "info" section of the policy YAML file).
4. If your processing rule runs transformation actions that use XSLT or GatewayScript files, these files must be stored in the following location: local://policy/*<policy-name>*.
5. If you have certificate and key files that must be stored in the cert: folder, the names of these files also must start with the name of the user-defined policy (as defined in the policy YAML file).
6. If your policy is using GatewayScript transformations, your policy code must require **`apim.custom.js`**, for example:

```
var apic = require('local://isp/policy/apim.custom.js');
```

The following steps describe how to create an implementation for your user-defined policy:

- Create a main processing rule.
- Create one or more processing actions:
  - Configure access to input properties.
  - Configure access to the runtime context.
  - Configure access to the input payload.
  - Configure access to the HTTP headers.
  - Modify the payload in XSLT or gatewayscript.
  - Configure the implementation to produce error information.
  - Set variables.
- Export your policy implementation.

.

Procedure

1. Create a main processing rule that is called *<policy-name>*-main where *<policy-name>* is the name of your user-defined policy (the value of the **`name`** property in the "info" section of the policy YAML file).
   Note: You must specify the following processing rule settings:
   - Rule direction: Both Directions
   - Non-XML Processing: on
2. Create one or more processing actions.
   Each processing action should have a unique name and must start with the name of the user-defined policy (as defined in the policy YAML file).
   Note: Different processing actions in DataPower might require different releases of the DataPower firmware. When using the GatewayScript actions, the minimum DataPower firmware that should be used is version 7.2.0.
   The following processing actions are available:

   - Configure access to the input properties in XSLT (**`policyProperties`**), or in GatewayScript (**`apic.getPolicyProperty`**).
     If required by the properties that are defined in the policy YAML file, when the policy is attached to an API the API developer must enter the input settings or variables for a particular property. This function provides the mechanism to retrieve these input settings or variables at run time. For an example code snippet, see Access to input properties code snippet.

   - Configure access to the runtime context in XSLT (**`getContext`**), or in GatewayScript (**`apic.getContext`**).

When an API is invoked, runtime information about the request can be accessed by using a user-defined policy, and this information is known as the runtime context. The function **getContext** provides the mechanism to access this runtime context. For an example code snippet, see Access to runtime context code snippet. For a complete list of context variables, see API Gateway context variables.

- Configure access to the input payload in XSLT (**payloadRead**), or in GatewayScript (**apic.readInput(callback)**).
  Some policies require access to the input message or payload that is provided by the application. Accessing the input message or payload during an assembly flow can be difficult, as this information might change as the policies and the assembly steps run. This function provides a mechanism to get the correct input message or payload at the time of policy execution. For an example code snippet, see Access to input payload code snippet.

  This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.

  Note: The **payloadType()** function can be called to determine what type of payload (XML or JSONx) will be returned by the **payloadRead()** or the **apic.readInput(callback)** function.
- Configure access to the HTTP headers in XSLT (**getContext**), or in GatewayScript (**apic.getContext**).
  The HTTP header information of a request can be retrieved from the request context. The HTTP header names are normalized to lowercase. The function **getContext()** provides the mechanism to access the HTTP header information. For an example code snippet, see Access to HTTP headers code snippet.

  Note: Access or modification of HTTP headers by using DataPower extensions, such as **dp:set-request-header**, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.
- Modify the payload in XSLT or GatewayScript.
  When a policy implementation is required to change a payload message, you must configure the DataPower Transform Processing Action to set the Output context field to *OUTPUT* (referred to as the *OUTPUT* named context).

  The output must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. To assist the API Gateway policy framework to accept the new or transformed message, call the **apim-output** template. For an example code snippet, see Modify the payload code snippet.

  Note: The modify the payload processing action works only with a proxy task. An HTTP or web service task always overwrites the output of a policy implementation.
- Configure the implementation to produce error information.
  If you require your policy implementation to produce error information when there is a failure, you must configure the implementation by calling the error template. For an example code snippet, see Configure error information code snippet.

- Set variables.
  Use the **setVariable** template to set a runtime variable to a specified string value. This value can then be retrieved by using the function **getVariable()**, or by mapping the value into a step. For an example code snippet, see Set variables code snippet.

3. Export your policy implementation from DataPower.
   From the DataPower user interface, export the objects and files that are referenced by your main processing rule as a compressed file. No other objects or files should be exported. The following file list is an example configuration of an export from DataPower:

```
Archive: checkmembership.zip

11819    11-19-2014 22:53 dp-aux/basetypes.xml
3028207  11-19-2014 22:53 dp-aux/drMgmt.xml
6456     11-19-2014 22:53 dp-aux/map-dmz.xsl
7299     11-19-2014 22:53 dp-aux/management.xsl
23130    11-19-2014 22:53 dp-aux/SchemaUtil.xsl
216003   11-19-2014 22:53 dp-aux/clixform.xsl
5284     11-19-2014 22:53 local/policy/checkmembership/check.xsl
5061     11-19-2014 22:53 export.xml
```

   The example shows the exported configuration file (export.xml) that contains all the processing actions and DataPower objects, the referenced files, and the DataPower configuration schemas that are created by using the configuration export in the DataPower user interface.

Results

You have created an implementation for your user-defined policy and exported this implementation from the DataPower user interface.

What to do next

Create a user-defined policy package that can then be imported into IBM API Connect. For details, see Packaging and importing your policies into IBM API Connect.

DataPower Gateway (v5 compatible) only

Packaging and importing your policies into IBM API Connect

Make your user-defined policy available to API developers by packaging it and importing it into an IBM® API Connect Catalog.

Before you begin

Before you can package a user-defined policy and import it into IBM API Connect, you must complete the following tasks:

1. Describe your policy in a YAML file.
2. Implement your policy by using DataPower processing rules and actions.

Procedure

To package and import your user-defined policy, complete the following steps:

1. Create a .zip file that contains the following folder structure:

   ```
   <policy-name>.yaml
   implementation/
                policy-name.zip
   ```

   where
   - *<policy-name>*.yaml is your policy definition file. The YAML file must use the name that is specified in its `name` property.
   - implementation/*policy-name*.zip is your policy implementation for a policy that is deployed to the DataPower Gateway. The policy implementation file contains the DataPower processing rules and actions that were exported from DataPower in step 2.

   The name of the .zip file must start with the name of the user-defined policy (as defined in the policy YAML file). If the implementation requires certificate and key files, these files must be added to the implementation directory.

   Note: Your package .zip file must contain a .zip policy implementation file.
2. Use the API Manager user interface to import your policy into a Catalog. For more information, see Importing a user-defined policy into a Catalog.
   Note:
   - You must import your user-defined policy into every Catalog in API Manager that you require your policy to run in.
   - For the policy to be displayed on the palette in the API assembly editor, you must import the user-defined policy into the Sandbox Catalog.

What to do next

Make your user-defined policy package accessible to the API Designer UI. To display user-defined policies in the API Designer UI, edit the .apiconnect/config file to point to the directory containing the policy.yaml file. You can edit the global config file (~/.apiconnect/config) or a project-specific config file (~/ProjectA/.apiconnect/config). Follow these steps:

1. Create one or more directories to hold your policy.yaml files that are accessible to Node.js, and copy the user-defined policy package into this directory. For example, create directories named /ProjectA/Policies and /ProjectB/Policies.
2. Extract the policy package so that the folder structure is visible, for example *policy*.yaml and implementation/*policy-name*.zip. The file containing the custom policies must be named policy.yaml.
3. Add the `userPolicies: [ ]` array object to the config file in ~/*ProjectA*/.apiconnect/ or ~/.apiconnect/, and edit the array object so it contains the absolute path to the director(ies) containing the policy.yaml file.
   Following is an example of an ~/.apiconnect/config file showing the userPolicies entry pointing to the directory containing the policy.yaml file:

   ```
   apim_server: us.apiconnect.ibmcloud.com
   us.apiconnect.ibmcloud.com.meta:
    formFactor: BLUEMIX_PUBLIC
    serverCapabilities:
       authTypes:
         - basic
         - token
    toolkit:
       version_recommended: 2.1.30
       version_minimum: 2.1.30
   catalog: >-
     apic-catalog://us.apiconnect.ibmcloud.com/orgs/sampleorg-myspace2/catalogs/sb
   app: >-
     apic-app://us.apiconnect.ibmcloud.com/orgs/sampleorg-myspace2/apps/acme-bank
   userPolicies:
     - /ProjectA/Policies
   ```

   Note:
   - The `userPolicies: []` array object contains a list of absolute paths to the policy director(ies). The values can point to a parent location, for example `userPolicies: ["~/mypolicies"]`. Alternatively, each policy location can be specified in the array, for example `userPolicies: ["~/mypolicies/policya", ~/mypolicies/policyb"]`. However, do not use both of these approaches in the same directory. For example, do not create policies in a directory structure like this ~/mypolicies, ~/mypolicies/policya, and ~/mypolicies/policyb.
4. Open the API Designer UI. The user-defined policy is available on the policy assembly palette, and you can add the policy to your API definition.

  Example code snippets to help the creation of a user-defined policy implementation.

DataPower Gateway (v5 compatible) only

Implementation code examples

Example code snippets to help the creation of a user-defined policy implementation.

Note: If you are using GatewayScript, you must include the following command:

```
var apic = require(./apim.custom.js);
```

where *apic* is the common name used for the GatewayScript examples in this topic. However, *apic* could be any given name of your choice, for example you could use:

```
var apim = require(./apim.custom.js);
```

and then you would start your calls with `apim`.

- Access to input properties code snippet
- Access to runtime context code snippet
- Access to input payload code snippet
- Access to HTTP headers code snippet
- Modify the payload code snippet
- Configure error information code snippet
- Set variables code snippet

Access to input properties code snippet

The following code block shows an example of how to access the input properties by using the XSLT `policyProperties()` function. The example defines a property that is named `a_property`, which is declared as an integer value, but is retrieved in XSLT as text.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />
<!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="p" select="apim:policyProperties()" />
    <xsl:message>
      The value of my input property is
      <xsl:value-of select="$p/a_property" />
      <apigw:set-variable name="'propfound'" value="'true'"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getPolicyProperty(propertyName)
```

where *`propertyName`* is the name of the input property that you want to access. If the input property name is blank, the action will return all input properties.

Access to runtime context code snippet

The following code block shows an example of how to access the runtime context by using the XSLT `getContext()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />
<!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="client-id" select="apim:getContext('client.app.id')" />
    <xsl:message>
      The calling application is
      <xsl:value-of select="$client-id" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getContext(varName)
```

where ***varName*** is the name of the context variable that you want to access.
For a complete list of context variables, see API Gateway context variables.

Access to input payload code snippet

The following code block shows an example of how to access the input payload by using the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />
<!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="input" select="apim:payloadRead()" />
    <xsl:message>
      The input payload is
      <xsl:copy-of select="$input" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.readInput(callback)
```

A callback is required because the actual payload read is asynchronous. The callback method is called when the payload is ready.
This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.
The following example shows how to use the **payloadType()** function to determine what type of payload (XML or JSONx) will be returned by the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />
<!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="payloadType" select="apim:payloadType()" />
    <xsl:message>
      <xsl:text>Payload type is [</xsl:text>
      <xsl:value-of select="$payloadType" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

Access to HTTP headers code snippet

The following code block shows an example of how to access the HTTP headers in XSLT by using the **getContext()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />
<!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="content-type" select="apim:getContext('request.headers.content-type')" />
    <xsl:message>
      The request content type is
      <xsl:value-of select="$content-type" />
    </xsl:message>
```

```
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getContext(request.headers.headerName)
```

where ***headerName*** maps to the name of the header you want to access.
Note: Access or modification of HTTP headers by using DataPower® extensions, such as **dp:set-request-header**, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.

Modify the payload code snippet

The output from a user-defined policy must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. The following code block shows an example of how to modify the payload in XSLT. To assist the API Gateway policy framework to accept the new or transformed message, call the **apim-output** template, as shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:jsonx="http://www.ibm.com/xmlns/prod/2009/jsonx"
  exclude-result-prefixes="apim"
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />

  <xsl:template match="/">
    <!-- Creates a JSON document (empty object is for simplicity) -->
    <jsonx:object>
    </jsonx:object>

    <!-- Indicates the media type of the output being produced -->

    <xsl:call-template name="apim:output">
      <xsl:with-param name="mediaType" select="'application/json'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where **mediaType**:

- **'application/json'** is when the output is written in JSONx format.
- **'application/xml'** is when the output is written in XML format.

If you are using GatewayScript, you must call the function:

```
apic.output(mediaType)
```

where ***mediaType*** is:

- **application/json** is when the output is written in JSONx format.
- **application/xml** is when the output is written in XML format.

Specifying the media type allows the next steps in the assembly flow to understand how to process the new payload.

Tip: The output from a user-defined policy must be XML or JSONx. JSONx is an IBM standard format to represent JSON as XML. One way to convert output GatewayScript JSON data into JSONx, is to add a **Convert Query Params to XML** action to follow the GatewayScript action within the same policy rule. The **Convert Query Params to XML** action must have an **Input Conversion** with the **Default Encoding** set to **JSON**. The output from the GatewayScript action must be the input for the **Convert Query Params to XML** action for JSONx to be produced.

Configure error information code snippet

The following XSLT code block shows an example of how to configure the policy implementation to produce error information by calling the **apim-error** template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="apim"
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />

  <!-- Indicates this policy has a failure and provides
       additional information for the client application -->
  <xsl:template match="/">
    <xsl:call-template name="apim:error">
      <xsl:with-param name="httpCode" select="'401'" />
      <xsl:with-param name="httpReasonPhrase" select="'Unauthorized'" />
      <xsl:with-param name="errorMessage" select="'Please select a Plan'" />
    </xsl:call-template>
  </xsl:template>
```

```
</xsl:stylesheet>
```

where:

- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **errorMessage** is the suggested action for the user.

If you are using GatewayScript, you must call the template:

```
apic.error(name, httpCode, httpReasonPhrase, message)
```

where:

- **name** is the name of the error.
- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **message** is the suggested action for the user.

Set variables code snippet

The following XSLT code block shows an example of how to set a runtime variable to a specified string value by calling the **setVariable** template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />
<!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="" select="'https://endpoint.host.com/data'" />
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'serviceEndpoint'" />
      <xsl:with-param name="value" select="$targetUrl" />
      <xsl:with-param name="action" select="'set'" />
    </xsl:call-template>
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$targetUrl" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$targetUrl}" response="xml" http-method="get"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **varName** is the name of the runtime variable that you want to set a value to.
- **value** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **value** as **$(request.headers.content-type)**.

If you are using GatewayScript, you must call the template:

```
apic.setvariable(varName, varValue, action)
```

where:

- **varName** is the name of the runtime variable that you want to set a value to, or that you want to add or clear.
- **varValue** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **varValue** as **request.headers.content-type**. This property is only required when **set** or **add** is specified as the action.
- **action** is the action that you want to apply to the variable. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

The following XSLT example shows how to retrieve the value of a runtime variable by using the **getVariable()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">
```

```
  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl" />
<!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="varValue" select="apim:getVariable('serviceEndpoint')" />
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$varValue" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$varValue}" response="xml" http-method="get"/>
  </xsl:template>

</xsl:stylesheet>
```

where

- `varValue` is the name of the runtime variable that you want to retrieve a value for.

If you are using GatewayScript, you must call the function:

```
apic.getvariable(varName)
```

where ***varName*** is the name of the runtime variable that you want to retrieve a value for.

API Gateway only

Authoring policies for the DataPower API Gateway

A user-defined policy for the DataPower API Gateway consists of a package containing configuration details that define the actions of the policy. You publish the package to the DataPower API Gateway to make it available to APIs that are deployed there.

There are two types of user-defined policies, *Catalog scoped* user-defined policies and *global scoped* user-defined policies:

Catalog-scoped user-defined policies
: Catalog-scoped user-defined policies are available to APIs only in the Catalogs that you specify. Use a Catalog scoped user-defined policy if you want to limit the availability of your policy on a Catalog specific basis. The possible actions of a Catalog scoped user-defined policy are limited to the API Connect built-in assembly policies. For more information, see Defining, packaging and publishing a catalog-scoped policy for the API Gateway.

Global-scoped user-defined policies
: Global-scoped user-defined policies are available to APIs in every Catalog in every provider organization. Use a global scoped user-defined policy in the following situations:

  - You want to make your policy available everywhere rather than limiting its availability to specific Catalogs.
  - Your policy uses a DataPower® implementation, where configuration changes are made directly on the DataPower API Gateway.

  Note: Global-scoped user-defined policies are not the same as global policies that you define with the toolkit CLI, as documented on Working with global policies. For more information, see Defining, packaging, and publishing a global-scoped policy for the API Gateway.

- **Defining, packaging and publishing a catalog-scoped policy for the API Gateway**
  Create a catalog-scoped, user-defined policy that can be used in API assemblies within the catalog where the policy is published.
- **Defining, packaging, and publishing a global-scoped policy for the API Gateway**
  Create a global-scoped, user-defined policy that is available to APIs in any of the catalogs in any provider organization.

Defining, packaging and publishing a catalog-scoped policy for the API Gateway

Create a catalog-scoped, user-defined policy that can be used in API assemblies within the catalog where the policy is published.

About this task

A published catalog-scoped policy can only be used with APIs in the same catalog. Complete the following tasks to define, package and publish the catalog-scoped policy.

Tip: During this task, you can create several zip files. On macOS, run the **zip** command on the command line with the following flags:

```
-x ".DS_Store" -x "__MACOSX"
```

Including the flags prevents the autogenerated .DS_Store and __MACOSX files from being added to the compressed file.

- **Structure of the catalog-scoped user-defined policy YAML file**
  Review the required structure of the YAML file that contains your catalog-scoped user-defined policy.

Step 1: Define a catalog-scoped policy for API Gateway

Use the DataPower web GUI to define a new policy that can be used in API assemblies within the catalog where the policy is published.

Procedure

1. Log in to the DataPower web GUI.
2. Create a new "test" domain and then switch to it.
   This test domain is used as a "sandbox" to build and export the custom policies.
3. Go to Assembly Function and create a new object:
   a. Name the object ***<org-name>_<catalogname>_udp-<policyname>_<version>***.
      Example: "testorg_stagecatalog_udp-testpolicy_1.0.0". Use the same name for all of the objects that you create in this task.
      Note: This naming convention specifies the provider organization and catalog where the policy is available, as well as the policy's name and version.
   b. Under the "Assembly" property, create a new Assembly.
   c. Under the new Assembly, create a new Rule.
   d. Under the new Rule, create a new API Action.
   e. Optionally add an implementation file for the new action.
      For example, an XSLT action requires an XSL file. Create the file in the using the following path and name (where "udp" refers to user-defined policy:

      local:///*<udp-name>*/*<udp-name>*.*<file-extension>*

   f. Click Apply and then save all of the new objects.
4. Export the new user-defined policy.
   a. Go to the newly created Assembly Function.
   b. Click Export to export the new user-defined policy to a file named *<policyname>*_*<version>*.zip.
   c. Open the exported *<policyname>*_*<version>*.zip file and confirm that all referenced files are included.
   d. Delete the dp-aux folder from the zip.
      This optional folder requires more storage spaces and might cause a problem when you package and publish the new policy in the next task.

Step 2: Package and publish a catalog-scoped policy for API Gateway

Decide how you want the new catalog-scoped policy to be managed, and then publish it to make it available to API assemblies within a particular catalog.

About this task

Be sure to complete Step 1: Define a catalog-scoped policy for API Gateway before attempting to package and publish the new policy.

There are two methods for packaging and publishing a user-defined policy, based on how you want the policy to be managed:

- Step 2, Option A: Package and publish a catalog-scoped policy directly in the DataPower configuration
- Step 2, Option B: Package and publish a catalog-scoped policy as a gateway extension that API Connect manages

Step 2, Option A: Package and publish a catalog-scoped policy directly in the DataPower configuration

Package and publish a catalog-scoped policy so it can be stored directly on the DataPower API Gateway.

About this task

When you store a catalog-scoped policy on the DataPower API Gateway, the policy exists in the gateway's startup domain configuration and will be unaffected by the API Manager lifecycle. If you want to store the catalog-scoped policy directly on DataPower, you do not need to package it for API Manager. Instead, complete the following steps.

Procedure

1. Import the custom policy created in Step 1: Define a catalog-scoped policy for API Gateway to the application domain for every DataPower node in the cluster.
2. Proceed to Step 3: Create and publish a policy.yaml file, where you create a file that describes the new policy so that API Manager can support it.

Step 2, Option B: Package and publish a catalog-scoped policy as a gateway extension that API Connect manages

Package and publish a catalog-scoped policy as a gateway extension in API Connect.

Before you begin

The xml-manager must be enabled on the default domain of every gateway that will have a gateway-extension published to it.

About this task

When you publish a catalog-scoped policy as a gateway extension in API Connect, it is subject to the API Manager lifecycle. The individual assembly functions will not be added to the API Connect Gateway Service (only global-scoped policies are added to the service).

Procedure

1. Rename the *<policyname>_<version>*.zip file (that you created in Step 1: Define a catalog-scoped policy for API Gateway) to *<org-name>_<cat-name>_<policyname>_<version>*.zip.
   The new file name indicates the provider organization and the catalog where the policy is used.

2. Create a gateway-extension manifest.json file as explained in Gateway extensions manifest.
   The manifest contains one or more entries. The following example contains a sample entry for the new catalog-scoped policy and references the new policy file name.

   ```
   {
       "filename": "<org-name>_<cat-name>_<policyname>_<version>.zip",
       "deploy": "immediate",
       "type": "dp-import",
   },
   ```

3. Create a new zip file called gateway-extension.zip that contains the following files:
   - manifest.json
   - *<org-name>_<cat-name>_<policyname>_<version>*.zip
4. Publish the new gateway extension that uses the toolkit CLI or the Cloud Manager UI:
   - API Connect toolkit CLI:
     Use the **apic gateway-extensions:create** command to publish the gateway extension (see toolkit CLI reference documentation).

   - Cloud Manager UI:
     Complete the following steps to publish the gateway extension from Cloud Manager:

     - Log in to Cloud Manager.
     - Click Topology > ⋮ > Configure gateway extensions > Upload gateway-extension.zip file and upload your new gateway-extension.zip file.
5. Verify that the new catalog-scoped policy is available in the API Assembler's Policy palette.
   a. Log in to API Manager and open the Catalog where you published the new catalog-scoped policy.
   b. Create an API.
   c. Open the API Assembler page and view the Policy palette; verify that your new catalog-scoped policy displays and can be added to the API.

Step 3: Create and publish a policy.yaml file

Create a file that describes the properties of the catalog-scoped policy, and then publish it to make it accessible to API Manager.

Procedure

1. Create a YAML file that describes the new catalog-scoped policy.
   a. Create a file named *<policyname>*.yaml.
   b. Paste the following content into the new file:

   ```
   attach:
   - rest
   - soap
   policy: 1.0.0
   info:
     title: <policyname>
     name: <policyname>
     version: 1.0.0
     description: <description-here>
   properties:
     $schema: 'http://json-schema.org/draft-04/schema#'
     type: object
     properties:
       exampleProperty:
         label: Test Property
         description: Enter any value
         type: string
       exampleProperty2:
         label: Another Test Property
         description: Enter any value
         type: string
     required:
       - exampleProperty2
   gateways:
   - datapower-api-gateway
   ```

   c. Modify the content as needed to correctly describe your new catalog-scoped policy.
   For more information, see Structure of the catalog-scoped user-defined policy YAML file.

   d. Save and close the file.
2. Create a new zip file called *<policyname>*.zip that contains the new YAML file.
3. Publish the new policy that uses either the toolkit CLI or the API Manager:
   - API Connect toolkit CLI:
     Use the **apic policies:create** command to publish the gateway extension (see toolkit CLI reference documentation).

   - API Manager:
     Complete the following steps to publish the new policy:

     - Log in to API Manager.
     - Click Manage Catalogs > Select Catalog > Gateways > *selected_gateway* > ⋮ > View policies and upload your new policy.zip file.
4. Verify that the new catalog-scoped policy is available in the API Assembler's Policy palette.
   a. In API Manager, select the Catalog where you published the new catalog-scoped policy.
   b. Create an API.
   c. Click ⚙ (next to Save) and for the Target Catalog, select the catalog where you published the new policy.

d. Save the API.
e. Open the API Assembler page and view the Policy palette. Verify that your new catalog-scoped policy displays and can be added to the API.

Structure of the catalog-scoped user-defined policy YAML file

Review the required structure of the YAML file that contains your catalog-scoped user-defined policy.

The .yaml file for a catalog-scoped user-defined policy contains the following sections:

- Specification version
- Information
- Attach
- Gateways
- Properties
- Assembly section

Specification version

Set the specification version by adding the following line to the beginning of the file:

```
policy: 1.0.0
```

Information

Complete the information section with details about the policy by using the following syntax:

```
info:
  title: Title of policy
  name: shortnameofpolicy
  version: 1.0.0
  description: An example policy
  contact:
    name: name1
    url: url1
    email: email1
```

where:

- **title** is the title of the policy. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
- **name** is the short name for the policy. Must be a single word, and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or less so that it can be displayed in the API Manager user interface.
  Important: The policy short name must be different from the OpenAPI names of the built-in policies, otherwise it will cause a policy conflict in the API assembly definition. For a list of the OpenAPI built-in policy names, see execute. Also, consider including an appropriate unique prefix or suffix string in the short names of your user-defined policy to prevent possible name conflicts with future built-in policies.
  Note: The **name:** property must be identical to the Node.js module name.
- **version** is the version number of the policy. This is a reserved property.
  Tip: The *version.release.modification* version numbering scheme is recommended, for example *1.0.0*.
  Note: The **info.version** in policy.yaml must match the **version** indicated in package.json.
- **description** (optional) is a short description of the policy.
- **contact** (optional) is the contact information for the policy, where:
  - **name** (string) is the identifying name of the contact person or organization.
  - **url** (string) is the URL that points to the contact information.
  - **email** (string) is the email address of the contact person or organization.

For example:

```
info:
  title: Custom Invoke Policy
  name: custom-invoke
  version: 1.0.0
  description: Invokes httpbin
  contact:
    name: IBM DataPower Samples
    url: 'https://github.com/ibm-datapower/'
    email: steve-product-manager@ibm.com
```

Attach

Complete the attach section by specifying which types of API flow the policy can be attached to.

- **rest** indicates that this policy can be attached to a REST API flow.
- **soap** indicates that this policy can be attached to a SOAP API flow.

The attach section must contain at least one API flow type. If a policy can be attached to both API flow types, they must both be indicated in the attach section.

For example:

```
attach:
  - rest
  - soap
```

Gateways

Specify the DataPower® API Gateway, as follows:

```
gateways:
  - datapower-api-gateway
```

Properties

Complete the properties section by defining a JSON schema (based on JSON Schema Specification Draft 4, but rendered in YAML format) that contains the list of properties the policy will declare as required input. These properties are presented to the API author at development time, when the properties can be configured or mapped to values as required. The JSON schema defines a root object that contains the following JSON properties:

- `type`
- `properties`
- `required`

The syntax and definition of these properties matches the JSON schema definition. The following code block shows an example of a simple schema that defines one required property (*a_property*):

```
properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    a_property:
    label: a label
    description: a description
    type: a type
  required:
    - a_property
```

The root *type* of the schema must be an `object`, as shown in the example schema. You can define zero or more properties in the schema. Required properties are declared by using the `required` parameter, as shown in the example schema. The policy will not be accessible in the API Manager assembly editor, unless all the required properties have values. Each property is an object with the following items:

- `label` is a short name for the property and is displayed in the Name column of the API Manager assembly editor.
- `description` is a short description for the property and is displayed in the Description column of the API Manager assembly editor.
- `type` must be one of the following primitives that are supported:
  - *integer*
  - *number*
  - *string*
  - *boolean* (this primitive is shown as a check box in the assembly editor)
  - *array*
- `default` (optional) specifies a default value for the property.
- `enum` (for properties with a `type` of *string*) is an array of valid values.

For example:

```
properties:
  $schema: 'http://json-schema.org/draft-04/schema#'
  type: object
  properties:
    test:
      label: Test Property
      description: Enter any value
      type: string
  required:
    - test
```

Assembly section

The assembly section defines the assembly policy flow that will be activated when the user-defined policy is invoked. For example:

```
assembly:
  execute:
    - invoke:
        version: 2.0.0
        title: custom-invoke
        header-control:
          type: blacklist
          values: []
        parameter-control:
          type: whitelist
          values: []
        timeout: 60
        verb: keep
        cache-response: protocol
        cache-ttl: 900
        stop-on-error: []
        target-url: 'http://httpbin.org/headers'
```

You can determine the correct content of this section in either of the following ways:

- Define the assembly flow by using the graphical assembly editor in either the API Designer or API Designer user interface, then copy the `assembly:` section from the Source tab. For more information on defining an assembly flow in the user interface, see The Assemble view and API policies and logic constructs.
- Code the policies in the `execute:` subsection of the `assembly:` section by hand; for details, see execute.

The assembly section can contain only the API Connect built-in policies. However, you can include a gatewayscript policy that references native DataPower configuration.

Defining, packaging, and publishing a global-scoped policy for the API Gateway

Create a global-scoped, user-defined policy that is available to APIs in any of the catalogs in any provider organization.

About this task

When a global-scoped policy is published, you can use it in the API Assembler's Policy palette for APIs in any catalog belonging to any provider organization. Complete the following tasks to define, package, and publish the global-scoped policy.

Tip: During this task, you will create several zip files. On macOS, run the **zip** command on the command line with the following flags:

```
-x ".DS_Store" -x "__MACOSX"
```

Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

Step 1: Define a global-scoped policy for API Gateway

Use the DataPower Web GUI to define a new policy that can be used in API assemblies in all catalogs belonging to all provider organizations.

Procedure

1. Log in to the DataPower Web GUI.
2. Create a new "test" domain and then switch to it.
   This test domain will be used as a "sandbox" to build and export the custom policies.
3. Navigate to Assembly Function and create a new object:
   a. Name the object ***<policyname>_<version>***.
      Example: "testpolicy_1.0.0". Use the same name for all of the objects that you create in this task. Because the policy will be available in all provider organizations and catalogs, there is no need to specify that information in the object name.
   b. Under the "Assembly" property, create a new Assembly.
   c. Under the new Assembly, create a new Rule.
   d. Under the new Rule, create a new API Action.
   e. Optionally add an implementation file for the new Action.
      For example, an XSLT Action requires an XSL file. Create the file in the using the following path and name (where "udp" refers to user-defined policy:

      local:///*<udp-name>*/*<udp-name>*.*<file-extension>*

   f. Click Apply and then save all of the new objects.
4. Export the new user-defined policy.
   a. Navigate to the newly created Assembly Function.
   b. Click Export to export the new user-defined policy to a file named *<policyname>*_*<version>*.zip.
   c. Open the exported *<policyname>*_*<version>*.zip file and confirm that all referenced files are included.
   d. Delete the dp-aux folder from the zip.
      This optional folder requires a lot of storage space and might cause a problem when you package and publish the new policy in the next task.

Step 2: Package and publish a global-scoped policy for API Gateway

Decide how you want the new global-scoped policy to be managed, and then publish it to make it available to API assemblies.

About this task

Be sure to complete the steps in Step 1: Define a global-scoped policy for API Gateway before attempting to package and publish the new global-scoped policy. There are two methods for packaging and publishing a user-defined policy, based on how you want the policy to be managed:

- Step 2, Option A: Package and publish a global-scoped policy directly in the DataPower configuration
- Step 2, Option B: Package and publish a global-scoped policy as a gateway extension that API Connect manages

Step 2, Option A: Package and publish a global-scoped policy directly in the DataPower configuration

Package and publish a global-scoped policy so it can be stored directly on the DataPower API Gateway.

About this task

When you store a global-scoped policy on the DataPower API Gateway, the policy exists in the gateway's startup domain configuration and will be unaffected by the API Manager lifecycle.

Procedure

1. Import the *<policyname>*_*<version>*.zip file containing the new global-scoped policy to the application domain for every DataPower node in the cluster.
   Complete the following steps on every DataPower node in the cluster--if you omit a node, then the policy will not be available in the API Assembly's Policy palette.
   a. On the DataPower node, navigate to the API Connect Gateway Service object.
   b. Under the "User-defined policies" property, add a new Assembly Function by importing the *<policyname>*_*<version>*.zip file containing your new global-scoped policy.
   c. Click Apply, and then Save.

2. Verify that the new global-scoped policy is available in the API Assembler's Policy palette.
    a. Log in to API Manager.
    b. Create an API.
    c. Open the API Assembler page and view the Policy palette; verify that your new global-scoped policy displays and can be added to the API.

Step 2, Option B: Package and publish a global-scoped policy as a gateway extension that API Connect manages

Package and publish a global-scoped policy as a gateway extension in API Connect.

Before you begin

The xml-manager must be enabled on the default domain of every gateway that will have a gateway-extension published to it.

About this task

When you publish a global-scoped policy as a gateway extension in API Connect, it is subject to the API Manager lifecycle.

Procedure

1. Make a copy of the *<policyname>_<version>*.zip file containing your new global-scoped policy and remove the ***<version>*** number from the file name.
   This name change ensures that the relative path of the file meets the requirement to match the following regular expression: **`implementation\/[\w_-]+\.zip`**.
   You can retain the copy of the file with its original name for tracking purposes.

2. Create a local folder named implementation and store the renamed zip file in that folder.
3. Create a YAML file that describes the new global-scoped policy.
    a. Create a file named *<policyname>*.yaml.
    b. Paste the following content into the new file:

```
policy: 1.0.0
info:
  title: <policyname>
  name: <policyname>
  version: 1.0.0
  description: <description-here>
```

    Only the **`policy`** and **`info`** sections are needed in the *<policyname>*.yaml for this task.

    c. Save and close the file.
4. Create a new zip file called *<policyname>_<version>*.zip that contains the following files:
    - The implementation folder
    - *<policyname>*.yaml
5. Create a gateway-extension manifest.json file as explained in Gateway extensions manifest.
   The manifest contains one or more entries. The following example contains a sample entry for the new global-scoped policy and references the original policy *<policyname>_<version>*.zip file that you created in Step 1: Define a global-scoped policy for API Gateway:

```
        {
            "filename": "<policyname>_<version>.zip",
            "deploy": "immediate",
            "type": "user-defined-policy",
        },
```

6. Create a new zip file called gateway-extension.zip that contains the following files:
    - manifest.json
    - *<policyname>_<version>*.zip
      This is the file that you created in step 4 of this task (it contains the implementation folder and the *<policyname>*.yaml file).

7. Publish the new gateway extension using one of the following methods:
    - API Connect toolkit CLI:
      Use the **`apic gateway-extensions:create`** command to publish the gateway extension (see toolkit CLI reference documentation).
    - Cloud Manager UI:
      Complete the following steps to publish the gateway extension from Cloud Manager:
        - Log in to Cloud Manager.
        - Click Topology > ⋮ > Configure gateway extensions and upload your new gateway-extension.zip file.
8. Verify that the new global-scoped policy is available in the API Assembler's Policy palette.
    a. Log in to API Manager.
    b. Create an API.
    c. Open the API Assembler page and view the Policy palette; verify that your new global-scoped policy displays and can be added to the API.

Socializing your APIs using Developer Portal

The Developer Portal serves as a comprehensive platform for facilitating API sharing with application developers.

In addition to allowing application developers to find and subscribe to APIs, the Developer Portal provides additional features including forums, blogs, comments, and ratings, together with an administrative interface for customizing the Developer Portal to your brand and theme. See the following topics for more information.

- **Using the Developer Portal**
  As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.

- **Configuring the Developer Portal site**
  Customize the look and feel of your Developer Portal site, and brand it for your organization.
- **Managing the Developer Portal by using the toolkit CLI**
  You can perform operations on your Developer Portal by using the API Connect toolkit CLI.
- **Troubleshooting guide for the Developer Portal**
  Use this guide to help you diagnose and resolve Developer Portal issues in IBM® API Connect. For example, why is the Developer Portal not connecting to the Management server, why is my site not created, and why can't I log in?
- **Migrating your Developer Portal from Version 5 to Version 10**
  Guidance on how to migrate a Developer Portal site from IBM API Connect version 5, to IBM API Connect version 10.
- **Upgrading your Developer Portal from Drupal 10 to Drupal 11**
  The Developer Portal is based on the open source Drupal content management system. From API Connect 10.0.10.0, Drupal 10 is upgrading to Drupal 11.
- **Developer Portal tutorials**
  Tutorials for using the Developer Portal.

Using the Developer Portal

As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.

The Developer Portal is a convenient place to share APIs with application developers. After a Developer Portal has been enabled through the API Manager, and one or more API Products have been published, application developers can browse and use the APIs. Typically, a Developer Portal is customized to fit the corporate branding and design requirements of a particular organization. For more information about configuring a Developer Portal site, see Configuring the Developer Portal site. However, when the Developer Portal is first enabled it can be used as is, for example for test and development purposes, or for internal use only.

The following topics provide information about the main API consumer concepts in the Developer Portal, and how an application developer can navigate the default site. However, bear in mind that the actual consumer experience might be very different depending on how the site is configured. For tutorials guiding you through enabling a Developer Portal site, and navigating and using APIs as an application developer, see Tutorial: Creating the Developer Portal and Tutorial: Creating Accounts and Applications on the Developer Portal.

- **Logging in as a consumer to the Developer Portal by using the CLI**
  Use the toolkit CLI to log in to the Developer Portal as a consumer.
- **Exploring APIs and Products in the Developer Portal**
  As an application developer, you can browse, test, and subscribe to APIs in the Developer Portal by exploring the available API Products.
- **Applications in the Developer Portal**
  You can view, edit, configure, and create applications in the Developer Portal.
- **Analytics in the Developer Portal**
  You can view analytics for APIs in the Developer Portal at the application and organization levels. This information is displayed in dashboard views that show the analytics metrics in the form of *visualizations* (represented as charts).
- **Consumer organizations in the Developer Portal**
  Consumer organizations provide a way of grouping application developers together. You can add, remove, and configure Consumer organizations in the Developer Portal.
- **User accounts, passwords, and support in the Developer Portal**
  You can change general elements such as user accounts and passwords in the Developer Portal.

Logging in as a consumer to the Developer Portal by using the CLI

Use the toolkit CLI to log in to the Developer Portal as a consumer.

Before you begin

To log in as a consumer, you must have created a developer account in the Developer Portal as explained in the following tutorial: Tutorial: Creating Accounts and Applications on the Developer Portal.

About this task

You can use the toolkit CLI to log in to the Developer Portal as a consumer to view it and test how it behaves for your customers.

Procedure

1. Set up the toolkit as explained in Installing the toolkit.
2. Determine the name of your identity provider.
   When you log in from the CLI, you must provide the name of the realm (identity provider) that hosts your API Connect user account. If you don't know the name of your account's realm, you can look it up by using the following command.

   In the CLI, run the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --server consumer_endpoint_api --mode consumer --catalog catalog_name_or_id --org
   <provider_org_name_or_id> --fields registry_type,realm
   ```

   Where:

- ***consumer_endpoint_api*** is the endpoint of the consumer API.
- ***catalog_name_or_id*** is the name or ID of your catalog.
- ***<provider_org_name_or_id>*** is the name of ID of your provider organization.

For example:

```
apic identity-providers:list -s consumer.abce-ci-15608-master.abce.ibm.com -m consumer -c sandbox -o org --fields
registry_type,realm
total_results: 1
results:
  - registry_type: 'lur'
    realm: 'consumer:4da2f1b9-05c1-4506-9e2d-951198d19ad3:faa5577d-625c-4fc8-8d19-26077c8aff95/sandbox-idp'
```

In the response, the realm consists of the following elements:

```
consumer:<provider_org_name_or_id>:<catalog_name_or_id>/<catalog_identity_provider_name>
```

For example, **consumer:myorg:mycatalog/sandbox-idp**.
Note that ***<catalog_identity_provider_name>*** is typically made up of ***catalog_name*-idp**, for example **sandbox-idp**.

3. In the toolkit CLI, run the following command to log in to the Developer Portal:
Command syntax:

```
apic login --mode consumer --server consumer_endpoint_api --username username --password password --realm realm
```

Where:
- ***consumer_endpoint_api*** is the endpoint of the consumer API.
- ***username*** is your API Connect username.
- ***password*** is the password that corresponds to your API Connect username.
- ***realm*** is the user registry realm for the specified ***<username>***.

Example:

```
apic login --mode consumer --server consumer.9a6e-88fa49bc.eu-gb.apiconnect.cloud.ibm.com -u my_username -p Blue123 -r
consumer:frankenstein:om-portal/portal-idp

Logged into consumer.9a6e-88fb51bc.eu-gb.apiconnect.cloud.ibm.com successfully
```

Exploring APIs and Products in the Developer Portal

As an application developer, you can browse, test, and subscribe to APIs in the Developer Portal by exploring the available API Products.

Browsing available APIs
: In API Connect API providers package their APIs into Products to offer one or more APIs to application developers. The providers then use Plans to control access to APIs and to manage API usage. Products are packages that contain both the APIs and the accompanying Plans.
From the Developer Portal home screen, click API Products to browse the available products. You can then select a Product to explore the available Plans and APIs further, including viewing API code snippets, and request and response examples.

You can also download all associated APIs as a ZIP file directly from the product page in the portal. The ZIP file supports downloading APIs of all types, including SOAP, WSDL, REST, and GraphQL with API names and versions preserved.

Note: If you have an account on the Developer Portal, you can specify a default programming language for the code snippets to display in by editing the Code Snippet Language in your account settings.

Subscribing to a Plan
: A Plan is a collection of API operations or subsets of operations from one or more APIs. In order to subscribe to a Plan, you must have an account on the Developer Portal and have created an App. For more information, see User accounts, passwords, and support in the Developer Portal and Applications in the Developer Portal.
Rate limits specify how many requests an App is allowed to make during a specified time interval. A Plan can have a shared rate limit for all the operations, or each operation can have a different rate limit. In addition, Plans can have multiple rate limits set per Plan and per operation, at second, minute, hour, day, and week time intervals. Plans can also have burst limits to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals.

After you have identified the Plan that you want to use, click Subscribe and then select the App that you want to use with this Plan. If the Plan is not restricted, you can use it immediately. If the Plan is restricted, the subscription is shown as Pending Approval, and you cannot use the requested Plan until the administrator approves your request.

You cannot subscribe to a monetized Plan without first adding your payment information to your Consumer organization. You can register your payment information by editing the Billing tab for your Consumer organization. Note: you must either be the Consumer organization owner, or have `Settings: Manage` permissions for your organization to be able to edit the billing information. Consumer organizations can have at most one payment method. You can delete your payment method and add a different method, for example if your credit card expires. If you change your subscription to a Plan that has a different pricing structure, the subscription billing system will add a prorated amount to the next invoice of your subscription billing cycle.

Testing an API
: You can test an API in the Developer Portal by using the interactive API document test tool. If the API operation that you want to test doesn't require a client ID, then you can use the test tool without the need to log in. For more information, see Testing an API by using the Developer Portal test tool.

Calling an API in your application
: When you have subscribed to a Plan and you begin coding your application, you must retrieve the operation URL in order to call the API. You can retrieve the operation URL from the API overview page. For more information, see Calling an API.

- **How to use a URL to navigate directly to a Product or API in the Developer Portal**
  You can navigate to a specific Product or API in the Developer Portal by using ***x-ibm-name:version*** in the URL.

  You can test the behavior of an API without the need to write any code by using the Developer Portal test tool. You provide the necessary API parameters within the test tool and click Invoke to see the response.
- **Calling an API**
  When you have a selected a Plan and you begin coding your application, you must retrieve the operation URL to call the API.

How to use a URL to navigate directly to a Product or API in the Developer Portal

You can navigate to a specific Product or API in the Developer Portal by using ***x-ibm-name:version*** in the URL.

To find a Product or API in the Developer Portal you typically navigate there by searching in the UI, clicking on the relevant Product, and then selecting the API. However, if you know the ***x-ibm-name:version*** of your Product or API, you can insert that information into the URL to go there directly.

To navigate directly to a specific API, use the following URL syntax:

portal.site.url*/productselect/*api_x-ibm-name*:*version

For example:

https://my.portal.com/myorg/sandbox/productselect/petstore-header-clientid:1.0.0

To navigate directly to a specific Product, use the following URL syntax:

portal.site.url*/product/*product_x-ibm-name*:*version

For example:

https://my.portal.com/myorg/sandbox/product/my-product:1.0.0

To navigate directly to a specific API within a specific Product, use the following URL syntax:

portal.site.url*/product/*product_x-ibm-name*:*version*/api/*api_x-ibm-name*:*version

For example:

https://my.portal.com/myorg/sandbox/product/my-product:1.0.0/api/petstore-header-clientid:1.0.0

Testing an API by using the Developer Portal test tool

You can test the behavior of an API without the need to write any code by using the Developer Portal test tool. You provide the necessary API parameters within the test tool and click Invoke to see the response.

Before you begin

To use the Developer Portal test tool with an API that requires an App client ID, you must first complete the following tasks:

- Create an App. For more information, see Registering an application.
- Subscribe to a Plan that contains the API that you want to test. For more information, see Exploring APIs and Products in the Developer Portal.

About this task

The Developer Portal test tool is an interactive API document test tool. If the operation that you want to test does not require a client ID, then you can use Developer Portal test tool without the need to sign in. However, if the operation that you want to interact with requires a client ID, then you must sign in to the Developer Portal first.

Using the Developer Portal test tool is subject to the rate limit that is applied to an operation or Plan. For example, if an operation has a rate limit of 10 requests per minute and you invoke the operation, the number of requests that can be made is reduced to nine. The limitations are triggered every time that you click invoke within the minute interval. This caveat affects the quota of the App that is selected to use with the Developer Portal test tool, but it does not affect the quota of the other Apps that are using the same operation or Plan.

To test an API in the Developer Portal, the Allow this API to be tested check box must be selected in the API Manager. For more information, see Creating API definitions.

Restriction:

- There are security mechanisms that prevent you using the Developer Portal test tool to test an Implicit or Authorization Code grant type in an OAuth provider API. Other grant types in the same OAuth provider API **can** be tested. If your OAuth provider allows those actions to function correctly from the test tool, you can disable this option. For more information, see Disabling test tool restrictions.
- You cannot use the Developer Portal test tool with suspended applications.
- You can only test an unenforced API if **`testable=true`**, and if the existing API implements CORS and is using HTTPS.

Note: GraphQL APIs can be tested from the Developer Portal user interface. However, not all authentication methods are supported. You must use one of the following authentication methods:

- Unsecured
- Client ID, passed in the header
- Client ID and secret, passed in the header

Also, **`cost`** metrics are not supported, and rate limits specific to GraphQL are not listed in Product plans.

Procedure

1. To use the Developer Portal test tool with an API that does not require the client ID of an App, complete the following steps:
   a. Click API Products.
      All of the APIs that can be used by application developers are displayed.
   b. Click the name of the API that you want to test.
   c. Select an operation and then select Try It.

d. Click Try this operation.
e. Supply the values for required headers or parameters.
f. If the operation is secured with Basic Authentication, supply the credentials.
g. Click Send Request.
The result is displayed in the Response Body field. You can continue to test different parameter values as necessary.
Note:
The first time that you click Try It, you might be presented with a security error. Copy the URL from the Request URL field, open it in a browser window, and accept the security certificate. You are not presented with the security error again.

Also, for performance reasons, if the payload is large, more than 1500 DOM highlighted elements, you get the response, but it is not pretty printed.

2. To use the Developer Portal test tool with an API that does require the client ID of an App, complete the following steps:
a. Sign in to the Developer Portal.
b. If you have not already done so, you must create an App so that you can test an API that requires a client ID. For more information, see Registering an application.
c. Ensure that your App is subscribed to the Plan that contains the API that you want to test. For more information, see Exploring APIs and Products in the Developer Portal.
d. Click API Products.
All of the APIs that can be used by application developers are displayed.
e. Click the *API* that you want to test.
f. Select the **`Provide credentials for Client ID (API Key)`** operation and then select Try It.
The API Key Identification window displays.
g. Use the Register an application in order to select a client ID drop-down list to select an App to test the API with.
h. Click Save credentials.
i. If a client secret is required, enter the value in the Client Secret field.
j. Find the operation that you want to test, then click Try It.
k. Supply the required parameters and values.
l. If the operation is secured with Basic Authentication, supply the credentials.
m. Click Send.
The result is displayed in the Response section. You can continue to test different field values as necessary.
Note: The first time that you click Invoke, you might be presented with a security error. Click the link that is provided to accept the security certificate. You are not presented with the security error again.

Related tasks

- Calling an API by using CORS

Calling an API

When you have a selected a Plan and you begin coding your application, you must retrieve the operation URL to call the API.

About this task

Be aware of the following points when you call APIs in IBM® API Connect:

- In the HTTP response message for status code 200 the reason phrase is replaced with `OK`.
- API error messages are displayed in English only.

Procedure

To retrieve the operation URL, complete the following steps:

1. Click API Products, then select a product.
2. Click the API that you want to work with.
The API overview page opens.
3. Select the operation that you need and then copy the endpoint.
This is the URL that the application calls, and its structure is defined:

Type of API	URL
REST APIs	**`https://`*`host`*`/`*`org`*`/`*`catalog`*`/api/`*`operation`*
SOAP APIs	**`https://`*`host`*`/`*`org`*`/`*`catalog`*`/api`** for all operations in the WSDL.

Where,
- *host* is the fully qualified hostname of your gateway cluster.
- *org* is the URL path of your organization.
- *catalog* is the name of your catalog.
- *api* is the name of your API.
- *operation* is the URL path of your operation.

4. Take note of any parameters, the request body, and the response body. Code your application to create the expected requests and handle the expected responses.

Depending on the Identify your application using setting for the API, you might have to provide a client ID, or client ID and client secret. To do this, complete the following steps.

5. To find the client ID, complete the following steps:
a. Click Apps, then click the application name that you want to work with.
b. Select the Show checkbox for Client ID.
The client ID is displayed.
c. Provide the client ID with the header parameter &client_id=

For example, the URL used in the API might be:

`https://host/org/catalog/api/quote?loanAmount=20000`

but when you call it with a client ID of *1234*, change the URL to:

`https://host/org/catalog/api/quote?loanAmount=20000&client_id=1234`

Note: API Gateway only A client ID is generated automatically by API Connect when you register an application. However, if you specify a customized client ID, by using the CLI or REST API, then the length must not exceed 512 bytes, otherwise the gateway will reject the API request and return a **401** error.

6. The client secret is produced when you register an application. Provide the client secret with the query parameter &client_secret=. If you did not note the client secret when you registered the application, you must reset it; for information, see Managing applications.

The client ID, or client ID and secret can be logged along with the URL. Web servers usually log the URL in their access logs, which would give away the client secret. If you do not want to expose your client ID or secret in the URL, complete the following steps.

7. For the client ID, set the header **X-IBM-Client-Id**, as part of the HTTP message that the application sends when it calls the API.
   An example URL statement might be:

   ```
   curl --header "X-IBM-Client-Id: 1234" https://host/org/catalog/api/quote?loanAmount=20000
   ```

   Note: API Gateway only A client ID is generated automatically by API Connect when you register an application. However, if you specify a customized client ID, by using the CLI or REST API, then the length must not exceed 512 bytes, otherwise the gateway will reject the API request and return a **401** error.
8. For the client secret, set the header, **X-IBM-Client-Secret**, as part of the HTTP message that the application sends when it calls the API.
   For example, the URL would be:

   `https://host/org/catalog/api/quote?loanAmount=20000`

   and set the following HTTP headers:

   ```
   X-IBM-Client-Id=1234
   X-IBM-Client-Secret=ABCD
   ```

What to do next

Monitor the API and application usage. For more information, see Managing applications.

- **Calling an API by using CORS**
  CORS (cross origin resource sharing) is a technique that allows calls to be made from code that is running in a browser to a third-party server (such as APIs running on an API Connect). These calls are, by default, not allowed as per the same origin security policy that is applied to the browser sandbox. Without CORS support, web developers are required to use more complex techniques such as server-side proxies.

Calling an API by using CORS

CORS (cross origin resource sharing) is a technique that allows calls to be made from code that is running in a browser to a third-party server (such as APIs running on an API Connect). These calls are, by default, not allowed as per the same origin security policy that is applied to the browser sandbox. Without CORS support, web developers are required to use more complex techniques such as server-side proxies.

About this task

Note: CORS support is available only on the DataPower® API Gateway.
API Connect Gateway servers support CORS to make it as easy as possible for web developers to use APIs within their web applications.
CORS is supported in the following browsers:

- Chrome 3+
- Firefox 3.5+
- Internet Explorer V11, or later
- Opera 12+
- Safari 4+

A CORS enabled browser automatically sends either a simple CORS request, consisting of the original request with the addition of the **Origin** header, or a preflight request followed by a simple CORS request.

An example CORS preflight request is as follows:

```
OPTIONS /org/env/api/resourceHTTP/1.1
User-Agent: useragent details
Access-Control-Request-Method: GET
Access-Control-Request-Headers: header names
Host: x.xx.xxx.xx
Origin: https://example.com
Accept: */*
```

You do not need to create CORS requests yourself, other than for testing or troubleshooting purposes.

A CORS response is received from the gateway; for example:

```
HTTP/1.1 200 OK
X-Backside-Transport: FAIL FAIL
Connection: Keep-Alive
Transfer-Encoding: chunked
Access-Control-Allow-Origin: https://example.com
```

```
Access-Control-Allow-Credentials: true
Access-Control-Allow-Headers:accept, accept-language, content-type, x-ibm-client-id
Access-Control-Allow-Methods: methods allowed on the resource
Vary: Origin
```

Applications in the Developer Portal

You can view, edit, configure, and create applications in the Developer Portal.

Before you can subscribe to a Plan that contains the API or APIs that you want to use, you must first register an application by creating an App. You can create more than one App, and these Apps can be edited and deleted as required.

To learn about applications in the Developer Portal, use the following topic links.

- **Registering an application**
  Before you can use an API, you must register your application to the Developer Portal.
- **Upgrading a Development application to Production status**
  If development application workflow is enabled for the Catalog associated with your Developer Portal, any new application that you register initially has Development status. When you have completed your application testing, you can request to upgrade your application to Production status.
- **Managing applications**
  You can show or reset a client ID for an application, verify or reset a client secret, and view the details of the APIs in the application. You can also unsubscribe from a Plan that the application is subscribed to.
- **Editing an application**
  You can edit applications in the Developer Portal. If a user has the correct permissions, they can edit the content of any application in their organization.
- **Deleting an application**
  You can delete applications in the Developer Portal.
- **Changing an application image**
  You can change the image for an application in the Developer Portal.
- **Verifying an application client secret**
  You can verify an application client secret in the Developer Portal

Registering an application

Before you can use an API, you must register your application to the Developer Portal.

About this task

When you register an application, you are provided with a client ID and client secret for the application. You must supply the client ID when you call an API that requires you to identify your application by using a client ID, or a client ID and client secret.

You can, optionally, add further client ID/client secret pairs to an application, any of which can be used to identify the application when calling an API.

Procedure

To register an application, complete the following steps:

1. Click Apps.
   The Apps page opens.
2. Click Create new app.
3. Optional: Specify a URL in the Application OAuth Redirect URL(s) field.
   You can specify multiple OAuth redirect URLs by clicking Add another item. If only one redirect URL is specified, and the application does not provide the `redirect_uri` in the OAuth request, then API Connect automatically uses the one redirect URL specified. However, if more than one redirect URL is specified, then the application must provide the `redirect_uri` in the OAuth request, or the OAuth request is rejected.
4. Click Submit.
   Your application is displayed.
5. The client secret is hidden; click the Show check boxes, make a note of your client secret because it is displayed only once.
   You must supply the client secret when you call an API that requires you to identify your application by using a client ID and client secret.
   Note: The client secret cannot be retrieved. If you forget it, you must reset it.
6. Optional: In the Certificate field, paste the public X509 certificate for your application, in PEM format.
   The Certificate field is available only if the APIs that have been published to the Developer Portal include at least one API that has been secured with TLS mutual authentication. You must complete this field if you want to call an API that has been secured with TLS mutual authentication. For more information, see Composing a REST API definition.

   These certificates are sent to the management server and to the gateway, and are used for certificate verification when the application calls an API that has been secured with TLS mutual authentication.

   Important: When you paste the certificate, ensure that it contains no line breaks, and that the `(-----BEGIN CERTIFICATE-----)` prefix and `(-----END CERTIFICATE----)` suffix are removed.
7. Optional: The client ID is hidden, to display the client ID for your application, click Subscriptions, then select the Show check box for Client ID.
   The client ID is displayed and can be hidden again by clearing the check box.
8. Optional: To verify your client secret, click Subscriptions, then click Verify, enter your client secret in the Secret field, then click Submit.
   You have confirmed whether your client secret is correct or incorrect.
9. To add an additional client ID and client secret to the application, complete the following steps:
   a. Click Subscriptions.
   b. Click Add alongside Credentials.

The "Add new application credentials" window opens.
c. Enter a name and an optional summary, and click Submit.
d. Select the Show Client ID or Show Client Secret check box to display the client ID or client secret for the new credentials.
e. To add a description to a set of client credentials, or to change the current description, click Update alongside the required credentials.
f. To remove a set of client credentials from the application, click Delete alongside the required credentials.

If you add additional credentials to an application, any of the associated client ID/client secret pairs can be used to identify the application when calling an API.
Note: If you add two or more sets of client credentials to an application, OAuth tokens are not shared between them; each client credential set uses a different OAuth token.

10. To add an image, click Upload image from the application overflow menu.
A new window opens; click Browse, select an image from your directory, and click Submit.
11. Optional: To change the URL that authenticated OAuth flows for this application should be redirected to, click Edit from the application overflow menu, then enter a URL in the Application OAuth Redirect URL(s) field.
12. Optional: To change the application name or description, click the Edit from the application overflow menu.

Results

Your application is registered.

What to do next

Select a Plan to use with your application, see Exploring APIs and Products in the Developer Portal.

- Creating an API key security definition

Upgrading a Development application to Production status

If development application workflow is enabled for the Catalog associated with your Developer Portal, any new application that you register initially has Development status. When you have completed your application testing, you can request to upgrade your application to Production status.

Procedure

To request to upgrade a Development application to Production status, complete the following steps:

1. From the Developer Portal home page, click Apps.
2. Click the title of the application that you want to upgrade.
3. Click Upgrade to production, then click Request upgrade to confirm the upgrade request.

Results

An upgrade approval request is submitted. Your application continues to have Development status while the approval request is pending, and a Pending Upgrade label is displayed on the application details page. When the request is approved, you will receive a notification, and the application will move automatically to Production status.

If the request is rejected, the status of the application remains unchanged, and the Pending Upgrade label is removed.

Managing applications

You can show or reset a client ID for an application, verify or reset a client secret, and view the details of the APIs in the application. You can also unsubscribe from a Plan that the application is subscribed to.

About this task

On the application details page, you can display and reset a client ID and client secret. You might want to reset a client secret if it is compromised or you forget it. A client secret is only displayed once, so after you reveal it for the first time at a time of your choosing, you can use this window to verify that what you have is correct or reset it if necessary.

You can, optionally, add further client ID/client secret pairs to an application, any of which can be used to identify the application when calling an API.

Note: You can see the Add, Reset Credentials, and Reset API Secret options on the Applications page only if it is selected in the Configure the IBM API Developer Portal page under Applications. For more information, see Configuring the application settings.

Procedure

To manage an application, complete the following steps:

1. Click Apps.
The Apps page opens.
2. Select the application that you want to work with from the displayed list.
3. Click Subscriptions.

4. The client ID is hidden; to display the client ID, select the Show check box. The client ID is displayed, and can be hidden again by clearing the Show check box.
5. To reset your client ID, click the options icon ⋮ and then click Reset Credentials.
   Warning: API calls made by the application with the existing client ID will fail.
6. If the client secret is compromised or you forget it, click the options icon ⋮ and then click Reset API Secret to generate a new value for the client secret.
7. If you are unsure whether the value that you have for the client secret is correct, you can click Verify, enter the value, and click Submit to confirm whether or not it is correct.
8. To add an additional client ID and client secret to the application, complete the following steps:
   a. Click Subscriptions.
   b. Click Add alongside Credentials.
      The "Add new application credentials" window opens.
   c. Enter a name and an optional summary, and click Submit.
   d. Select the Show Client ID or Show Client Secret check box to display the client ID or client secret for the new credentials.
   e. To add a description to a set of client credentials, or to change the current description, click Update alongside the required credentials.
   f. To remove a set of client credentials from the application, click Delete alongside the required credentials.

   If you add additional credentials to an application, any of the associated client ID/client secret pairs can be used to identify the application when calling an API.
   Note: If you add two or more sets of client credentials to an application, OAuth tokens are not shared between them; each client credential set uses a different OAuth token.
9. To view more details about an individual API, click the API name.
   The operations are listed.
10. To unsubscribe from a Plan, click Unsubscribe alongside the Plan name.

Related information

- API Connect overview

Editing an application

You can edit applications in the Developer Portal. If a user has the correct permissions, they can edit the content of any application in their organization.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the target application.
3. Click Edit from the application overflow menu.
4. Make any required changes, then click Submit.

Deleting an application

You can delete applications in the Developer Portal.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the required application.
3. Click Delete from the application overflow menu.
4. Click Delete again to confirm.

Changing an application image

You can change the image for an application in the Developer Portal.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the required application.
3. Click Upload image from the application overflow menu.
4. Browse for the target image, then click Submit.
   You can remove the image by clicking Remove.

Verifying an application client secret

You can verify an application client secret in the Developer Portal

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the target application.
3. Click Subscriptions.
4. Click Verify for the client secret.
5. Enter your secret string and click Submit.
   You received a notification saying whether the secret that you entered is correct.

Analytics in the Developer Portal

You can view analytics for APIs in the Developer Portal at the application and organization levels. This information is displayed in dashboard views that show the analytics metrics in the form of *visualizations* (represented as charts).

Restriction:

- If the Catalog that is associated with this Developer Portal has two or more gateway services enabled then, for analytics data to be available, the gateway services must all be associated with the **same** analytics service. If the set of associated analytics services for the gateway services includes two or more different analytics services then the Developer Portal does **not** display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see Associating an analytics service with a gateway service.
- If the visualizations in your dashboard views display no data, show data only for a time period in the past, or the Dashboard tab does not show up, a possible reason might be that access to analytics data within API Connect has been switched off. Contact your API provider for confirmation.
- What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings. For more information, see Configuring analytics in the developer portal.

Use the following topic links to learn how to access the various analytics available to you in the Developer Portal:

- **Application analytics in the Developer Portal**
  From the Developer Portal, you can view interactive analytics information about all of the APIs used by an application.
- **Organization analytics in the Developer Portal**
  From the Developer Portal, you can view interactive analytic information about the APIs within an organization.

Application analytics in the Developer Portal

From the Developer Portal, you can view interactive analytics information about all of the APIs used by an application.

About this task

All members of the consumer organization can view analytics information relating to APIs used by an application.

Note: What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings. For more information, see Configuring analytics in the developer portal.

Procedure

1. Click Apps from the Developer Portal dashboard.
2. Click the name of the application for which you want to view analytics information.
   From the Dashboard tab, you can see your application analytics including, API Stats, Total Calls, and Total Errors.

Organization analytics in the Developer Portal

From the Developer Portal, you can view interactive analytic information about the APIs within an organization.

About this task

All members of the consumer organization can view analytics information about the APIs that are used within an organization.

Note: What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings. For more information, see Configuring analytics in the developer portal.

Procedure

1. Click your username from the Developer Portal dashboard.
2. From the drop-down menu, select My organization.
3. Click the Analytics tab.
   From the Analytics tab, you can see your organization analytics such as API Stats, Total Calls, and Total Errors.

Consumer organizations in the Developer Portal

Consumer organizations provide a way of grouping application developers together. You can add, remove, and configure Consumer organizations in the Developer Portal.

Developer Portal users must be a member of at least one Consumer organization. A Consumer organization can have multiple members and multiple applications. Members must register an application before they can subscribe to an API. A Consumer organization owns all the applications that are created within it. The members do not own any applications. As long as there is one member of a Consumer organization, all applications continue unchanged.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **`A user already exists with this email address`**.
To learn more about Consumer organizations in the Developer Portal, see the following topics.

- **Adding a Consumer organization from within the Developer Portal**
  You can create a new Consumer organization from within your user account in the Developer Portal. The new Consumer organization appears also in the API Manager UI after it is created.
- **Editing the name of a Consumer organization**
  You can edit the name of your Consumer organization from within the Developer Portal.
- **Switching Consumer organizations**
  You can switch from one Consumer organization to another in the Developer Portal.
- **Adding users to a Consumer organization**
  If the API Provider organization administrator has granted you permission to collaborate, you can invite users to join your Consumer organization. Those organization members can then access the Developer Portal and use the APIs that have been made available to the Consumer organization.
- **Removing a user from a Consumer organization**
  You can remove a developer from a Consumer organization in the Developer Portal.
- **Changing the ownership of a Consumer organization**
  You can change the ownership of a Consumer organization in the Developer Portal.
- **Deleting a Consumer organization**
  You can delete a Consumer organization in the Developer Portal.

Adding a Consumer organization from within the Developer Portal

You can create a new Consumer organization from within your user account in the Developer Portal. The new Consumer organization appears also in the API Manager UI after it is created.

Procedure

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page.
3. Select Create organization from the drop-down menu.
4. In the Organization Title field, type the name of the new Consumer organization, then click Submit.

Results

Your new Consumer organization is created, and you can switch to it by clicking on its name in the Organization drop-down menu on the home page.

Editing the name of a Consumer organization

You can edit the name of your Consumer organization from within the Developer Portal.

Procedure

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page, and click My organization.
3. In the Manage tab, click the vertical ellipsis Manage organization icon, and click Edit organization.
4. Enter the new name for your Consumer organization in the Organization Title field, and then click Submit.
   You changed the name of your Consumer organization.

Switching Consumer organizations

You can switch from one Consumer organization to another in the Developer Portal.

Procedure

1. If you are a member of more than one Consumer organization, click the menu of Consumer organizations in the Developer Portal home page.
2. Select the Consumer organization that you want to switch to, and ensure that any applications you register are registered to the correct catalog.

Adding users to a Consumer organization

If the API Provider organization administrator has granted you permission to collaborate, you can invite users to join your Consumer organization. Those organization members can then access the Developer Portal and use the APIs that have been made available to the Consumer organization.

About this task

Depending on the permissions enabled by the Provider organization administrator, members can view applications and application activity, create and edit applications, manage client keys and subscribe to API Plans, or perform all activities.
Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.

Procedure

To invite users to join your Consumer organization, complete the following steps.

Note: The ability to invite users is only visible if the API Provider organization administrator has granted you permission to collaborate.

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page, and click My organization.
   The organization page is displayed.
3. On the Manage tab, select Invite.
4. Enter the email address of the new user in the Email field.
5. Under the Assign Roles heading, use the radio buttons to select a role for the new user, the roles are:
   - **Administrator**-- Can administer the Consumer organization, including invite new members, and can create, and edit applications, manage client keys, and subscribe to API Plans.
   - **Developer**-- Can create and edit applications, manage client keys, and subscribe to API Plans.
   - **Viewer**-- Can only view applications and application activity.

   For full details of the permissions that are assigned to the Developer Portal roles, see API Connect user roles.
6. Click Submit.
   An invitation is sent to the new user.

Results

The user is added to the Consumer organization list of members, and they are sent an email inviting them to join the organization. The user must click the link that is provided in the email to activate their account, and complete the setup.

Removing a user from a Consumer organization

You can remove a developer from a Consumer organization in the Developer Portal.

Before you begin

Make sure that you are the owner of your Consumer organization and you previously added the developer that you want to remove from the organization.
Removing a user from a Consumer organization does not delete their user account, it only removes them from that organization.

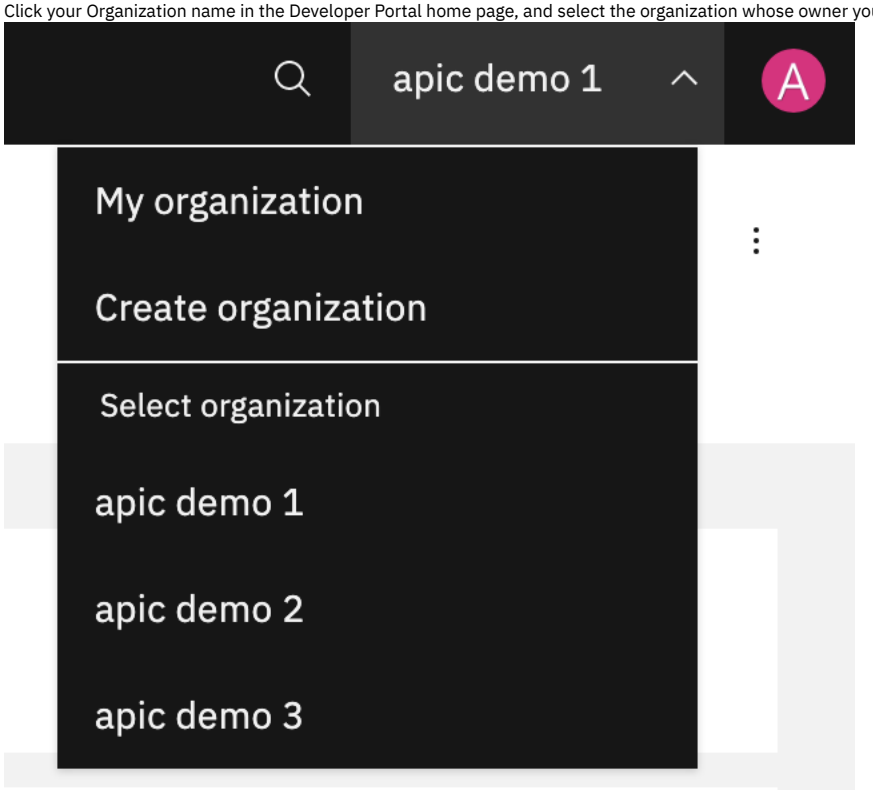
Procedure

1. Click your username in the Developer Portal home page.
2. Click My organization in the menu.
3. Click Remove user for the user you want to remove.

Changing the ownership of a Consumer organization

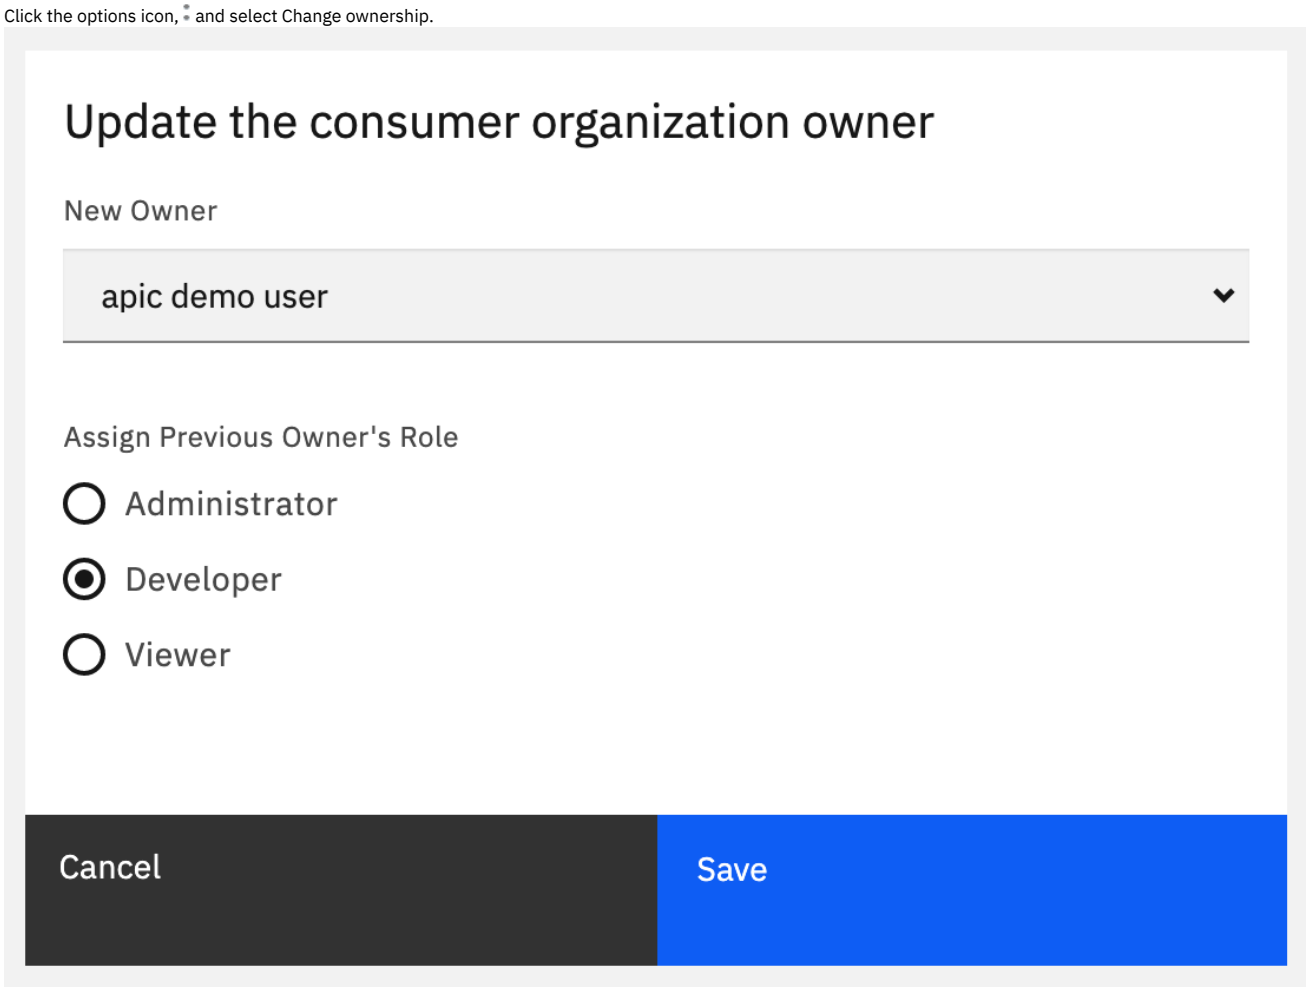
You can change the ownership of a Consumer organization in the Developer Portal.

Before you begin



You can change the ownership of a Consumer organization only if you are the owner of that organization. The user that you transfer ownership to must already be a member of the organization. To have an account on a Developer Portal, you must be a member of at least one Consumer organization.

About this task



Transferring the ownership of a Consumer organization to another organization member, changes your role in that organization to App Developer.

Procedure

1. Click your Organization name in the Developer Portal home page, and select the organization whose owner you want to change by using the drop-down arrow.

2. Click your Organization name in the Developer Portal home page, and select My organization.
3. Click the options icon, ⋮ and select Change ownership.

4. Select the **`New Owner`** by using the drop-down arrow.
5. Use the radio buttons to **`Assign Previous Owner's Role`**, then click Submit.

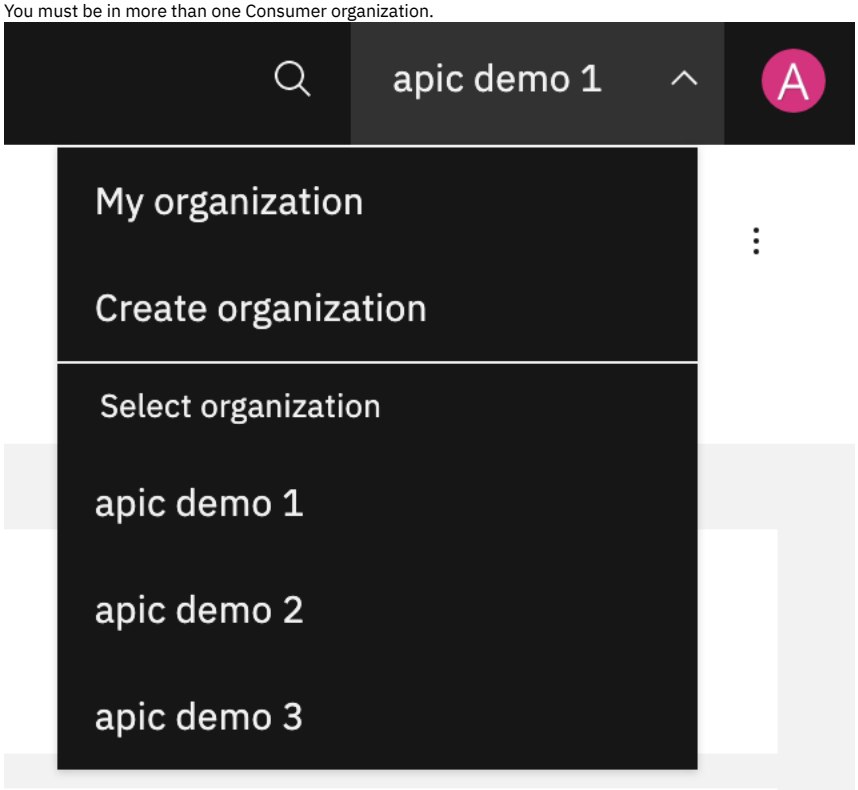
Results

You successfully transferred ownership of a Consumer organization in the Developer Portal.

Deleting a Consumer organization

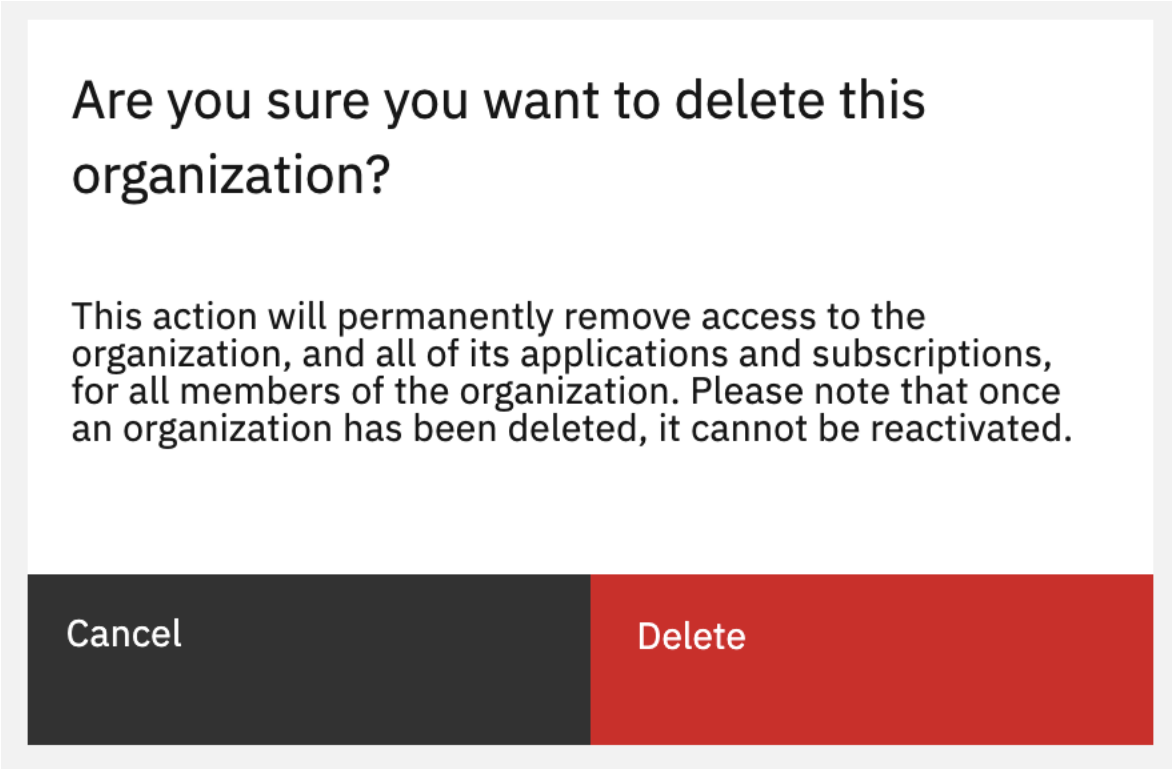
You can delete a Consumer organization in the Developer Portal.

Before you begin



You can delete a Consumer organization only if you are the owner of that organization. To have an account on a Developer Portal, you must be a member of at least one Consumer organization. Therefore, if you are a member of only one Consumer organization, to delete that organization you must first either join or create another Consumer organization, or you can delete your whole developer account. For more information, see Deleting your developer account.

About this task



Deleting a Consumer organization in the Developer Portal permanently removes access to the organization, and all of its applications and subscriptions, for all members of the organization. Consider carefully the impact on any members of your Consumer organizations before you delete the organization. Any users that were members of only the deleted organization, must create a new Consumer organization when they next logon to the Developer Portal.
Important: When an organization is deleted, it cannot be reactivated. You might want to consider changing the ownership of a Consumer organization, rather than deleting it. For more information, see Changing the ownership of a Consumer organization.

Procedure

1. Click your Organization name in the Developer Portal home page, and select the organization that you want to delete by using the drop-down arrow.
   You must be in more than one Consumer organization.

2. Click your Organization name in the Developer Portal home page, and select My organization.
3. Click the options icon, ⋮ and select Delete organization.

4. Click Delete.

Results

You permanently deleted a Consumer organization in the Developer Portal.

User accounts, passwords, and support in the Developer Portal

You can change general elements such as user accounts and passwords in the Developer Portal.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **`A user already exists with this email address`**.
To learn about general user features of the Developer Portal, see the following topics:

- **Creating a new developer account**
  You can create new developer accounts, and their associated Consumer organizations, in the Developer Portal.
- **Changing your account settings**
  You can edit your user account settings in the Developer Portal, such as changing your name, password, time zone, and language settings.
- **Deleting your developer account**
  You can delete your account in the Developer Portal.

Creating a new developer account

You can create new developer accounts, and their associated Consumer organizations, in the Developer Portal.

Before you begin

You need to provide an email address to create a new account. That email address must be a valid email address, and the domain that is used is required to have a valid MX record that is determined by DNS. You can disable the security module that checks that the email domain has a DNS record.

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Extend > Disable module.
4. In the search bar enter **`Check DNS`**, then select the Check DNS module and click Disable.
5. Click Disable to confirm that you want to disable the module.

About this task

In order to use the Developer Portal, you must have a developer account, and be a member of at least one Consumer organization. When you create a developer account, a Consumer organization is created at the same time. You can be an owner, and a member of, multiple Consumer organizations. For more information about Consumer organizations, see Consumer organizations in the Developer Portal.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **`A user already exists with this email address`**.

Procedure

1. From the Developer Portal home page, click Create account.
2. Populate the available fields with the details of the developer account and Consumer organization that you want to create.
3. Click Sign up.
   The email address that you provided for the new developer account is sent an email that contains an activation link for the new developer account. Use this link to activate your new account.

Changing your account settings

You can edit your user account settings in the Developer Portal, such as changing your name, password, time zone, and language settings.

About this task

You can edit various details about your user account, for example, change your password, update your code snippet language, change your time zone, select your preferred site language, and select an avatar.

Procedure

1. Click your user name in the Developer Portal home page, and click My account.
2. To update your password, click Change Password, and update the fields as required.
3. To update other elements of your account, such as your name, time zone, and language, click Edit and update the fields as required.
4. Click Save to save your changes.

Deleting your developer account

You can delete your account in the Developer Portal.

Before you begin

You must be the owner of the developer account that you want to delete, and you must not own more than one Consumer organization. If you do own more than one Consumer organization, you must either change the ownership of those organizations, or delete them, before you can delete your account. If you own only one Consumer organization, when you delete your account the Consumer organization is deleted at the same time as your account.

About this task

When you delete your account, any Consumer organizations that you own must also be deleted or transferred to new owners. If there are other members in a Consumer organization that you delete, these members will no longer have access to that organization, or any of its applications and subscriptions. Consider carefully the impact on any members of your Consumer organizations before you delete your account. For more information, see Deleting a Consumer organization.

Important: When an organization has been deleted, it cannot be reactivated. You might want to consider changing the ownership of your Consumer organizations before you delete your account. For more information, see Changing the ownership of a Consumer organization.

Procedure

1. Click your user name in the Developer Portal home page, and select My account.
2. Click the Edit tab.
3. Click Delete account.
4. Click Delete to confirm deletion of the account.
   This action deletes your developer account and, if you own a Consumer organization, this organization is also deleted.

Results

You successfully deleted your developer account in the Developer Portal.

Configuring the Developer Portal site

Customize the look and feel of your Developer Portal site, and brand it for your organization.

In IBM® API Connect Version 10 the Developer Portal is based on the open source Drupal 10 content management system, and consequently it is almost infinitely customizable. What an individual user is able to configure, depends on the role the user has been assigned, and the associated permissions of that role. A user can be assigned one of four Developer Portal roles:

Authenticated user
: An authenticated user is, typically, an application developer, and can perform all of the actions that are described in the Using the Developer Portal section.

Forum Moderator, Content Author, or Administrator
: In addition to performing all of the tasks that an Authenticated user role can, a Forum Moderator, Content Author, or Administrator role have additional permissions related to configuring the Developer Portal site. For more information, see Working with roles in the Developer Portal.
Note: By default, the Developer Portal administration operations are available only if you have Administrator access.

Before you start to configure your Developer Portal site, you should familiarize yourself with the various concepts and terminology that is referenced throughout the Developer Portal. See Concepts in the Developer Portal.

When you are ready to start configuring your Developer Portal site, see Getting started configuring the Developer Portal site for a quick start guide on customization. There is also a tutorial that you can follow that takes you through an example customization scenario; see Tutorial: Creating a custom theme for the Developer Portal.

If you are migrating from Version 5 to Version 10, see Migrating your Developer Portal from Version 5 to Version 10 for guidance about how to transfer any specific customizations, such as custom modules and themes, from the Drupal 7 baseline to the Drupal 10 baseline.

In addition to the previous options, Developer Portal configuration operations are described in detail in the following sections:

Appearance
: Control and configure the general appearance of your Developer Portal site by setting and configuring a default theme.
Important: Editing API Connect themes, modules, or Drupal core on the filesystem is not permitted or supported. For more information, see Creating a sub-theme and Extend.

Content
: Control multiple content entities in the Developer Portal, including the customization and restriction of specific content.

Structure
: Control the layout of the Developer Portal, such as configuring the front page, adding and changing blocks, and displaying Products and APIs in categories.

Configuration
: As an administrator, you can control multiple aspects of the Developer Portal configuration, including managing security and general configuration tasks.

People
: You can manage and customize the user experience in the Developer Portal, by altering permissions and assigning roles to specific users.

Forums
: Create and control forums in the Developer Portal.

Reports
: You can view reports about the general configuration and status of your Developer Portal site.

Extend
: You can extend the Developer Portal by creating and installing custom modules, or installing additional Drupal contributed modules.

Concepts in the Developer Portal

The Developer Portal is built on Drupal 10, an open source content management technology. A good understanding of Drupal concepts and terminology enhances your ability to work with the Developer Portal.

In Drupal, most content on the website is treated as variations on the concept of a **node**. Node types, such as static pages, blog posts, and news items, are all stored in the same way. The navigation structure of the site is designed separately by editing **menus**, **views**, and **blocks**. Finally, the **theme** of the system controls the overall appearance of the site to visitors. Access to these depends on the permissions that your role possesses. These are explained more fully in the following sections.

Nodes

A node is a set of individual related content such as a page, a poll, an article, a forum topic, or a blog post. For example, when you create a blog post, and define the body text, you also define its title, content, author link, creation date, and taxonomy . Some of these elements are shown by the theme layer when the node is displayed, and some elements are metadata that control where and when the node is displayed at all. Each set of content in a Developer Portal site is a node. You can apply new features or changes to all content of a single node type.

Fields

A field is somewhere that you can add extra metadata to a node. The following types of data are examples of fields:

- Title
- Body
- Comment body
- Tags
- Image

You can create different types of fields, and they can be defined at the content-type level for content items and comments, at the vocabulary level for taxonomy terms, and at the site level for user accounts. Field types are defined by modules, and managed by the Field module. In addition, other modules might enable fields to be defined for their data.

Content types

A content type is a predefined collection of fields. Content types define the default fields that content editors use to add content in a Developer Portal site, and help structure the authoring and developing of content. Content types can be displayed in the Developer Portal. You can control which content types, and the order and format that they are displayed, in the Developer Portal.

Themes

You can use themes to control the overall appearance of your Developer Portal site. You can modify the appearance of the theme in following ways:

1. Extend the code of an existing theme.
2. Identify and use a theme that is provided by the Drupal community or a third-party website, and modify the theme settings.
3. Create a complete custom theme from scratch.

However, you cannot directly edit the API Connect theme as editing is not supported. Any edited versions of these files are overwritten when a fix pack or iFix is installed. So, the way to create a custom theme is to create a custom subtheme of the standard API Connect theme that the Developer Portal uses by default. A subtheme inherits all of the settings of its parent theme, apart from the settings that are overridden. For more information, see Creating a sub-theme.

Most themes use the Twig template engine for PHP.

Regions

The specific areas of a Developer Portal site in which content can be placed. Regions are customized and styled in the theme.

Blocks

Blocks are boxes of content that can be displayed in regions on your Developer Portal page. Blocks can be made available to your Developer Portal site by enabling specific modules. After a block is created, its appearance can be modified. You can also define which Developer Portal page or pages blocks appear on. Some modules can provide multiple blocks when they are enabled, while other modules might not define new blocks. For more information, see Adding and changing the blocks displayed on Developer Portal pages.

Modules

Modules are similar to the concept of plug-ins, in that they extend the core functions of the Developer Portal site. A set of modules is implemented by default with the Drupal core, and there are extra modules that can be enabled to extend the default functions. You can find and add more modules to your Developer Portal site from the internet. For more information, see Extend.

Views

You can use views to manipulate the content that is displayed on a page, block, and other visual elements in the Developer Portal site. Views can be used along with content types to format the appearance of your site to your specification. For more information, see Using the Views module in the Developer Portal.

Pages

Pages are used by the features that can modify the appearance of the Developer Portal to customize the appearance of your Developer Portal site. Pages can be customized to be as specific as you require, and can be configured to satisfy the context of the situation that they are used in.

Users

After you log in to the Developer Portal site, you have a user record in the Developer Portal database. User ID 1 is always reserved for the administrator account. Regardless of whether other user accounts are using remote authentication such as LDAP, the administrator account is always a local account to enable administration of the Developer Portal site. For more information, see People.

Roles

A role is a collection of permissions that define the actions that a user can do in the Developer Portal site. Users can be given one or more roles. By default, a user that is logged in to the Developer Portal is in the Authenticated role. Other roles that can be assigned to a user include:

- Administrator
- Forum Moderator
- Content Author

You can also create new custom roles. For more information, see Working with roles in the Developer Portal.

Permissions

Permissions define the actions that a user can or cannot do in a Developer Portal site. Permissions are additive. If a permission that enables a user to do an action is not assigned, the user cannot do the action. If a user has multiple roles, and any of them contain a specific permission, the user is able to do that action. There are also permissions that have security implications, and you are recommended to assign those permissions to trusted roles. For more information, see Controlling access to Developer Portal content.

Templates

Template files define how the output of a particular component can look. They are formatted as Twig template files. The following are examples of where you can use templates:

- html.html.twig - the template for Developer Portal HTML pages
- page.html.twig - the body of Developer Portal HTML page
- node.html.twig - the template for all of the content nodes
- comment.html.twig - the template for all of the comment nodes
- search-result.html.twig - the template for search results
- node--product.html.twig - the template for nodes that use the Product content type
- node--product--teaser.html.twig - the template for the previews for the Product content type

For more information about overriding templates in the Developer Portal, see Applying a modified content type template.

Getting started configuring the Developer Portal site

A quick start guide to the main tasks involved in configuring the Developer Portal to your brand or theme.

The Developer Portal is based on the open source Drupal 10 content management software, and therefore is almost customizable. The following sections take you through the most common tasks to get started with branding the Developer Portal to your organizational requirements, including links to the related topics in the main table of contents. Many more customizing options are described in the main table of contents. The best way of finding help with a specific customization in this content, is to use the documentation search bar.
Important:
All of the customizations that are detailed in this topic are preserved when you update to new versions of API Connect. Drupal updates, as well as new functionality, defect fixes, and security updates, are made available through API Connect update packages as determined by IBM. These update packages can be applied by upgrading your deployment; see the upgrade instructions for your platform in Installing and maintaining your IBM API Connect cloud. To find out what update packages are available, select your product on IBM Fix Central.

Directly editing any API Connect themes, modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when an update package is installed. Customizations must be done by using the proper mechanisms as described in this topic, such as custom modules and themes, and not by directly editing the source.

For more information about the API Connect support policy, see IBM® API Connect Support Lifecycle Policy.

- Create a custom theme
- Changing the page layout
- Changing the front page
- Advanced theme development
- Custom modules
- Hiding the admin login form
- What to do next - exploring the main configuration content

Create a custom theme

If you want your Developer Portal to have your corporate branding and style, you need to create a custom theme. Themes are composed primarily of Cascading Style Sheets (CSS) files, although they can include much more; see Advanced theme development.

Directly editing the API Connect theme is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed. The way to create a custom theme is to create a custom sub-theme of the standard API Connect theme that the Developer Portal uses by default. A sub-theme inherits the parent theme's resources, and this means that your custom sub-theme CSS file needs to contain only the changes or overrides that you want to make from the default theme. The CSS file can contain as little or as many updates as you like.

For more information, see Creating a sub-theme. You can also follow a tutorial that takes you through how to use the theme generator, customize a theme, and install a custom theme; see Tutorial: Creating a custom theme for the Developer Portal.

While experience with Drupal is beneficial, the only skill you really need to create a sub-theme is CSS.

Changing the page layout

While the theme defines *regions* of the page, such as a footer, or sidebar first, the page layout is defined by configuring which blocks appear in which regions. Blocks are controlled by using the Structure > Block layout options on the Developer Portal administrator dashboard. You can then further limit those blocks to show only on specific pages, or show on all pages except certain ones, to show only for certain roles, or for certain languages, and more.

For information about how to configure the page layout, see Adding and changing the blocks displayed on Developer Portal pages.

Changing the page layout is done entirely in the Developer Portal UI as an Administrator.

Changing the front page

The front page is a special case and does not use the blocks system that is mentioned previously. Instead, you configure it from the Structure > Pages options on the Developer Portal administrator dashboard.

For information about how to configure the front page, see Configuring the front page.

Further options that you might want to consider when designing your front page include:

- Change the banner block content or image: Changing the front page banner block.
- Display featured API Products by creating a featured content block: Changing the front page Featured Content block.
- Create custom blocks with your own HTML content: Adding and changing the blocks displayed on Developer Portal pages.
- Set up the social block to include your organization Twitter feed: Integrating X data into the social block.
- Add a carousel to the front page to display a series of images: Implementing an image carousel.

Again, changing the front page is done entirely in the Developer Portal UI as an Administrator.

Advanced theme development

The DOM structure for specific blocks and parts of the page is controlled by templates. These templates are Twig files that define the actual HTML output for a particular piece of content. You can override a Twig template by copying the original template into the templates folder of your custom sub-theme, and then editing the template to your specification. The Developer Portal then uses your template in preference to the original one. For more information, see Applying a modified content type template.

Modifying Twig templates allows very fine-grained control over the structure of pages. However, it also means you might miss new features and defect fixes that are made to the original templates, as your Developer Portal is using your overrides instead of the originals. So, if you override a template, it is your responsibility to check the templates in the latest API Connect releases, and to ensure that any equivalent changes that are needed to your overrides to maintain functional equivalence are made.

If you're developing custom templates, knowledge of Twig templating language, Drupal, HTML, and CSS is recommended.

Custom modules

If you need to modify the functional behavior of the Developer Portal, then you can create a custom module to do so. Drupal has an extensible programmatic API that is built around a system of *hooks*. By using these hooks in your custom modules you can change what happens when, for example, forms are displayed, forms are submitted, or make extra variables available to custom templates, and other options.

For more information on writing custom modules, see Extend. You can also follow a tutorial that includes using a custom module, see Tutorial: Adding validation to a field on the sign-up form.

Custom modules are written in PHP, and so Drupal experience and PHP knowledge are very beneficial.

Hiding the admin login form

If your Developer Portal is public facing, you might want to hide the admin registry as an option on the login form. You can do this simply from the administrator dashboard, by clicking Configuration > System > IBM API Developer Portal, and selecting Hide the admin registry on the login form. For more information, see Hiding the admin registry on the login form.

What to do next - exploring the main configuration content

There are an almost infinite number of configuration options available to you on the Developer Portal. Explore the following sections to find out more:

- Appearance - control general appearance elements, and learn how to create a custom theme.
- Content - add, configure, and control content elements, such as meta tags, custom pages, custom content types, and adding content to an API or Product.
- Structure - control how the content in your Portal is displayed, for example configuring the front page, changing block display, and using the Views module.
- Configuration - configure content moderation, perform general configuration tasks, and manage Developer Portal security.
- People - create and customize site configuration roles, control access to sites and to content, and create internal Consumer organizations to allow customization of specific API properties.
- Forums - create and control forums.
- Reports - list of available reports about the general configuration and status of your site.
- Extend - introduction to and instructions for creating custom modules, including information about developing in PHP, and how to use hooks in custom modules.
- Developer Portal tutorials - guided examples taking you through the simple and the more complex areas of configuration.

Appearance

Control and configure the general appearance of your Developer Portal site by setting and configuring a default theme.

To learn how to control the appearance of your Developer Portal site, use the following topic links.

- **Controlling general appearance elements in the Developer Portal**
  You can control general appearance aspects of the Developer Portal.
- **Adding custom JavaScript to a custom theme**
  To increase customization of the Developer Portal, you can add custom JavaScript to custom themes that you install.
- **Applying a modified content type template**
  You can apply a modified content type template to override a default content type template in the Developer Portal. For example, you can override the product content type template to change its layout.
- **Creating a sub-theme**
  Create a custom theme for your Developer Portal site by generating and configuring a sub-theme. A sub-theme is a theme that inherits all the resources of a specified parent theme. You can then override specific resources to configure your required customizations.
- **Installing additional themes**
  You can install additional themes in the Developer Portal.
- **Deleting themes**
  You can delete a theme from your Developer Portal site.

Controlling general appearance elements in the Developer Portal

You can control general appearance aspects of the Developer Portal.

To learn how to control general aspects of the Developer Portal appearance, use the following topic links:

- **Changing the shortcut icon**
  You can change the shortcut icon, or favicon, in the Developer Portal.
- **Changing the site email address**
  You can change the site email address in the Developer Portal.
- **Changing the site logo**
  You can change the site logo for your Developer Portal.
- **Changing the site name or site slogan**
  You can change the site name, or the site slogan, for your Developer Portal.
- **Changing the visibility of site branding**
  You can toggle the visibility of your site branding elements for your Developer Portal.

Changing the shortcut icon

You can change the shortcut icon, or favicon, in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The shortcut icon, or favicon, is displayed in the address bar or bookmarks of most browsers. Drupal provides a default favicon, the water drop logo, but if you want to make your Developer Portal stand out, you should provide your own.
The default Drupal favicon is 32 pixels high by 32 pixels wide. As a favicon is displayed only in the address bar and favorites (bookmarks) list, any favicon that you create should be similarly small.

Procedure

To change the shortcut icon, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Appearance in the administrator dashboard.
3. Click Settings for the default theme.
4. Click Favicon in the Override Global Settings section.
5. Deselect the Use the favicon supplied by the theme check box.
6. Provide a path to a custom icon on the server by entering it in the Path to custom icon field. Alternatively, you can browse for, and upload, a favicon image under the Upload favicon image subheading.
7. Click Save configuration.
   Note: If the changes don't appear immediately in your browser, clear your browser's cache and reload the page. If you've bookmarked the site, you may need to delete the bookmark and then create it again, so the new favicon is used.

Results

You have changed the favicon for the site.

Changing the site email address

You can change the site email address in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To change the site email address, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.

3. Under the System heading, click Basic site settings.
4. In the SITE DETAILS section, enter the new site email address in the Email address field.
5. Click Save configuration.

Results

You changed the email address for the site.

Changing the site logo

You can change the site logo for your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To change the site logo, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Appearance in the administrator dashboard.
3. Click Settings for the default theme.
4. Click Logo image in the Override Global Settings section.
5. Deselect the Use the logo supplied by the theme check box.
6. Provide a path to your custom logo by completing the Path to custom logo field. Alternatively, you can browse and upload a logo image under the Upload logo image subheading.
7. Click Save configuration.
   Note: If the changes don't appear immediately in your browser, clear your browser's cache and reload the page.

Results

You changed the site logo for your Developer Portal. How the site logo is used depends on the settings for your theme.

Changing the site name or site slogan

You can change the site name, or the site slogan, for your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The site name is used to identify the site and can be displayed in browsers. You can also set a site slogan for your theme.

Procedure

To change the site name or site slogan, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration > System > Basic site settings in the administrator dashboard.
3. In the SITE DETAILS section, enter the new site name in the Site name field, or enter a new slogan in the Slogan field.
4. Click Save configuration.

Results

The site name or site slogan is updated. How the site name and the site slogan are used depends on the settings for your site theme. For more information, see Changing the visibility of site branding.

Changing the visibility of site branding

You can toggle the visibility of your site branding elements for your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The site branding block includes the site logo, name, and slogan. You can choose which of these branding elements you want to be displayed in this block.

Procedure

To change the visibility of your site branding elements, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Block layout in the administrator dashboard.
3. Find the Site branding block in the Navigation section, and click Configure.
4. In the TOGGLE BRANDING ELEMENTS section, use the check boxes to select which branding elements you want to be visible.
5. Click Save block to save your changes.

Results

You changed the visibility of your site branding elements. How these elements are used depends on the settings for your theme.

Adding custom JavaScript to a custom theme

To increase customization of the Developer Portal, you can add custom JavaScript to custom themes that you install.

Procedure

1. Add your JavaScript file to your theme. For example, in a sub-directory named js and the file `myfilename.js`.
2. Add the JavaScript file to your theme, by editing your {custom_theme}.libraries.yml file and adding in the JavaScript file.
   An example of the JavaScript file:

   ```
   myfile:
     js:
       js/myfilename.js: {}
   ```

3. Add the following code to your theme's .info.yml file:

   ```
   libraries:
   - {custom_theme}/myfile
   ```

   Note: You must replace `{custom_theme}` with your theme name. Also, both files must reference `myfile`.
4. Zip up the directory and upload it to your portal site. For more information, see Installing additional themes.

Applying a modified content type template

You can apply a modified content type template to override a default content type template in the Developer Portal. For example, you can override the product content type template to change its layout.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You must also have a custom subtheme, and a copy of an existing template that you want to update. For information about how to create a subtheme, see Creating a sub-theme.

To obtain a copy of an existing template, you can download a copy from the following locations on GitHub:

- https://github.com/ibm-apiconnect/devportal/tree/master/ibm_apim/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/apic_api/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/apic_app/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/product/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/consumerorg/templates

Copy the template to your subtheme, and then modify the content. Do not modify the content that is stored on GitHub.

About this task

You can override the Developer Portal core templates by creating a custom subtheme, and then adding your modified templates to the subtheme folder. A subtheme inherits all of the settings of its parent theme, apart from the settings that are overridden, such as by applying modified templates. After you have applied a modified

content types template, these changes take precedence over the default content types template. The Developer Portal templates are formatted as Twig template files. The following levels are examples of where you can use templates:

- html.html.twig - the template for Developer Portal HTML pages
- page.html.twig - the body of Developer Portal HTML page
- node.html.twig - the template for all of the content nodes
- comment.html.twig - the template for all of the comment nodes
- search-result.html.twig - the template for search results
- node--product.html.twig - the template for nodes that use the Product content type
- node--product--teaser.html.twig - the template for the previews for the Product content type

For more information about Twig templates, see Working with Twig templates and Debugging Twig templates on the Drupal documentation website.
Modifying Twig templates allows very fine-grained control over the structure of pages. However, it also means you might miss new features and defect fixes that are made to the original templates, as your Developer Portal is using your overrides instead of the originals. So, if you override a template, it is your responsibility to check the templates in the latest API Connect releases, and to ensure that any equivalent changes that are needed to your overrides to maintain functional equivalence are made.

Important:
Directly editing any API Connect theme files is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.

Procedure

To override a default content type template:

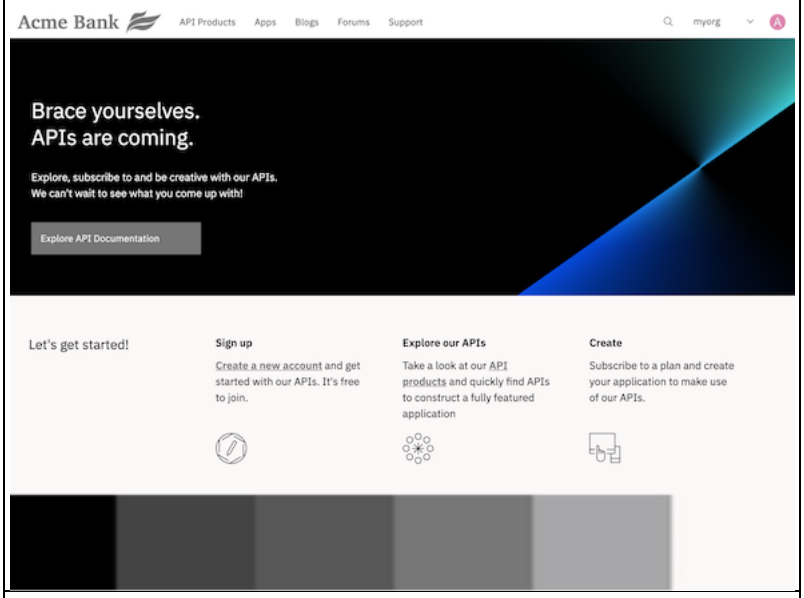
1. Apply the modifications that you require to the default template that you obtained.
   Warning: Although the ability to override templates is supported, if you override a template they are your responsibility. Templates can be from multiple sources and compatibility with an earlier version is not ensured. Check the templates in the latest API Connect release to check whether you need to make equivalent changes to your overrides to maintain functional equivalence.
2. Create a directory in your custom subtheme, and name it templates.
3. Add your modified template to the templates directory.
   Note: The modified template file name must be identical to the original name of the template file that it is overriding.
4. Log in to the Developer Portal UI as an administrator.
5. If the administrator dashboard is not displayed, click Manage to display it.
6. Install your custom subtheme onto the Developer Portal by clicking Appearance > Install new theme on the administrator dashboard.
7. Click Choose file, select your subtheme, and then click Install.
8. Click Install newly added theme, find your new theme in the list of Uninstalled themes, and click Install and set as default to set your new custom subtheme as the default theme for your site.
   Your new theme, which contains the modified template file, is now set as the default theme, and is listed in the Installed themes section.

Results

You successfully modified and applied a template to override a default content type template in the Developer Portal.

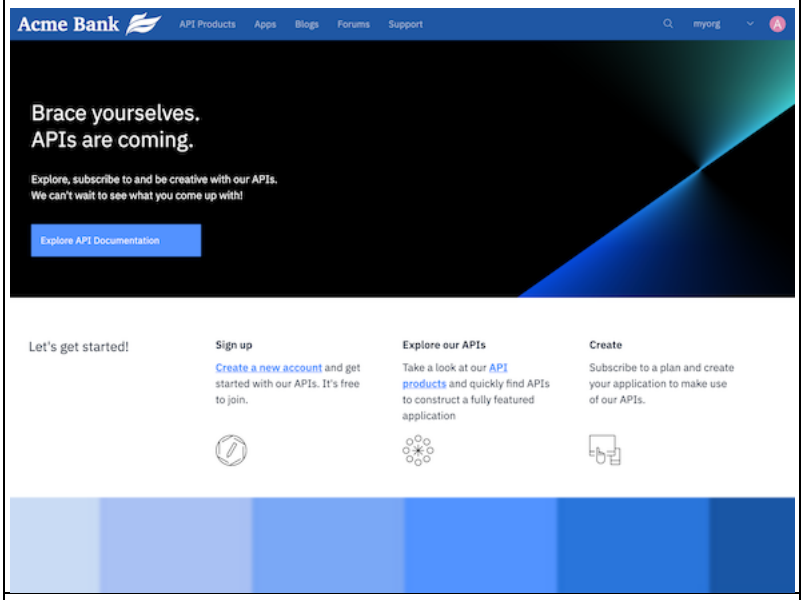
Creating a sub-theme

Create a custom theme for your Developer Portal site by generating and configuring a sub-theme. A sub-theme is a theme that inherits all the resources of a specified parent theme. You can then override specific resources to configure your required customizations.



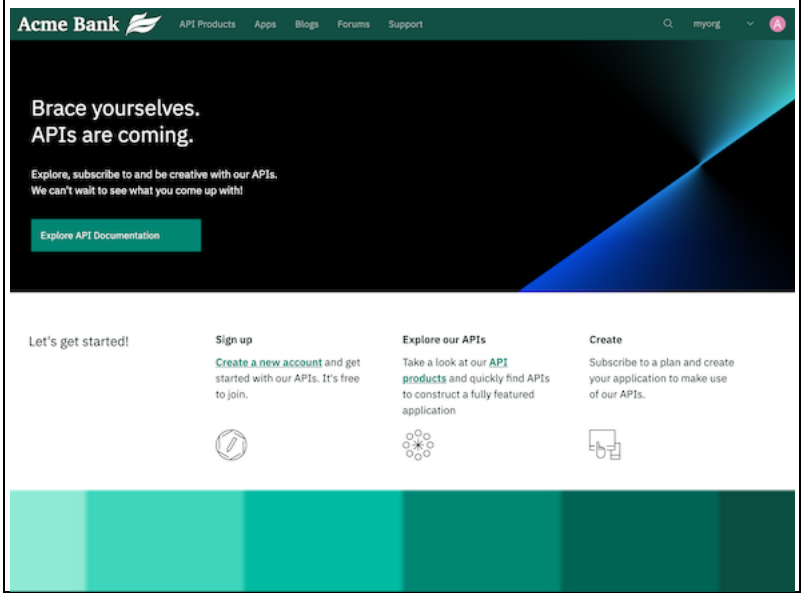
Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

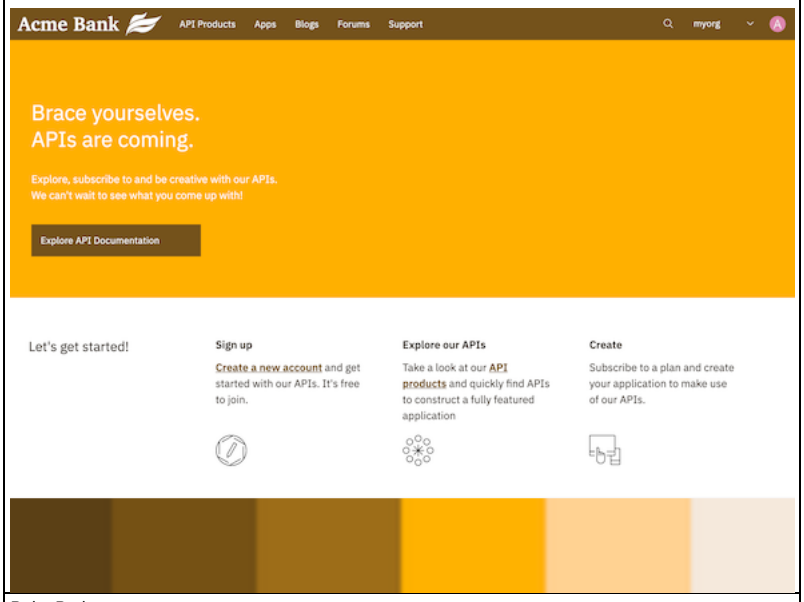


About this task

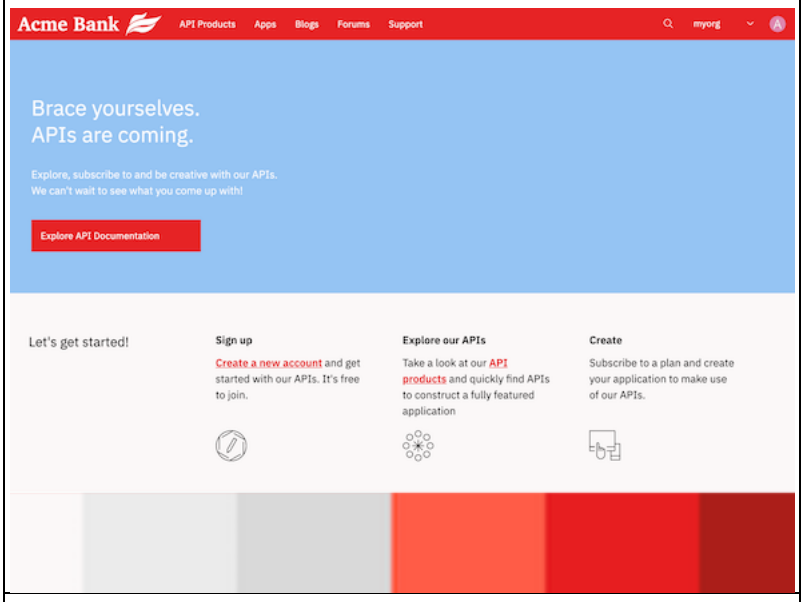
Directly editing the API Connect theme isn't permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed. So, the way to create a custom theme is to create a custom sub-theme of the standard API Connect theme that the Developer Portal uses by default. You can also create a sub-theme that is based on one of the following color templates:



Business Mono



Sapphire Blue



Emerald Green

Golden Brown

Ruby Red

Selecting a color template provides you with a base theme that you can build on more easily to produce your required site branding and styling.
Create a sub-theme by using the theme generator in the Developer Portal UI, customize the appearance as required, and then upload the compressed file back onto the site.

Important:

- You're not permitted to include any IBM® API Connect code within any custom themes that you create. Also, directly editing any API Connect themes on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom themes is supported, IBM API Connect do not provide support in their development or modification.

For a guided example on creating a sub-theme, see Tutorial: Creating a custom theme for the Developer Portal. In this example, you create a sub-theme, and then customize the styling by editing the overrides.css file.

Procedure

1. On the administrator dashboard, click Appearance > Generate sub-theme.
   The Generate sub-theme page is displayed.
2. Enter a Sub-theme name, and select the Sub-theme type that you would like to use. The name can contain only lowercase characters a - z, and numerals 1 - 9.
   - CSS - Cascading Style Sheets; the language that is used to describe how to display the HTML elements in the theme.
   - SCSS - Sass CSS; a superset of CSS. SCSS contains all the features of CSS, but is extended to include the features of Sass as well. However, SCSS must be compiled into CSS before it can be installed and used in the Developer Portal.
3. Select the template to base your sub-theme on:
   - Default - the standard connect_theme that the Developer Portal is based on.
   - Business Mono - a black and white color theme.
   - Sapphire Blue - a blue color theme.

- Emerald Green - a green color theme.
- Golden Brown - a brown color theme.
- Ruby Red - a red color theme.

4. Click Generate.
   Your sub-theme is available to download from the Generate sub-theme page.
5. Click your new sub-theme and save it to your preferred location.
6. Extract the resources from the sub-theme file, and then edit the specific resources to configure the customizations that you require.
   Define your theme by creating metadata in the *your_theme_name*.info.yml file. You can then customize the appearance of your theme by configuring the overrides.css file. For detailed information about how to customize themes, see Theming Drupal.
7. After you have completed your customizations, compress the sub-theme resources back into the .zip file.
   Note that the following file extensions are also supported: tar, tgz, gz, and bz2.
8. Install your new sub-theme onto the Developer Portal by clicking Appearance > Install new theme.
9. Click Choose file, select your sub-theme, and then click Install.
10. Click Install newly added theme, find your new theme in the list of Uninstalled themes, and click Install and set as default to set your new custom sub-theme as the default theme for your site.
    Your new theme is now set as the default theme, and is listed in the Installed themes section.

Results

You created and installed a new sub-theme for your Developer Portal site.

What to do next

You can edit the display settings for your new theme, by clicking Settings next to your theme.

Installing additional themes

You can install additional themes in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To install additional themes, complete the following steps:

1. Click Appearance in the administrator dashboard.
2. Click + Add new theme.
3. You can enter a path to the theme in the Install from a URL field. Alternatively, you can upload a theme under the Upload a module or theme archive to install heading.
4. Click Install.
5. Click Enable newly added themes.
6. Click Enable and set default for the theme that you want to be displayed in the Developer Portal.
   Your theme is displayed in the Developer Portal when you navigate to the home page.

Deleting themes

You can delete a theme from your Developer Portal site.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

If you have a custom theme which is disabled, you can remove it from the Developer Portal. Deleting a theme is useful if you have identified a theme that you do not want to use again.

Procedure

1. Click Appearance from the administrator dashboard.
2. Identify the custom theme that you want to delete, and ensure that it is disabled.
3. Click Delete against the theme.
   The theme is now deleted from your Developer Portal site.

Results

You deleted a disabled theme in the Developer Portal.

Content

Control multiple content entities in the Developer Portal, including the customization and restriction of specific content.

A *content entity* is an item of content data, which can consist of text, HTML markup, images, attached files, and other data that is intended to be displayed to site visitors. Content entities can be defined by the core software or by modules. Content entities are grouped into *entity types*, which have different purposes and are displayed in different ways on the site. Most entity types are also divided into *entity sub-types*, which are divisions within an entity type to allow for smaller variations in how the entities are used and displayed.

The Developer Portal site contains the following content entity types:

- API
- Application
- Article
- Basic page
- Blog post
- Book page
- Consumer Organization
- FAQ
- Forum Topic
- Product

Within content entity items the data is stored in individual *fields*, each of which holds one type of data, such as formatted or plain text, images or other files, or dates. Field types can be defined by the core software or by modules.

Fields can be added by an administrator on content entity sub-types, so that all the entity items of a given entity sub-type have the same collection of fields available. When you create or edit entity items, you are specifying the values for the fields on the entity item.

To learn how to configure the content entities of your Developer Portal site, use the following topic links.

- **Adding content elements in the Developer Portal**
  You can add content elements in the Developer Portal.
- **Configuring and restricting content in the Developer Portal**
  You can configure and restrict certain content elements in the Developer Portal.
- **Turning content on or off in the Developer Portal**
  You can turn certain content elements on or off in the Developer Portal

Adding content elements in the Developer Portal

You can add content elements in the Developer Portal.

Note: You can export and import entities from the Developer Portal UI. When you're editing a content entity type in the UI, you can click Export in the side navigation bar. To create an export entity container and export that entity, including any required embedded entities, click Export entity. Or, if you have an existing export entity container, you can select the required container, and click Add to the export. You can also view and manage all of your export entities by clicking Content > Content synchronizer > Exports, and all of your import entities by clicking Content > Content synchronizer > Imports.
To learn how to add various content elements in the Developer Portal, use the following topic links:

- **Adding and configuring meta tags**
  You can customize the Developer Portal by adding and configuring meta tags.
- **Adding custom pages**
  You can create custom pages within the Developer Portal. You can add a basic page for static content, or an article for news content.
- **Integrating X data into the social block**
  You can retrieve and integrate data from an X (formerly known as Twitter) account of interest and display it into a social block in a Developer Portal site.
- **Adding content in multiple languages**
  You can create content in multiple languages in the Developer Portal.
- **Adding custom pages to APIs and Products**
  After you create a custom page in the Developer Portal, you can add a link to the new page to any APIs and Products that exist in the Developer Portal.
- **Adding new frequently asked questions**
  You can add new FAQs to the Developer Portal.
- **Applying an image to an API or Product**
  You can apply an image to an API or a Product in the Developer Portal.
- **Attaching a documentation file to APIs**
  You can attach a file to APIs in the Developer Portal, and display them as documentation attachments. You can attach multiple files to APIs.
- **Configuring blogs**
  You can post new blog entries in the Developer Portal, and configure them to suit your requirements. You can also turn blogs off.
- **Configuring the taxonomy menu block**
  To display your tag hierarchy in the Developer Portal, you must configure the taxonomy menu block.

- **Customizing the URL alias for a specific API or Product page**
  You can customize the URL of an API or Product page from the default alias that they are assigned.
- **Embedding multimedia in site content**
  You can embed multimedia elements in site content in the Developer Portal.
- **Linking from one piece of site content to another**
  You can link from one piece of site content to another in the Developer Portal.
- **Linking to social media sites**
  You can link to social media sites from the Developer Portal. You can configure where and how these links are displayed and which sites you want to link to.
- **Managing tags in the Developer Portal**
  These instructions show you how to add new tags to your taxonomy, and how to manage the tag hierarchy in the Developer Portal. You can use tags to classify your Developer Portal content.
- **Posting a poll**
  You can post a poll in the Developer Portal.
- **Adding images to site content**
  You can add .jpg, .png and .gif images to your site content in the Developer Portal.

Adding and configuring meta tags

You can customize the Developer Portal by adding and configuring meta tags.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Meta tags provide preview information that is displayed for a link to a website. The preview information can include images, descriptions, tags, and links. Meta tags are used when you link to external website, for example Facebook, Twitter, and Slack.

You can see which entities have the meta tag form available on their respective edit pages by default, and can be configured, Configuration > Search and metadata > Metatags > Settings:

- CONTENT
  - API
  - APPLICATION
  - ARTICLE
  - BLOG POST
  - BOOK PAGE
  - CONSUMER ORGANIZATION
  - FAQ
  - FORUM TOPIC
  - BASIC PAGE
  - PRODUCT
- TAXONOMY TERM
  - FORUMS
  - TAGS
- USER
  - USER

Procedure

1. In the administrator dashboard, click Extend > Update, then click List.
2. Enter `meta tag` in the Filter list field.
3. Select the check boxes for the Meta tags you want to enable, click Enable.

- **Disabling external search engine indexing**
  If you do not want your Developer Portal site content to be indexed by external search engines, then you can disable the indexing.

Disabling external search engine indexing

If you do not want your Developer Portal site content to be indexed by external search engines, then you can disable the indexing.

Before you begin

You must have administrator or content author access to complete this task.

About this task

By disabling the external search indexing, you can increase the confidentiality of your content and restrict its exposure.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration.
3. In the SEARCH AND METADATA section, click Metatag.
4. Click Edit for the GLOBAL type.
5. Expand the ADVANCED section and, in the Robots section, select Prevents search engines from indexing this page.
6. Click Save.

Results

You have disabled external search engine indexing.

Adding custom pages

You can create custom pages within the Developer Portal. You can add a basic page for static content, or an article for news content.

Before you begin

You must have administrator or content author access to complete this task.

About this task

Use basic pages for your static content, such as an "About us" page. Typically, a basic page is used for static content that can be linked into the main navigation bar, although this is not a requirement. Use articles for time-sensitive content, like news, press releases, or blog posts.

Procedure

To add custom pages, complete the following steps.

1. Log in to the Developer Portal as an administrator or content author.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Content.
4. Click +Add content, then click either Basic page or Article, depending on the type of content you want to display.
5. Enter a page title, select the language, and enter the content.
6. Specify the remaining page options as required.
   If you want your new page to be linked to from a menu, you must complete the Menu settings section.
7. Optional: Click Edit summary and specify a summary page description.
8. Click Save to publish the new page immediately. If you don't want to publish the new page immediately, ensure that you deselect Published before saving.

Results

You added a new custom page to the Developer Portal. You can edit the page after it is created by clicking Edit for the custom page.

Integrating X data into the social block

You can retrieve and integrate data from an X (formerly known as Twitter) account of interest and display it into a social block in a Developer Portal site.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You must have an X App for the X account of interest. The X App contains information that is used to configure the social block. For information on creating X Apps, see https://apps.twitter.com/.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration.
3. In the WEB SERVICES section, click IBM Social Block settings.
4. Using the information from your X App, enter the Consumer Key, Consumer Secret, Access Token, and Token Secret in the corresponding fields.
5. Click Save configuration.
   X data from an X account of interest has been integrated with the Developer Portal, and is displayed on the social block of the site.

- **Editing the social block**
  After you have integrated Twitter data into the Developer Portal social block, you can edit the content, appearance, and functionality of the social block.

Editing the social block

After you have integrated Twitter data into the Developer Portal social block, you can edit the content, appearance, and functionality of the social block.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You must have Twitter data integrated into the Developer Portal social block. For more information, see Integrating X data into the social block.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Structure > Pages.
3. Click Edit next to the Welcome page (or next to the page that contains the social block that you want to edit).
4. From the Variants navigation tree, select Panels > Content, and click Edit next to the Social Block.
   The Edit block window is displayed.
5. Edit the social block by configuring any of the following options:

   Title
   : Update the title as required.

   Number of tiles to display
   : Configure the number of tiles that you want to display on the social block by entering a number in the Number of tiles to display field. The default number of tiles that are displayed on the social block is 9, and there is a limit of 100 tiles.

   FORUM
   : Use the check boxes to specify the forum topics that you want to display.

   Get tweets from
   : From the Get tweets from drop-down list, select whether you want to display Twitter data from users or a search term.

   Twitter search parameter
   : Enter the Twitter search parameter.

   Types of tweets to display
   : Select the types of tweets that you want to display from the drop-down list. You can select to display tweets, or tweets and replies.

6. After you have configured the social block, click Update block.
   Your social block is configured, and the configurations are implemented when you return to the home page.

Adding content in multiple languages

You can create content in multiple languages in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

About this task

You can provide custom pages in multiple languages to your APIs and Products to improve your customer experience and understanding. By default, multiple languages are enabled in the Developer Portal.

Note: In API Designer, translations for APIs and products must be done within a document. For more information, see Using `x-ibm-languages` to create multilingual API and Product documentation.

Procedure

1. Log in to the Developer Portal as an administrator or content author.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Content.
4. If you are creating a new page to be translated, click +Add content.
   a. Click Basic page, then select type, for example `Basic page`.
   b. Enter a title for your custom page in the Title field.
   c. Enter your information in the Body field.
   d. Click Save.
   e. Click Translate.
   f. Click Add for the language you want to translate.
   g. Provide the language content.
   h. Click Save (this translation).
5. If you are translating an existing page, find the page that you want to update in the list.
   a. Click Translate from the drop-down list for the page.
   b. Click Add for the language you want to translate.
   c. Provide the language content.

d. Click Save (this translation).

Results

You successfully created a translated version of your content.

Adding custom pages to APIs and Products

After you create a custom page in the Developer Portal, you can add a link to the new page to any APIs and Products that exist in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

You must have an API or Product to add the custom page to.

About this task

You can add custom pages to your APIs and Products to provide further information on their use and value.

For example, you can create a custom documentation page on the implementation of an API in a specific circumstance, and add this custom documentation page to the API.

Procedure

1. Log in to the Developer Portal as an administrator or content author.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Content, then click +Add content.
4. Click Basic page.
   The Create Basic page window is displayed.
5. Enter a title for your custom page in the Title field.
6. Enter your information of interest in the Body field.
7. If you want to add the custom page to a specific Product, enter the Product name in the Link to one or more specific Products field. As you type into this field, a list of available Products is displayed for you to select. You can add more Products by clicking Add another item. If you want to add the custom page to all Products, select the Link to all Products check box.
8. If you want to add the custom page to a specific API, select the APIs tab, and then enter the API name in the Link to one or more specific APIs field. As you type into this field, a list of available APIs is displayed for you to select. You can add more APIs by clicking Add another item. If you want to add the custom page to all APIs, select the Link to all APIs check box.
9. Optional: Configure the additional settings of the custom page to your specification.
10. Click Save.

Results

Your custom page is created and linked to the APIs or Products that you have specified. You can edit the page after it is created, and update the APIs and Products that it is linked to, by clicking Edit for the custom page.

Adding new frequently asked questions

You can add new FAQs to the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

About this task

To add new FAQs, you create a new FAQ node and add questions and answers to that node. Each FAQ node represents an FAQ topic, and each topic can contain multiple questions and answers.

Procedure

To add new FAQs, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Content in the administrator dashboard.
4. Click +Add content.
5. Click FAQ.
   The Create FAQ page displays.
6. Provide a Title for the new FAQ topic.

7. Enter the question in the Question field, and enter the answer in the Answer field.
8. Optional: If you have more content for this FAQ topic, click Add another item and complete the Question and Answer fields. Repeat this step as required.
9. Click Save to save your new FAQ topic.
   Your new FAQ topic is displayed in the Support section of the Developer Portal.

Results

You successfully added new FAQs to the Developer Portal.

What to do next

You can edit the current content of FAQs by clicking Content in the administrator dashboard, finding the FAQ content that you want to edit, and clicking Edit against that FAQ.

Applying an image to an API or Product

You can apply an image to an API or a Product in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To add an image to an API or Product, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click Edit next to the API or Product that you want to edit.
4. Under the Image heading, click Choose File to select an image.
5. Click Save and keep published to publish the updated content,or select Save and unpublish if you want to publish the updated content later.
   You have added a new picture to the selected API or Product.

Attaching a documentation file to APIs

You can attach a file to APIs in the Developer Portal, and display them as documentation attachments. You can attach multiple files to APIs.

Before you begin

You must have administrator or content author access to complete this task.

About this task

You can attach only one file at a time. The default file upload size limit applies to the files that you want to attach, and you can attach up to 10 files to an API by default.
Note: You can change the default limit for the number of files that you want to attach.
An administrator can configure the types of file that are uploaded, and the number of files that a user can upload.

The following file types can be uploaded:

- txt doc pdf
- xls ppt pptx
- docx xlsx rtf
- odt ods odp md json
- yaml tgz tar zip

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click Edit next to the API you want to attach the file to.
4. In the Documentation section, click Browse and identify the file that you want to upload, then click Open.
5. Click Upload, then click Save.
6. Optional: Clear the Display checkbox for the file if you want to upload and attach the file to the API, but not show it in the Developer Portal.
7. Optional: Enter a description for your file in the Description field. This description can be used as the label of the link to the file.
8. Optional: If you uploaded multiple files, you can use the drag handle next to the file name to rearrange them.

Results

You successfully attached a documentation file to your API.

Configuring blogs

You can post new blog entries in the Developer Portal, and configure them to suit your requirements. You can also turn blogs off.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To post a new blog entry, complete the following steps:

- If the administrator dashboard is not displayed, click Manage to display it.
- Click Content in the administrator dashboard.
- Click Add content.
- Click Blog post.
- Enter required values in the Title and Body fields.
- Click Save and keep published to publish the updated content,or select Save and unpublish if you want to publish the updated content later.
  You have posted a new blog entry.

To configure a blog post, complete the following steps:

- If the administrator dashboard is not displayed, click Manage to display it.
- Click Content in the administrator dashboard.
- Click Edit next to the blog post that you want to configure.
- You can configure the selected blog from this view.
- Click Save and keep published to publish the updated content,or select Save and unpublish if you want to publish the updated content later.
  You have configured the selected blog post.

Configuring the taxonomy menu block

To display your tag hierarchy in the Developer Portal, you must configure the taxonomy menu block.

Before you begin

You must have administrator or content author access to complete this task.

About this task

Along with controlling how your tag hierarchy is displayed through configuring your taxonomy menu block, you can configure options for the taxonomy tree. The following options can be configured for your taxonomy menu block:

- Vocabulary
- Parent option
- Depth
- Node options and content
- Region settings
- Visibility settings

Important: The taxonomy block will appear after configuration only if there are tags for it to display.

Procedure

1. In the Administrator dashboard, click Structure > Blocks.
2. Click configure for the Taxonomy Menu Block (Tags) block.
3. Configure the options that are available for your taxonomy menu block.
4. When you have configured your taxonomy menu block, click Save block.
   You have configured your taxonomy menu block, and your tag hierarchy is displayed based on your configurations.

Customizing the URL alias for a specific API or Product page

You can customize the URL of an API or Product page from the default alias that they are assigned.

Before you begin

You must have administrator or content author access to complete this task.

About this task

Creating a custom URL, or path, alias is useful if you want to make the URL relevant to the API or Product page.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Content.
3. Identify the API or Product page that you want to customize the URL alias for, and click Edit.
4. In the Path Alias text field, enter the custom URL alias that you want to assign your API or Product page.
   Note: All Path Alias must be unique, and can contain only the following characters: [A-Za-z0-9_-.].
5. Click Save to publish the updated content.

Results

You have applied a custom URL alias for your specified API or Product page, and it is displayed in the URL of your browser when the API or Product page is selected. Depending on whether it is added to an API or a Product page, the application of the Path Alias differs. For example, if you add **`my_new_path_alias`**, you will have:

- **`<my_site_url>/api/my_new_path_alias`** for an API
- **`<my_site_url>/product/my_new_path_alias`** for a Product

Embedding multimedia in site content

You can embed multimedia elements in site content in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To embed multimedia in site content, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Under the TITLE heading, click the title of the required content.
4. Click the Edit tab.
5. Use the Insert Media Embed icon  in the in the WYSIWYG editor to embed multimedia in the content.
   Note: The Insert Media Embed icon is available only if you have selected Full HTML mode.
6. Click Save and keep published to publish the new page immediately, or select Save and unpublish if you want to publish the page later.
   You have embedded multimedia in the selected site content.

Linking from one piece of site content to another

You can link from one piece of site content to another in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To link from one piece of site content to another, complete the following steps:

1. Click Content in the administrator dashboard.
2. Under the TITLE heading, click the title of the required content.
3. Select the Edit tab.
4. Use the Link to content icon  in the WYSIWYG editor.
5. Click Save.
   You have linked the selected site content to another site content element.

Linking to social media sites

You can link to social media sites from the Developer Portal. You can configure where and how these links are displayed and which sites you want to link to.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. Click Structure in the administrator dashboard.
2. Click Blocks.
3. Under the Disabled heading, locate the Follow site block.
4. Select the location for your social media block from the drop-down list for Follow Site in the REGION column.
   The Follow Site block will appear under the heading that corresponds to the region you selected in the REGION drop-down list.
5. Required: Click Save blocks before you begin configuring your new block.
6. Click configure for the Follow Site block.
7. In the Block title field, type the name of your block.
8. Under the Default block title heading, select one of the following leading text options for your block using the radio buttons for each option:
   - "Follow *your.portal.site* on"
   - "Follow me on"
   - "Follow us on"
9. Use the User pages check box to decide whether you want your block to display on your user's profile pages.
10. Use the Alignment and Icon Style drop-down lists to adjust the appearance of your block.
11. Click Save block.
12. Click Configuration in the administrator dashboard.
13. Under the WEB SERVICES heading, click Follow.
14. Type the URL under the URL heading for each of the social media sites you want your users to access. The following is an example of a link to the @ibmapiconnect twitter handle:

    ```
    https://twitter.com/ibmapiconnect
    ```

15. Click Submit.

Managing tags in the Developer Portal

These instructions show you how to add new tags to your taxonomy, and how to manage the tag hierarchy in the Developer Portal. You can use tags to classify your Developer Portal content.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To manage your tags, complete the following steps

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Taxonomy > Tags in the administrator dashboard.
   The List window for Tags is displayed.
3. You can add new terms, delete, and reorganize terms from this view.
   a. To add a new term, click Add term, define the new term, then click Save.
   b. To delete a term, select Delete from the OPERATIONS menu next to the term that you want to delete. Then click Delete to confirm.
   c. To reorganize terms, ensure that the row weights are hidden by clicking Hide row weights if necessary, then use the drag-and-drop handles to manage the tag hierarchy. Terms can be dragged to organize a parent grouping hierarchy. Then click Save.

- **Tagging APIs based on their lifecycle phase**
  In the Developer Portal, you can have APIs automatically tagged with their lifecycle phase; realized, identified, or specified.

Related tasks

- Editing tags for a specific item

Tagging APIs based on their lifecycle phase

In the Developer Portal, you can have APIs automatically tagged with their lifecycle phase; realized, identified, or specified.

Before you begin

You must have administrator or content author access to complete this task.

About this task

APIs are tagged in the API Manager with a lifecycle phase as follows:

- Realized (default) - The API is in the implementation phase.

- Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
- Specified - The API has been fully designed and passed an internal milestone, but has not yet been implemented.

You can configure the Developer Portal to tag APIs with their lifecycle phase automatically.

Procedure

Tagging APIs with their phase is disabled by default. To enable the function:

1. On the administrator dashboard, click Configuration > System > IBM API Developer Portal.
2. Select Automatically tag APIs with their phase, and then click Save configuration to automatically tag APIs with their lifecycle phase.

What to do next

You can manage the tag hierarchy of your APIs. For more information, see Managing tags in the Developer Portal.

Posting a poll

You can post a poll in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To post a poll, complete the following steps:

1. Click Content in the administrator dashboard.
2. Click Add content.
3. Click Poll.
4. Enter the poll question in the Poll question field.
5. Under the Choice heading, add answers to the available fields as choices.
6. From the Poll duration drop-down menu, select a time limit for the poll.
7. Click Save.
   You have posted a poll.

What to do next

See Editing sample content to learn how to add a links to your poll to sample content.

Adding images to site content

You can add .jpg, .png and .gif images to your site content in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Note: The SVG support is disabled by default in site content. To enable the use of SVG images in site content, install the **`SVG Image Field - Media Bundle`** module and edit the media type to include an SVG field.

Procedure

To upload images for use in site content, complete the following steps:

1. Click Content in the administrator dashboard.
2. In the Title field, enter the `title` of the required content.
3. Click the Edit tab.
4. Use the Image icon  in the in the WYSIWYG editor to add an image.
5. Click Save and keep published to publish the new page immediately, or select Save and unpublish if you want to publish the page later.

Configuring and restricting content in the Developer Portal

You can configure and restrict certain content elements in the Developer Portal.

To learn how to configure and restrict content in the Developer Portal, use the following topic links:

- **Creating content types**
  Content types define default fields for editors to add content on your Developer Portal site and are the building blocks for authoring content. You can control which content types are available
- **Configuring documentation upload limitations**
  You can attach documentation to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded documentation.
- **Configuring image upload limitations**
  You can attach an image file to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded image files.
- **Configuring the appearance of ratings in the Developer Portal**
  You can configure the appearance of ratings in the Developer Portal.
- **Customizing the privacy policy statement**
  You can define and customize a privacy policy statement that sets out the privacy conditions of your Developer Portal site. The privacy policy can be linked to from the cookie compliance banner.
- **Customizing the terms of use statement**
  You can define and customize terms of use statement that sets out the terms and conditions that your users must accept to use your Developer Portal site.
- **Editing a site comment**
  You can edit site comments in the Developer Portal.
- **Editing sample content**
  You can edit sample content, such as basic pages, in the Developer Portal.
- **Editing tags for a specific item**
  You can edit tags for a specific item in the Developer Portal.

Creating content types

Content types define default fields for editors to add content on your Developer Portal site and are the building blocks for authoring content. You can control which content types are available

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

After you create your content type, it is added to the following list of default content types that are present in the Developer Portal:

- API
- Application
- Article
- Basic page
- Blog post
- Book page
- Consumer organization
- Forum topic
- Product

The content type that you create, and the default content types, can be edited and configured further to your specifications.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. Click +Add content type.
5. Enter a name for your content type in the Name field.
6. Optional: Enter the text that you want to appear on the Add new content page, in the Description field.
7. Enter a title field label for your content type in the Title field label field.
8. Optional: Configure any of the following options for your content type:
   - Submission form settings
   - Publishing options
   - Language settings
   - Display settings
   - Menu settings
9. After you have configured your content type to your specifications, click Save and manage fields.
   You have created a new content type.

What to do next

You can add fields to your new content type; see Adding fields to content types.

- **Adding fields to content types**
  Fields can be added to content types in the Developer Portal for customization, and to add functionality.

Adding fields to content types

Fields can be added to content types in the Developer Portal for customization, and to add functionality.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can specify the type of data that a field can store, and the form element to edit the data with. The type of form element that is available is dependent on the type of data that your field stores.

Note: You can specify the number of values that a field can store, including an unlimited amount. You can configure the value after the field is created. Reducing the number of values that can be stored after the field is created might lead to data loss.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types, and identify the content type that you want to add a field to.
4. Click Manage fields for the content type, then click Add field.
5. Select a field type or select an existing field to reuse, then enter a label for your field in the Label field.
   The label that you specify for your field is displayed in the UI.
6. Optional: If you want to edit the machine name that is automatically created based on your label, click Edit and enter the new name.
   You cannot change the machine name after the field is created.
7. Click Save and continue.
8. Modify the field type specific settings as required, then click Save field settings.
   You have added a field to your content type.

Configuring documentation upload limitations

You can attach documentation to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded documentation.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The set of configurable limitations that you can place on uploading documentation is different to the set of limitations that you can place on uploading images.

The file size limit that is applied when you upload documentation is also different to the limit that is applied when you upload images.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structurein the administrator dashboard.
3. Click Content types.
4. For the API content type, click Manage fields.
5. For the Documentation field, click Edit.
6. Configure the type of files that are allowed to be uploaded in the Allowed file extensions field.
7. Enter the file size upload limit in the Maximum upload size field.
   The default size is 10MB, while the maximum upload size possible is 64MB.
8. Click Save settings.
   You have configured the documentation upload limitations.

Configuring image upload limitations

You can attach an image file to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded image files.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structurein the administrator dashboard.
3. Click Content types.
4. For the API content type, click Manage fields.
5. For the Image field, click Edit.
6. Configure the type of image files that are allowed to be uploaded in the Allowed file extensions field.
7. Specify the maximum and minimum allowed image sizes in the Maximum image resolution and Minimum image resolution fields.
8. Enter the file size upload limit in the Maximum upload size field.
   The default size is 2MB, while the maximum upload size possible is 64MB.
9. Click Save settings.
   You have configured the image upload limitations.

Configuring the appearance of ratings in the Developer Portal

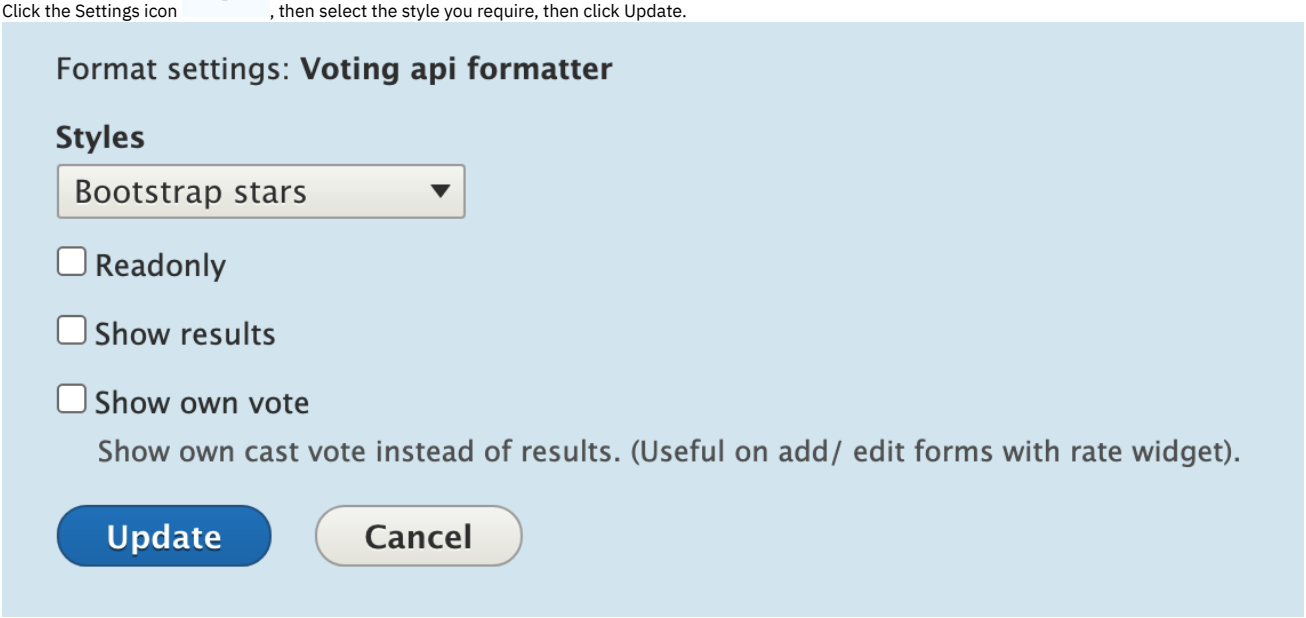
You can configure the appearance of ratings in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can configure the appearance of ratings for only the following content types in the Developer Portal:



- APIs
- Applications
- Products

Note: The Applications and Products content types rating functionality is set to hidden by default.

Procedure

These following steps describe how to customize the rating on a selected API, Application, or Product. To ensure that the configured rating is also displayed in the list view of APIs, Applications, or Products, then you must repeat these steps on the Teaser tab in the Manage Display window:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. Select Manage display from the list in OPERATIONS column, next to the required content type.
5. Click the Settings icon , then select the style you require, then click Update.

6. Click Save. You have configured the appearance of the ratings feature for the required content type.

Customizing the privacy policy statement

You can define and customize a privacy policy statement that sets out the privacy conditions of your Developer Portal site. The privacy policy can be linked to from the cookie compliance banner.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To define or customize a privacy policy, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Content, then enter `privacy` into the title search filter, and click Filter.
   The Privacy Policy content item is displayed in the list of content.
4. Click Edit next to the Privacy Policy content item.
5. Update the content as required. For example, you can complete the following tasks:
   a. Edit the text of the privacy policy statement.
   b. Set the display settings.
   c. Link the content to Products and APIs.
   d. Enter an explanation of the changes that have been made to the privacy policy since the last version.
6. Click Save to save your changes.

Results

The privacy policy statement is successfully updated.

What to do next

You can set your cookie compliance banner to link to your updated privacy policy. For more information, see Enabling a cookie compliance banner.

Related tasks

- Enabling a cookie compliance banner
- Customizing the terms of use statement

Customizing the terms of use statement

You can define and customize terms of use statement that sets out the terms and conditions that your users must accept to use your Developer Portal site.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To define or customize terms of use statement, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Content, then enter the `terms` into the title search filter, and click Filter.
   The Terms of use content item is displayed in the list of content.
4. Click Edit next to the Terms of use content item.
5. Update the content as required.
   For example, you can complete the following tasks
   a. Edit the text of the terms of use statement.
   b. Set the display settings.
   c. Link the content to Products and APIs.
   d. Enter an explanation of the changes that have been made to the terms of use since the last version.
6. Click Save to save your changes.

Results

The terms of use statement is successfully updated.

What to do next

You can force new users to accept the terms and conditions on the Developer Portal. For more information, see Forcing new users to accept terms and conditions.

Related tasks

- Enabling a cookie compliance banner
- Customizing the privacy policy statement

Editing a site comment

You can edit site comments in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To edit a site comment, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click the Comments tab.
4. In the OPERATIONS column, click Edit alongside the comment that you want to edit.
5. Edit the content of the comment as required.
6. Click Save.
   You have edited the selected comment.

Editing sample content

You can edit sample content, such as basic pages, in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To edit sample content, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. In the OPERATIONS column, click Edit alongside the content item that you want to edit.
4. Edit the sample content of the selected element as required.
5. Click Save and keep published to publish the updated content,or select Save and unpublish if you want to publish the updated content later.

Editing tags for a specific item

You can edit tags for a specific item in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

You must have some tags that are available to apply to your content; see Managing tags in the Developer Portal.

Procedure

To edit tags for a specific item, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.

3. In the list of content items, click Edit alongside the content item that you want to update.
4. In the Tags section, select the required tag.
5. To add another tag, click Add another item, then select the required tag.
6. If you want to publish the updated content, ensure the Published check box is selected. Deselect the check box if you want to publish the updated content later.
7. Click Save.

- **Turning the ability to tag specific content types off in the Developer Portal**
  You can turn the ability to tag specific content types on or off in the Developer Portal.

Deleting a site comment

You can delete site comments in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To delete a site comment, complete the following steps

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click the Comments tab.
4. From the UPDATE OPTIONS list, select Delete the selected comments.
5. Select the comments that you want to delete, then click Update.
   The confirmation screen displays.
6. Click Delete comments.
   You have deleted the selected comments.

Deleting blocks

You can delete blocks in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

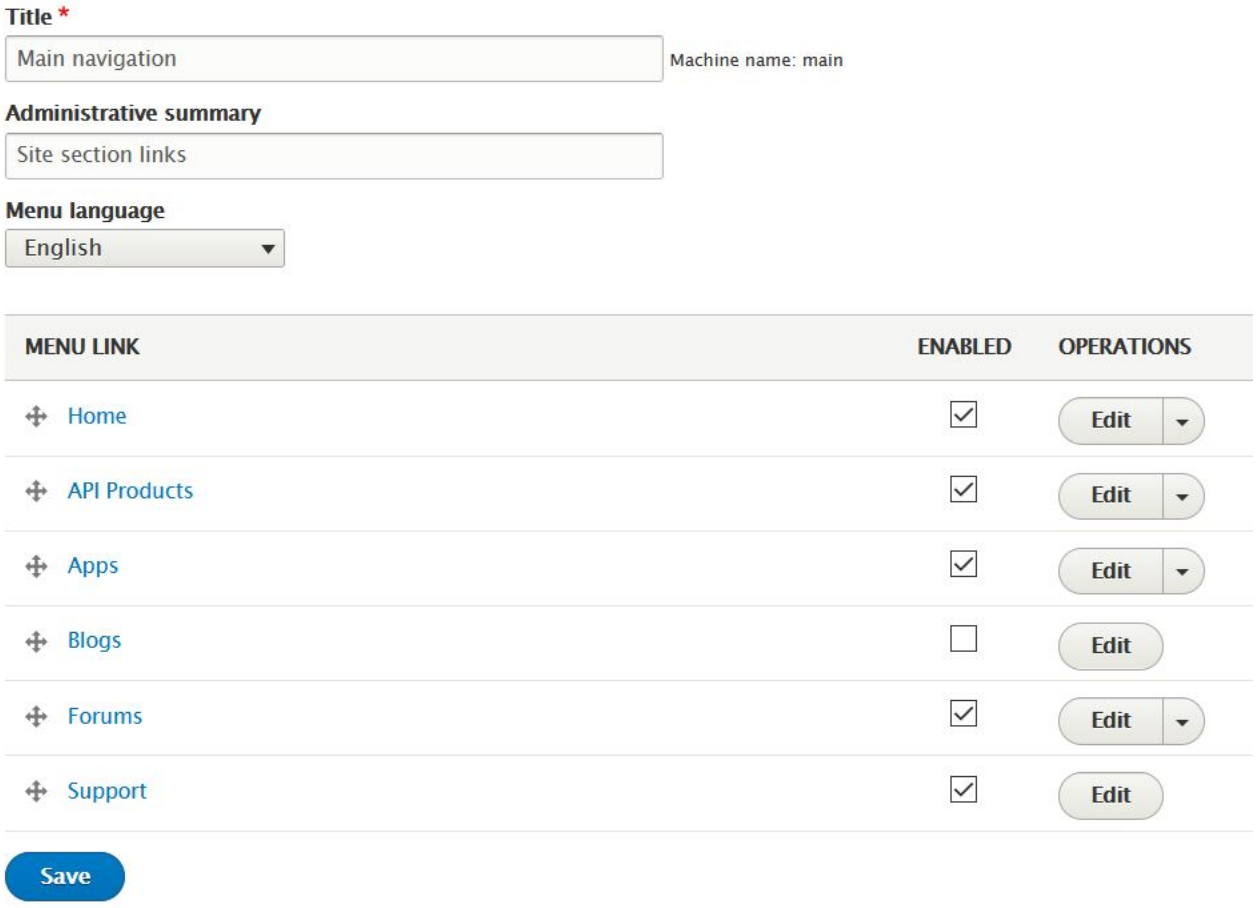
Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Pages.

4. In the OPERATIONS column, find the welcome page row and select Edit from the drop-down list.
5. Expand Panels, then click Content.
6. In the OPERATIONS column, find the block that you want to delete and select Delete for the drop-down list
7. Click Delete to confirm, then click Update and save.

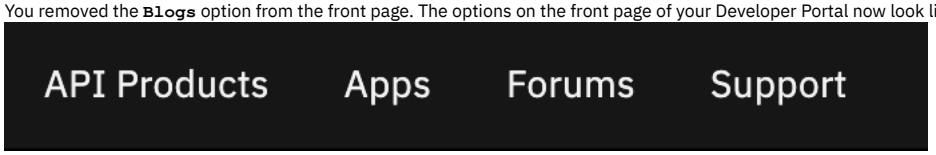
Disabling blogs

You can disable blogs on your Developer Portal.



Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Before any changes are made, **`Blogs`** show as an option on the front page like this:

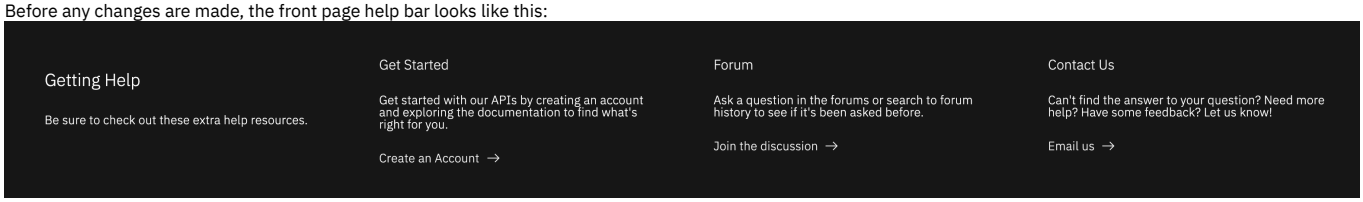


Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Menus from the administrator dashboard.
3. In the OPERATIONS column, click Edit menu for **`Main navigation`**.
4. Clear Enabled for the **`Blogs Menu link`**, then click Save.

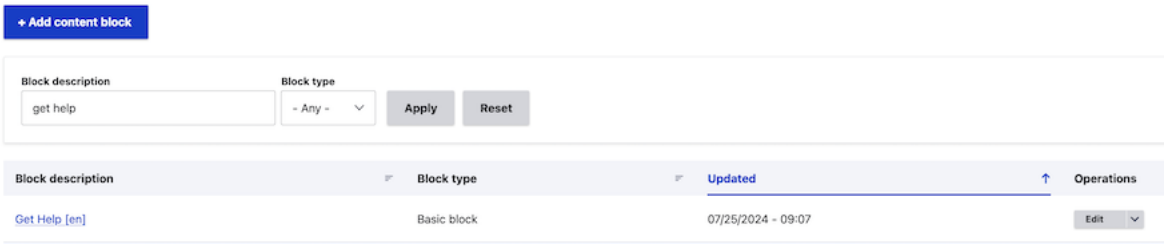
Results

You removed the **`Blogs`** option from the front page. The options on the front page of your Developer Portal now look like this:



Deleting forums from the front page

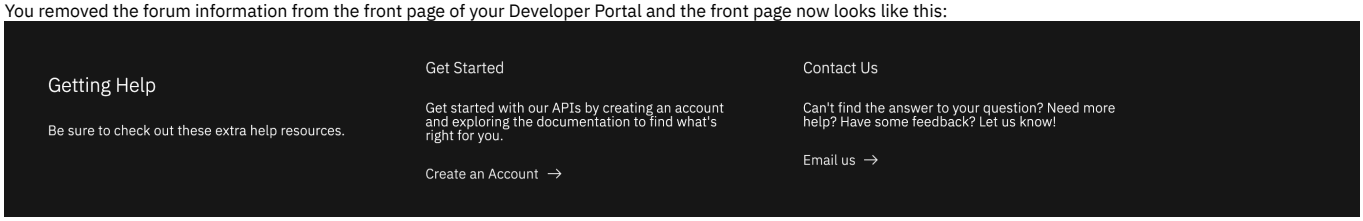
You can delete the help information on forums from the front page of your Developer Portal.



Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Before any changes are made, the front page help bar looks like this:

Procedure



1. Click Blocks and enter `Get help` in the Block description field.
2. Click Apply.

3. In the Operations column, click Edit.
4. In the **Body** section, delete the forum information, then click Save.

Results

You removed the forum information from the front page of your Developer Portal and the front page now looks like this:

Turning comments for specific content types on or off in the Developer Portal

You can turn the comments for specific content types on or off in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To turn comments for specific content types on or off in the Developer Portal, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. In the OPERATIONS column, click Manage fields for the required content type.
5. In the OPERATIONS column, click Edit for the Comments field.
   Note:
   - If there is no Comments field, you can enable commenting for the selected content type by adding one as follows:
     - Click Add field.
     - From the Add a new field list, select Comments.

- Enter a field label, then click Save and continue.
- Select the required comment type, then click Save field settings.

- You can completely disable commenting for the selected content type, and permanently remove all current comments, by selecting Delete.

6. Select the required option in the DEFAULT VALUE section.
   a. To allow commenting, select Open.
   b. To keep existing comments but disallow further commenting, select Closed.
   c. To hide all comments, select Hidden.
7. When done, click Save settings.

Turning comments off for an individual item

You can turn off comments for individual items within a content type.

Before you begin

Users with edit permission for the selected content type can perform this task.

Procedure

To turn off comments for a single item, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. In the OPERATIONS column, click Edit for the required content item.
4. Click Comment settings in the side pane.
5. Select Closed to turn comments off for the selected item.
6. Click Save.

Turning off ratings for specific content types in the Developer Portal

You can turn off ratings for specific content types in the Developer Portal by hiding the ratings field.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To turn off ratings for specific content types in the Developer Portal, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. In the OPERATIONS column for the required content type, select Manage fields from the drop-down list.
5. Click on the Manage form display tab. In the FIELD list, select Rating and drag and drop it into the Disabled section, then click Save.
6. Click on the Manage display tab. Content items are displayed by using different view modes, such as Default, Card, and Teaser, and these modes are shown at the beginning of the Manage display page. For each view mode that is applicable to the content type you're editing, click the mode, and in the FIELD list select Rating, and drag and drop it into the Disabled section.
7. Click Save.

Turning the ability to tag specific content types off in the Developer Portal

You can turn the ability to tag specific content types on or off in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To turn the ability to tag specific content types on or off in the Developer Portal, complete the following steps:

1. Click Structure in the administrator dashboard.
2. Click Content types.
3. Click Manage fields next to the required content type.

4. From the Tags field, click Edit.
5. Click Delete, then confirm the Delete as the action cannot be undone.
   You have turned the ability to tag specific content types off.

Structure

Control the layout of the Developer Portal, such as configuring the front page, adding and changing blocks, and displaying Products and APIs in categories.

To learn how to control the layout of the content on your Developer Portal site, use the following topic links.

- **Configuring the front page**
  You can configure the Developer Portal front page.
- **Adding a menu**
  You can add a menu to the Developer Portal, and define the items that are included in the menu.
- **Adding and changing the blocks displayed on Developer Portal pages**
  You can add new blocks, and modify the existing blocks that are displayed on Developer Portal pages.
- **Changing the front page banner block**
  You can change the front page banner content and image that is displayed on the home page when a user first logs in to the Developer Portal.
- **Changing the front page Featured Content block**
  You can display featured Products or APIs on the front page of your Developer Portal by configuring the Featured Content block.
- **Changing the case studies content block on the front page**
  Configure the case studies content block on your Developer Portal as required.
- **Changing the items in the main menu**
  You can change the items in the main menu that is displayed on all pages in the Developer Portal.
- **Changing the ratings display**
  You can change the appearance of the content ratings in the Developer Portal.
- **Displaying APIs and Products in categories**
  You can create taxonomies in the Developer Portal, which dictate the categorization of APIs and Products, and how they are displayed. The taxonomies that you define can be used by API developers to categorize APIs and Products in YAML files.
- **Implementing an image carousel**
  You can customize your Developer Portal home page to display images in a carousel. The image carousel provides your Developer Portal home page with a continuous slide show that is customized to your specifications.
- **Making your application's image public**
  You might want to display your application's image in an oauth authentication page to reassure customers that they are authenticating the correct application in the Developer Portal. That authentication uses a URL to the image that is stored on the Developer Portal. However, by default, those images are private unless you are logged in, which doesn't work if you want to display it in an oauth page. The solution is for the admin to change the `application_image` field to use public instead of private.
- **Providing navigation by tag hierarchy**
  You can provide the ability for users in the Developer Portal to navigate by using tag hierarchy.
- **Using the Views module in the Developer Portal**
  By using the Views module, you can fetch content from your Developer Portal site, and present it to users in different formats such as lists, graphs, and tables.

Configuring the front page

You can configure the Developer Portal front page.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Create a customized welcome page for your users. Note that blocks that are placed on the front page of the Developer Portal are visible to all users, regardless of whether the blocks have access restrictions placed on them. The visibility of blocks to all users also extends to the Featured Content block.

Procedure

To configure the front page, complete the following steps:

1. Click Structure, then click Pages.
2. Alongside the welcome entry, click Edit.
3. Use the options provided to configure the front page.
   Here you can edit the page information, access, and configuration of the welcome page.
4. Click Update and save to save your changes.

What to do next

You can create a custom page. For more information, see Creating custom pages.

- **Disabling blogs**
  You can disable blogs on your Developer Portal.

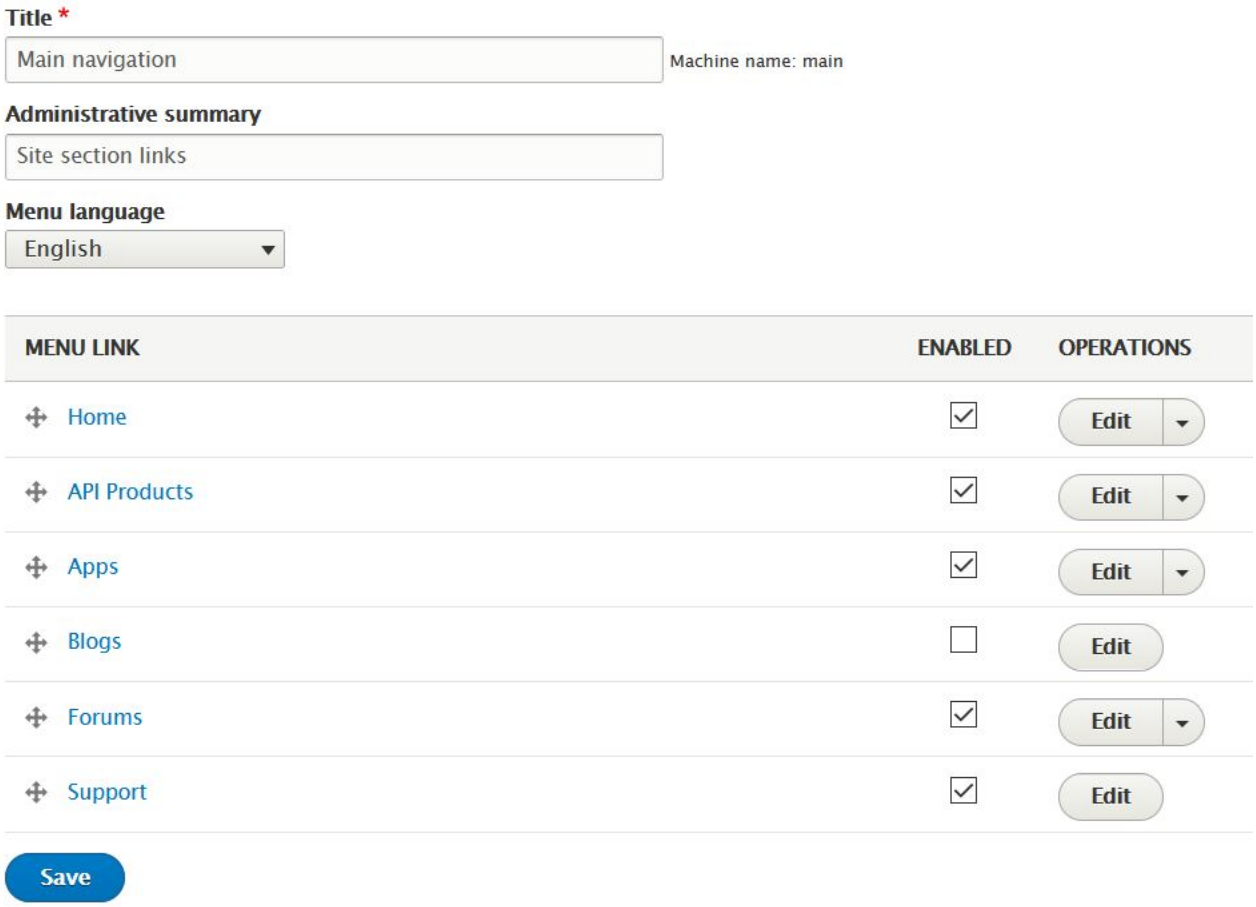
- **Deleting forums from the front page**
  You can delete the help information on forums from the front page of your Developer Portal.

Related tasks

- Changing the front page banner block
- Changing the front page Featured Content block

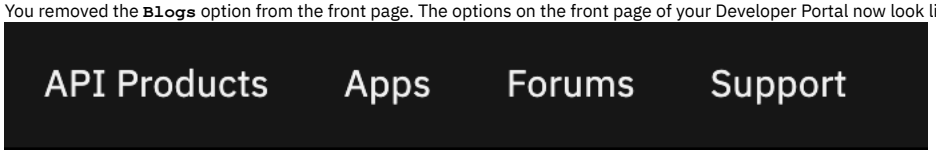
Disabling blogs

You can disable blogs on your Developer Portal.



Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Before any changes are made, **`Blogs`** show as an option on the front page like this:

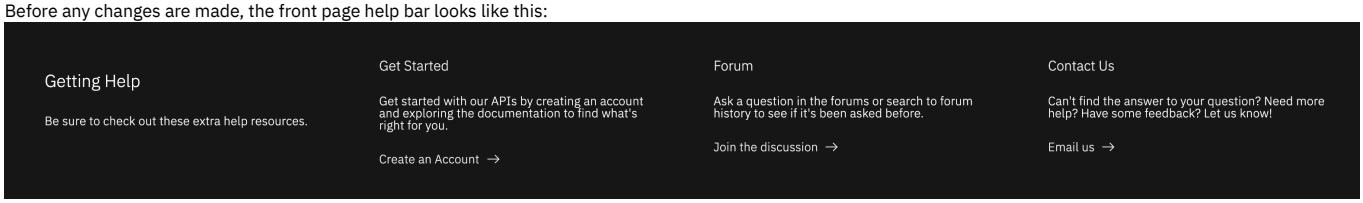


Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Menus from the administrator dashboard.
3. In the OPERATIONS column, click Edit menu for **`Main navigation`**.
4. Clear Enabled for the **`Blogs`** **`Menu link`**, then click Save.

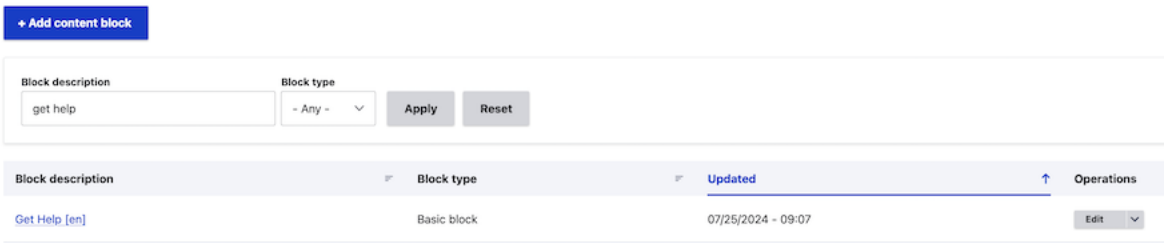
Results

You removed the **Blogs** option from the front page. The options on the front page of your Developer Portal now look like this:



Deleting forums from the front page

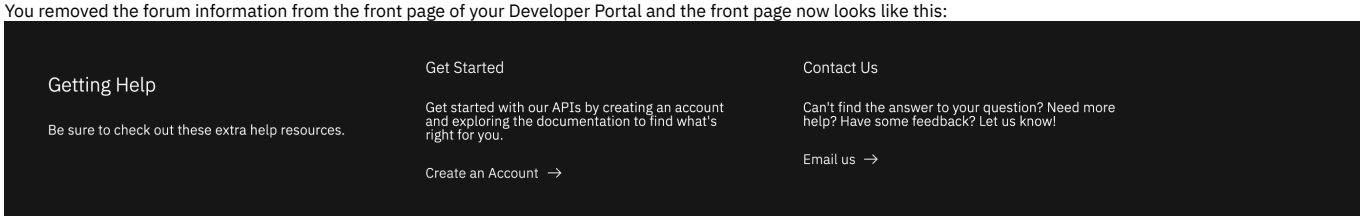
You can delete the help information on forums from the front page of your Developer Portal.



Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Before any changes are made, the front page help bar looks like this:

Procedure



1. Click Blocks and enter `Get help` in the Block description field.
2. Click Apply.

3. In the Operations column, click Edit.
4. In the **Body** section, delete the forum information, then click Save.

Results

You removed the forum information from the front page of your Developer Portal and the front page now looks like this:

Adding a menu

You can add a menu to the Developer Portal, and define the items that are included in the menu.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To add a menu, complete the following steps:

1. Click Structure > Menus.

2. Click Add menu, provide a title, and an optional summary and menu language, and click Save.
3. To add items to your menu, click Add link, and configure the menu link details that you require.
4. Click Save to save your changes.
   A new block for your menu is created automatically, and your menu is now in the **Menus** list.

What to do next

You can use block configuration options to control which pages your menu is displayed on, and where it is positioned. You can use your menu with, or instead of, other menus available within the site. For more information, see Changing the blocks displayed on Developer Portal pages.

You can also update an existing menu, or change your menu. For more information, see Changing the items in the main menu.

Adding and changing the blocks displayed on Developer Portal pages

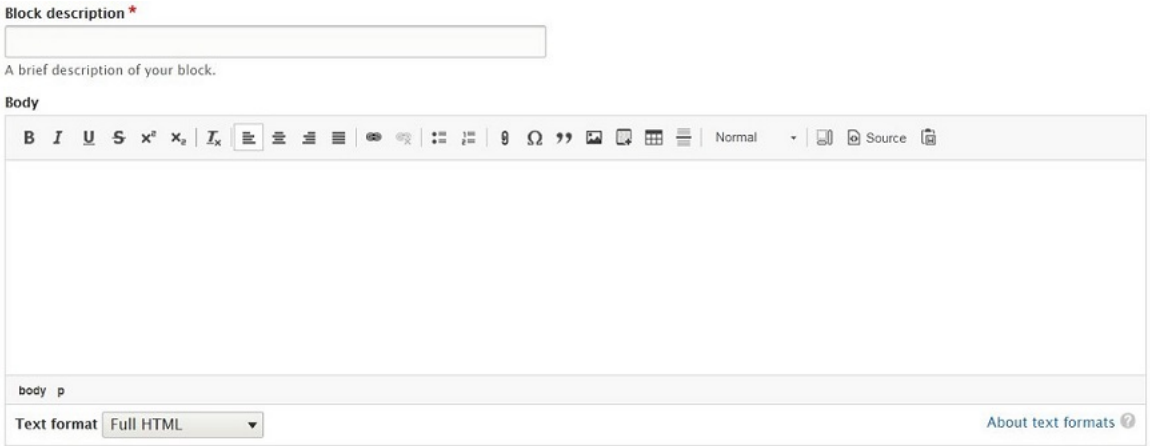
You can add new blocks, and modify the existing blocks that are displayed on Developer Portal pages.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

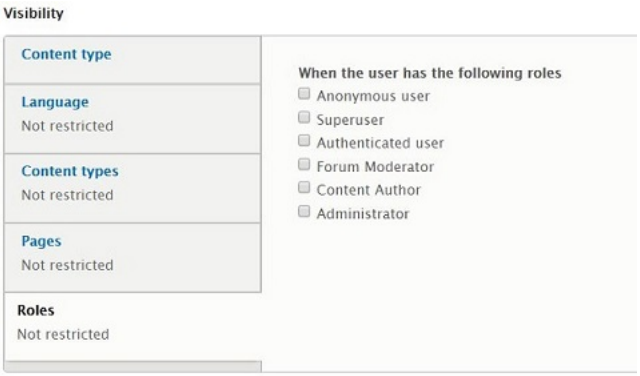
About this task

Blocks are boxes of content that are rendered into an area, or region, of a page. The content can be custom HTML, Github Markdown, or plain text, and you can specify the appearance, size, position, and also configure which pages a block appears on by editing its visibility settings. You can also modify an existing block to change its appearance, size, position, and visibility.



- Add a new block
- Edit the content of an existing block
- Modify the layout or visibility of an existing block

Procedure



To add a new basic block, complete the following steps.

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure, then click Block layout.
   All of the blocks that are in the system are displayed by theme. From the Block layout page you can assign blocks to a region, and control the order of the blocks within the region. Blocks are positioned on a per-theme basis, so if you enable more than one theme on your site, you can place blocks differently for each theme.
3. Click Place block > Add custom block.
   The Add custom block page is displayed.
4. Complete the Block description field.
5. Enter the content that you require for your block into the Body section.
   You can set the text format to Full HTML, Basic HTML, Restricted HTML, or Github Markdown. You can use the edit icons in the Body section to configure your content. Click the Source icon 

to enter code source, such as HTML.

6. Click Save.
   The new custom block is saved and the Configure block page is displayed.
7. Complete the block Title field.
8. In the Visibility section, specify how you want the block to be displayed.
   You can specify the content types, configure the language settings, restrict the block to show only on pages that display specific content types, set which pages the block is displayed on, and restrict which user roles the block is visible to.

9. In the Region section, select the region where the block should be displayed.
10. Click Save block.
    The new custom block is added to your Developer Portal site.

To edit the content of an existing block, from the Block layout page complete the following steps.

11. Click the Custom block library tab (or select Structure > Block layout > Custom block library from the administrator dashboard).
12. Click Edit alongside the required block.
13. Change the block description and body content as required.
14. Click Save to save your changes.

To modify the layout or visibility settings of an existing block, from the Block layout page complete the following steps.

15. To change the region in which a block is positioned, select the required Region from the drop-down list next to the required block.
16. To change the vertical sort-order of a block within a region, drag the block to the required position.
17. To edit the visibility settings of an existing block, click Configure from the Operations drop-down menu next to the required block.
18. To enable or disable an existing block, select Enable or Disable from the Operations drop-down menu next to the required block.
19. Click Save blocks to save your changes.

Changing the front page banner block

You can change the front page banner content and image that is displayed on the home page when a user first logs in to the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

About this task

You can change the front page banner by editing the Welcome Banner block in the custom block library.

Procedure

To change the front page banner block, complete the following steps.

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Blocks and enter `welcome` in the **`Block description`** field.
3. Click Edit against the Welcome Banner block entry.
   The Edit Basic block Welcome Banner page is displayed.
4. Edit the Body section with the content and image that you require.
   You can set the text format to Full HTML, Basic HTML, Restricted HTML, or Github Markdown. You can use the edit icons in the Body section to configure your content. Click the Source icon 

   to view and edit the code source, such as HTML.
5. Configure the language and translation settings as required.
6. Click Save to save your changes.

Results

You successfully updated the front page banner block.

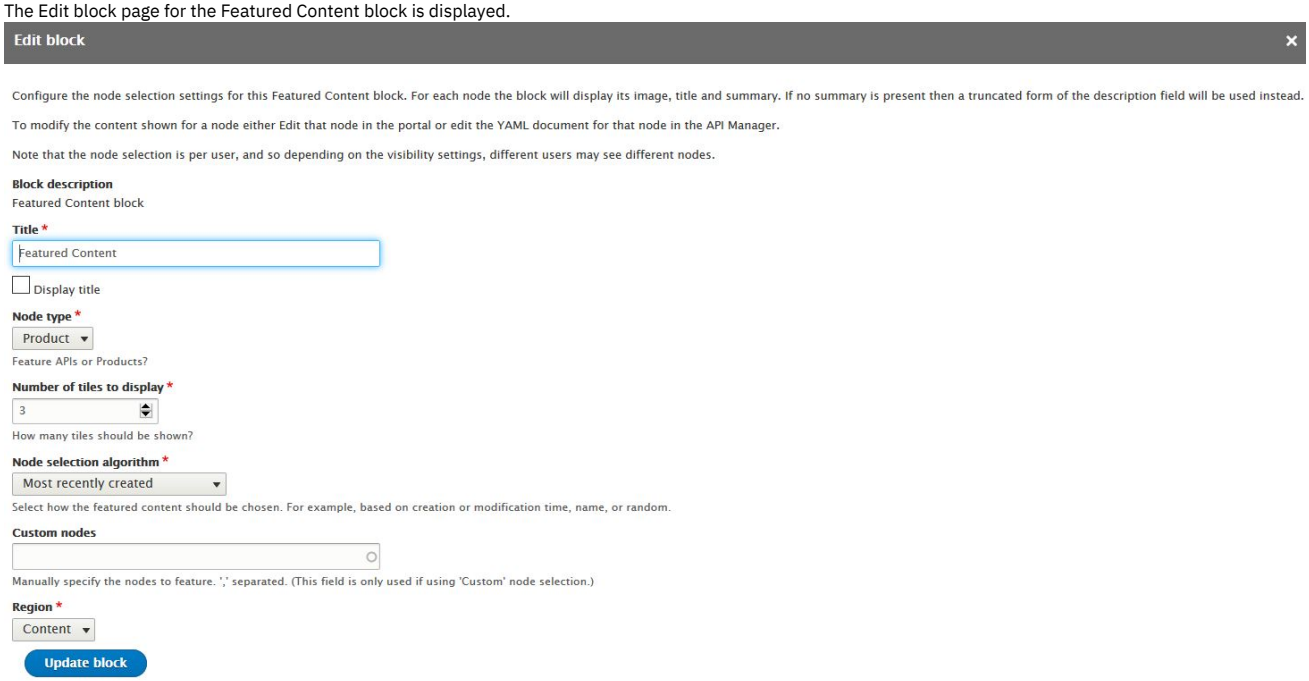
Related tasks

- Configuring the front page
- Adding and changing the blocks displayed on Developer Portal pages

Changing the front page Featured Content block

You can display featured Products or APIs on the front page of your Developer Portal by configuring the Featured Content block.

Before you begin



You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can configure the Featured Content block on the front page of your Developer Portal. By default this block displays a list of the most recently created Products, but you can configure the block to display Products or APIs, and select how the featured content is chosen.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Structure > Pages.
4. Click Edit against the welcome page.
   The edit menu for the Welcome page is displayed.
5. Select Panels > Content from the navigation column, and then click Edit against the Featured Content block.
   The Edit block page for the Featured Content block is displayed.

6. Configure the Feature Content block as required.
   You can choose to display the title or not, select whether to use Products or APIs, for your node type. You can choose how many tiles to display, and select which algorithm is used to select the node. If you start typing in the **`Custom nodes`** field, you can choose from the options you are given.
7. Click Update block, then Update and save, to save your changes.

Results

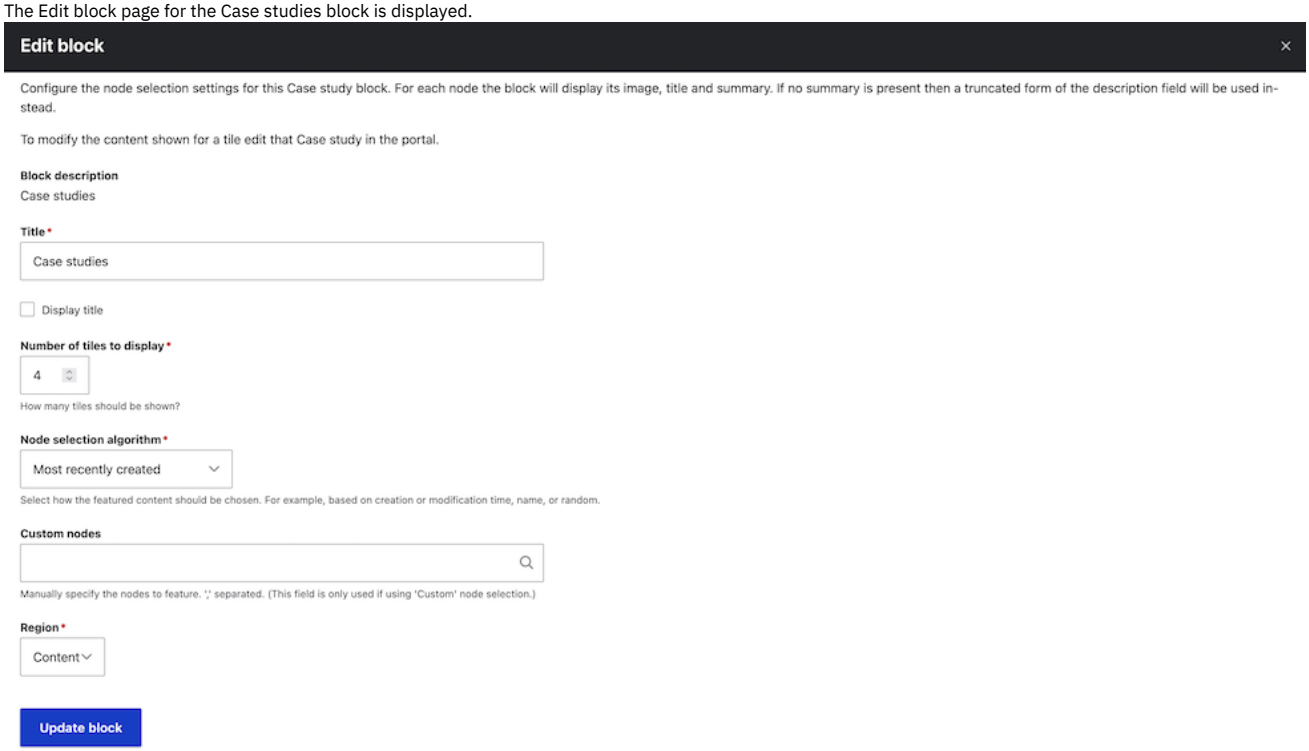
You successfully configured the Featured Content block on the front page of your Developer Portal.

Changing the case studies content block on the front page

Configure the case studies content block on your Developer Portal as required.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.



About this task

You can configure the **`Case studies`** content block on the front page of your Developer Portal. By default this block displays a list of the most recently created case studies, but you can configure the block to display the case studies based on a different algorithm. You can also configure the numbers of tiles to display and the visibility

of the content block title.

Procedure

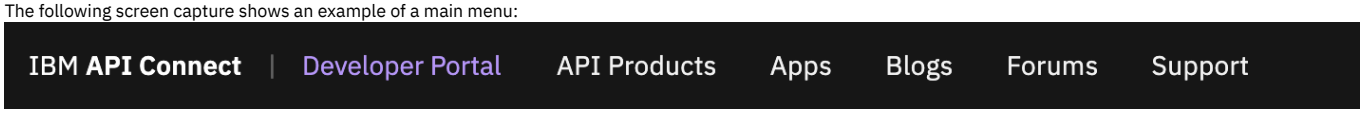
1. Log in to the Developer Portal as an administrator.
2. Click Structure > Pages.
3. Click Edit against Welcome.
   The edit menu for the Welcome page is displayed.
4. Select Panels > Content from the navigation column, and then click Edit against the Case studies block.
   The Edit block page for the Case studies block is displayed.

5. Configure the case studies block as required.
   You can choose to whether to display the title, how many tiles to display, and select which algorithm is used to select the node. If you start typing in the **`Custom nodes`** field, you can choose from the options you are given.
6. Click Update block.
7. Click Update and save to save your changes.

Results

You successfully configured the case studies Content block on the front page of your Developer Portal.

Changing the items in the main menu



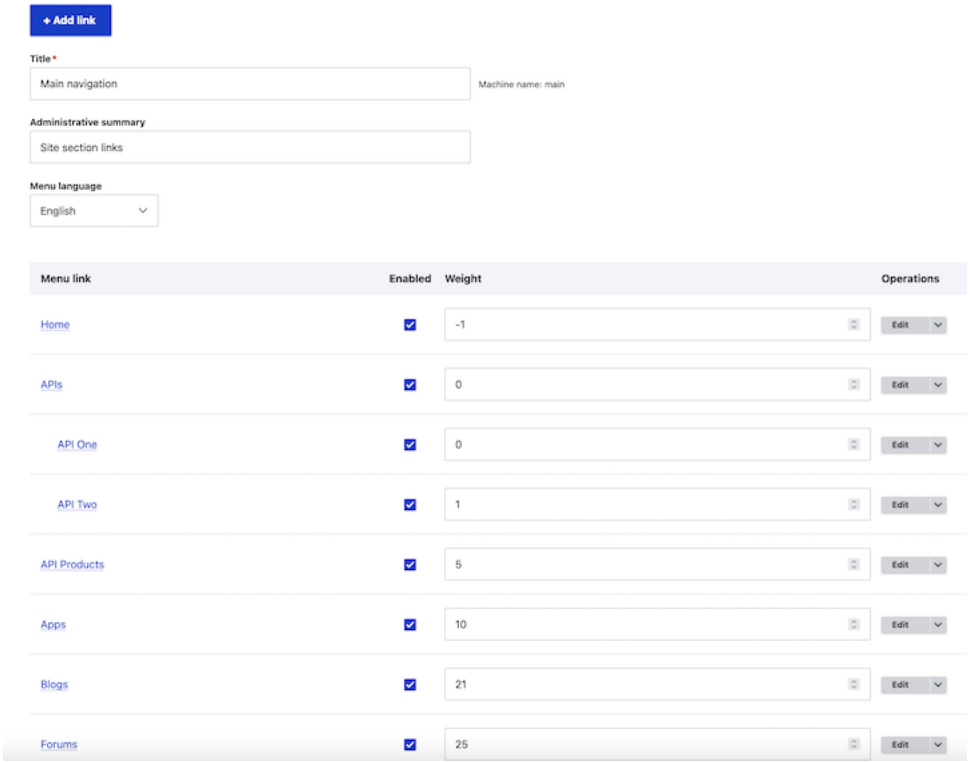
You can change the items in the main menu that is displayed on all pages in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The following screen capture shows an example of a main menu:



However, you can add new menu items, remove items, and change the item order.

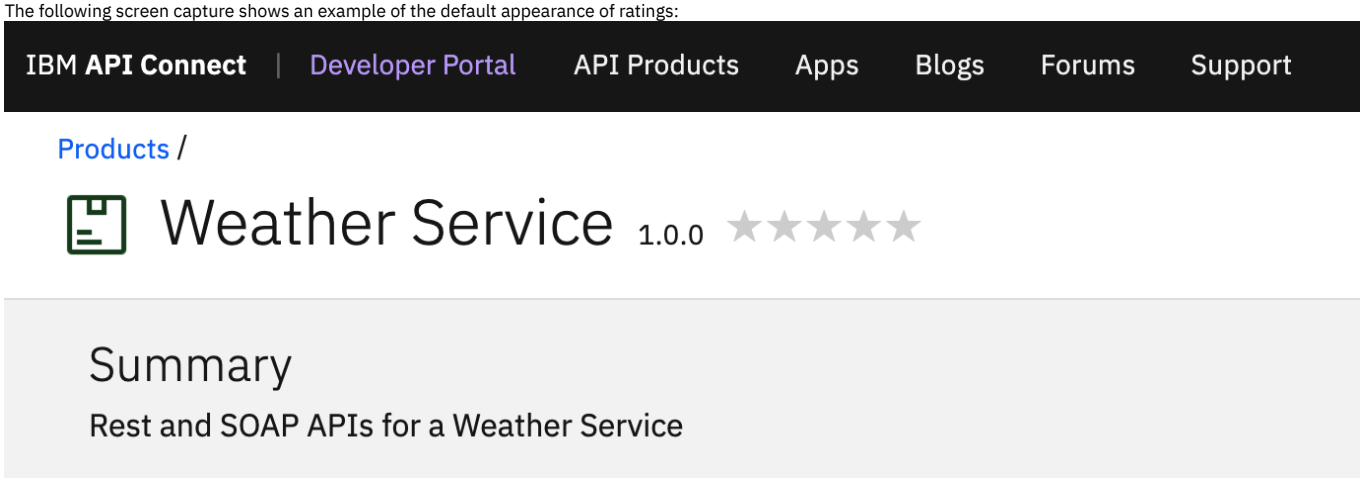
Procedure

To change the items in the main menu, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. Click Structure > Menus. Find the **`Main navigation`** title and click Edit menu.

3. Use the configuration settings on the Edit menu main navigation page to change the menu items as required.
4. Click Save to save your changes.

Changing the ratings display



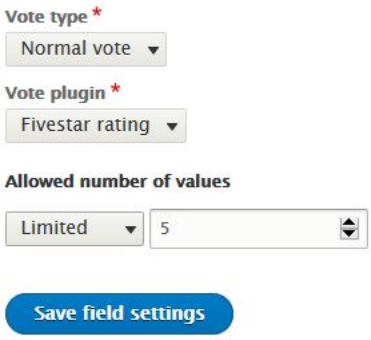
You can change the appearance of the content ratings in the Developer Portal.

Before you begin

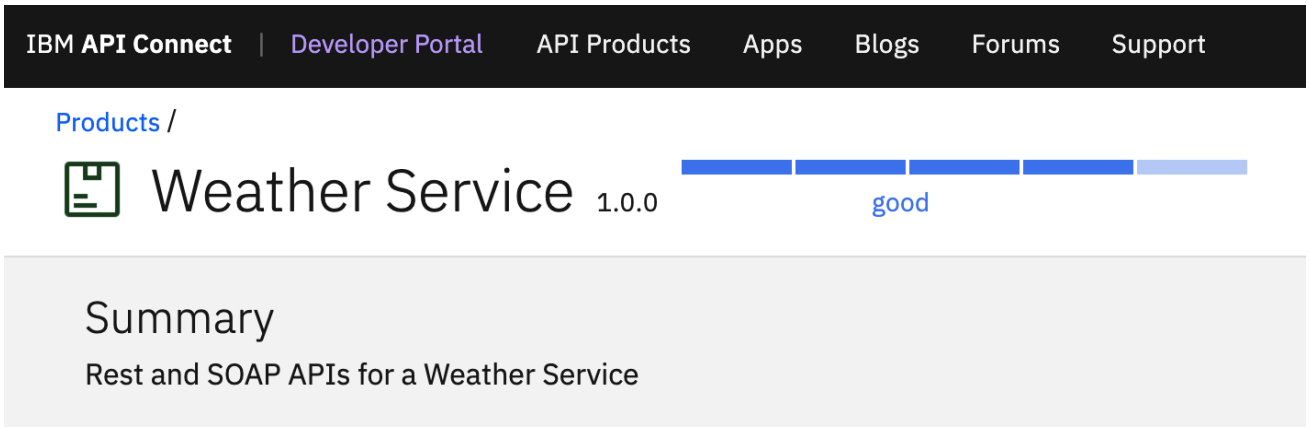
You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The following screen capture shows an example of the default appearance of ratings:



You can change this display if you want to.



Procedure

1. Log in to the Developer Portal as an administrator.

2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Structure > Content types.
4. Click the Manage fields drop-down against the content type you want to change, for example `Product`.
5. Click Edit on the `Rating` row. Then, select the Field settings tab.
   These settings apply to the *Rating* field everywhere it is used.

6. Change the style settings as required and click Save field settings.
   Here is an example of an alternative Ratings style:

Results

You successfully changed the ratings display for a content type in your Developer Portal.
Note: There are different view modes, and the settings would need to be changed for each view mode for each content type.

Displaying APIs and Products in categories

You can create taxonomies in the Developer Portal, which dictate the categorization of APIs and Products, and how they are displayed. The taxonomies that you define can be used by API developers to categorize APIs and Products in YAML files.

You might want to create taxonomies to control which set of APIs and products can and cannot be used in the Developer Portal.

By default, all taxonomies must be created in the Developer Portal. For more information, see Managing tags in the Developer Portal.

After you create your taxonomies for your APIs and Products, API developers can assign content to those taxonomies manually in the Developer Portal, or by using categories in YAML files.

However, if you create categories for your APIs and Products in the API Designer or API Manager UI, you can have your APIs and Products that are displayed in those categories in the Developer Portal. For more information about how to create categories for your APIs and Products in the API Designer or API Manager UI, see Organizing your Products into categories. For information about how to have your APIs and Products that are displayed in those categories in the Developer Portal, see Enabling dynamic category creation.

You can add more Developer Portal taxonomies to the categories that are defined in the API Designer or API Manager UI.

You can also provide the ability for users in the Developer Portal to navigate by using tag hierarchy. For more information, see Providing navigation by tag hierarchy.

- **Enabling dynamic category creation**
  You can display APIs and Products in pre-defined categories in the Developer Portal. You can define the categories that the APIs and Products are displayed in, in the API Designer or API Manager UI.

Enabling dynamic category creation

You can display APIs and Products in pre-defined categories in the Developer Portal. You can define the categories that the APIs and Products are displayed in, in the API Designer or API Manager UI.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Your APIs and Products must be categorized in the API Designer or API Manager UI, and they must be published. For more information, see Organizing your Products into categories.

About this task

By organizing your APIs and Products into categories, you can provide a hierarchical display for your APIs and Products in the Developer Portal.
Note: Organizing APIs and Products into a hierarchical view in the API Manager UI is different from tagging in the Developer Portal.
The categories that are defined in the API Designer or API Manager UI can be overridden by creating taxonomies in the Developer Portal. For more information, see Displaying APIs and Products in categories.

Procedure

1. To enable the Developer Portal to display the categories for your APIs and Products:
   a. On the administrator dashboard, click Configuration > System > IBM API Developer Portal.
   b. In the Categories section, select the Create taxonomies for categories if they do not already exist check box.
   c. Click Save configuration.
2. To enable the Developer Portal to display the change to the categories you made in step 1, you must republish your APIs and products.

Results

You enabled the Developer Portal to display the categories that you defined for your APIs and Products. You can see the categories that you defined, including the number of APIs and Products that are in each category, by selecting your APIs and Products in the Developer Portal.

Implementing an image carousel

You can customize your Developer Portal home page to display images in a carousel. The image carousel provides your Developer Portal home page with a continuous slide show that is customized to your specifications.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

By implementing an image carousel, you can replace the default welcome banner or any previously set images.

Procedure

1. Create a content type of Image for your carousel.
   a. Click Structure > Content types > Add content type.
   b. Enter the name of your content type in the Name field.
      For example, *Slide show picture*.
   c. Optional: Specify the description of your content type in the Description field.
      For example, *A picture to display in the slideshow*.
   d. Click Save and manage fields for your newly created content type.
   e. Click Add field.
   f. Select Image for Add a new field, and enter a label for your field.
      For example, *slide image*.
   g. Click Save and continue.
      The Field settings page for your new field is displayed.
   h. In the DEFAULT IMAGE section, click Choose file to assign the image that you want as your default image for your slide show if no other images are found.
   i. Optional: Complete the Alternative text and Title fields.
   j. Click Save field settings.
   k. In the Manage fields tab for your newly created content type of *Slide show picture*, delete the `Body` field by clicking Delete on the OPERATIONS drop-down menu. Click Delete again to confirm.
2. Upload the images that you want to appear in your carousel.
   a. Click Content > Add content, then click the content type that you added in step 1.
   b. Enter a title for your image in the Title field.
      For example, if you had an image of a lighthouse, you can label the content as *Lighthouse*.
   c. Click Choose file under Slide image and select an image for your slide show. Complete the Alternative text field with some text to use when the image cannot be loaded.
   d. Click Save.
   e. Repeat sub-steps 2.a to 2.d until you are satisfied with the content of the slides for your carousel.
3. Create a view for your carousel.
   a. Click Structure > Views > Add new view.
   b. Complete View name.

For example, Slide show.
c. Select the Create a block check box in the BLOCK SETTINGS section.
d. Select Slick Carousel for the display format.
e. Enter the number of slides you have for your carousel in the Items per block field, then click Save and edit.
The Edit page for your slide show view is displayed.
f. Click the title of the view and enter `<none>` into the text field. Click Apply.
g. In the FIELDS section click Add, select the check box for slide image, and click Add and configure fields.
h. Ensure the check box for Create a label is not selected, and click Apply.
i. In the FIELDS section, click Content: Title > Remove.
j. In the FORMAT section, click Settings for Slick Carousel, and then set Skin Main to Default.
k. Scroll down to the CAPTION FIELDS section, and select the Content: slide image and Override main optionset check boxes.
l. In the OVERRIDABLE OPTIONS section, select the Autoplay, Dots, and Draggable check boxes.
m. Click Apply.
n. In the FILTER CRITERIA section, click Content: Published > Remove.
o. Click Save to save the Slide show view.
4. Configure your home page to host the carousel.
a. Click Structure, then click Pages.
b. Click edit for the welcome page, then click content in the Panels section.
c. To remove the current welcome banner, click the down-arrow under the OPERATIONS column for the Welcome Banner, and select Delete. Click Delete again to confirm.
d. To add your carousel, click Add new block and select the slide show view you created in step 3. Deselect Display title and click Add block.
e. Click Update and save.

Results

Your Developer Portal front page now has a slide show carousel.

Making your application's image public

You might want to display your application's image in an oauth authentication page to reassure customers that they are authenticating the correct application in the Developer Portal. That authentication uses a URL to the image that is stored on the Developer Portal. However, by default, those images are private unless you are logged in, which doesn't work if you want to display it in an oauth page. The solution is for the admin to change the **`application_image`** field to use public instead of private.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Structure > Content types > Application > Manage fields
4. Navigate to the Image label, then in the **`Edit`** drop down, select **`storage settings`**.
5. Click **`Public files`** for **`Upload destination`**.
6. Click **`Save field settings`**.

Providing navigation by tag hierarchy

You can provide the ability for users in the Developer Portal to navigate by using tag hierarchy.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The Categories block provides the ability to navigate by tag hierarchy. The Categories block is disabled by default, so you need to enable the block and then configure it to your requirements.

Procedure

To provide navigation by tag hierarchy, complete the following steps:

1. Click Extend, in the filter box enter `Hierarchical Taxonomy Menu`.
2. Select **`Hierarchical Taxonomy Menu`**, then click Enable.
3. Click Structure > Block layout.
All of the blocks in the connect_theme are displayed.

4. Scroll to the region that you want to add the block to, for example Collapse right, click Place block.
5. Find the **`Hierarchical Taxonomy Menu`** block in the list and click Place block.
6. Complete any configuration tasks that you require for the **`Collapse right`** block, including selecting the correct taxonomy to use and indicating what pages to display the block on.
7. Click Save block to save your changes.
   You can add new blocks, and modify the existing blocks that are displayed on Developer Portal pages. For more information, see Adding and changing the blocks displayed on Developer Portal pages.

Related tasks

- Editing tags for a specific item

Using the Views module in the Developer Portal

By using the Views module, you can fetch content from your Developer Portal site, and present it to users in different formats such as lists, graphs, and tables.

The Views module is a powerful SQL query builder that can access almost all the information in your Developer Portal site database and display it in any format.

There are many uses cases for views, but the following list shows some of the common ones:

- You want to display some of the content differently, such as Products, APIs, and applications.
- You want to display a block with the five most recent posts of some kind.
- You want to change the way that articles are displayed.
- You want to provide an unread forum posts list.
- You want to provide a monthly archive of posts.

For information about how to create a view in the Developer Portal, see the following topic. You can also follow a tutorial about creating a custom sort order view; see Tutorial: Using a custom weighting sort order on the product list page.

- **Creating views in the Developer Portal**
  You can create new views in the Developer Portal, such as content lists of Products, APIs, and applications, by using the Views module.
- **Configuring the search results view in the Developer Portal**
  You can configure the way that the search results are displayed in the Developer Portal.
- **Configuring the default number of items in a view list in the Developer Portal**
  You can configure the default number of items that are displayed in a view list in the Developer Portal.

Creating views in the Developer Portal

You can create new views in the Developer Portal, such as content lists of Products, APIs, and applications, by using the Views module.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Creating views in the Developer Portal enables you to control the presentation of specific content for users. For more information about views, see Using the Views module in the Developer Portal.

Procedure

To create a view, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Structure > Views > Add new view.
   The Add view page is displayed.
4. Complete the View name and, optionally, the Description.
5. Complete the VIEW SETTINGS section with details of what you want your view to show, and how you want it to be sorted.
   For example, to create a view of APIs that are sorted by title, select Show `Content`, of type `API`, and sorted by `Title`.
6. Select whether to Create a page, Create a block, or both, for your view.
   A page is a full-screen page in the Developer Portal. Whereas a block would be a site block that you can then place on whatever pages you want to show a smaller view of the content, for example the 10 newest APIs.
7. Complete the options that you require for your view. For example, the display format, the number of items per page or block, whether to include a pager, whether to create a menu link, and whether to include an RSS feed.
8. Click Save and edit.
   Your new view opens in the Edit tab.
9. Refine your view further.

Here you can further modify the display of your view or add new displays. More options include formatting of the view, what fields to include in a table or grid format, filtering and sorting criteria, add header or footer details, as well as advanced options around contextual filters, relationships, and behavior when there are no results to display. The Edit tab also includes a preview area, so you can check your view before publishing.

10. Click Save to make your changes permanent.
    When saved, your new view is visible in the Structure > Views pane.

Results

You created a new view in the Developer Portal.

Configuring the search results view in the Developer Portal

You can configure the way that the search results are displayed in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

In the Developer Portal, the search results are displayed as a view, and so you can control the presentation of this search content. For more information about views, see Using the Views module in the Developer Portal.

Procedure

To configure the search results view, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Structure > Views.
   The list of views is displayed.
4. Find the Search content view in the list, and click Edit.
5. Edit the Search content view settings as required.
   Here you can modify the display of the view or add new displays. For example, you can configure the formatting of the view, the filtering and sorting criteria, add header or footer details, as well as more advanced options around contextual filters, relationships, and behavior when there are no results to display. There is also a preview area so you can check the view before publishing.
6. Click Save to make your changes permanent.

Results

You updated the view of the search results in the Developer Portal.

What to do next

You can configure the search index and server that are used to generate the search results. For more information, see Configuring search indexes and servers.

- Drupal Views module

Configuring the default number of items in a view list in the Developer Portal

You can configure the default number of items that are displayed in a view list in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

In the Developer Portal, you can manage how many items in a list are shown for each page on a view. For more information about views, see Using the Views module in the Developer Portal.

Procedure

To configure the search results view, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Structure > Views.
   The list of views is displayed.
4. In the list, find the view name that you want to update, for example, Products, then click Edit.
5. Click Pager.
6. Select Display a specified number of items, click Apply.
7. Set the Items per page as required, click Apply.
8. Click Save to make your changes permanent.

Results

You updated the default number of items in a view of the search results in the Developer Portal.

What to do next

The Views module is a powerful SQL query builder that can access almost all the information in your Developer Portal site database and display it in any format. For more information, see Using the Views module in the Developer Portal.

Configuration

As an administrator, you can control multiple aspects of the Developer Portal configuration, including managing security and general configuration tasks.

To learn how to configure specific aspects of your Developer Portal site, use the following section links.

- **Configuring content moderation**
  By configuring content moderation, you can configure a review and approval process for content types in the Developer Portal. You can specify which roles can perform which actions by assigning them the appropriate permissions.
- **General configuration tasks**
  You can perform general configuration tasks in the Developer Portal as an administrator.
- **Managing Developer Portal security**
  You can manage multiple security elements in the Developer Portal.

Configuring content moderation

By configuring content moderation, you can configure a review and approval process for content types in the Developer Portal. You can specify which roles can perform which actions by assigning them the appropriate permissions.

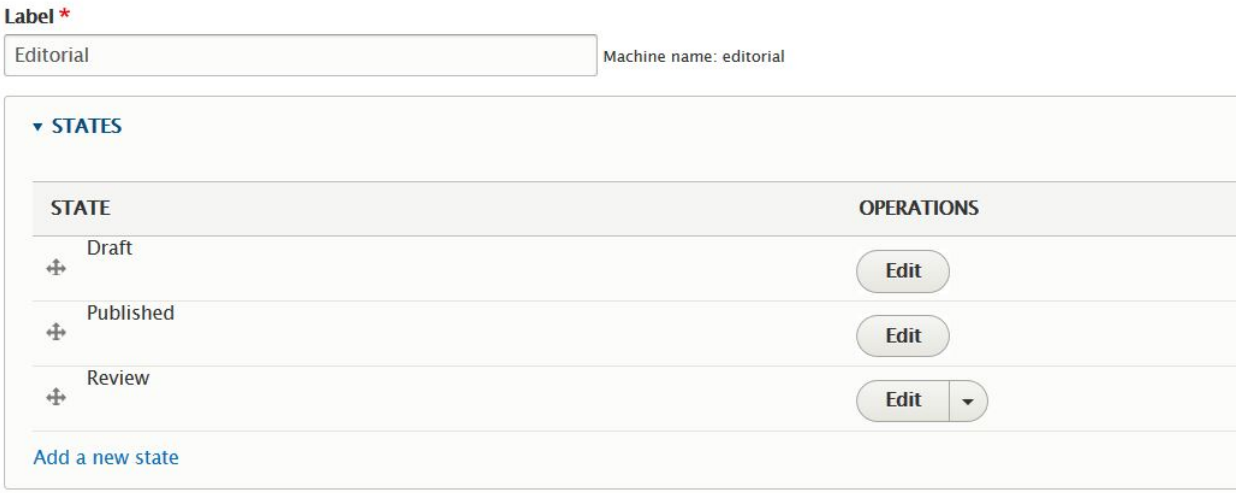
Before you begin

An example use case for configuring content moderation would be for a professional documentation writer to review an APIs documentation before it is published on the Developer Portal. They might, for example, notify the API Developer of typographical errors, suggest improvements to operation descriptions, or attach an image file. Edits might then be made before the documentation was republished to the API and then published to the Developer Portal.

You must have a Developer Portal enabled, and you must have administrator access to complete this task.

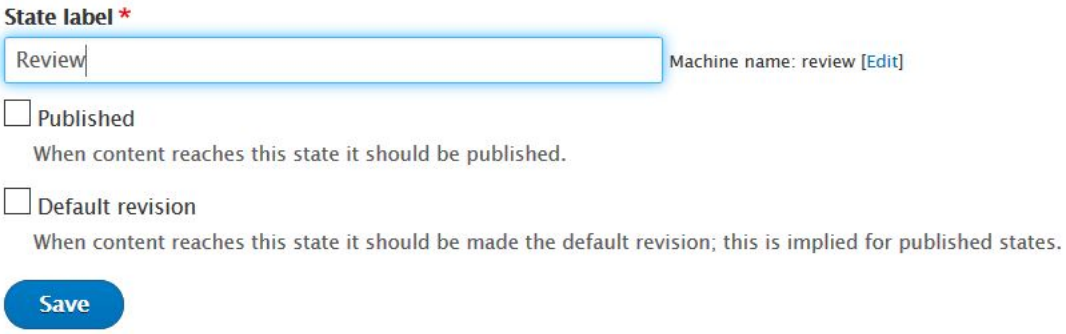
About this task

By using content moderation, you can configure the workflow of your Developer Portal site so that you can moderate content types, such as APIs and Products. However, you cannot moderate Consumer organizations or applications.

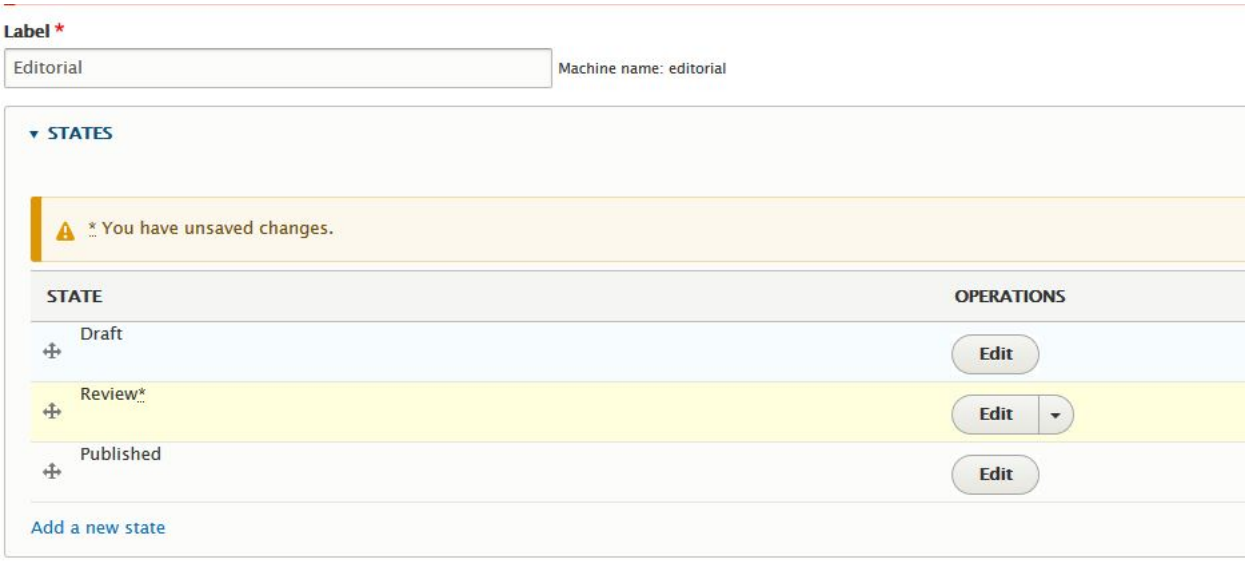


Procedure

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Enable the required modules:
   a. On the administrator dashboard, click Extend.
   b. In the search bar enter **`workflows`**, then select the Workflows module and click Enable.
   c. In the search bar enter **`content moderation`**, then select the Content Moderation module and click Enable.
4. Navigate to Configuration > Workflow > Workflows
5. Check that **`Editorial`** is listed as a workflow. If it isn't listed:
   a. Click **`+ Add workflow`**.



b. Enter **`Editorial`** as the label.
c. Select the workflow type **`Content moderation`**.
d. Click **`Save`**.



6. Set up the workflow:
   a. Click **`Edit`** on the **`Editorial`** workflow.
   b. Click the **`Add a new state`** link.

   c. Enter the value **`Review`** in the **`State label`** field, leave the **`Published`** and **`Default revision`** check boxes cleared then click Save.

   d. Drag the **`review`** state to between the **`Draft`** and **`Published`** states then click 'Save'. If the drag handles are not visible, then click the **`Hide row weights`** link in the **`STATES`** section to make them appear.

e. Click the **Add a new transition** link.
f. Enter the value **Review** in the **Transition Label** field, tick the **Draft** check box in the **From** section and click **Review** in the **To** section then click Save.
g. Drag the **Review** transition to between the **Create New Draft** and **Publish** transitions, then click Save.
h. Click the **Edit** operation on the **Create New Draft** transition.
i. In the **From** check box list, untick **Published** and tick **Review** then click Save.
j. Click the **Edit** operation on the **Publish** transition.
k. In the **From** check box list, untick **Draft** and tick **Review** then click Save.
l. Click **Select** for the **Content types** item in the **THIS WORKFLOW APPLIES TO** section.
m. Select the **Product** content type then click Save.

7. Set up the permission schema for the workflow:
   a. Click People > Roles > Add a new role.
   b. In the **Role Name** field, enter the value **Editor** then click Save.
   c. Drag the **Editor** role to between the **Content Author** and **Administrator** roles then click Save.
   d. Click the Permissions tab and scroll down to the **Content Moderation** permission section.
   e. For the EDITOR role, select all the permissions in the **Content Moderation** section.
   f. For the CONTENT AUTHOR role, select the permissions **Editorial workflow: Use Create New Draft transition**, **View any unpublished content**, and **View the latest version** then click Save permissions.
   g. Ensure that the EDITOR and CONTENT AUTHOR roles have the permission **Use the administration toolbar**.
8. Assign the permissions to users in the portal. If you do not already have some registered users in your portal, create a new consumer organization and invite two new users to it.
   a. Click People.
   b. Tick the check box next to one of the users in the list, but not the admin user, then from the **Action** drop-down select **Add the Content Author role to the selected user(s)** then click **Apply to selected items**.
   c. Tick the check box next to another one of the users in the list, but not the admin user, then from the **Action** drop-down select **Add the Editor role to the selected user(s)** then click **Apply to selected items**.

Results

You successfully configured content moderation on your Developer Portal. You can now use the API manager user interface to publish a product to the portal, and transition the product from draft to review state.

- **Editing, reviewing, and publishing moderated content**
  If you have published content from API Manager UI to your Developer Portal or created content within the Developer Portal, you can edit and review the content through the Moderated content page before you publish it in the Developer Portal.

Editing, reviewing, and publishing moderated content

If you have published content from API Manager UI to your Developer Portal or created content within the Developer Portal, you can edit and review the content through the Moderated content page before you publish it in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You must have content that is published to the Developer Portal from the API Manager UI.

Your role must have the necessary permissions that help you to complete the tasks. For more information on assigning the necessary tasks, see Configuring content moderation.

About this task

In addition to editing content through the content moderation page, you can specify whether the content needs further review, or even publish the content if you have the permission.

Procedure

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. On the administrator dashboard, click Content.
4. Click the Moderated content tab.
5. If you have the necessary permissions to edit your content type, for example, you are a **`Content author`**:
   a. Click the Title of the content type that you want to edit, then click the Edit.
   b. Edit your content to your specification, then click Save.
   You are redirected to the **`View`** tab.
   c. When you have finished editing your content type on the **`edit`** tab, ensure that the **`Review`** state is selected from the **`Change to`** drop-down, then click Save.
6. If you have the necessary permissions to review and publish your content type. For example, you are a **`Reviewer`**:
   a. On the administrator dashboard, click Content.
   The content page is displayed listing all content.
   b. Click the Moderated content tab.
   c. Click the Title of the content type that you want to review.
   d. Optional: If the content that you are reviewing requires editing, click Edit, apply the changes to your content type, then click Save.
   You are redirected to the View tab.

Results

You edited, reviewed, and published your draft content type.

General configuration tasks

You can perform general configuration tasks in the Developer Portal as an administrator.

To learn how to configure specific aspects of your Developer Portal site, use the following topic links.

- **Adding a page load progress indicator**
  You can extend your Developer Portal site by adding a page load progress indicator. This option might be useful on servers that have a slow connection to the API Manager, or for customers that are using OIDC and have slow response times from their OIDC provider.
- **Adding custom fields to user records**
  You can add custom fields to user records in the Developer Portal.
- **Checking the site status report**
  You can check the site status report in the Developer Portal.
- **Clearing the server caches**
  You can clear the server caches from within the Developer Portal.
- **Configuring a proxy**
  You can configure the proxy settings in your Developer Portal.
- **Configuring the visibility of analytics in the Developer Portal**
  How to configure the visibility of API consumer analytics in the Developer Portal.
- **Configuring the API details visibility for non-authenticated users**
  You can configure the API details visibility settings in the Developer Portal to limit non-authenticated users from viewing API details published in a product.
- **Configuring API product recommendations**
  Enable the **`API product recommendations`** setting in the Developer Portal to display product recommendations to the API product consumers.
- **Adding a case study**
  The Community managers and API product owners can use the case study module in the Developer Portal to promote and highlight their published API products.
- **Configuring Stripe in the Developer Portal**
  You can offer free use of your Product Plans to your API consumers, or you can offer Products with paid Plans. To enable API consumers to subscribe to Products with paid Plans, you must first configure the Stripe payment method in your Developer Portal.
- **Configuring cron to run scheduled tasks**
  You can configure cron to run scheduled tasks in the Developer Portal.
- **Configuring search indexes and servers**
  You can configure search indexes and servers in the Developer Portal by using the Search API module.
- **Configuring the date and time**
  You can configure the date and time in the Developer Portal.
- **Configuring the notifications event log settings**
  You can configure the settings of the notifications event log for the activity feed on your Developer Portal.
- **Configuring the application settings**
  You can configure the application settings in the Developer Portal to limit or allow credential access to the consumer organization members.
- **Configuring the site default time zone**
  You can configure the site default time zone in the Developer Portal.
- **Configuring the site error handling**
  You can configure the site error handling in the Developer Portal.

- **Configuring which buttons are displayed in the WYSIWYG rich text editor**
  You can configure which buttons are displayed in the WYSIWYG rich text editor in the Developer Portal.
- **Configuring which languages are available**
  You can configure which languages are available in the Developer Portal.
- **Customizing user account settings**
  You can customize the user account options that are displayed to users when they register and use the Developer Portal.
- **Disabling languages**
  You can extend your Developer Portal site by managing which languages are available for use on the site.
- **Disabling test tool restrictions**
  The default OAuth provider contains security mechanisms that prevent the ability to obtain authorization tokens in the Developer Portal test tool when you use Implicit or Authorization Code grant types. If your OAuth provider allows those actions to function correctly from the test tool, you can disable this option.
- **Enabling a cookie compliance banner**
  You can add a cookie compliance banner to your Developer Portal site by configuring the EU Cookie Compliance module.
- **Enabling code languages for code snippets**
  You can specify the languages that code snippets for APIs can be displayed in.
- **Enabling code snippets for SOAP APIs**
  By default, code snippets are only shown for REST APIs. You can enable code snippets for SOAP APIs.
- **Forcing new users to accept terms and conditions**
  You can extend your Developer Portal site by forcing new users to accept the terms and conditions before they are able to create accounts.
- **Hiding the admin registry on the login form**
  You can hide the admin registry as an option on the login form. The use case for this option might be a public facing Developer Portal where you want to remove the admin access from customer view.
- **Hiding the certificate in the header for APIs secured with mutual TLS**
  You can hide the certificate in the header for APIs secured with mutual TLS. By default, the **`x-client-certificate`** header is shown in an API when mutual TLS is configured. You can choose to turn off this option in your Developer Portal.
- **Importing and exporting taxonomies**
  You can import and export taxonomies in the Developer Portal.
- **Removing keys beginning with x-ibm from Open API document download**
  You can remove keys that begin with x-ibm from the Open API document download in the Developer Portal.
- **Restricting access by IP address**
  You can restrict access to a role or a user by IP address in the Developer Portal.
- **Restricting or preventing access from search engines**
  You can restrict or prevent access to your Developer Portal from search engines. You might want to control the access if you have a development or test site.
- **Toggling the site in and out of maintenance mode**
  You can put the Developer Portal site into maintenance mode for short periods of time. During maintenance mode, only an administrator is able to access the site, and all other users who enter the site URL get a maintenance message set by the administrator.
- **Viewing available updates**
  You can view available updates in the Developer Portal.

Adding a page load progress indicator

You can extend your Developer Portal site by adding a page load progress indicator. This option might be useful on servers that have a slow connection to the API Manager, or for customers that are using OIDC and have slow response times from their OIDC provider.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected check box. The disabled modules are displayed without a selected check box.
3. Enter `page_load_progress` into the search filter.
   The **`Page Load Progress`** content item is displayed in the list of content.
4. By default, the **`Page Load Progress`** module is enabled. However, if not, select the check box and click Enable.
   You have now enabled the default settings for the **`Page Load Progress`** module.
5. To change the default settings for the module, navigate to Configuration > User interface > Page Load Progress.
6. Decide which settings you want to change, for example, **`Time to wait before locking the screen`**, and click Save.
   Note: Changing the settings does not apply to the OIDC buttons. If it is enabled, the OIDC buttons use the page load process indicator, but do not allow any configuration.
7. To enable the permissions, navigate to People > Permissions.
8. Scroll down to **`Page Load Progress`**, check the boxes for anonymous and authenticated for **`Use Page Load Progress`**.

9. Click Save permissions.

Results

You successfully enabled the **`Page Load Progress`**. Now, the page loading spinner is automatically added to the login and register forms for OIDC buttons.

What to do next

You can customize the appearance of the modal page and spinner in CSS in a custom theme.

Adding custom fields to user records

You can add custom fields to user records in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Any data that is added to a custom field for user records will remain in the Developer Portal database.

Procedure

1. In the administrator dashboard, click Configuration > People > Account settings.
2. Click the MANAGE FIELDS tab.
3. Click Add field.
4. Specify the type of data that your field can store by selecting the type from the Add a new field list.
5. Enter a label for your field in the Label field.
6. Optional: If you want to edit the machine name that is automatically created based on your label, click Edit and enter the new name.
7. Click Save and continue.
8. Configure any additional values for the new field then click Save field settings.
   You have added a custom field to your user record.

What to do next

You can configure the contents of your custom field depending on what type of data you specified it could store.

Checking the site status report

You can check the site status report in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To check the site status report, complete the following steps:

1. Click Reports in the administrator dashboard.
2. Click Status report.
3. You can review information relating to the site status report from this view.

Clearing the server caches

You can clear the server caches from within the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

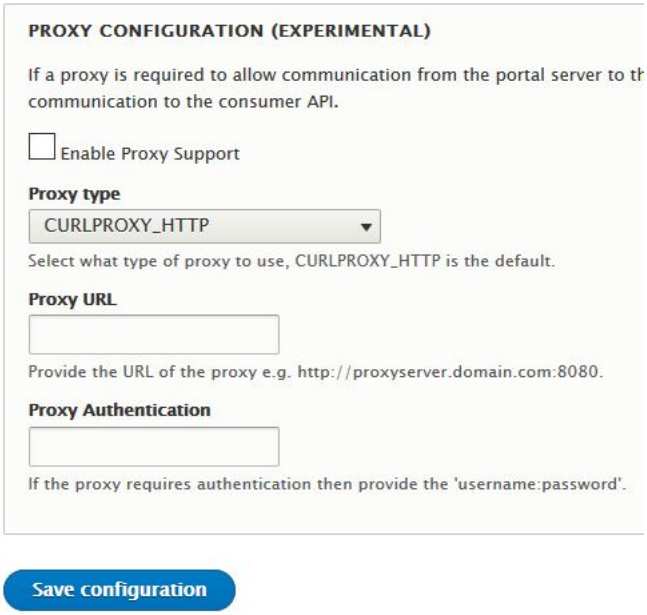
1. In the administrator dashboard, click Configuration, then in the Development section, click Performance.
2. Click Clear all caches.
   You have cleared the server caches, and a message will be displayed stating: `Caches cleared`.

Configuring a proxy

You can configure the proxy settings in your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.



About this task

The Developer Portal communicates with the management server by way of the consumer and product APIs. For a Developer Portal that is deployed externally to the management server zone, and does not have access to the consumer and product APIs, a proxy can be used.

Procedure

To configure a proxy to use for communicating with management server APIs, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > System > IBM API Connect in the administrator dashboard.
4. To configure a proxy, select **`Enable Proxy Support`**, and make the required changes.

5. When your changes are complete, click Save configuration.

Results

You successfully configured a proxy on your Developer Portal.

Configuring the visibility of analytics in the Developer Portal

How to configure the visibility of API consumer analytics in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Restriction:

- If the Catalog that is associated with this Developer Portal has two or more gateway services enabled then, for analytics data to be available, the gateway services must all be associated with the **same** analytics service. If the set of associated analytics services for the gateway services includes two or more different analytics services then the Developer Portal does **not** display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see Associating an analytics service with a gateway service.
- If the visualizations in your dashboard views display no data, show data only for a time period in the past, or the Dashboard tab does not show up, a possible reason might be that access to analytics data within API Connect has been switched off. Contact your API provider for confirmation.

About this task

What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings.

Procedure

- To configure the visibility of the API consumer analytics in Developer Portal, complete the following steps:
  1. If the administrator dashboard is not displayed, click Manage to display it.
  2. Click Configuration in the administrator dashboard.
  3. Under the System heading, click IBM API Developer Portal.
  4. Under the Configuration section, clear the Display Analytics checkbox to remove all the analytics links from the portal site. By default, the Display Analytics checkbox is selected and the analytics section is visible in the portal site.
  5. Click Save configuration to save the changes.
     You have configured the visibility of analytics in the Developer Portal.
- To configure the visibility of the API analytics charts, complete the following steps:
  1. If the administrator dashboard is not displayed, click Manage to display it.
  2. Click Configuration in the administrator dashboard.
  3. Under the System heading, click IBM API Developer Portal Consumer Analytics.
  4. From the list of Metrics and charts, clear the checkboxes corresponding to the charts that you want to remove from the analytics section in the portal site. By default, all the charts that are displayed under the metrics and charts section are visible in the analytics section.
  5. Click Save configuration to save the changes.
     You have configured the visibility of Metrics and charts in the analytics section.

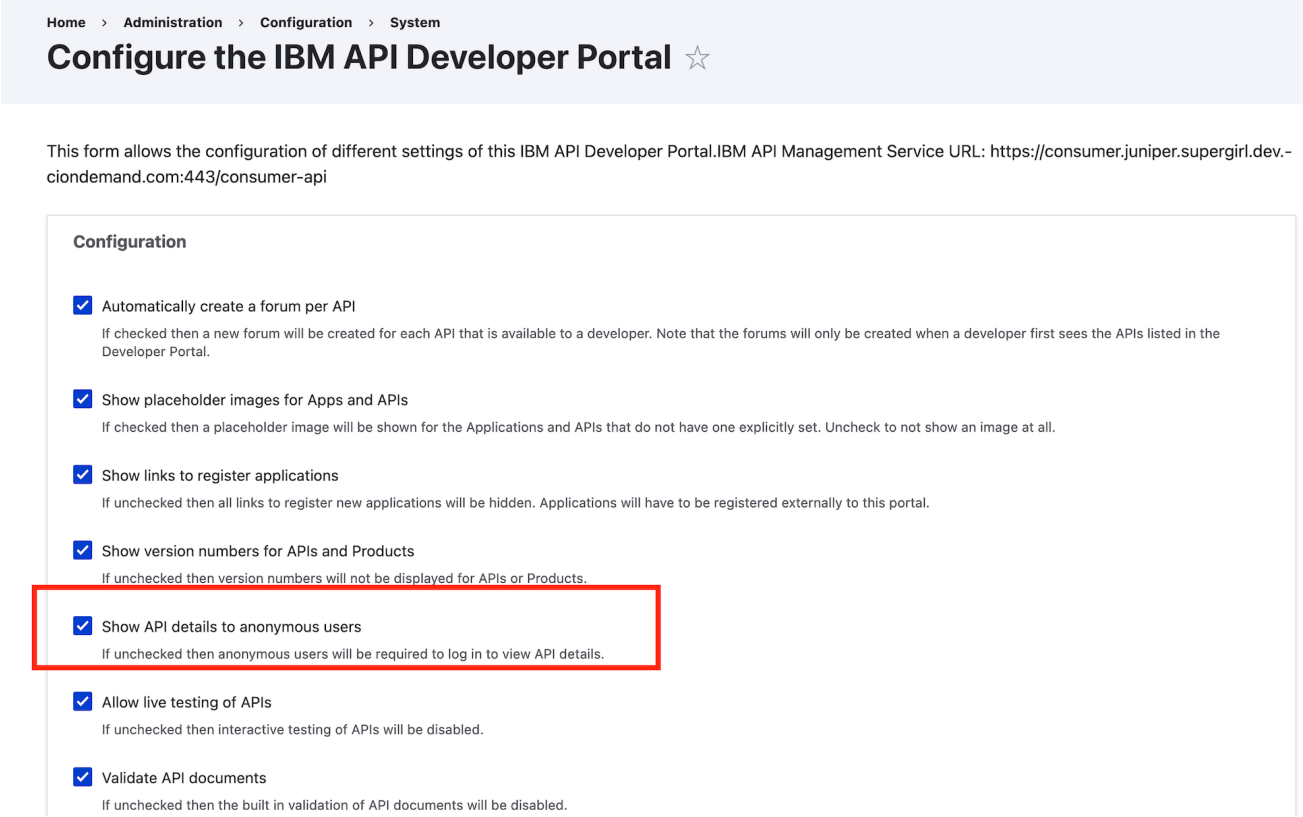
Configuring the API details visibility for non-authenticated users

You can configure the API details visibility settings in the Developer Portal to limit non-authenticated users from viewing API details published in a product.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task



You can configure the **`Show API details to anonymous users`** setting in the Developer Portal to limit the visibility of API details to non-authenticated users. If you enable this setting, the non-authenticated users can see only the following basic API details:

- Name
- Description
- Icon
- Version number
- **Rating** (if configured; for more details, see Changing the ratings display)

The non-authenticated users can view these details on the API tiles that are displayed on individual API Product pages, API list view, or from the search results. To view more API details published in a product, the users must log in to the Developer Portal.

Procedure

1. Log in to your Developer Portal as an administrator.
2. Click Configuration > System > IBM API Developer Portal.
3. Scroll down to **`Show API details to anonymous users`**. By default, the configuration option is selected and both the authenticated and non-authenticated users can view all the API details if the respective API product is viewable.

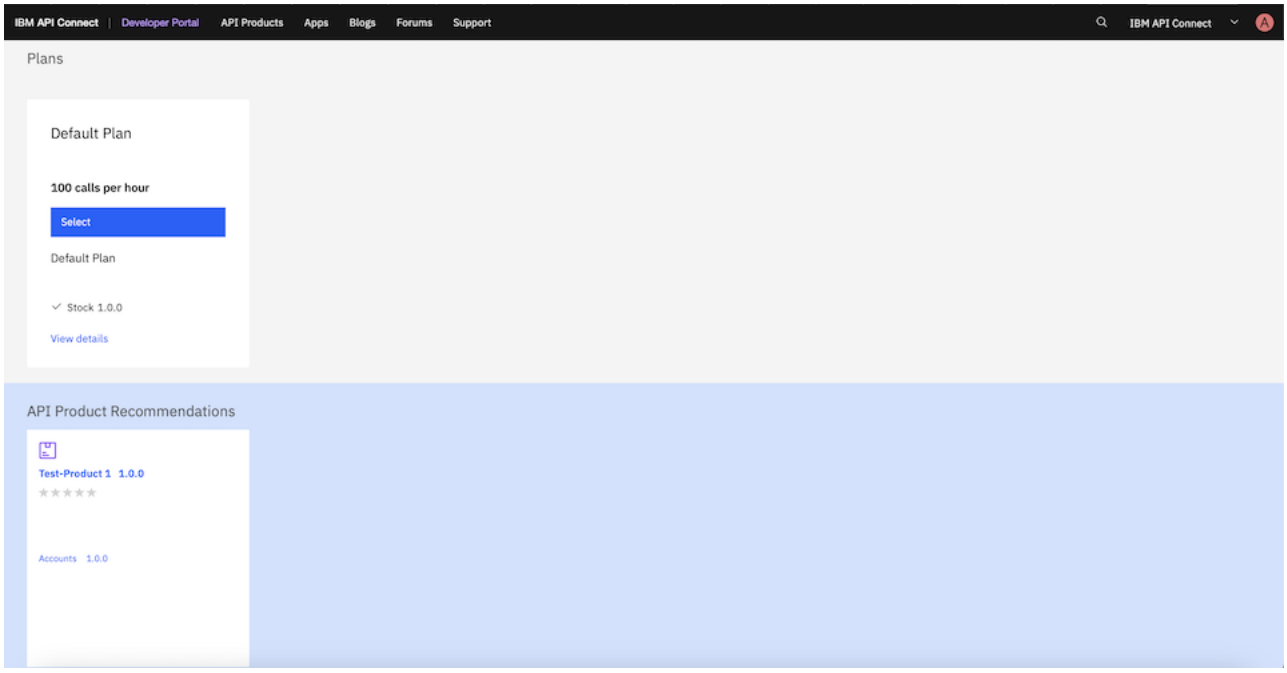
Clear the Show API details to anonymous users checkbox to allow only the authenticated users to view more API details such as endpoints, protocols, type, and security features.

4. Click Save configuration to save the changes.
   When a non-authenticated user clicks on an API tile to view more details, the Developer Portal login page is displayed directing the user to log in to proceed further.

Results

You successfully configured the API details visibility setting for non-authenticated users on your Developer Portal.

Configuring API product recommendations

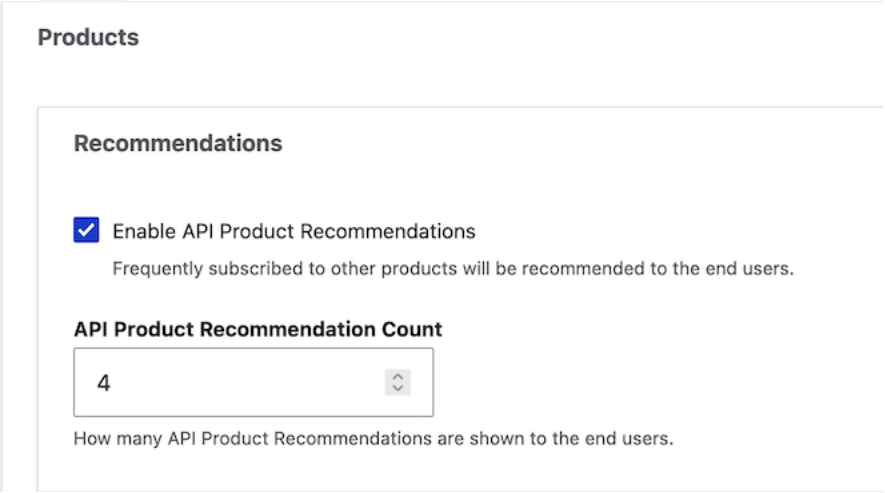


Enable the **`API product recommendations`** setting in the Developer Portal to display product recommendations to the API product consumers.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this topic

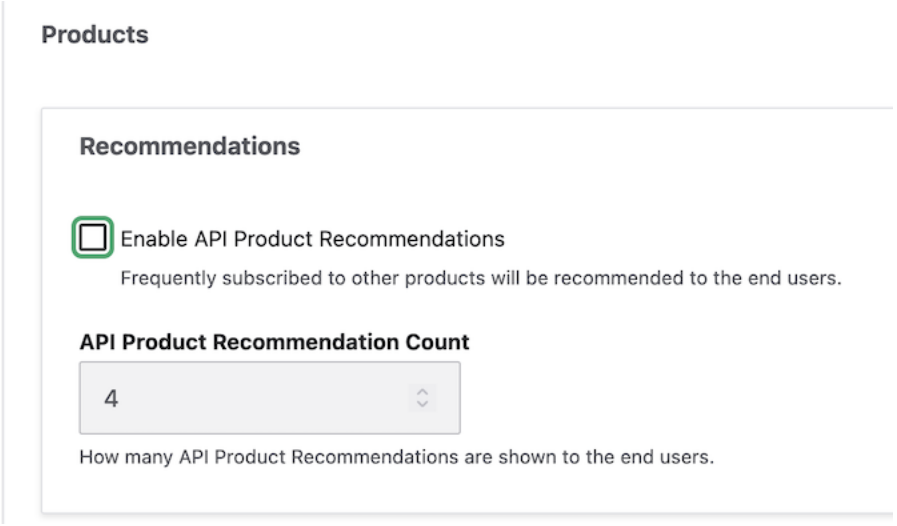


You can enable the **`API product recommendations`** setting in your Developer Portal site to display the **`API product recommendations`** block on the API Products page and the Summary tab for the Subscription wizard. This block suggests API products to the consumers based on their current subscription plan and browsing history.

Enable API product recommendations

Complete the following steps to enable the **`API product recommendations`** setting in the Developer Portal:

1. Log in to the Developer Portal as an administrator.
2. Click Configuration > System > IBM API Developer Portal.
3. In the **`Products`** section, select the Enable API Product Recommendations checkbox.



4. From the API product count recommendation count box, select a `value` based on the number of recommendations that you want to display to the user.
5. Click Save configuration to save the changes. The API Products page and the Summary tab of the subscription wizard on the Developer Portal displays the API product recommendations block.

Disable API product recommendations

Complete the following steps to disable the **`API product recommendations`** setting in the Developer Portal:

1. Repeat steps 1 and 2.
2. In the **`Products`** section, clear the Enable API Product Recommendations checkbox.

3. Click Save configuration to save the changes. The API product recommendations block is removed from the API Products page and the Summary tab of the subscription wizard on the Developer Portal.

Note:

- The **`API product recommendations`** setting is enabled by default in the Developer Portal.
- The API product recommendations block is displayed on the API Products page and the Summary tab for the Subscription wizard of the Developer Portal only if you satisfy the following conditions:
  - The API product must have at least one subscription.
  - The application that is subscribed to the API product must be subscribed to at least one another API product.

You successfully configured the API product recommendations settings in the Developer Portal.

Adding a case study

The Community managers and API product owners can use the case study module in the Developer Portal to promote and highlight their published API products.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The case study module offers valuable context and practical examples to highlight how the APIs published in their Developer Portal addresses real-world business challenges. The module also highlights the success stories of the users who have integrated these API products into their application.

Create a case study

Complete the following steps to create a new case study:

1. On the Admin dashboard, click Create > Case study.
2. On the Create case study page, provide the following details:
   a. In the **`Title`** field, provide a `title` for the case study.
   b. From the Language list, select an option. By default, English is selected.
   c. Click Browse to browse and select an image for the new case study and provide an alternative text for the image.
   d. In the Summary field, enter a `description` for the case study. This information is displayed on the case study tile.
   e. In the Body field, enter the main **`html`** body for the case study. This information is displayed on the case study page.
   f. Under Associated API products, start typing the name of your API product in the text box and you can choose from the options that are displayed.
   g. To associate more API products with the case study, click Add another item and repeat step (f).
3. Click Save.
   The new case study tile is displayed on the Developer Portal home page under **`Case studies`**. The tile displays the following details:
   - Case study tile
   - Case study summary
   - Case study image

   To configure the case study module in the Developer Portal, see Configure the case study module.
   Note: The case study module is enabled by default in the Developer Portal.
   To change the front page of the case studies content block, see Changing the case studies content block on the front page.

What you did in this task

You created a case study and the Developer Portal home page now displays the case studies content block. Click the case study tile to view the case study page that displays all the associated API products. Click a product tile to view the corresponding product details page. The following actions are available on both the case study and API product pages:

- View
- Edit
- Delete
- Revisions
- Translate

- **Configure the case study module**
  Use the case study module in the Developer Portal to promote and highlight published API products.

Configure the case study module

Use the case study module in the Developer Portal to promote and highlight published API products.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can enable or disable the case study module in the Developer Portal. You can create a new case study only if the module is enabled. For more information, see Adding a case study.
Note: The case study module is enabled by default in the Developer Portal.
Complete the following steps to enable the case study module in the Developer Portal:

1. On the Admin dashboard, click Extend > Extend.
2. In the **Filter** field, enter `case study`. The case study module is displayed under IBM API Developer Portal.
3. Select the Case study checkbox and click Enable.

Complete the following steps to disable the case study module in the Developer Portal:

1. On the Admin dashboard, click Extend > Extend > Disable module.
2. In the **Filter** field, enter `case study`. The case study module is displayed.
3. Select the Case study checkbox and click Disable.
4. The Confirm disable page displays the list of configurations that will be deleted if the module is disabled. Click Disable to confirm the action.
   Warning: When a **Case study** module is disabled, all the case study content associated with the module is permanently deleted and cannot be restored

What you did in this task

You configured the case study module in the Developer Portal.

Configuring Stripe in the Developer Portal

You can offer free use of your Product Plans to your API consumers, or you can offer Products with paid Plans. To enable API consumers to subscribe to Products with paid Plans, you must first configure the Stripe payment method in your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes for more information about this requirement.

The billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on Kubernetes for more information.

Billing integration support must be configured in the API Manager. For more information, see Monetizing your Products.

About this task

API Connect includes a subscription billing feature that allows API providers to define pricing Plans in their API Products, and monetize their API offerings. If a Product contains a pricing Plan, API consumers must enter their payment information into the Developer Portal before they can subscribe to that Plan.

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Support is provided for Stripe in the Developer Portal, but before API consumers can enter their payment information, you need to configure the Stripe billing support in every Developer Portal where you will offer paid Plans. After this support is configured, API consumers can provide their payment information, and then subscribe to the paid Plans. Complete the following instructions to enable the APIC Monetization Stripe Integration module, and then configure your Stripe API credentials.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected checkbox. The disabled modules are displayed without a selected checkbox.
3. Enter `stripe` into the search filter.
   The **`ibm_stripe_payment_method`** module called APIC Monetization Stripe Integration is displayed in the list of contents.
4. Select APIC Monetization Stripe Integration and click Enable.
   The default settings for the **`ibm_stripe_payment_method`** module are now enabled.
5. In the administrator dashboard, click Configuration > System > IBM API Developer Portal Billing.
   The IBM API Developer Portal Billing Settings page is displayed.
6. Change the drop-down option to be the newly enabled APIC Monetization Stripe Integration (ibm_stripe_payment_method) as the module to use to create payment methods for the Stripe billing provider. Click Save configuration.
7. In the administrator dashboard, click Configuration > System > IBM APIC Stripe Integration, and enter your Stripe API credentials. These credentials must match the Stripe API credentials for the billing integration resource that is attached to the Catalog for this Developer Portal.
   Refer to your Stripe dashboard to get your publishable key and secret key; see https://dashboard.stripe.com/apikeys.
   Note: Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.
8. Click Save integration.

Results

You successfully configured the Stripe payment method in the Developer Portal. API consumers can now add a payment method to their consumer organization, so that they can subscribe to Products with paid Plans.

What to do next

After both the Catalog and the Developer Portal are configured, you can create Products with pricing Plans. See Defining a Product with billing integration for more information.

- Monetizing your Products
- Considerations when changing a Product lifecycle with billing

Configuring cron to run scheduled tasks

You can configure cron to run scheduled tasks in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To configure cron to run scheduled tasks, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the SYSTEM heading, click Cron.
3. Use the drop-down list for the module you want to configure and select Edit.
4. From the Run cron every drop-down menu, select the frequency of cron runs for this module.
5. Click Save.
   You have configured cron to run scheduled tasks.

Configuring search indexes and servers

You can configure search indexes and servers in the Developer Portal by using the Search API module.

Before you begin

You must have administrator access to the Developer Portal to complete this task.

Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The Search API module provides a generic framework for search capabilities within the Developer Portal, and you can customize the default database server and content index setup that is provided. By default, the search in the Developer Portal runs over the entire OpenAPI and WSDL documentation. It is not possible to restrict the search to specific sections of an Open API or WSDL document. The search can be configured to include any custom fields that were added to the Developer Portal, but it does not include any attached files.
The search results page is a view in the Developer Portal, and so it can also be configured. For more information, see Configuring the search results view in the Developer Portal.

Procedure

To configure the default database server and content index settings, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > Search and metadata > Search API in the administrator dashboard.
4. To configure the server settings, click Edit against the Database Server and make the required changes. For example:
   - Server name; the displayed name for the server.
   - Description; a description of the server.
   - CONFIGURE DATABASE BACKEND; the minimum number of characters a word must consist of to be indexed, and whether to search on parts of a word. However, wildcard searching can make searches on large sites very slow.
   - AUTOCOMPLETE SETTINGS; how suggestions are computed when autocompletion is used.
5. To configure the index settings, click Edit against the Default content index and make the required changes. For example:
   - Index name; the displayed name for the index.
   - Data sources; the data sources of the items to be stored in the index.
   - CONFIGURE THE DATASOURCE; for each data source, set which bundles of content should be indexed, and in which languages.
   - Server; the server that the index should use.
   - Description; a description for the index.
   - INDEX OPTIONS; whether the index is read only, whether to index new or updated items immediately, and setting how many items to index when indexing items during a cron run.
6. When your changes are complete, click Save.
   The View page of the updated default database server or default content index is displayed.

Results

You successfully configured the search indexes and servers in the Developer Portal.

What to do next

You can configure how searches are displayed by editing the Search content view. For more information, see Configuring the search results view in the Developer Portal.

- Search API module

Configuring the date and time

You can configure the date and time in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To configure the date and time, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. Under the Region and language heading, click Date and time formats.
4. Click Edit for the format you want to change.
5. Change the settings of the format then click Save format.
   You have configured the date and time.

Configuring the notifications event log settings

You can configure the settings of the notifications event log for the activity feed on your Developer Portal.

About this task

The Developer Portal includes an activity feed that shows Consumer organization users the details of events that occur on the organization, such as application creation, subscriptions, and so on. You can view these details under Notifications for each application and organization.

The default number of days that events are kept for is 30. You can edit this setting in the IBM APIC Notifications Settings page of your Developer Portal, as described in the following instructions.

Procedure

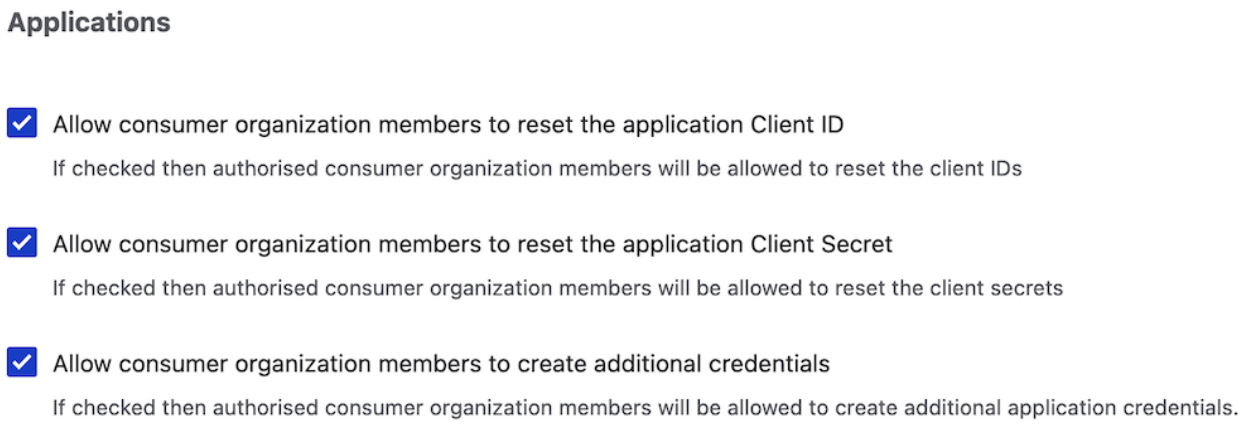
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > System > IBM APIC Notifications Settings.
   The IBM APIC Activity Feed Settings page is displayed.
4. Enter the required number of days to keep events for in the Retention Days field.
5. Click Save configuration.

Configuring the application settings

You can configure the application settings in the Developer Portal to limit or allow credential access to the consumer organization members.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.



About this task

You can configure the application settings in the Developer Portal to limit or allow the following credential access to the consumer organization members:

- Reset the application client ID.
- Reset the application client secret.
- Add more credentials.

Procedure

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > System > IBM API Connect in the administrator dashboard.
4. Scroll down to **`Applications`**. By default, all the configuration options are selected.

   The consumer organization members can see the following credential options on the respective Applications page under the Subscriptions tab:
   - Add
   - Edit
   - Reset Credentials
   - Reset API Secret

   For more information, see Managing applications.
5. Clear one or more checkboxes based on the options you want to remove from the application credentials.
   Note: If you clear all the checkboxes, the consumer organization members can only see the Edit option on the Applications page under the Subscriptions tab.
6. Click Save configuration to save the changes.

Results

You successfully configured the application credential settings on your Developer Portal.

Configuring the site default time zone

You can configure the site default time zone in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To configure which languages are available, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the REGIONAL AND LANGUAGE heading, click Regional settings.
3. From the Default Time Zone drop-down menu, select the default time zone.
4. Click Save configuration.
   The default time zone is configured.

Configuring the site error handling

You can configure the site error handling in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To configure the site error handling, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the DEVELOPMENT heading, click Logging and errors.
3. You can review and configure all information relating to site error handling from this view.
   Note: On a production system, set Logging and errors to `none` to avoid any security issues.
4. Click Save configuration.
   The site error handling is configured.

Configuring which buttons are displayed in the WYSIWYG rich text editor

You can configure which buttons are displayed in the WYSIWYG rich text editor in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To configure which buttons are displayed in the WYSIWYG rich text editor, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration > Content authoring > Text formats and editors.
3. Click Configure for the Full HTML profile.
4. In the `TOOLBAR CONFIGURATION` section, edit the buttons that you want to expose.
5. Click Save configuration.
   You have configured the editor buttons that are displayed in the WYSIWYG rich text editor.

Configuring which languages are available

You can configure which languages are available in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To configure which languages are available, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the REGIONAL AND LANGUAGE heading, click Languages.
3. Under the DEFAULT heading, select the radio button for the language you want to set as default.
4. To add a new language, click +Add language. Use the drop-down menu to select the language you want to add.
5. Click Save configuration.
   You have configured the languages that are available.
6. You can also provide your own translations, for strings of the website that are not translated, from the User interface translation view, under Configuration > Regional and Language in the administrator dashboard.

Results

You have configured the available languages for the Developer Portal.
Note: Multilingual API and Product documentation can be created by using an **`x-ibm-languages`** extension directly in the OpenAPI definition. For more information, see Using **`x-ibm-languages`** to create multilingual API and Product documentation.

Customizing user account settings

You can customize the user account options that are displayed to users when they register and use the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can change what fields users of the Developer Portal see when they register to use the site, when they log in, and when they view their user account profile. For instance, you can change the field order display, hide fields, and add custom fields.
As an example, the Consumer organization field is a required entry field when a user creates an account on the Developer Portal. However, you can configure this field to be hidden, in which case the field is automatically completed with a default entry of **`firstname lastname`** of the new user instead.

Procedure

To customize the user account settings, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > People > Account settings in the administrator dashboard.
   The Account settings page is displayed.
4. From the Settings tab you can edit the following options:
   a. CONTACT SETTINGS; enable or disable the personal contact form for new users.
   b. PASSWORD RESET TIMEOUT; set the timeout in seconds for one-time login links. This setting applies only to the admin user of the Developer Portal.
   c. ANONYMOUS USERS; set the name to be used to indicate anonymous users.
   d. ADIMINISTRATOR ROLE; assign the administrator role that is automatically given new permissions whenever a new module is enabled. The default is Superuser.
      Note: The Superuser role has the highest level of permissions in the Developer Portal. This role bypasses all content access control, which means that users that have a Superuser role can see all of the site content. For more information, see Working with roles in the Developer Portal.
   e. LANGUAGE SETTINGS; enable or disable translation.
   f. REGISTRATION AND CANCELLATION; enable or disable the password strength indicator, and set the action to take when a user account is canceled.
   g. Notification email address; set the email address to use as the from address for all account notifications.
   h. Emails; edit the emails that are sent when an account is blocked or canceled, or when a new password is requested.
   i. Click Save configuration to save your updates.
5. Click the Manage fields tab to customize the fields that are available for storing user data.
   Here you can edit the settings for current fields, delete fields, and add new fields. Remember to save any updates that you make.
6. Click the Manage form display tab to configure how the user forms are displayed.
   a. Click the Default form mode to configure how the form fields display when a user profile is being edited.

b. Click the Register form mode to configure how the form fields display when a new user creates an account.
For each user form mode you can edit the field settings, enable and disable fields, and drag the fields to change their display order. You can also manage the form modes.
For example, to hide the Consumer organization field when a new user creates an account, click the Register form mode, and drag the Consumer organization into the Disabled section.

c. Click Save to save your updates.

7. Click the Manage display tab to configure how fields are displayed on a user profile page.
You can edit the field settings, enable and disable fields, and drag the fields to change their display order. You can also manage the display view modes. Remember to save any updates that you make.
8. Click the Translate account settings tab to configure the language options for the user account settings. Remember to save any updates that you make.

Results

You successfully customized the user account settings in the Developer Portal.

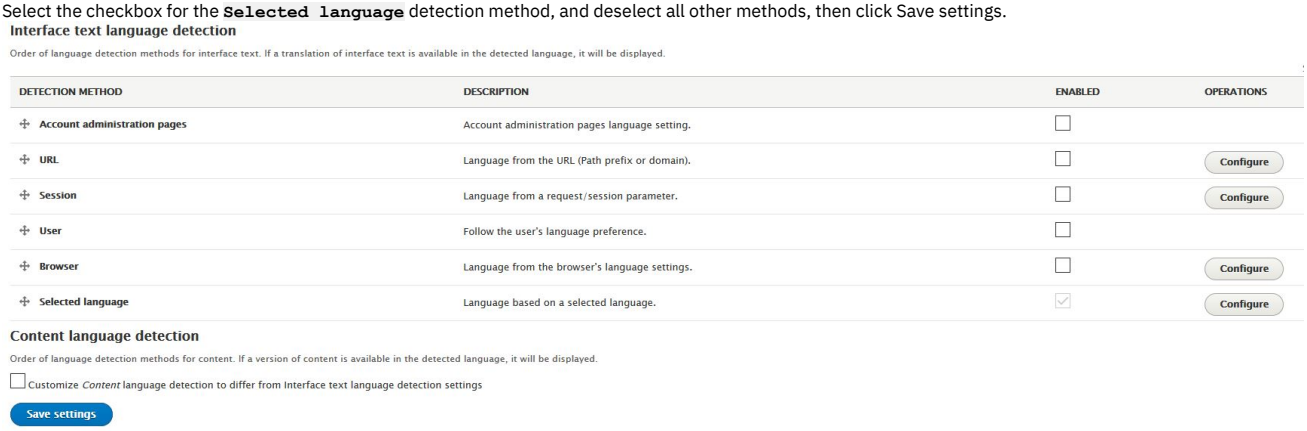
Disabling languages

You can extend your Developer Portal site by managing which languages are available for use on the site.

Before you begin



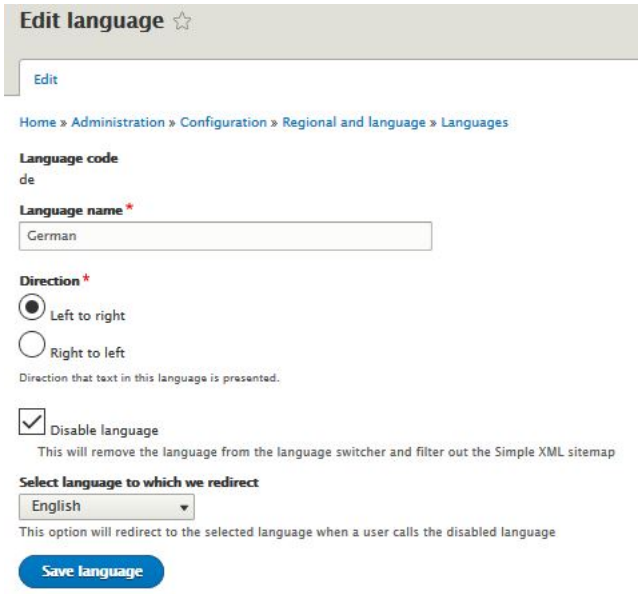
You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.

To disable all languages apart from English.

2. Navigate to Configuration > Regional and language > Languages > Detection and selection.
3. Select the checkbox for the **`Selected language`** detection method, and deselect all other methods, then click Save settings.



To disable one or more languages.

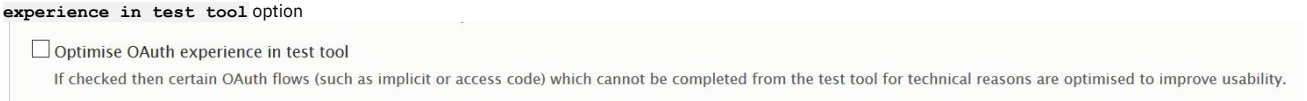
4. In the administrator dashboard, click Extend.
The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected checkbox. The disabled modules are displayed without a selected checkbox.
5. Enter `disable language` into the search filter.
The Disable Language content item is displayed in the list of content.
6. Select the checkbox for the **`Disable Language`** module, and click Enable.
7. Navigate to Configuration > Regional and language > Languages > Detection and selection.
8. Select the checkbox to enable URL, and click Save settings.

9. Navigate to Configuration > Regional and language > Languages.
10. Click Edit on the language that you want to disable.
11. Select the checkbox to **`Disable language`**, then click Save language.

Results

You successfully disabled your chosen language.

Disabling test tool restrictions



The default OAuth provider contains security mechanisms that prevent the ability to obtain authorization tokens in the Developer Portal test tool when you use Implicit or Authorization Code grant types. If your OAuth provider allows those actions to function correctly from the test tool, you can disable this option.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Configuration > System > IBM API Connect.
3. In the **`CONFIGURATION`** section, deselect the **`Optimise OAuth experience in test tool`** option

4. Click Save configuration.

Results

You successfully disabled the **`Optimise OAuth experience in test tool`** option. You can now use the Developer Portal test tool to test an Implicit or Authorization Code grant type in an OAuth provider API, if your OAuth provider allows those actions to function correctly from the test tool.

What to do next

You can enable the **`Optimise OAuth experience in test tool`** option by repeating the task but selecting the option and then clicking Save configuration.

Enabling a cookie compliance banner

You can add a cookie compliance banner to your Developer Portal site by configuring the EU Cookie Compliance module.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The EU Cookie Compliance module provides a customizable pop-up notification that informs visitors to your site that cookies are being used. The notification enables your site visitors to find out more about cookies, and to decide not to browse the site if they disagree with using cookies. You can also provide a link from your cookie compliance banner to an internal or external privacy policy. For more information about configuring an internal privacy policy, see Customizing the privacy policy statement.
The EU Cookie Compliance module is enabled by default. The following instructions show you how to configure the notification.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > System > EU Cookie Compliance.
   The Settings tab of the EU Cookie Compliance page is displayed.
4. In the SETTINGS section select Enable banner, otherwise the notification does not display.
5. In the PRIVACY POLICY section, edit the Privacy policy link field to provide a link to your privacy policy or other page that explains cookies to your site visitors. The default link is `/privacy`, which links to the Privacy Policy content that is configured within the Developer Portal. For more information, see Customizing the privacy policy statement.
   External links should start with `http://` or `https://`. For example:

   ```
   https://example.com/privacy
   ```

6. Configure the remaining options as required. For example, you can change the wording, and edit the display size and color.
7. Click Save configuration to save your updates.

Results

You successfully enabled a cookie compliance banner on your Developer Portal site. New visitors to your site are now prompted to accept cookies.

Enabling code languages for code snippets

You can specify the languages that code snippets for APIs can be displayed in.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. On the administrator dashboard, click Configuration > System > IBM API Connect.
2. In the API Code Snippets section, select the check boxes for the languages that you want to make available for the code snippets to be displayed in.
3. Click Save configuration.
   The languages that you have enabled are displayed as options for your code snippets.

Enabling code snippets for SOAP APIs

By default, code snippets are only shown for REST APIs. You can enable code snippets for SOAP APIs.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Code snippets for SOAP APIs use raw HTTP, and do not use any SOAP libraries.

Procedure

1. On the administrator dashboard, click Configuration > System > IBM API Connect.
2. In the API Code Snippets section, select the Display code snippets for SOAP APIs as well as REST APIs check box.

3. Click Save configuration.
   The languages that you have enabled are displayed as options for your code snippets.

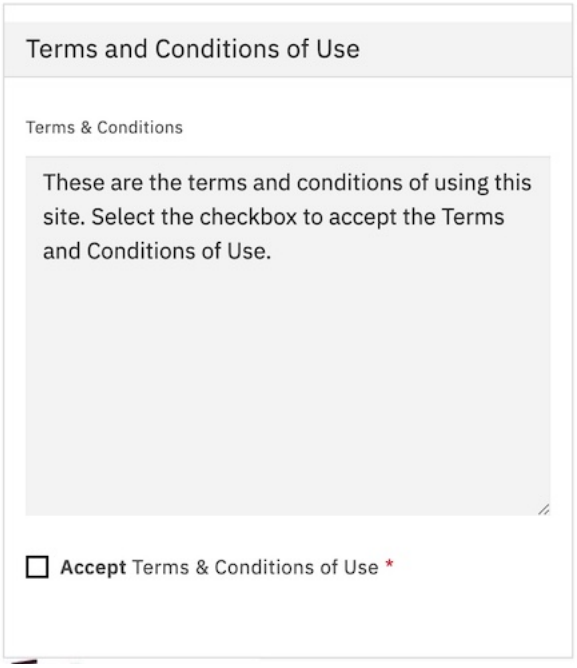
Forcing new users to accept terms and conditions

You can extend your Developer Portal site by forcing new users to accept the terms and conditions before they are able to create accounts.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Note: From IBM® API Connect Version 10.0.4.0, the **Legal** module is included in the list of core Developer Portal modules. The **Terms of use** module is still available in the Developer Portal, but the **Legal** module provides more configuration options.

About this task



Use the following instructions to enable and configure the **Legal** module for your site terms and conditions.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected check box. The disabled modules are displayed without a selected check box.
3. Enter `legal` into the search filter.
   The Legal content item is displayed in the list of content.
4. Select the check box for the **Legal** module, and click Enable.
5. Navigate to Configuration > People > Legal.
6. Enter your Terms & Conditions statement, and select the Text format that you require.
7. Click Save configuration.

Results

You successfully enabled the **Legal** module. Now, when a user tries to create an account on your Developer Portal site, they must agree to the terms and conditions as a part of the registration.

What to do next

You can edit the terms and conditions page by navigating to Configuration > People > Legal, and making the changes that you require. You can disable the use of terms and conditions during site registration by deleting the terms and conditions content, and then disabling the **Legal** module.

If you prefer to use the **Terms of use** module, you can enable the module, and then navigate to Configuration > People > Terms of use, and select the page that contains your site terms and conditions, for example **Terms of use (1)**. For information about how to customize the statement, see Customizing the terms of use statement.

The terms are displayed when you create an account and also from the link in the site footer. You can disable the use of terms and conditions during site registration by disabling the module.

Hiding the admin registry on the login form

You can hide the admin registry as an option on the login form. The use case for this option might be a public facing Developer Portal where you want to remove the admin access from customer view.

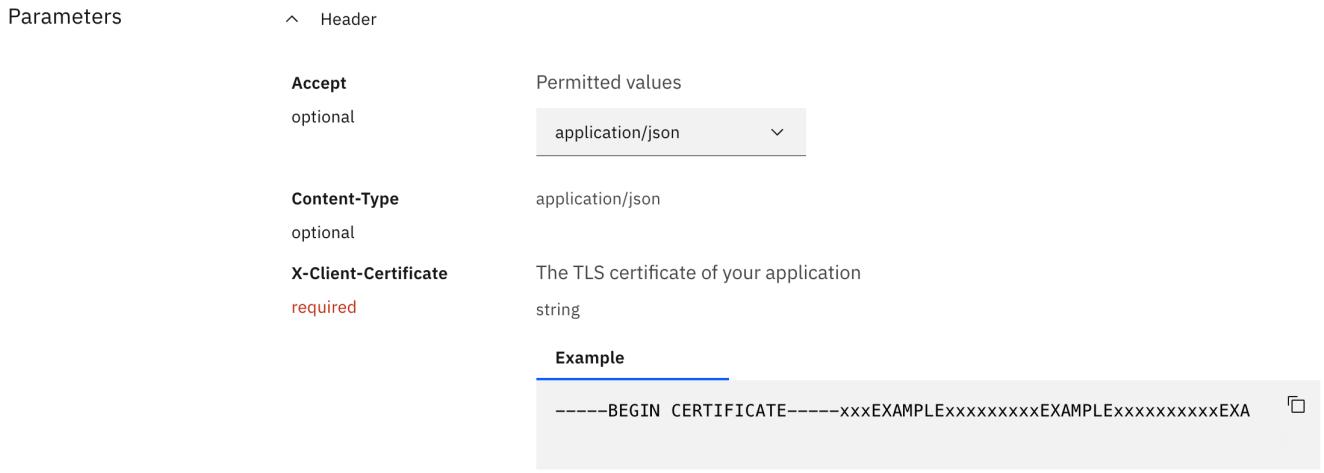
Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration > System > IBM API Developer Portal.
3. In the Configuration section, select the check box for **`Hide the admin registry on the login form`**.
4. Click Save configuration.
   The **`Hide the admin registry on the login form`** configuration is saved.

What to do next



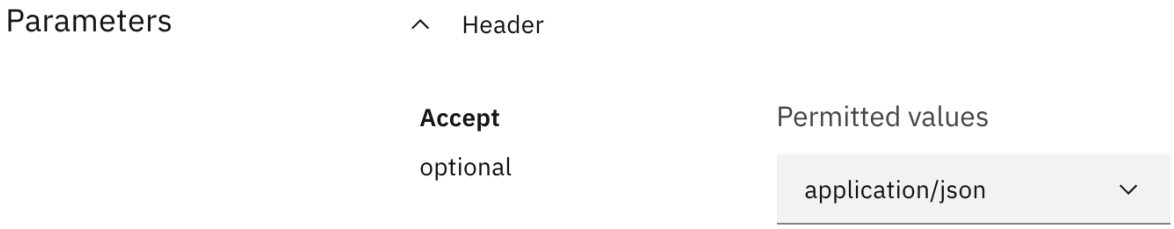
The admin registry is no longer shown on the login form. However, it is still accessible directly. The user can navigate to **`<site_url>/user/login?registry_url=/admin`**.

Hiding the certificate in the header for APIs secured with mutual TLS

You can hide the certificate in the header for APIs secured with mutual TLS. By default, the **`x-client-certificate`** header is shown in an API when mutual TLS is configured. You can choose to turn off this option in your Developer Portal.

Before you begin

The parameters for the example API showing the certificate.



You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

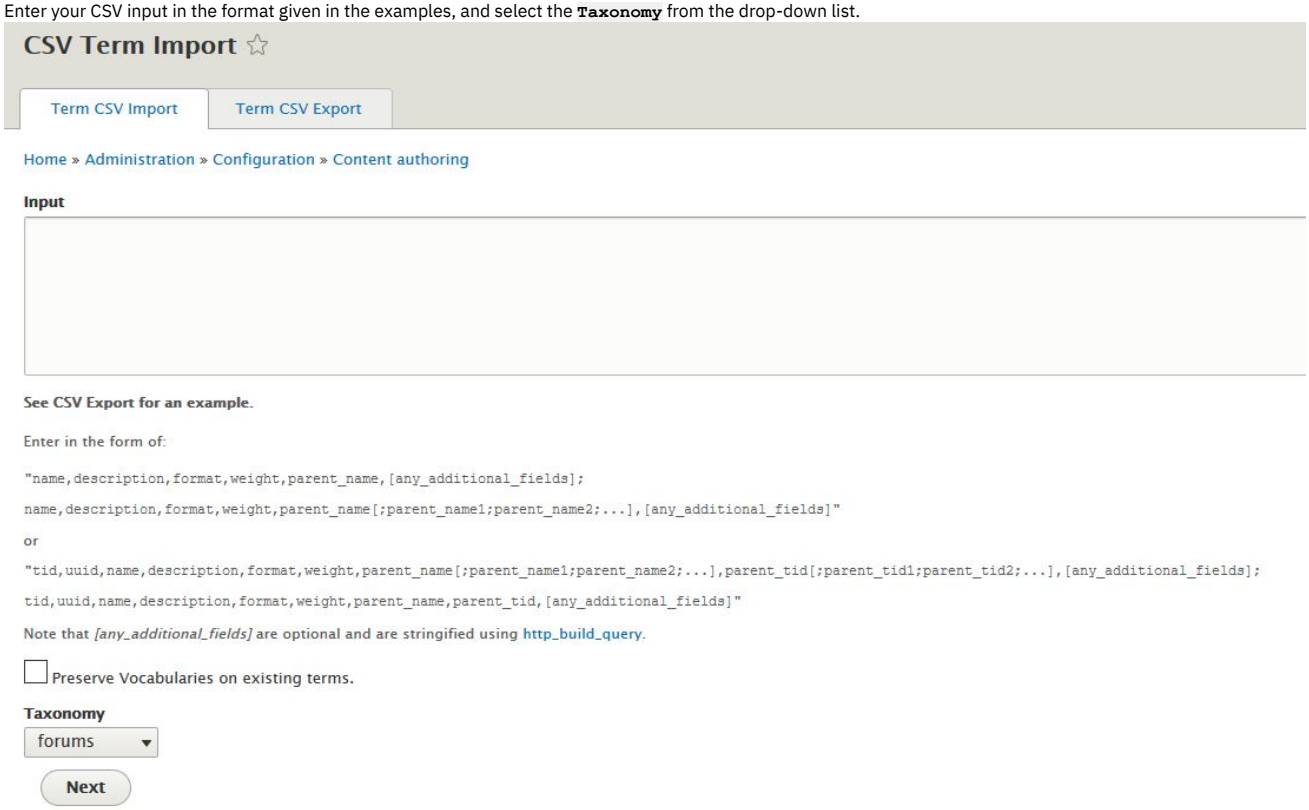
1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration > System > IBM API Developer Portal.

3. In the Configuration section, deselect the checkbox for **`Show certificate in header for APIs secured with mutual TLS.`**
4. Click Save configuration.
   The **`Show certificate in header for APIs secured with mutual TLS.`** configuration is saved.
   The parameters for the example API now not showing the certificate:

Importing and exporting taxonomies

You can import and export taxonomies in the Developer Portal.

Before you begin



You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Configuration > Content authoring > Term CSV Export/Import.
4. Select Term CSV Import, or Term CSV Export.

For Term CSV Import

5. Enter your CSV input in the format given in the examples, and select the **`Taxonomy`** from the drop-down list.

6. Click Next.
7. Click Import.

For Term CSV Export

8. Select the **Taxonomy** from the drop-down list, and check any other options that you want.

9. Click Export.

Results

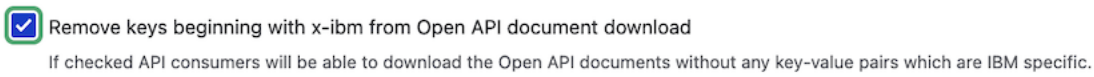
You successfully imported or exported a taxonomy.

Removing keys beginning with x-ibm from Open API document download

You can remove keys that begin with x-ibm from the Open API document download in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.



About this task

By removing keys that begin with x-ibm from the Open API document download, you can download the Open API documents without any key-value pairs that are IBM specific. Enabling this configuration setting removes the information about the API Management provider from the Open API document that is downloaded in the Developer Portal. The **file**, **filename**, and **url** keys are also automatically removed from the downloaded YAML file if the OpenAPI document includes the **x-ibm-schema** element with the type set to **graphQL**.
Warning: Removing keys that begins with x-ibm from the Open API document download also removes certain details from the downloaded API document. For example, the x-ibm-languages key that provides language support to the API will be removed from the downloaded API document after you enable this configuration.

Procedure

To remove keys that begin with x-ibm from the Open API document download in the Developer Portal, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > System > IBM API Developer Portal.
   The Configure the IBM API Developer Portal page is displayed.
4. Select the **Remove keys beginning with x-ibm from Open API document download** option.

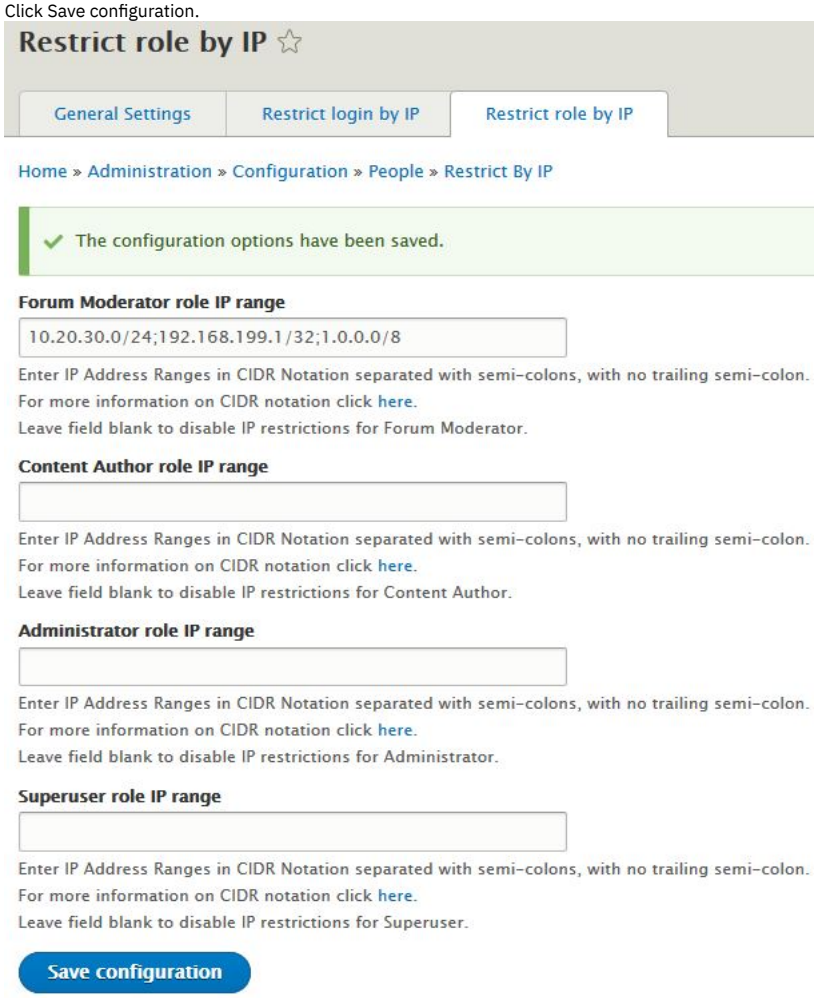
5. Click Save configuration to save the changes.
   The keys beginning with x-ibm is removed from the JSON or YAML download of the Open API definition.

Restricting access by IP address

You can restrict access to a role or a user by IP address in the Developer Portal.

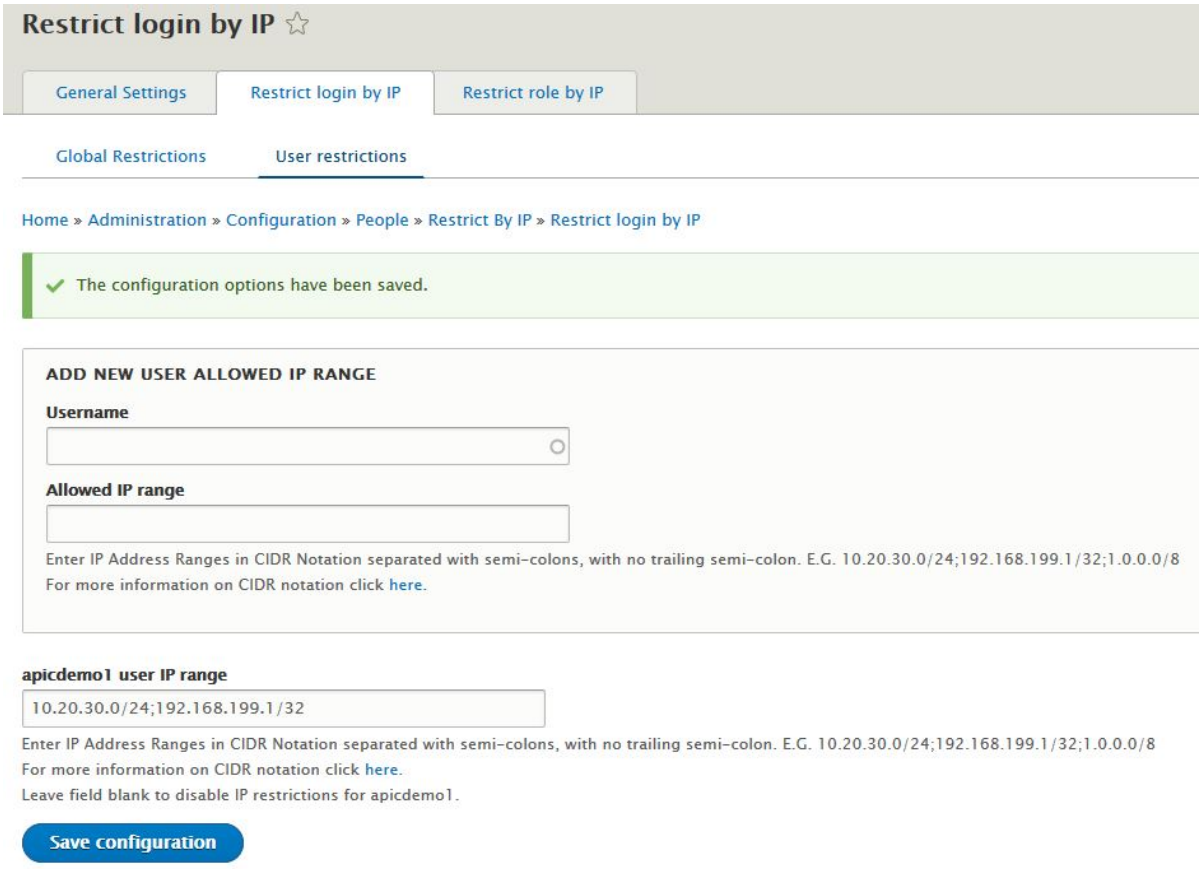
Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.



About this task

By restricting access to a role by IP address, that role is unavailable to users outside of the IP address ranges that you define. If a role restriction is triggered, the user's session is unaffected, but the restricted role is no longer available to the user. Role restriction affects only the availability of the restricted role to users. Role restrictions are available for all roles, except `anonymous user` and `authenticated user`.



By restricting login access of a user by IP address, the user is unable to log in outside of the IP address ranges that you define. You can also specify global IP address ranges, which apply to all users. IP restrictions are checked on every page load. If a user restriction is triggered by an attempt at logging in being denied, then the user is logged out and sent to the 'error page' that is specified by the site administrator.
Note: IP address ranges must be entered in CIDR notation that is separated with semi-colons and no trailing semi-colon. For more information on CIDR notation, see CIDR format.

Procedure

1. In the Developer Portal, click Configuration > People > Restrict by IP, then click **`Restrict log in by IP`**.
2. On the **`Global restrictions`** tab, enter the address of the page to which the user is redirected to if they are not allowed to log in, in the Login denied error page.
3. Select one of the following options:
   - To restrict access to a role by IP address, complete the following steps:
     - Click Restrict role by IP.
     - Decide which role you want to restrict, the roles that you can restrict include Administrator, Content Author, and Forum Moderator.
     - Enter the IP address range (in CIDR notation) that you do not want to restrict log in for in the field for that role, for example, Forum Moderator role IP range.
     - Click Save configuration.

   - To restrict login access of a user by IP address, complete the following steps:
     - Click Restrict login by IP, then click **`User restrictions`**.
     - In the **`ADD NEW USER ALLOWED IP RANGE`** section, enter a user name in the **`Username`** field.
     - Enter an IP address Range (in CIDR notation), that you do not want to restrict log in for in the **`Allowed IP range`** field.
     - Click Save configuration. Your new log in restriction can be seen after the **`ADD NEW USER ALLOWED IP RANGE`** section.

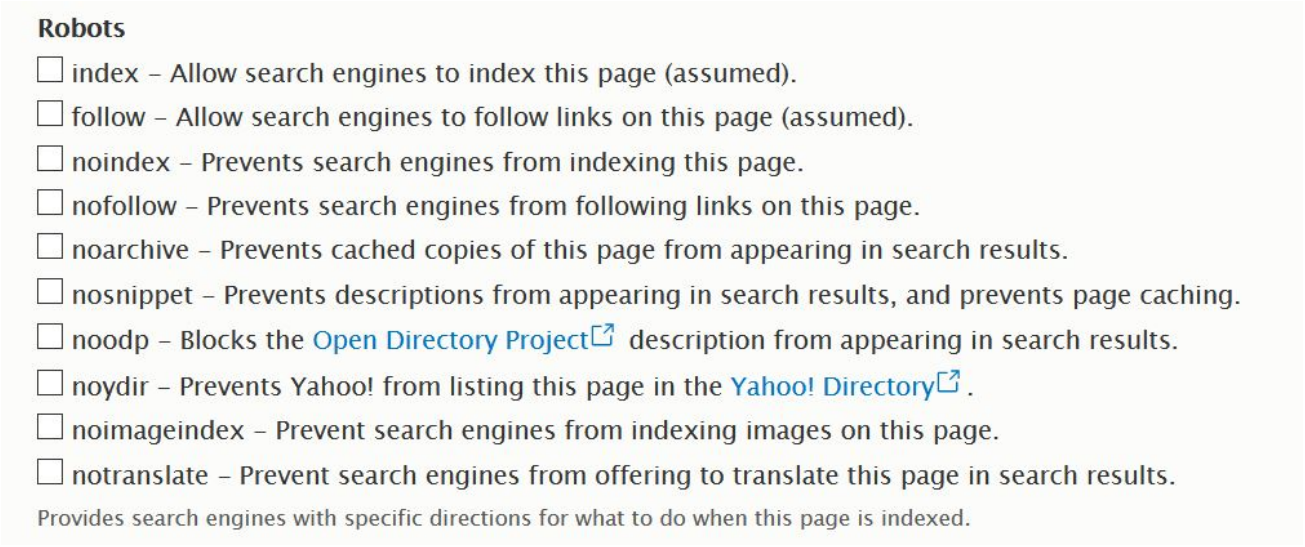
- To restrict login for all users, complete the following steps:
  - Click Restrict login by IP, then click **`Global restrictions tab`**.
  - Enter the global IP address ranges (in CIDR notation) in the Restrict global login to allowed IP range field.
  - Click Save configuration.

4. To remove an IP restriction, delete the value that is associated with the restriction, then click Save configuration.

Restricting or preventing access from search engines

You can restrict or prevent access to your Developer Portal from search engines. You might want to control the access if you have a development or test site.

Before you begin



You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You might have a development or test Developer Portal site on the internet, but do not want them to be indexed by Google, or other search engines, making them visible to your customers. Google explicitly advises not to use **`robots.txt`** as a blocking mechanism. A correct solution is to control access by using Metatag.

Procedure

1. In the Developer Portal, click Configuration > Search and metadata > Metatag.
2. On the **`Global restrictions`** tab, click Edit.
3. In the Advanced section, select the meta tags that you want to use to restrict or prevent the access:

4. Click Save.

Toggling the site in and out of maintenance mode

You can put the Developer Portal site into maintenance mode for short periods of time. During maintenance mode, only an administrator is able to access the site, and all other users who enter the site URL get a maintenance message set by the administrator.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Important:

- Maintenance mode is designed for short-term site maintenance; it is not meant for long-term usage. While a site is in maintenance mode, the database is not updated with new content from API Manager. As soon as the maintenance tasks are finished, you must take the site out of maintenance mode.
- Do not log out of the Developer Portal while the site is in maintenance mode, as you will not be able to log back in to the UI. In this case, maintenance mode can be turned off only by using the toolkit CLI; see the following instructions for details.

Procedure

To put the site into maintenance mode, complete the following steps.

1. Click Configuration in the administrator dashboard.
2. Under the DEVELOPMENT heading, click Maintenance mode.
3. Select the Put site into maintenance mode checkbox.
4. Enter a site message, or leave the default site maintenance text.
   This message is what will be seen by users who visit the site while it is in maintenance mode.
5. Click Save configuration.
   Your site is now in maintenance mode.

To take the site out of maintenance mode, complete one of the following steps.

6. If you remained logged in to the site as the admin user during the maintenance period, you can use the Developer Portal UI to disable maintenance mode:
   a. Click Configuration in the administrator dashboard.
   b. Under the DEVELOPMENT heading, click Maintenance mode.
   c. Clear the Put site into maintenance mode checkbox .
      Your site is now available to users, and out of maintenance mode.
7. If you're no longer logged in to the site, you can use the toolkit CLI to disable maintenance mode:
   a. Log in to the toolkit CLI as a Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
```

```
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

b. Run the following command to disable maintenance mode on your Developer Portal:

```
apic --mode portaladmin drupal-state:set --server management_server --org orgid/name --catalog catalogid/name --
state_key system.maintenance_mode  --input_format integer --state_value 0
```

Where:

- ***management_server*** is the endpoint URL of your management server (required).
- ***catalogid/name*** is the ID or name of the catalog that your site belongs to (required).
- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
- **--state_key** is the name of the state key (required). Must be set to **system.maintenance_mode**.
- **--input_format** is the input format of the value of the state key. Must be set to **integer** for configuring the maintenance mode.
- **--state_value** is the value to assign to the state key (required). Set to **0** to disable maintenance mode.

For example, to disable maintenance mode for a Developer Portal in the **myOrg** organization, and in the **dev** catalog:

```
apic --mode portaladmin drupal-state:set --server my.management.server.com --org myOrg --catalog dev --state_key
system.maintenance_mode  --input_format integer --state_value 0
Successfully set state system.maintenance_mode to the value of 0.
```

Your site is now available to users, and out of maintenance mode.

What to do next

You can use the toolkit CLI to enable, and disable, maintenance mode. For more information, see the scenario How to enable and disable maintenance mode on your Developer Portal.

Viewing available updates

You can view available updates in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To view available updates, complete the following steps:

1. Click Reports in the administrator dashboard.
2. Click Available updates.
3. You can see what updates are available from this view. However, updates can be applied only by applying the latest available API Connect release; see Upgrading in a Kubernetes environment, for more information.

Managing Developer Portal security

You can manage multiple security elements in the Developer Portal.

- **Configuring CAPTCHA**
  You can add a CAPTCHA challenge to any of your Developer Portal pages to protect your site from spam.
- **Configuring reCAPTCHA**
  You can configure reCAPTCHA on your Developer Portal site to provide more protection from spam and abuse.
- **Configuring session timeout and limit**
  You can specify session timeout settings to control when a user is automatically logged out of the Developer Portal. You can also restrict the number of sessions a single user has available to them.
- **Configuring the timeout length for the password reset link**
  You can configure the timeout length for the one-time password reset link that is sent from the Developer Portal to the admin user account.

- **Configuring your site password policy**
  You can configure your site password policy to define the constraints that are applied to the passwords of your Developer Portal users.
- **Disabling CORS warnings**
  You can disable cross-origin resource sharing (CORS) warnings for unenforced APIs in the Developer Portal.
- **Disabling live testing of APIs**
  You can disable live testing of APIs in the Developer Portal to restrict exposure of an API.
- **How to enable penetration testing, and information about Developer Portal cookies**
  Many security features are available in the Developer Portal, but if you need to do a penetration test of your Developer Portal site, some of these features might block the scan that is required as part of the testing. This topic provides guidance on the security features that you might need to disable to allow penetration testing of your site, as well as information about Developer Portal cookies.
- **How to manage IP security in the Developer Portal**
  The Developer Portal offers the ability to perform various IP address security measures, such as adding and removing specific IP addresses from the banned IP address list, automatically banning client IP addresses by using the Drupal Perimeter Defence module, or managing login security by using flood control.
- **Managing banned IP addresses**
  You can ban specific IP addresses from accessing your Developer Portal site.
- **Using flood control for login security**
  You can configure login security for your Developer Portal by using flood control.
- **Login security**
  You can configure the login security for your Developer Portal at an IP and user level. You can also configure login security for Developer Portal contact forms.
- **Using the Security kit**
  You can improve the security of your website by configuring various options that are available in the Security Kit module, in the Developer Portal.
- **Using Honeypot for spam protection**
  Honeypot protection provides security mechanisms to protect your Developer Portal site from form submission by spam bots. If spam bot activity is detected, form submission is blocked.

Configuring CAPTCHA

You can add a CAPTCHA challenge to any of your Developer Portal pages to protect your site from spam.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The types of CAPTCHA challenges that are available include Image and Math based CAPTCHAs. Both types of CAPTCHA challenges are configurable in the CAPTCHA dialog box. By default, your Developer Portal site is configured with the Image based CAPTCHA challenge enabled.
You can also configure reCAPTCHA on your site. For more information, see Configuring reCAPTCHA.

Procedure

To configure CAPTCHAS, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click CAPTCHA module settings.
   The CAPTCHA settings window opens.
4. Use the CAPTCHA configuration options provided as required. For example, you can complete the following tasks:
   a. Specify the CAPTCHA challenge type.
   b. Specify which forms must include a CAPTCHA challenge.
   c. Add a description to the CAPTCHA.
   d. Enable CAPTCHA statistics.
5. Click Save configuration to save your changes.

Configuring reCAPTCHA

You can configure reCAPTCHA on your Developer Portal site to provide more protection from spam and abuse.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

reCAPTCHA is a CAPTCHA-like system that is designed to establish that a computer user is human. The types of reCAPTCHA that are available include Checkbox, Invisible, and Android.
Note: To use reCAPTCHA the administrator of your Developer Portal is required to sign up to Google's reCAPTCHA API, and your portal server must have internet access.

Procedure

To configure reCAPTCHA, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration > People > CAPTCHA module settings > reCAPTCHA in the administrator dashboard.
   The reCAPTCHA settings window opens.
3. In the GENERAL SETTINGS section, click register for reCAPTCHA.
   The Google registration site for reCAPTCHA is displayed.
4. Follow the instructions on Google to register your Developer Portal site, and obtain the Site key and Secret key.
5. Return to the reCAPTCHA settings window in the Developer Portal, and enter the Site key and Secret key that you obtained from Google into the GENERAL SETTINGS section.
6. Optional: Update the WIDGET SETTINGS section as required.
7. Click Save configuration to save your changes.
8. Click the CAPTCHA Settings tab, and in the FORM PROTECTION section change the Default challenge type to reCAPTCHA (from module reCAPTCHA).
9. Click Save configuration.

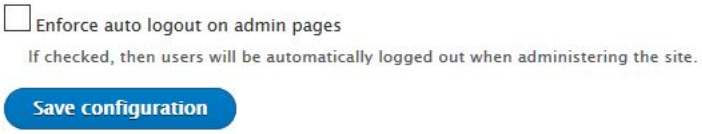
Results

The reCAPTCHA module is now enabled on your Developer Portal site.

Related tasks

- Configuring CAPTCHA

Configuring session timeout and limit



You can specify session timeout settings to control when a user is automatically logged out of the Developer Portal. You can also restrict the number of sessions a single user has available to them.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. To manage the automated logout settings, complete the following steps:
   a. Click Configuration in the administrator dashboard.
   b. In the PEOPLE section, click Automated logout settings.
      Note: You must check **`Enforce auto logout on admin pages`** for **`autologout`** to apply when navigating the admin areas of the site.

   c. Use the session timeout configuration options provided as required. For example, you can complete the following tasks:
      - Specify the length of inactivity time, in seconds, before a user is automatically logged out.
      - Specify session timeout values for individual user roles.
        Note: The default session timeout is 30 minutes.
      - Provide a redirection URL at logout.
      - Provide session expiry message texts.

   d. Click Save configuration to save your changes.
3. To restrict the number of sessions available to a user, complete the following steps:
   a. Click Configuration in the administrator dashboard.
   b. In the PEOPLE section, click Session limit.
   c. Specify the default maximum number of sessions for a user by entering the number into the Default maximum number of active sessions field.
   d. Select the required action from the When the session limit is exceeded options.
   e. From the Logged out message severity list, select the severity of the message that the user receives when they are logged out.
   f. Optionally, in the ROLE LIMITS section, specify separate session limits for each role.
   g. Click Save configuration to save your changes.

Configuring the timeout length for the password reset link

You can configure the timeout length for the one-time password reset link that is sent from the Developer Portal to the admin user account.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

By completing the steps in this task, you are configuring the timeout length for the one-time password reset link that is sent to the admin user account by the Developer Portal.
Note:

- Setting the password reset timeout length in the Developer Portal affects only the admin user account.
- You are not affecting the user activation or password reset links that are used by any other identification provider type in API Manager.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click Account settings.
   The Account settings window opens.
4. In the Account settings window, navigate to the PASSWORD RESET TIMEOUT section.
5. Enter your required value for the timeout in the Password Reset Timeout field.
   Note: The timeout value is specified in seconds, and is 86400 seconds by default.
6. Click Save configuration.
   You have configured the timeout length for the one-time link that is sent from the Developer Portal for the admin user account.

Configuring your site password policy

You can configure your site password policy to define the constraints that are applied to the passwords of your Developer Portal users.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Any passwords that are stored in the API Manager must comply with the API Manager password policy. You can configure your password policy to be the same as or stricter than the API Manager password policy.

Procedure

To configure your site password policy, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SECURITY section, click Password Policy.
   The Password Policies page opens.
4. In the OPERATIONS column for the default password policy, click Edit.
   Note: You can create a new password policy by clicking Add Policy and apply different password policy settings to different roles. If you need only a single password policy, configure the pre-supplied default policy.
5. Click Next.
   The Configure Constraints page opens.
6. Configure the password constraints as required.
   a. To configure a constraint, click Edit in the OPERATIONS column for the required constraint.
   b. To delete a constraint, select Delete in the OPERATIONS column.
   c. To add a constraint, select the required constraint type from the drop-down list, then click Configure Constraint Settings.
   d. When you are done, click Next.
      The Apply to Roles page opens.
7. Select the roles to which the password policy settings are to be applied and then click Finish.

Disabling CORS warnings

You can disable cross-origin resource sharing (CORS) warnings for unenforced APIs in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

By disabling the CORS warnings, users will not receive further warnings regarding the usage of unenforced APIs.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SYSTEM section, click IBM API Connect.
4. Ensure that the Display CORS warnings for unenforced APIs check box is cleared.
5. Click Save Configuration.
   You have disabled CORS warnings in the Developer Portal. To enable CORS warnings, repeat the steps and ensure that the Display CORS warnings for unenforced APIs check box is selected.

Disabling live testing of APIs

You can disable live testing of APIs in the Developer Portal to restrict exposure of an API.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SYSTEM section, click IBM API Connect.
4. Ensure that the Allow live testing of APIs check box is cleared.
5. Click Save configuration.
   You have disabled live testing of APIs. To enable live testing of APIs, repeat the steps and ensure that the Allow live testing of APIs check box is selected.

How to enable penetration testing, and information about Developer Portal cookies

Many security features are available in the Developer Portal, but if you need to do a penetration test of your Developer Portal site, some of these features might block the scan that is required as part of the testing. This topic provides guidance on the security features that you might need to disable to allow penetration testing of your site, as well as information about Developer Portal cookies.

Penetration testing, or pen testing, is the practice of testing a computer system, network, or web application for potential security vulnerabilities that an attacker might exploit. For certain elements of your pen testing, you might want to disable some of the security features that block scanning of the Developer Portal. The following sections describe the security features in the Developer Portal that you might need to disable. The actual requirements depend on your Developer Portal configuration, and on the type of pen testing that you are running. Note also the final section, which discusses testing for Distributed Denial of Service attacks.
Important:

- If you run a pen test, and you give the automated test tool the admin credentials, the tool submits all of the administration configuration forms as well, and this action is likely to break the Portal site configuration. Best practice is to use different credentials for the testing.
- If you disable security modules, and then run security scans, your Portal site configuration might be broken by the scanning process. Before running any security testing, ensure that you have a valid backup of your Portal site.
- If your Portal site configuration is broken by the security testing, then you must delete the Portal site from the API Manager Catalog settings and re-create it, or restore it from a backup.
  For information about restoring your site, see the appropriate topic for your environment:
  - Restoring the Developer Portal on Kubernetes and OpenShift
- Note that disabling of security modules makes it highly likely that you will find issues that are not actually vulnerabilities, because you have disabled the modules that are designed to protect against these vulnerabilities. Therefore, any issue that is found in these circumstances must be replicated in an environment without the security modules disabled, before contacting IBM Support.
- Do not use the **`Enforced`** mode of the **`Content Security Policy`**, this mode is not supported and can break core Developer Portal functionality such as API rendering and the content editor. The **`Content Security Policy`** must be in **`Report only`** mode.

Note: You might need to disable the **`Honeypot`** module to allow your penetration test to run. For more information, see Using Honeypot for spam protection.
This topic contains the following sections:

- CAPTCHA and reCAPTCHA verifications
- Drupal Perimeter Defense module
- Login Security module
- Developer Portal cookies
- Should I test the Developer Portal for vulnerability to Distributed Denial of Service attacks?

CAPTCHA and reCAPTCHA verifications

CAPTCHA and reCAPTCHA verifications are a type of challenge-response test that are used in web applications to check whether the user is human. By default, your Developer Portal site is configured with an Image based CAPTURE challenge enabled, but you can also configure a Math based CAPTCHA challenge, and Checkbox, Invisible, and Android reCAPTCHA challenges. If you need to disable these verifications before pen testing, see the following instructions.

To disable the CAPTCHA and reCAPTCHA verifications, you must disable the modules as follows:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Extend > Disable module.
4. Search through the list of modules, and select the check boxes next to the Image CAPTCHA and reCAPTCHA modules.
5. Click Disable, and click Disable again to confirm.
6. On the Disable tab, select the check box next to the CAPTCHA module, and click Disable. The display shows the forms that the CAPTCHA configuration is removed from.
7. Click Disable again to confirm. Note that the modules must be disabled in this order.

The CAPTCHA and reCAPTCHA modules are now disabled, and you can complete your pen testing. After pen testing, you can enable the modules again by clicking Extend on the administrator dashboard, selecting the check box for each module in the List tab, and clicking Enable.

Drupal Perimeter Defense module

The Drupal Perimeter Defense module (machine name: perimeter) immediately bans the IP addresses of those users that send suspicious requests to your site, so any pen testing scans would be blocked. This module is enabled by default on the Developer Portal. For more information about the module, see the Drupal documentation Drupal Perimeter Defense module.

If you need to disable the Drupal Perimeter Defense module before pen testing, see the following instructions:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Extend > Disable module.
4. Search through the list of modules, and select the check box next to the Drupal Perimeter Defense module.
5. Click Disable, and click Disable again to confirm.

The Drupal Perimeter Defense module is now disabled, and you can complete your pen testing. After pen testing, you can enable the module again by clicking Extend on the administrator dashboard, selecting the check box next to the Drupal Perimeter Defense module in the List tab, and clicking Enable.

Login Security module

The Login Security module (machine name: login_security) enables the site administrator to improve the security options in the login operation of your Developer Portal site. For example, controlling the number of invalid login attempts before blocking users, and denying access by IP address. This module is enabled by default on the Developer Portal. For more information about the module, see the Drupal documentation Login Security module.

If you need to disable these security options before pen testing, you need to manually modify the configuration of your security options according to your requirements. For example, you might need to change the number of login attempts that are allowed before a user or IP address is blocked. To configure the security options, see the following instructions:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Configuration > People > Login Security.
4. In the Login Security window, update the security options according to your requirements.
5. Click Save configuration to save your updates.

The Login Security options are now updated, and you can complete your pen testing. After pen testing, you can reconfigure your security options in the Login Security window.

Developer Portal cookies

Cookies are small text files that are placed on a computer by websites when they are visited. The Developer Portal uses cookie that remain on the computer for varying times. Some cookies expire at the end of each session, and some remain longer to enhance the user experience in the future.
Note: The cookie generated by Bigpipe does not have the **`httponly`** flag set. Thus, JavaScript can delete the cookie whenever required.
The list here explains the cookies that are used by the Developer Portal, and why they are used.
Note: Any load balancer that sits in front of the Developer Portal must be a transparent proxy that enables all cookies returned by the Developer Portal to pass through to the browser.

Drupal session identifier cookie
: This is the main cookie that all of the Developer Portal sites have, and it stores the session identification. The session cookie is named in the format SSESS*UUID*, where *UUID* is a randomly generated unique string of characters for that session, and this is the session token itself. The session cookie is always marked with the following flags as instructions to the browser client:

  - **`Secure`** - means that the cookie is sent only over a secure connection (that is, over TLS).
  - **`HttpOnly`** - means that the browser adds this cookie on outbound requests only, and not provide the value to client side javascript.

session_store.id cookie
: This cookie is used to store information on where a user is in the subscription flow, and any options that they selected, if they haven't yet signed in, so the Developer Portal can redirect them back there later. The session_store.id cookie is also marked with the **`Secure`** and **`HttpOnly`** flags, and it does not contain any confidential information.

Drupal.visitor.startSubscriptionWizard cookie
: This cookie is used to store information on where a user started in the subscription flow if they haven't yet signed in, so the Developer Portal can redirect them back there later. The Drupal.visitor.startSubscriptionWizard cookie is also marked with the **`Secure`** and **`HttpOnly`** flags, and it does not contain any confidential information.

portal_web cookie

This cookie is used to achieve session persistence, which it does by ensuring that web traffic between the user and the Developer Portal is correctly routed to the server. The portal_web cookie is used for both HTTP and HTTPS communications, so that routing is meaningful irrespective of the transfer protocol, and ensuring consistent behavior if the switching of protocols is required. The cookie contains only a hash of the pod that served the traffic to maintain session persistence, and does not contain any confidential information. The cookie is provided by the Portal ingress. This cookie is not marked as **`Secure`** or **`HttpOnly`**, as the Kubernetes ingress does not yet support these attributes.

Other cookies

In addition to the cookies listed previously, there are other (usually temporary) cookies that might be created depending on the configuration options of your Developer Portal site. For example, if the site uses OAuth for authentication, then during the OAuth token activation flow a JSON Web Token is sent to the browser. This token is stored in a cookie for a limited lifetime. This action is part of the normal function of an OAuth flow. As the creation of these other cookies depends on your particular Developer Portal configuration, we cannot provide a complete list of cookies here.

Should I test the Developer Portal for vulnerability to Distributed Denial of Service attacks?

When you run penetration testing, it's important to understand that individual systems are not responsible for (nor capable of dealing with) Distributed Denial of Service (DDoS) attacks. DDoS attacks are launched by huge numbers of external computers simultaneously, with a goal of using up all of the resources of a system, and thereby denying service to legitimate users. These kinds of attacks are usually defended against at the level of the network and edge gateways, and information about how to protect against them is out of the scope of this topic. Although the Developer Portal does have some capabilities, including the modules mentioned previously, for potentially mitigating some of the effects of a DDoS attack, do not rely on these capabilities as the first line of defense; rather they are designed to assist in dealing only with any elements of an attack that might have gotten through the outer network layers of protection.

How to manage IP security in the Developer Portal

The Developer Portal offers the ability to perform various IP address security measures, such as adding and removing specific IP addresses from the banned IP address list, automatically banning client IP addresses by using the Drupal Perimeter Defence module, or managing login security by using flood control.

See the following links for information about how to manage IP security in the Developer Portal:

- Enable and disable IP security
- Correctly passing through client IP addresses
- Managing banned IP addresses

Enable and disable IP security

The ability to enable or disable IP security related actions can be controlled at the Portal service level by using the Developer Portal CLI command **`ip-security-enabled`**. When IP security is enabled, modules such as the Drupal Perimeter Defence module, or flood control, will block client IP addresses suspected of malicious behavior, as expected. When IP security is disabled, all IP related security is switched off. For example, the perimeter module won't block client IP addresses when IP security is disabled. You might want to turn off IP security if you are performing penetration tests, or if you cannot pass through the client IP address from your external load balancer. For more information, see Using the ip-security-enabled command.

Correctly passing through client IP addresses

In order to correctly use modules that make use of client IP banning, such as the Drupal Perimeter Defence module, you must ensure that any external load balancer that fronts the Portal cluster passes through the client IP address. This can be achieved by passing the client IP address through in an **`'x-forwarded-for'`** header, or by making use of the proxy protocol (provided both the load balancer and the ingress controller are compatible with the proxy protocol, and have the protocol enabled). Failure to correctly pass through the client IP address, results in the load balancer IP address being blocked when a client attempts to send a suspicious request to the portal.

If you are fronting the Portal cluster with an HAProxy setup acting as the load balancer, then you can make use of the proxy protocol by adding the **`send-proxy`** directive to the end of the Portal server declarations in the HAProxy configuration file, for example:

```
server portal0 portal_host:port check send-proxy
```

You must restart the HAProxy for the change to take effect. Note that if your load balancer IP address has already been blocked, you will need to remove the blocked IP address from the banned list by using the **`security`** command in theDeveloper Portal CLI, see Using the security command.

If you find your load balancers are being banned by Portal's IP Security modules, then you might need to configure your system's ingresses to send the **`'x-forwarded-for'`** headers. For instance, the default behavior of the **`nginx-ingress-controller`** is to ignore the inbound **`'x-forwarded-for'`** header and construct a new one. To configure the **`nginx-ingress-controller`** to pass through the inbound **`'x-forwarded-for'`** header you need to add the following to the **`nginx-ingress-controller`** config map:

```
data:
 compute-full-forwarded-for: "true"
 use-forwarded-headers: "true"
```

For more information about the Drupal Perimeter Defence module, see Drupal Perimeter Defense module.

Managing banned IP addresses

You can manage banned IP addresses for a particular site by using the administrator dashboard for a particular Developer Portal site. For more information, see Managing banned IP addresses.

Related concepts

- How to enable penetration testing, and information about Developer Portal cookies

Related tasks

- Disabling modules
- Login security
- Blocking and unblocking specific users
- Managing banned IP addresses

Managing banned IP addresses

You can ban specific IP addresses from accessing your Developer Portal site.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To manage banned IP addresses, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click IP address bans.
   The IP address bans window opens.
4. You can complete the following tasks:
   a. To ban an IP address, enter the address in the IP address field, then click Add.
      The address is added to the BANNED IP ADDRESSES list.
   b. To remove an IP address from the banned list, click Delete alongside the required address.

   Note:
   - There is automatic login "flood" protection built into the Developer Portal. This feature means that an excess of login attempts from the same IP address in one hour will cause that IP to be temporarily banned. For more information, see Using flood control for login security.
   - You can also clear banned user/IP addresses by using the Developer Portal CLI command **`security:clear-bans`**. For more information, see Using the security command.

Using flood control for login security

You can configure login security for your Developer Portal by using flood control.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Navigate to Configuration > System > Flood Control.
3. Enter values in the following fields in the LOGIN SETTINGS section according to your requirements:
   - Failed IP login limit (min 1) - the number of failed login attempts from the same client IP.
   - Failed IP login window in seconds (0 = Off) - the time window, in seconds, for the number of failed login attempts from the same client IP.
   - Failed User login limit (min 1) - the number of failed login attempts from a user.
   - Failed User login window in seconds (0 = Off) - the time window, in seconds, for the number of failed login attempts from a user.
4. Enter values in the following fields in the CONTACT FORM section according to your requirements:
   - Emails sent limit - the number of emails that can be sent.
   - Emails sent window in seconds - the time window, in seconds, for the number of emails that can be sent.
5. Click Save configuration.

What to do next

To unblock a user, see Blocking and unblocking specific users. To unblock an IP address, see Managing banned IP addresses.

Login security

You can configure the login security for your Developer Portal at an IP and user level. You can also configure login security for Developer Portal contact forms.

Before you begin

Important: The Login Security module is being removed from future releases. It has been replaced by Flood Control. Existing users of the Login security module should configure Flood Control with the same limits and time windows as specified here. For more information, see Using flood control for login security.
You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click Login Security.
4. Enter values in the following fields in the GENERAL SETTINGS section according to your requirements:
   - Track time - the time window to check for security violations.
   - User - the number of login failures before blocking a user.
   - Soft host - the number of login failures before soft blocking a host. The host can still browse the site as an anonymous user.
   - Host - the number of login failures before hard blocking a host. The host cannot access the site at all.
   - Attack detection - the number of login failures before warning about an ongoing attack.
5. Select the check boxes that satisfy your notification requirements in the NOTIFICATION section:
   - Disable login failure error message
   - Notify the user about the number of remaining login attempts
   - Display last login timestamp
   - Display last access timestamp
6. Optional: Edit the EMAIL FOR ONGOING ATTACK DETECTION section.
7. Optional: Edit the EMAIL FOR BLOCKED ACCOUNT section.
8. Optional: You can edit the notification texts that are displayed by configuring the following options:
   - Failed login attempt
   - Banned host (soft IP ban)
   - Banned host (hard IP ban)
   - Blocked user by uid
9. After you have configured your login security options, click Save configuration.

What to do next

To unblock a user, see Blocking and unblocking specific users. To unblock an IP address, see Managing banned IP addresses.

Using the Security kit

You can improve the security of your website by configuring various options that are available in the Security Kit module, in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

The Security Kit module provides your website with various options to mitigate risks of common web application vulnerabilities like Cross-site Scripting, Cross-site Request Forgery and Clickjacking. It also has some options to improve your SSL/TLS security.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SYSTEM section, click Security Kit settings.
4. In the Security Kit module, configure the security settings for your website as required.
5. When you are done, click Save configuration.

Using Honeypot for spam protection

Honeypot protection provides security mechanisms to protect your Developer Portal site from form submission by spam bots. If spam bot activity is detected, form submission is blocked.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Honeypot protection provides the following security mechanisms:

- A hidden field, unseen by users, is added to the form. If a value has been entered in the field when the form is submitted then this indicates that the form was completed by a spam bot, and the submission is blocked. You can specify the name of the hidden field.
- If the form is submitted before a specified time has elapsed (five seconds by default), it is assumed that this is too short a time for a human to have completed the form, and the submission is blocked. You can specify the time length.

Honeypot protection is provided by the Honeypot module, which is enabled by default.
Note: If you want to carry out automated testing of your Developer Portal, you might need to disable the Honeypot module, because Honeyspot spam protection is designed specifically to block automated Developer Portal usage. For details on how to disable a module, see Disabling modules.

Procedure

To configure Honeypot for spam protection in the Developer Portal, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the CONTENT AUTHORING section, click Honeypot configuration.
4. Specify the forms that you want to protect with Honeypot.
    a. To enable Honeypot protection for all the forms on your Developer Portal site, select Protect all forms with Honeypot.
    b. To choose which forms you want to protect with Honeypot, clear the Protect all forms with Honeypot check box, then select the required forms in the HONEYPOT ENABLED FORMS section.

   By default, Honeypot protection is enabled for all user management forms and all comment forms.
5. To have details of all blocked form submissions written to the log file, select Log blocked form submissions.
6. In the Honeypot element name field, specify the name of the hidden form field.
   The default field name is url. You need to change the value if your form already has a field of the same name. For the most effective protection, use a generic field name; for example, email, homepage, or link.
7. In the Honeypot time limit field, specify the number of seconds that must elapse before it is assumed that a form is being submitted by a human rather than a spam bot. If the form is submitted before this time has elapsed then the submission is blocked.
   The default value is five seconds.
8. When done, click Save configuration.

People

You can manage and customize the user experience in the Developer Portal, by altering permissions and assigning roles to specific users.

To learn how to configure the user experience for your Developer Portal site, use the following section links.

- **Blocking and unblocking specific users**
  You can block and unblock specific users in the Developer Portal.
- **Controlling access to Developer Portal content**
  In IBM® API Connect, you can restrict access to content for Consumer organizations through an access content list. However, you can also assign permissions in the Developer Portal that override the access content list, and allow users to access and edit all of the content for Products, APIs, and Applications.
- **Creating a developer account to customize API properties**
  You can allow specific users in the Developer Portal to customize the properties for certain APIs, including APIs that are not viewable by the administrator, or other customizable features, by creating an internal Consumer organization.
- **Email Subscribers**
  As a site administrator, you can use the email subscribers wizard to send messages to your Developer Portal community.
- **How to style the Developer Portal emails**
  You can apply a theme to the HTML emails that are sent by the Developer Portal by using CSS and templating.
- **Working with roles in the Developer Portal**
  As a site administrator, you can create and customize site configuration roles in the Developer Portal.

Blocking and unblocking specific users

You can block and unblock specific users in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To block or unblock a specific user, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
   A list of users is displayed.
3. Select the check box next to the target user.
4. From the drop-down list under Action, select Block the selected user(s) or Unblock the selected user(s).
5. Click Apply to selected items.
   You have blocked or unblocked specific users from the Developer Portal.
   Note: If a user reports that they are unable to login, but they do not appear as blocked, then it might be that they have been blocked by Flood Control. To unblock such users, select Configuration > System > Flood unblock. You can configure your Flood Control settings; see Using flood control for login security for more information.

Related tasks

- Using flood control for login security

Controlling access to Developer Portal content

In IBM® API Connect, you can restrict access to content for Consumer organizations through an access content list. However, you can also assign permissions in the Developer Portal that override the access content list, and allow users to access and edit all of the content for Products, APIs, and Applications.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

A user with a Content Author role is a curator of content for the Developer Portal. A Content Author user can perform the following actions:

- Set taxonomies on the content
- Provide custom icons for content
- Upload additional documentation files
- Create documentation pages in the Developer Portal.

By default, Content Author users are assigned the following user permissions:

Edit any Product content
: The user can access and edit all of the Products available in the Catalog that the Developer Portal is associated with. The user can also access APIs that belong to those Products.

Edit any API content
: The user can access and edit all of the APIs that are available in the Catalog, but not the Products with which they are associated. (Note that this permission is a subset of Edit any Product content; as Content Author users are assigned both permissions they can access and edit all of the Products and the associated APIs that are available.)

The Edit any Application permission grants the user access to all of the Applications that are in the Developer Portal, but is not assigned to any user or role by default.
Note: There are security implications if you grant the Edit any Application permission, and it should be assigned only to trusted roles.
A user can configure, attach, and upload content if they are assigned the appropriate permissions.

Procedure

To check and assign permissions that grant users access to all content, proceed with one of the following options:

- Assign a user to the Content Author role. For more information, see Assigning users to a role.
- Create a custom role, to which you can add the relevant permissions and add users to your new custom role. For more information, see Creating a new role, Assigning permissions to a role, and Assigning users to a role.

Creating a developer account to customize API properties

You can allow specific users in the Developer Portal to customize the properties for certain APIs, including APIs that are not viewable by the administrator, or other customizable features, by creating an internal Consumer organization.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

Every user in the Developer Portal must be a member of a Consumer organization. To enable additional users to be editors of particular content in the Developer Portal, you can create an internal Consumer organization. You can then invite these additional editors to this organization, and assign them a specific role that grants certain editing permissions. For example, the following API properties can be customized by any member of the new Consumer organization that have been assigned the Administrator or Content Author role:

- Image uploading
- Tag assignment
- File attachment
- Custom field editing

Procedure

To create a new Consumer organization within the Developer Portal, complete the following steps:

1. Log in to the Developer Portal as an administrator or Content Author.
2. Click the arrow next to `your_organization_name` from the Developer Portal home page, and select Create organization.
3. In the Organization Title field, type the name of the organization that you want, then click Submit.

To invite the editor users to your new organization, complete the following steps:

4. Switch to your newly created organization by clicking the arrow next to `your_current_organization_name`, and select your new organization name from the list.
5. Click the arrow next to `your_new_organization_name` and select My organization.
   Your new organization page is displayed.
6. For each new user, click Invite, complete their Email details, and click Submit. Note that you can leave the default role of Developer selected and then change the role later, or you can select the Administrator role now. However, be aware that an administrator is able to perform any task within the Developer Portal that does not involve the creation of APIs, Products, and Apps. You should be careful to ensure that only trusted users are given this access and level of control of your site. Each new user will receive an invitation email, and they need to click on the link in the email to activate their Developer Portal account.

To assign the required permissions to the users of your organization, you must log in as an administrator and complete the following steps:

7. Log in to the Developer Portal as an administrator.
8. If the administrator dashboard is not displayed, click Manage to display it.
9. Click People on the administrator dashboard.
10. Select the check box for the user, or users, to whom you want to give new permissions.
11. Under the Action heading, select the relevant role from the drop-down list.
    For example, selecting Add the Content Author role to the selected user(s) means they can edit images and content within the Developer Portal.
12. Click Apply to selected items to update the roles.

What to do next

If you want specific Products or APIs to be customized by the editor users, you must ensure that the relevant Products are visible to the internal Consumer organization that you have created. For more information on how to make a plan visible in API Manager, see Changing the availability of a Product.
Note that you can also create new roles and assign specific permissions to those roles. For more information, see Creating a new role and Assigning permissions to a role.

Email Subscribers

As a site administrator, you can use the email subscribers wizard to send messages to your Developer Portal community.

You can email all the subscribers of a specific API, plan, product, or all registered consumer organizations. For each consumer organization, you can select whether to email just the owner or all of the members. Each recipient receives an individual email.

You can use the wizard to specify context-specific tokens in the email subject and body. The tokens available and their replacement values depend on which flow is selected, for example, API, plan, product, or all.

- **Emailing all subscribers**
  As a site administrator, you can use the email **`All users`** wizard to email all the subscribers or a specified list of users of all the consumer organizations on your Developer Portal.
- **Emailing API subscribers**
  As a site administrator, you can use the email **`API subscribers`** wizard to send messages to all subscribers of all product plans that contain a one or more APIs on your Developer Portal.
- **Emailing plan subscribers**
  As a site administrator, you can use the email **`Plan subscribers`** wizard to send messages to all subscribers of a chosen plan that belongs to a specific product on your Developer Portal.

- **Emailing product subscribers**
  As a site administrator, you can use the email **Product subscribers** wizard to send messages to all subscribers of any plan for a one or more products in your Developer Portal.
- **Emailing consumer organizations**
  As a site administrator, you can use the email **Consumer organizations** wizard to email all or a specified list of users of a chosen Consumer organization on your Developer Portal.
- **Token reference**
  You can use the email subscribers wizard to specify context-specific tokens in the email subject and body. The tokens available and their replacement values depend on which flow is selected, for example, API, plan, product, or all.

Emailing all subscribers

As a site administrator, you can use the email **All users** wizard to email all the subscribers or a specified list of users of all the consumer organizations on your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can use the **All users** wizard to send messages to all consumer organizations. You can select whether to email just the owner, or all of the members of the consumer organizations. Each recipient receives an individual email.

Procedure

1. Navigate to People > Email subscribers.
2. Select **All users**, and click Save.
3. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
4. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text
5. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
6. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **Priority**: Set the priority of the email. Many email programs ignore a priority setting.
   - **Request receipt**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **Additional headers**: Set any additional headers to be sent with the email.
7. Use the remaining check boxes to configure what messages are to be sent and how:
   - **Send the message directly by using the Batch API**: This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
   - **Only send one email per user**: Select this option to ensure that each user receives the email only once even if the user is a part of multiple selected APIs, products, plans, or consumer organizations.
   - **Send a copy of all messages to the sender**: As the emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
   - **Send a copy of the original message to the sender**: This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
8. Click Next.
9. Confirm that the email is ready to send, then click Next. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a summary page that shows the total number of emails that were sent. If you chose to spool the delivery of the emails, you are redirected to the Summary page that shows the total number of emails that are spooled.
10. Click Finish.

Results

You successfully sent an email to all members, or all of the owners of each consumer organization on your Developer Portal.

Emailing API subscribers

As a site administrator, you can use the email **API subscribers** wizard to send messages to all subscribers of all product plans that contain a one or more APIs on your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can use the email **`API subscribers`** wizard to send messages to all subscribers of all product plans that contain a specific API in your Developer Portal community. For each consumer org, you can select whether to email just the owner or all members. Each recipient receives an individual email.

Procedure

1. Navigate to People > Email subscribers.
2. Select **`API subscribers`**, and click Save.
3. In the text box, enter the name of the API whose subscribers you want to email. If you start typing in the text box, you can choose from the options that you are given. Click Next.
   Note: You can select more than one API as a comma-separated list.
4. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
5. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text
6. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
7. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
8. Use the remaining check boxes to configure what messages are to be sent and how:
   - **`Send the message directly by using the Batch API`**: This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
   - **`Only send one email per user`**: Select this option to ensure that each user receives the email only once even if the user is a part of multiple selected APIs.
   - **`Send a copy of all messages to the sender`**: As the emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
   - **`Send a copy of the original message to the sender`**: This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
9. Click Next.
10. Confirm that the email is ready to send, then click Next. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a Summary page that shows the total number of emails that were sent. If you chose to spool the delivery of the emails, you are redirected to the Summary page that shows the total number of emails that are spooled.
11. In the Summary page, enter a name in the text box to save the email list.
    Note: To delete the saved email list,
    a. Go to Configuration > System > Email subscriber settings and click Delete against the email list name.
    b. Click Delete again to confirm the action.
    c. Click Save configuration.
12. Click Finish.

Results

You successfully sent an email to all members or all owners of each consumer org that contained a subscription to all product plans that contain the chosen API on your Developer Portal.

Emailing plan subscribers

As a site administrator, you can use the email **`Plan subscribers`** wizard to send messages to all subscribers of a chosen plan that belongs to a specific product on your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can use the email **`Plan subscribers`** wizard to send messages to all subscribers of a chosen plan that belongs to a specific product on your Developer Portal community. For each consumer org, you can select whether to email just the owner or all members. Each recipient receives an individual email.

Procedure

1. Navigate to People > Email subscribers.
2. Select **`Plan subscribers`**, and click Save.
3. In the text box, enter the name of the product whose subscribers you want to email. If you start typing in the text box, you can choose from the options that you are given. Click Next.
   Note: You can select more than one product as a comma-separated list.
4. Select the name of the plan whose subscribers you want to email. Click Next.
5. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
6. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text
7. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
8. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
9. Use the remaining check boxes to configure what messages are to be sent and how:
   - **`Send the message directly by using the Batch API`**: This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
   - **`Only send one email per user`**: Select this option to ensure that each user receives the email only once even if the user is a part of multiple selected plans.
   - **`Send a copy of all messages to the sender`**: As the emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
   - **`Send a copy of the original message to the sender`**: This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
10. Click Next.
11. Confirm that the email is ready to send, then click Next. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a Summary page that shows the total number of emails that were sent. If you chose to spool the delivery of the emails, you are redirected to the Summary page that shows the total number of emails that are spooled.
12. In the Summary page, enter a name in the text box to save the email list.
    Note: To delete the saved email list,
    a. Go to Configuration > System > Email subscriber settings and click Delete against the email list name.
    b. Click Delete again to confirm the action.
    c. Click Save configuration.
13. Click Finish.

Results

You successfully sent an email to all members or all owners of each consumer org that contained a subscription to the chosen plan within the chosen product, on your Developer Portal.

Emailing product subscribers

As a site administrator, you can use the email **`Product subscribers`** wizard to send messages to all subscribers of any plan for a one or more products in your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can use the email **`Product subscribers`** wizard to send messages to all subscribers of any plan for a specific product in your Developer Portal community. For each consumer org, you can select whether to email just the owner or all members. Each recipient receives an individual email.

Procedure

1. Navigate to People > Email subscribers.
2. Select **`Products`**, and click Save.
3. In the text box, enter the name of the product whose subscribers you want to email. If you start typing in the text box, you can choose from the options that you are given. Click Next.
   Note: You can select more than one product as a comma-separated list.
4. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
5. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text

6. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
7. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
8. Use the remaining check boxes to configure what messages are to be sent and how:
   - **`Send the message directly by using the Batch API`**: This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
   - **`Only send one email per user`**: Select this option to ensure that each user receives the email only once even if the user is a part of multiple selected products.
   - **`Send a copy of all messages to the sender`**: As the emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
   - **`Send a copy of the original message to the sender`**: This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
9. Click Next.
10. Confirm that the email is ready to send, then click Next. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a Summary page that shows the total number of emails that were sent. If you chose to spool the delivery of the emails, you are redirected to the Summary page that shows the total number of emails that are spooled.
11. In the Summary page, enter a name in the text box to save the email list.
    Note: To delete the saved email list,
    a. Go to Configuration > System > Email subscriber settings and click Delete against the email list name.
    b. Click Delete again to confirm the action.
    c. Click Save configuration.
12. Click Finish.

Results

You successfully sent an email to all members or all owners of each consumer org that contained a subscription to any plan within the chosen product on your Developer Portal.

Emailing consumer organizations

As a site administrator, you can use the email **`Consumer organizations`** wizard to email all or a specified list of users of a chosen Consumer organization on your Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

You can use the **`Consumer organizations`** wizard to send messages to all the owners or members of the chosen consumer organizations. You can select whether to email just the owner, or all members of the consumer organizations. Each recipient receives an individual email.

Procedure

1. Navigate to People > Email subscribers.
2. Select **`Consumer organizations`**, and click Save.
3. In the text box, enter the name of the consumer organization. If you start typing in the text box, the list of available options are displayed. Select the required option and click Next.
   Note: You can select more than one consumer organization as a comma-separated list.
4. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
5. Enter the content of the email by providing necessary details in the Subject and Body fields.
6. Select one of the Text Format options:
   - **`Basic HTML`**
   - **`Plain text`**
7. Expand Replacements, and click Browse available tokens to view the tokens that you can add to the subject and body fields for replacement.
   You can select a token by either typing the token name directly, or by clicking in the subject or body field. You are then select the required option from the given a list of available tokens. For a reference list of tokens, see Token reference.
8. Expand Additional email options to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
9. Select one of the following checkboxes to configure what and how the messages must be sent:

- **`Send the message directly by using the Batch API`**: This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
- **`Only send one email per user`**: Select this option to ensure that each user receives the email only once even if the user is a part of multiple selected consumer organizations.
- **`Send a copy of all messages to the copy recepient`**: As the emails might contain context specific tokens, new email content is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the copy recipient configured in the Developer Portal settings.
- **`Send a copy of the original message to the copy recipient`**: This option sends a single copy of the email to the copy recipient without the replacement of any tokens that might have been selected.

10. Click Next.
11. Confirm that the email is ready to send, then click Next. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a Summary page that shows the total number of emails that were sent. If you chose to spool the delivery of the emails, you are redirected to the Summary page that shows the total number of emails that are spooled.
12. In the Summary page, enter a name in the text box to save the email list.
    Note: To delete the saved email list,
    a. Go to Configuration > System > Email subscriber settings and click Delete against the email list name.
    b. Click Delete again to confirm the action.
    c. Click Save configuration.
13. Click Finish.

Results

You successfully sent an email to all members, or all of the owners of the consumer organizations on your Developer Portal.

Token reference

You can use the email subscribers wizard to specify context-specific tokens in the email subject and body. The tokens available and their replacement values depend on which flow is selected, for example, API, plan, product, or all.

Application Tokens

Tokens that are related to an individual Application.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Description	`[application:description]`	The description that is given to the application.	✓	✓	✓	
Enabled	`[application:enabled]`	The state that the application is in.	✓	✓	✓	
ID	`[application:id]`	The ID of the application.	✓	✓	✓	
Image URL	`[application:image_url]`	The URL of the image for the application.	✓	✓	✓	
Lifecycle State	`[application:lifecycle_state]`	The lifecycle state of the application.	✓	✓	✓	
Name	`[application:name]`	The name of the application.	✓	✓	✓	
Title	`[application:title]`	The title of the application.	✓	✓	✓	

Consumer Organization Tokens

Tokens that are related to the individual consumer organization.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
ID	`[consumer-org:id]`	The ID of the consumer organization.	✓	✓	✓	✓
Name	`[consumer-org:name]`	The name of the consumer organization.	✓	✓	✓	✓
Title	`[consumer-org:title]`	The title of the consumer organization.	✓	✓	✓	✓

Product Tokens

Tokens that are related to an individual product.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
APIs	`[product:apis]`	A comma separated list of APIs (name:version) within the product.	✓	✓	✓	
ID	`[product:id]`	The ID of the product.	✓	✓	✓	
Image URL	`[product:image_url]`	The URL of the image for the product.	✓	✓	✓	
Name	`[product:name]`	The name of the product.	✓	✓	✓	
Plans	`[product:plans]`	A comma separated list of plan names within the product.	✓	✓	✓	
State	`[product:state]`	The state of the product.	✓	✓	✓	
Title	`[product:title]`	The title of the product.	✓	✓	✓	

Plan Tokens

Tokens that are related to an individual product plan.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Approval required	`[product-plan:approval]`	Whether the plan requires approval or not.		✓		
Description	`[product-plan:description]`	The description of the plan.		✓		
Name	`[product-plan:name]`	The name of a given plan within the product.		✓		
Rate limits	`[product-plan:rate-limits]`	A comma separated list of rate limit name value pairs that the plan contains.		✓		
Title	`[product-plan:title]`	The title of the plan.		✓		

API Tokens

Tokens that are related to an individual API.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
ID	`[api:id]`	The ID of the API.			✓	
Image URL	`[api:image_url]`	The URL of the image for the API.			✓	
Name	`[api:name]`	The name of the API.			✓	
OAI Version	`[api:oai_version]`	The OAI version of the API.			✓	
Protocol	`[api:protocol]`	The protocol of the API.			✓	
State	`[api:state]`	The current state the API is in.			✓	
Title	`[api:title]`	The title of the API.			✓	
Version	`[api:version]`	The version of the API.			✓	

User Tokens

Tokens that are related to the individual user account of the recipient.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Account Name	`[user:account-name]`	The login name of the user account.	✓	✓	✓	✓
Created	`[user:created]`	The date the user account was created.	✓	✓	✓>	✓
Display Name	`[user:display-name]`	The display name of the user account.	✓	✓	✓	✓
Email	`[user:mail]`	The email address of the user account.	✓	✓	✓	✓
First Name	`[user:first_name]`	The first name of the user.	✓	✓	✓	✓
Last Name	`[user:last_name]`	The last name of the user.	✓	✓	✓	✓
Roles	`[user:roles]`	The user roles associated with the user account.	✓	✓	✓	✓
State	`[user:apic_state]`	List (text) field.	✓	✓	✓	✓
User ID	`[user:uid]`	The unique ID of the user account.	✓	✓	✓	✓

Current User Tokens

Tokens that are related to the current user who is initiating the sending of the emails.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Account name	`[current-user:account-name]`	The login name of the user account.	✓	✓	✓	✓
Display name	`[current-user:display-name]`	The display name of the user account.	✓	✓	✓	✓
Email	`[current-user:mail]`	The email address of the user account.	✓	✓	✓	✓

Site Information Tokens

Tokens that are related to site-wide settings and other global configuration.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Email	`[site:mail]`	The administrative email address for the site.	✓	✓	✓	✓
Login page	`[site:login-url]`	The URL of the site's login page.	✓	✓	✓	✓
Name	`[site:name]`	The name of the site.	✓	✓	✓	✓
Slogan	`[site:slogan]`	The slogan of the site.	✓	✓	✓	✓

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
URL	`[site:url]`	The URL of the site's front page.	✓	✓	✓	✓
URL (brief)	`[site:url-brief]`	The URL of the site's front page without the protocol.	✓	✓	✓	✓

Current Date Tokens

Tokens that are related to the current date and time.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Custom format	`[current-date:custom:?]`	A date in a custom format. See the PHP documentation for details.	✓	✓	✓	✓
Fallback date format	`[current-date:fallback]`	A date in 'fallback' format. (Fri, 01/08/2021 - 14:19)	✓	✓	✓	✓
HTML Date	`[current-date:html_date]`	A date in 'html_date' format. (2021-01-08)	✓	✓	✓	✓
HTML Datetime	`[current-date:html_datetime]`	A date in 'html_datetime' format. (2021-01-08T14:19:19+0000)	✓	✓	✓	✓
HTML Month	`[current-date:html_month]`	A date in 'html_month' format. (2021-01)	✓	✓	✓	✓
HTML Time	`[current-date:html_time]`	A date in 'html_time' format. (14:19:19)	✓	✓	✓	✓
HTML Week	`[current-date:html_week]`	A date in 'html_week' format. (2021-W01)	✓	✓	✓	✓
HTML Year	`[current-date:html_year]`	A date in 'html_year' format. (2021)	✓	✓	✓	✓
HTML Yearless date	`[current-date:html_yearless_date]`	A date in 'html_yearless_date' format. (01-08)	✓	✓	✓	✓
Long format	`[current-date:long]`	A date in 'long' format. (Friday, January 8, 2021 - 14:19)	✓	✓	✓	✓
Medium format	`[current-date:medium]`	A date in 'medium' format. (Fri, 01/08/2021 - 14:19)	✓	✓	✓	✓
Raw timestamp	`[current-date:raw]`	A date in UNIX timestamp format (1610115559)	✓	✓	✓	✓
Short format	`[current-date:short]`	A date in 'short' format. (01/08/2021 - 14:19)	✓	✓	✓	✓
Time-since	`[current-date:since]`	A date in 'time-since' format. (6 minutes)	✓	✓	✓	✓

How to style the Developer Portal emails

You can apply a theme to the HTML emails that are sent by the Developer Portal by using CSS and templating.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You must have a custom theme. For information about how to create a custom theme, see Creating a sub-theme.

About this task

You can apply custom styling to the HTML content of the emails that are sent by the Developer Portal, such as the emails that are sent by the Email subscribers wizard. The custom styling consists of two parts: editing a twig template and, optionally, also editing a CSS file in your custom theme. See the following instructions for details.
Note: These instructions apply only to emails that are sent by the Developer Portal. These instructions don't apply to the consumer invitation, activation, and password reset emails, as these emails are sent by the API Manager. For information about how to style API Manager emails, see Configuring notifications and Sending messages to consumer organization owners.

Procedure

1. Download the ibm-apic-mail-message.html.twig template from https://github.com/ibm-apiconnect/devportal/tree/master/ibm_apim/ibm_apic_mail/templates, and save it to your custom theme templates directory.
2. Edit the ibm-apic-mail-message.html.twig template to fit your custom theme.
   You can add styles directly into this twig template, or you can add them to the css/mail.css file in your custom theme, which will mean that they are automatically included in the HTML email content that is sent.

   If you are using an SCSS theme that has been generated by the Developer Portal theme generator, then you can put the custom SCSS mail styles into the mail-overrides.scss file. These styles will then be compiled into the mail.css file.

   Note: If you are using an older theme that was generated before API Connect Version 10.0.4.0, then the theme won't contain the mail theme support. However, you can workaround this by generating a new sub-theme with the same name, copying the overrides.css, or overrides.scss, as appropriate, logo.png, and *.theme files from the old theme into the new sub-theme, and then compress and install the new sub-theme as usual. (See Creating a sub-theme for details.)

3. Define a standard set of classes in the ibm-apic-mail-message.html.twig template that the Developer Portal administrators can use.
   The twig template lists the variables that can be used within it. The HTML **<body>** element is the actual content of the email message as defined within Drupal. For example, that content could be the information that's entered in the WYSIWYG editor of the Email subscribers wizard. Note that the HTML content in the WYSIWYG editor is more restricted for security reasons, for example, it's not possible to use inline styles in the HTML content in the editor. However, it is possible to use CSS class names, and then define the class in the mail.css file, which is then included in the emails. Therefore, it's recommended that you define a standard set of classes that the Developer Portal administrators can use when they're creating emails.

4. Optional: Add images to the ibm-apic-mail-message.html.twig template.
   Images can be used by adding a **** reference in the twig template. The **src** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

   Note: The **logo** will be automatically set to the fully qualified URL for the site logo image.
5. Compress all of your sub-theme resources back into a .zip file, and install into the Developer Portal. See Installing additional themes for details.

What to do next

It is possible to have multiple email templates. For example for different modules, where one template could be used for the emails that are sent by the contact module, and another template for the emails that are sent by the Email subscribers wizard. This more advanced configuration can be done by using the module and key attributes, and is explained within the twig template itself. Essentially, you create a twig template that's called ibm-apic-mail-message.contact.html.twig, for example, to override the default template for only the contact module. Then the most specific template for a module is used by the Developer Portal, before falling back on the more general template.

Working with roles in the Developer Portal

As a site administrator, you can create and customize site configuration roles in the Developer Portal.

Rather than assigning individual permissions to each user, permissions are assigned to roles, and then roles are assigned to users. Using roles gives administrators greater control over permissions, and makes it easy to assign and remove roles when necessary.

Administrators can assign the following site configuration roles to users in the Developer Portal:

Superuser
: The Superuser role has the highest level of permissions in the Developer Portal, and is the role that is assigned by default to the admin user, in addition to the Administrator role, when they enable a Developer Portal site in the API Manager. This role bypasses all content access control, which means that users that have a Superuser role can see all of the site content. This level of access can lead to some unexpected behavior when they access content such as their Consumer organizations and their applications. Careful consideration should be given before you assign users to a Superuser role.

Administrator
: An Administrator can use the administrator dashboard to customize and configure the Developer Portal. An Administrator is able to perform any task within the Developer Portal that does not involve the creation of APIs, Products, and Apps.

Content Author
: A Content Author is a curator of content for the Developer Portal. A Content Author can perform the following actions:

  - Set taxonomies on the content.
  - Provide custom icons for content.
  - Upload additional documentation files.
  - Create documentation pages in the Developer Portal.

Forum Moderator
: A Forum Moderator can moderate the content of a forum in the Developer Portal.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **A user already exists with this email address**.
To learn how to create and customize roles in the Developer Portal, use the following topic links:

  You can create additional administrator users for an Developer Portal.
- **Assigning users to a role**
  Assign users to one or more roles in the Developer Portal to enable role specific permissions.
- **Assigning permissions to a role**
  You can assign permissions to a new role in the Developer Portal, and update the permissions for current roles.
- **Creating a new role**
  You can create a new role within the Developer Portal.

Creating administrator users for the Developer Portal

You can create additional administrator users for an Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

After you enable a Developer Portal site in the API Manager, you are sent an email that contains a one-time log in link for the Developer Portal site Admin user. The Admin user can administer the Content Management System (CMS) capabilities of the Developer Portal. For more information about enabling a site, see Creating and configuring Catalogs.

However, you can also create additional administrative roles for users from within the Developer Portal by assigning the role to users that have access to the Developer Portal. A user with an Administrator role can use the administrator dashboard to customize and configure the Developer Portal. An Administrator is able to perform any task within the Developer Portal that does not involve the creation of APIs, Products, and Apps. You should be careful to ensure that only trusted users are given this access and level of control of your site.

Procedure

To create additional administrative users, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
3. Select the List tab.
4. Select the check boxes for the target users.
5. From the drop-down list under the Action heading, select Add the Administrator role to the selected user(s).
6. Click Apply to selected items.

Results

You have assigned the selected users to the Administrator role.
Note: For improved security and accountability, create named user accounts for all administrators. After assigning the Administrator role to these users and verifying their access, consider disabling the default Portal administrator account. This avoids shared credentials and ensures all actions are traceable.

Assigning users to a role

Assign users to one or more roles in the Developer Portal to enable role specific permissions.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To assign users to a role, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
3. Select the List tab.
4. Select the check boxes for the target users.
5. From the drop-down list under the Action heading, select the role that you want to assign.
6. Click Apply to selected items.

Results

You have assigned the selected users to the required role.

Assigning permissions to a role

You can assign permissions to a new role in the Developer Portal, and update the permissions for current roles.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To assign or update permissions for a role, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
3. Select the Permissions tab.
4. Assign a permission to a role, by selecting the check box in the relevant column for the permission that you want to assign.
5. Click Save permissions.

Results

You have assigned permissions to the target role.

Creating a new role

You can create a new role within the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To create a new role, complete the following steps:

1. Click People in the administrator dashboard.
2. Select the Roles tab.
3. Click Add role.
4. Enter a name for the new role in Role name, and click Save.
5. Your new role is displayed in the list of roles. You can drag any of the roles to re-order them. It's recommended to order roles from least permissive (for example, Anonymous user) to most permissive (for example, Administrator user). Users who aren't logged in have the Anonymous user role. Users who are logged in have the Authenticated user role, plus any other roles granted to their user account.

Results

You have created a new role in the Developer Portal.

What to do next

The new role is created with the same permissions as an Authenticated user role. You can click the Permissions tab and edit the permissions as required.

Forums

Create and control forums in the Developer Portal.

The Developer Portal lets you create threaded discussion boards, called forums, on your site. To learn how to configure forums, use the following topic links.

- **Creating a new forum**
  You can create a new forum in the Developer Portal.
- **Creating new forum containers**
  You can create new forum containers in the Developer Portal.
- **Configuring the creation of new forums for each API**
  You can choose whether or not to automatically create a new forum when an API is created in the Developer Portal.
- **Locking forum topics**
  You can lock forum topics in the Developer Portal.
- **Marking content in a forum as sticky**
  You can mark content in a forum as sticky in the Developer Portal.
- **Removing forum posts**
  You can remove forum posts in the Developer Portal.
- **Turning off forums in the Developer Portal**
  You can turn off forums in the Developer Portal by disabling the Forum module. This action prevents users from viewing, and contributing to, forums.

Creating a new forum

You can create a new forum in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

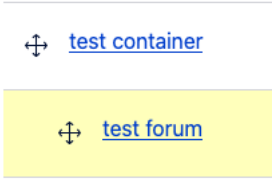
Procedure

To create a new forum, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Forums.
4. Click Add forum.
5. Fill in the Name and Description fields for the new forum.
6. From the Parent drop-down list, select the hierarchical position of the new forum.
7. Click Save. You have created a new forum.

Creating new forum containers

You can create new forum containers in the Developer Portal.



Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To create a new forum containers, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Forums.
4. Click + Add container.
5. Fill in the `Name` and `Description` fields for the new forum container.
6. Click Save. The newly created container is listed in the table.
7. Click + Add forum.
8. Fill in the `Name` and `Description` fields for the new forum container.
9. Click Save. The newly created forum is listed in the table.

10. Use the slider beside the forum to position it as a child to the container.
11. Click Save.

Results

You have created a new forum container.

Configuring the creation of new forums for each API

You can choose whether or not to automatically create a new forum when an API is created in the Developer Portal.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

To configure the creation of new forums for each API, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. Under the System heading, click IBM API Developer Portal.
4. Select or clear the Automatically create a forum per API check box to turn the feature on or off.
5. Click Save configuration.

You have configured the creation of new forums for each API.

Locking forum topics

You can lock forum topics in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To lock forum topics, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click Edit for the forum topic that you want to lock.
4. Click Comment settings. The view expands.
5. Select Closed .
6. Keeping the Published selected, click Save.
   You have disallowed any further replies and marked the topic as locked.

Marking content in a forum as sticky

You can mark content in a forum as sticky in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To mark content in a forum as sticky, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. From the Action drop-down menu, select Make content sticky.
4. Select the check boxes next to the forum topics that you want to make sticky.
5. Click Apply to selected items.
   You made the selected forum content sticky.

Removing forum posts

You can remove forum posts in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To remove forum posts, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. From the Action drop-down menu, select Delete content.
4. Select the check boxes next to the forum posts that you want to remove.
5. Click Apply to selected items.
   You removed the selected forum posts.

Turning off forums in the Developer Portal

You can turn off forums in the Developer Portal by disabling the Forum module. This action prevents users from viewing, and contributing to, forums.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

About this task

To turn off forums, you must first remove all Forums terms, and then you can disable the Forum module.

Procedure

To turn off the forums, complete the following steps.

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Delete all Forums terms by completing the following steps:
   a. Click Structure > Taxonomy > Forums in the administrator dashboard.
      The list of Forums terms is displayed.
   b. For each item in the list of terms, select Delete from the drop-down list in the Operations column, and then click Delete again to confirm.
      All of the Forums terms are deleted.
3. Disable the Forum module by completing the following steps:
   a. Click Extend > Disable module in the administrator dashboard.
   b. Select the Forum module, then click Disable.
   c. The display then shows a list of forum configuration that is removed when the Forum module is disabled. Click Disable again to confirm that you agree to this removal.
4. Remove the Forums menu from the Developer Portal home page by completing the following steps:
   a. Click Structure > Menus > Main navigation.
   b. Click Edit menu in the Operations column.
      The Main navigation edit menu page lists all the menu options that are displayed on the Developer Portal home page.
   c. Clear the Enabled checkbox against Forums.
   d. Click Save to save the changes.

Results

You successfully turned off forums in the Developer Portal.
If you want, you can enable the Forum module again by clicking Extend, selecting the Forum module on the List tab, and clicking Enable.

Reports

You can view reports about the general configuration and status of your Developer Portal site.

Use the Reports section in the Developer Portal to view information about the following areas:

Available updates
: Status report about available updates for your installed modules and themes.

Node Type Count
: Status report about how much of each content type there is in your portal site, and whether it is published or not. It can also provide totals of how many users there are of each role.

Available translation updates
: Status report about available interface translations for your installed modules and themes.

Field list
: Overview of fields on all entity types.

Status report
: Short overview of your site's parameters, as well as any problems detected with your installation.

Views plugins
: Overview of the plugins that are used in all views.

Extend

You can extend the Developer Portal by creating and installing custom modules, or installing additional Drupal contributed modules.

Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

Modules provide functionality to your site, and the *core modules* that are included in the standard Developer Portal installation, provide all of the basic functions that most sites need. However, some of the core modules are not enabled by default, so you might want to examine the module list under the Extend menu of your site, to see whether the functionality you require is available from a core module before starting to investigate custom and contributed modules. If you still require additional custom or contributed modules, consider the following topics to help you create and implement modules consistently.
Note: The Developer Portal contains a Rules framework for event based actions. Some of those actions and triggers might exhibit unexpected behavior. A workaround is to create a custom module instead, because the same events and actions are possible there.

Custom module development: an introduction to Drupal tools for PHP development

Some guidance about the Drupal tools and environment considerations when developing in PHP, to help when writing custom modules to extend your Developer Portal functionality.

The following sections provide an overview of the key automation tools and environment considerations for PHP development in the Developer Portal. For a complete list of Drupal tools, see Development tools overview on Drupal.org, however, note that you are not permitted to access the shell inside the Developer Portal containers.
Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

Devel, Devel Generate Kint, and Webprofiler development modules

The Devel, Devel Generate Kint, and Webprofiler modules are all packaged within the Devel module. These modules provide the following development support:

- *Devel* - Helper functions for Drupal developers.
- *Devel Generate Kint* - Accelerate development of your site or module by quickly generating nodes, comments, terms, users, and more.
- *Kint* - Pretty print of variables with `kint($my_var)`.
- *Webprofiler* - Port of the Symfony WebProfiler Bundle as a Drupal module.

For more information, see Devel module on drupal.org, and Devel on drupalship.org.

Admin Toolbar module

The Admin Toolbar module improves the default Drupal Toolbar by transforming it into a drop-down menu, providing fast access to the administration pages. It also adds extra links to the Drupal icon on the admin toolbar to development tools such as flush all caches, run cron, and run updates.

For more information, see Admin toolbar module on drupal.org.

Examples for developers project

The Examples for Developers project aims to provide high-quality, well-documented API examples for a broad range of Drupal core functionality.

The project contains many modules that illustrate best practices for implementing Drupal core APIs. For example there are examples for Block, Cache, Config and Content Entity, Cron, Database API, Email, Events, Form API, Field, Field Permission, File, Hooks, Javascript, Node Type, Page, Pager, PHPUnit, Plugin Type, Queue, Simple Test, Stream Wrapper, Table Sort, Testing, and Tour.

For more information, see Examples for developers project on drupal.org.

Coding standards

The Drupal Coding Standards apply to code within Drupal and its contributed modules. For more information, see Coding standards on drupal.org.

- Drupal tools for developers

Custom module development: background and prerequisites

You can create custom modules in the Developer Portal to extend functionality. The following information provides a getting started developer guide to custom module development.

Custom modules are written in PHP, which is an open source server-side scripting language that is used for creating dynamic web pages. For general information on the Drupal tools for PHP development, see Custom module development: an introduction to Drupal tools for PHP development.

The following sections provide an overview of custom module development, with links to learn more about the required development languages and concepts. Creating custom modules affects the source of your Developer Portal site, so it is recommended that you gain Drupal experience and PHP knowledge before you start creating modules.

Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

Object-Oriented Programming (OOP)

OOP is established as best practice for development, so ensure your knowledge of OOP is good. The PHP documentation on Classes and Objects is a good place to start. For a general overview of PHP best practices, see PHP The Right Way. The following resources are also helpful:

- Object-oriented programming (on Wikipedia)
- Object Oriented Programming with PHP (on phpro.org)
- Object-Oriented PHP for Beginners (on tutsplus.com)
- Object Oriented Programming in PHP (on tutorialspoint.com)

Drupal also uses some common design patterns, so you need to ensure you have a basic understanding of these. See the following pattern resources:

- The Factory Pattern (on phptherightway.com), and Late Static Bindings (on php.net)
- Software design pattern (on Wikipedia)
- Programming Foundations: Design Patterns (on lynda.com)

PHP namespaces

You must be familiar with the concept of namespaces in PHP. In most cases, the Drupal code is namespaced based on the module that code belongs to.

For example, the namespace for `block.module` is:

```
namespace Drupal\block;
```

When you create Drupal modules, it is important to consider that PHP has a global namespace, and that function names must be unique. You are recommended to prefix the name of any methods with the module name.

For example, if you have a module that is named `custom_module`, a `create` method within it is called `custom_module_create()`.

For more information about namespaces, see the following resources:

- Drupal namespace standards (on drupal.org)
- How to use PHP namespaces (on sitepoint.com)
- PHP Namespaces (on php.net)

Dependency injection

It is important that you have a baseline understanding of dependency injection. Drupal makes heavy use of this concept, so you will need this understanding to be able to access and make use of many of the core APIs.

To find out more about dependency injection, see Dependency Injection (on phptherightway.com), as well as the additional articles that are linked to on that page. See also Services and dependency injection in Drupal (on drupal.org).

Symfony

Symfony is a set of reusable PHP components and a PHP framework for web projects. Drupal borrows from this framework in order to reduce code duplication across various PHP projects. Much of the code that Drupal uses to handle routing, sessions, and the services container, amongst other things, is borrowed from Symfony.

To understand how Symfony works, see the Symfony Documentation on symfony.com.

Other useful resources

- Drupal API Annotations - list of the different annotation types that Drupal uses for plugin discovery, and to provide additional context/meta-data for the code that's being executed.
- Plugin API overview - overview about how plugins are used in Drupal.
- Tools are available for checking your custom modules, such as drupal_check on GitHub, which checks Drupal code for deprecations.

Custom module development: creating a module skeleton

You can extend your Developer Portal site by creating custom modules. The starting point for a new module is to create a module skeleton.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You must also have experience in Drupal and PHP development. For more information, see Custom module development: an introduction to Drupal tools for PHP development and Custom module development: background and prerequisites.

Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

About this task

Every custom module creation starts with creating an .info.yml file. This file, or module skeleton, is used to store the metadata about the custom theme. After the module skeleton is created, the module can be installed onto your site by using the Extend menu on the administrator dashboard of the Developer Portal UI. However, without any module specific code, your site won't be affected.
The following instructions guide you through creating a custom module skeleton. What to do next in your custom module creation depends on what you want your module to do. Options are shown at the end of this task.

Procedure

1. Choose a short name, also known as a machine name, for your custom module.
   The machine name is used in several files and functions in your module, as well as by Drupal core to programmatically refer to your module. The name must conform to the following rules:
   - It must start with a letter.
   - It must contain only lowercase letters and underscores. (Note that if uppercase letters are used in the name, Drupal won't recognize any hook implementations in your module.)
   - It must not contain any spaces.
   - It must be unique within your Developer Portal site.
   - It should not be any of the following reserved terms: **src**, **lib**, **vendor**, **assets**, **css**, **files**, **images**, **js**, **misc**, **templates**, **includes**, **fixtures**, **Drupal**.
2. Create a module folder in a location of your choice, for example, /modules/*module_name*.
   You don't have to name the folder the same name as your module machine name, however, you must remember to use the machine name programmatically within your module's code and filenames.
3. Create a *module_name*.info.yml file in your module folder.
   Where *module_name* is the short name, or machine name, that you chose in Step 1.
4. Insert the metadata for your custom module into the *module_name*.info.yml file as follows:

```
name: Example module name
description: Description of the module.
package: Custom

type: module
core: 8.x
core_version_requirement: '^8 || ^9'
version: 1.0

dependencies:
  - module_name

test_dependencies:
  - module_name
```

```
configure: example.settings

php: 7.1

hidden: true
```

where

- **name** (required) is the name of your module, and is the text that is shown on the module administration page in the Developer Portal UI.
- **description** (optional) is a description of your module, and is the text that is shown on the module administration page in the Developer Portal UI.
- **package** (optional) is a key that enables you to group similar modules together.
- **type** (required) is the type of extension that you are creating, for example, a module, theme or profile. In this instance you are creating a module.
- **core** (optional) specifies with which Drupal core version your module is compatible.
- **core_version_requirement** (required) specifies which versions of Drupal your module is compatible with. This example specifies that the module is compatible with all versions of Drupal 8 and 9.
- **version** (required) is the version number of your module. Note that **version** is not required if you are publishing your module on Drupal.org.
- **dependencies** (optional) is a YAML list of any modules that your module depends on. They must be namespaced in the format ***module_name***, where *module_name* is the module's machine name.
- **test_dependencies** (optional) is list of any modules (in the same format as **dependencies**) that are needed to run certain automated tests for your module on Drupal's automated test runner (DrupalCI), but are not needed as module dependencies in general.
- **configure** (optional), if your module offers a configuration form, specify the route to this form here.
- **php** (optional) is the minimum PHP version that is required for your module. For the Developer Portal the minimum PHP version is 7.1.
- **hidden** (optional) is an option that, if set, will hide your module from the Extend section of the administrator dashboard on the Developer Portal UI. This option might be useful if your module only contains tests, or if the module is meant as an example to other developers.

5. Save your *module_name*.info.yml.

Results

You successfully created your module skeleton.

Example

An example .info.yml file:

```
name: User field example
type: module
description: Developer Portal tutorial about a user field example
package: IBM API Connect Tutorials
core: 8.x
core_version_requirement: '^8 || ^9'
version: 8.x-0.0.1
dependencies:
  - ibm_apim
  - auth_apic
```

What to do next

You now need to create the appropriate content for your custom module, depending on what you want the module to do. For information about the various options, see Creating custom modules on Drupal.org. There is also a walkthrough example of creating a basic custom module that is available on Drupal.org, see: A "Hello World" custom page module.
Note: If you are defining URL paths in the routing file of your module, you must consider any potential implications of those paths, and avoid conflicts with other parts of the Developer Portal. For example, you are recommended not to prefix any paths with **ibm_apic**.
After you have created your custom module content, you need to package your custom module files up into a zip, tar, tgz, gz, or bz2 file. This file can then be installed onto your Developer Portal site by using the Extend menu on the administrator dashboard. For more information, see Installing custom modules.

Custom module development: using hooks

You can use hooks in custom modules to alter the behavior of Drupal core or other modules in your Developer Portal.

Custom modules enable you to extend the functionality of your Developer Portal site. For more information about how to create custom modules, see Custom module development: an introduction to Drupal tools for PHP development, and Custom module development: background and prerequisites.

Hooks are one of the ways that custom modules can use to interact with other modules and with Drupal core subsystems. The following sections provide an overview of hooks, and a list of the IBM® API Connect specific hooks.

Important:

- You are not permitted to include any IBM API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

About hooks

Hooks define functions that alter the behavior of Drupal core. So one way for custom modules to alter these functions, is to use hooks. Hooks are specially-named functions that a module defines (this is known as *implementing the hook*), these hooks are then discovered and called at specific times to alter or add to the base behavior or data (this is known as *invoking the hook*). Each hook has a name (for example: **`hook_batch_alter()`**), a defined set of parameters, and a defined return value. Your custom modules can implement hooks that are defined by Drupal core, by API Connect, or by other modules that they interact with. Your custom modules can also define their own hooks in order to let other modules interact with them. For more information, see Understanding Hooks on Drupal.org.

Note: If you write a hook implementation function, the function must not throw errors or exceptions, or use **`alert`** level log messages. Errors, exceptions, and **`alert`** level log messages can break all the processing in the parent code. For example, if you write a hook that calls an external server when an application is updated, the code needs to have error handling in place to handle the server not being found, or not returning the expected result. Otherwise, Drupal stops parsing the function and the application might not get updated correctly. It can cause webhook and snapshot parsing to abort leaving the portal in an inconsistent state.
For a list of all the hooks that are available on Drupal core, and how to implement them in your custom module, see Drupal API Hooks.

For a list of all the API Connect specific hooks, see the following section.

Using hooks in custom modules

To invoke a hook you need to add a function to your .module file in your custom module, and prefix the hook with your custom module name. For example, when using an API Connect hook in a custom module, you must replace the word **`hook`** in the hook name with the name of your custom module. For example:

`hook_apic_app_create`

should be referenced in your custom module as:

***`moduleName`*`_apic_app_create`**

API Connect specific hooks

The following tables list the hooks that are specific to the API Connect Developer Portal. Each section contains a link to the .php file on the API Connect Developer Portal repository on GitHub for those hooks. This file contains examples of how you can use the hooks in your modules.

Hooks about Applications

The following table lists the hooks that relate to Applications in the Developer Portal. For examples of how to use Application hooks, see apic_app/apic_app.api.php on GitHub.

Table 1. Hooks about Applications

Hook name	Description
`hook_apic_app_create`	Triggered when an Application is created.
`hook_apic_app_update`	Triggered when an Application is updated.
`hook_apic_app_pre_delete`	Triggered when an Application is deleted, before the node deletion or cascade has happened.
`hook_apic_app_post_delete`	Triggered when an Application is deleted, after the node deletion or cascade has happened.
`hook_apic_app_promote`	Triggered when an Application is promoted.
`hook_apic_app_creds_create`	Triggered when a new set of credentials is created for an Application.
`hook_apic_app_creds_update`	Triggered when a set of credentials is updated for an Application.
`hook_apic_app_creds_delete`	Triggered when a set of credentials is deleted for an Application.
`hook_apic_app_subscribe`	Triggered when a subscription is created.
`hook_apic_app_migrate`	Triggered when a subscription is migrated to a new Plan.
`hook_apic_app_unsubscribe`	Triggered when an Application is unsubscribed from a Plan.
`hook_apic_app_image_create`	Triggered when a custom Application image is created.
`hook_apic_app_image_delete`	Triggered when a custom Application image is deleted.
`hook_apic_app_clientid_reset`	Triggered when a credential client ID is reset.
`hook_apic_app_clientsecret_reset`	Triggered when a credential client secret is reset.
`hook_apic_app_modify_getplaceholderimage_alter`	Alter the Application placeholder image provided in \Drupal\apic_app\Application::getPlaceholderImage(). Can be used to define a specific placeholder image to use when the consumer has not uploaded their own custom image for their Application.
`hook_apic_app_modify_getimageforapp_alter`	Alter the Application placeholder image provided in \Drupal\apic_app\Application::getImageForApp(). Can be used to provide a full path to a specific image to use for an Application that overrides any custom image that might have been uploaded.
`hook_apic_app_modify_client_id_reset_alter`	Alter the client ID provided by API Manager when the ID is reset.
`hook_apic_app_modify_client_secret_reset_alter`	Alter the client secret provided by API Manager when the secret is reset.
`hook_apic_app_modify_create_alter`	Alter the credentials provided by API Manager when a new Application is created.
`hook_apic_app_modify_credentials_create_alter`	Alter the credentials provided by API Manager when new credentials are created.

Hooks about Consumer organizations

The following table lists the hooks that relate to Consumer organizations in the Developer Portal. For examples of how to use Consumer organization hooks, see consumerorg/consumerorg.api.php on GitHub.

Table 2. Hooks about Consumer organizations

Hook name	Description
`hook_consumerorg_create`	Triggered when a Consumer organization is created.
`hook_consumerorg_update`	Triggered when a Consumer organization is updated.

Hook name	Description
`hook_consumerorg_pre_delete`	Triggered when a Consumer organization is deleted, before the node deletion or cascade has happened.
`hook_consumerorg_post_delete`	Triggered when a Consumer organization is deleted, after the node deletion or cascade has happened.
`hook_consumerorg_payment_method_create_alter`	Triggered to allow modification of the payment method creation form.
`hook_consumerorg_myorg_tabs_alter`	Triggered to allow more tabs to be added to the `my organization` page.

Hooks about APIs

The following table lists the hooks that relate to APIs in the Developer Portal. For examples of how to use API hooks, see apic_api/apic_api.api.php on GitHub.

Table 3. Hooks about APIs

Hook name	Description
`hook_apic_api_create`	Triggered when an API is created.
`hook_apic_api_update`	Triggered when an API is updated.
`hook_apic_api_delete`	Triggered when an API is deleted.

Hooks about Products

The following table lists the hooks that relate to Products in the Developer Portal. For examples of how to use Product hooks, see product/product.api.php on GitHub.

Table 4. Hooks about Products

Hook name	Description
`hook_product_create`	Triggered when a Product is created.
`hook_product_update`	Triggered when a Product is updated.
`hook_product_delete`	Triggered when a Product is deleted.

Other IBM API Connect Hooks

The following table lists the hooks that can be for other uses.

Table 5. Other APIC Hooks

Hook name	Description
`hook_ibm_apim_subscription_wizard_summary_alter`	Triggered to allow modification of the summary page of the subscription wizard.

- Installing custom modules

Related information

- Creating custom modules

Installing custom modules

You can extend your Developer Portal site by installing custom modules that you created, and also installing contributed modules from the Drupal community.

Before you begin

Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

About this task

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You can add extra functions to your site by installing new custom or contributed modules. For more information on creating custom modules, see Custom module development: background and prerequisites. Contributed modules are modules that are contributed by Drupal community members. To search for contributed modules, go to Drupal Download & Extend. You can install both types of modules into your Developer Portal site by using the following instructions.
Note: The following modules are unsupported and their installation is blocked in the Developer Portal:

- `advagg`
- `advagg_bundler`
- `advagg_css_minify`
- `advagg_ext_minify`
- `advagg_js_minify`
- `advagg_mod`
- `advagg_validator`
- `backup_migrate`
- `content_sync`
- `delete_all`
- `devel_themer`

- `domain`
- `email_tfa`
- `php`
- `simple_html_mail`
- `statistics`
- `swiftmailer`
- `tfa`
- `theme_editor`

Procedure

1. Click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The modules that are displayed with a selected checkbox are enabled, the modules that are displayed without a selected checkbox are not enabled.
2. Click + Install new module, and either complete the Install from a URL field, or click Choose file to upload a *filename*.tar.gz module file from your local computer.
3. Click Install.
   The Update manager confirms that the module was installed successfully.
4. Click Enable newly added modules to return to the List tab for the Extend page.
5. Find your newly added module in the list of modules, select its checkbox, and click Enable.
   Your newly added module is now enabled and available for you to use in the Developer Portal.

Deleting custom modules

You can delete custom modules from your Developer Portal if you want to remove them entirely from your site.

Before you begin

Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

Note that any custom modules that you want to delete must be disabled first, including disabling any associated sub-modules. For more information, see Disabling modules. Any modules that are shipped with IBM API Connect cannot be deleted.

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Extend.
4. Click the Delete tab.
   The list of disabled custom modules that can be deleted is displayed. Note that any disabled modules that have sub-modules that are still enabled, are prevented from being disabled.
5. After you have found the module that you want to disable, select the check box next to the module, then click Delete.
6. At the confirmation dialogue, select Delete to delete the module completely from your site, or select Cancel to cancel the operation.

Results

You successfully deleted the module.

What to do next

To install a module, see Installing custom modules.

Disabling modules

You can disable an entire module in the Developer Portal if you want to improve performance, or remove functionality.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Note that the disable process removes all data related to a module.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed, some of which are enabled (displayed with a selected check box), and some of which are not enabled (where the check box is not selected).
4. Click the Disable tab.
   The list of modules that can be disabled is displayed. Note that any modules that are required by other enabled modules, are prevented from being disabled.
5. Either enter the name of the module that you want to disable in the Filter by name or description field, or scroll through the list of modules.
6. After you have identified the module that you want to disable, select the check box next to the module, then click Disable.
7. At the confirmation dialogue, select Disable to disable the module and remove any data that relates to it, or select Cancel to cancel the operation.

Results

You successfully disabled the module.

What to do next

To enable a module, return to the List tab, select the check box next to the module that you want to enable, and click Enable.
You can also delete custom modules completely from your Developer Portal site; see Deleting custom modules.

Using Developer Portal metadata on API Manager

For content created or updated after Version 10.0.1.0, the Developer Portal propagates more metadata to API Manager for **consumerorgs**, **users**, and **applications**.

This metadata might be values that the user provided by adding extra fields to content types, or added programmatically by using custom modules.

The benefit of this is that when you add custom fields to **consumerorgs**, **users**, and **applications**, this data is now also stored as metadata in API Manager. Storing this data allows the Developer Portal to correct or repopulate the custom fields from a webhook or a snapshot.

Related tasks

- Installing custom modules

Related information

- Creating custom modules

Using a custom module for payment method creation

You can offer free use of your products to your customers or you can configure your Developer Portal to bill your customers when they use your products. You can use a custom module to configure creation of payment methods.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
You must have configured billing support in API Manager.

Create your custom module. Your custom module needs to implement the **consumerorg_payment_method_create_alter** hook, so it needs to have a function like this:

```
my_custom_module_consumerorg_payment_method_create_alter(&$form, $integration, $billing) {
// do this payment function with $form
}
```

For more information, see Custom module development: background and prerequisites.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected checkbox. The disabled modules are displayed without a selected checkbox.
3. Click + Install new module, and either complete the Install from a URL field, or click Choose file to upload a *filename*.tar.gz module file from your local computer.
4. Click Install.
   The Update manager confirms that the module was installed successfully.
5. Click Enable newly added modules to return to the List tab for the Extend page.
6. Find your newly added module in the list of modules, select its checkbox, and click Enable.

Your newly added module is now enabled and available for you to use in the Developer Portal.

7. In the administrator dashboard, click Configuration > System > IBM API Connect Billing Settings in the administrator dashboard.
8. Change the drop-down option to be your newly enabled module for your billing provider.

Results

You successfully enabled your payment method by using a custom module.

Managing the Developer Portal by using the toolkit CLI

You can perform operations on your Developer Portal by using the API Connect toolkit CLI.

- **Getting started with the Portal CLI commands**
  The toolkit CLI provides developer portal-specific commands for managing your portal servers and sites.
- **Developer Portal CLI commands**
  A summary of the commands that are supported in the Developer Portal CLI.
- **Scenarios that use the Portal CLI**
  Here are some scenarios of how you can use the Portal commands in the toolkit CLI to accomplish tasks that are more complex to complete, or not possible in the Developer Portal UI.

Getting started with the Portal CLI commands

The toolkit CLI provides developer portal-specific commands for managing your portal servers and sites.

Procedure

1. Install the toolkit: Setting up the API Connect toolkit
2. Log in to the Management server. Toolkit CLI Login.

   ```
   apic login --server <management hostname/api base url> --username <username> --realm <realm>
   ```

   Where:
   - *<management hostname/api base url>* is the FQDN or base URL of your management API endpoints, for example: `mgmt.example.com` or `https://mgmt.example.com`.
   - *<username>* is either the admin user or provider org owner, depending on whether you want to run cloud or provider organization scoped operations.
   - *<realm>* is the user registry realm for the specified *<username>*. By default this is `admin/default-idp-1` for the admin user, and `provider/default-idp-2` for provider organization users.

   Note: All portal CLI commands are either cloud admin or provider org scoped.
3. View the available toolkit portal commands by using `-m portaladmin -h`. Example:

```
apic -m portaladmin -h
...Usage:
  apic [flags]
  apic [command]

Available Flags:
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
  -h, --help                  Help for apic
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")

Available Commands:

  Creating applications and artifacts
     config                               Manage configuration variables

  Publishing to the cloud
     api                                  Api operations
     apic-config                          Apic Config operations
     application                          Application operations
     backups                              Backups operations
     consumer-org                         Consumer Org operations
     custom-module                        Custom Module operations
     custom-theme                         Custom Theme operations
     custom-translation                   Custom Translation operations
     custom-webserver-page                Custom Webserver Page operations
     drupal-config                        Drupal Config operations
     drupal-state                         Drupal State operations
     entity                               Entity operations
     factory-reset                        Factory Reset operations
     ip-security-enabled                  Ip Security Enabled operations
     modules                              Modules operations
     php-memory                           Php Memory operations
     platforms                            Platforms operations
     product                              Product operations
     security                             Security operations
     service-ip-allowlist                 Service Ip Allowlist operations
     site                                 Site operations
     site-config                          Site Config operations
```

```
    sites                                  Sites operations
    themes                                 Themes operations
    twig                                   Twig operations

  Other commands
    licenses                               Review the license for API Connect
    validate                               Validate an API or product definition
    version                                Get the APIConnect toolkit version

Additional help topics:

Use "apic [command] --help" for more information about a command.
```

4. To view command-specific help, run the command with `-h`:

```
apic -m portaladmin php-memory -h
Usage: apic php-memory:list [flags]

Php Memory operations

Flags:
      --format string                    Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
  -h, --help                             Help for list
      --portal_service_name string       The name of the portal service (required)
  -s, --server string                    management server endpoint (required)

Type "apic [command] --help" for help on the following related commands:
      php-memory:list    List the PHP memory limit on the platform.
      php-memory:update  Set the PHP memory limit on the portal platform.

apic -m portaladmin php-memory:list -h
Usage: apic php-memory:list [flags]

List the PHP memory limit on the platform.

Lists the PHP memory_limit setting on the portal platform.

Flags:
      --format string                    Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
      --portal_service_name string       The name of the portal service (required)
  -s, --server string                    management server endpoint (required)
```

Developer Portal CLI commands

A summary of the commands that are supported in the Developer Portal CLI.

Authenticating

Use the **`apic login`** command to authenticate, and the **`apic logout`** command to remove your local authentication credentials. For more information, see Getting started with the Portal CLI commands.

Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. Therefore, you must set the file permissions in such a way that your credentials are not accessible by others.

Command summary

The following tables summarize **`apic --mode portaladmin`** commands.

Table 1. Summary of the **`portaladmin`** commands

Command	Description	Subcommands
`apic api`	Manage your **`api`**.	• **`apic api:add-attachment`** - Add an attachment for an API • **`apic api:add-tag`** - Add a tag for an API. • **`apic api:get`** - Get an API from a portal service. • **`apic api:get-document`** - Get a specific entire API document from the portal of the given organization and catalog. • **`apic api:list`** - List the APIs of the given organization and catalog. • **`apic api:set-icon`** - Set an icon for an API. For more information, see Using the api commands.
`apic apic-config`	Manage your **`apic-config`**.	• **`apic apic-config:get`** - Get the configuration of a site. For more information, see Using the apic-config commands.
`apic application`	Manage your **`application`**.	• **`apic application:get`** - Get an application from a portal service. • **`apic application:list`** - List the applications on a portal service. For more information, see Using the application commands.
`apic backups`	Manage your **`backups`**.	• **`apic backups:list`** - List the backups of a portal service. For more information, see Using the backups commands.

Command	Description	Subcommands
`apic consumer-org`	Manage your `apic consumer-org`.	• `apic consumer-org:get` - Get a consumer org from a portal service. • `apic consumer-org:list` - List the consumer orgs on a portal service. For more information, see Using the consumer-org commands.
`apic content`	Manage your `content` entity types.	• `content:create-export` - Create a task to export a .tgz file containing your site content entities. • `content:create-import` - Create a task to import an archive of your site content. • `content:delete-export` - Cancel any currently running `content:create-export` tasks, and delete any related artifacts. • `content:delete-import` - Cancel any currently running `content:create-import` tasks, and delete any related artifacts. • `content:get-export-status` - Return the status of a specific export task. • `content:get-export` - Stream the content of a specific export task to a .tgz file. • `content:get-import-status` - Return the status of a specific import task. • `apic content:list` - List all of the entities in your site for a given content entity type and, if required, bundle. • `apic content:list-type` - List the content entity types that are exportable from your site. For more information, see Using the content commands.
`apic custom-module`	Manage your `custom modules`.	• `apic custom-module:create-export` - Create an export of a `custom module`. • `apic custom-module:create-import` - Create an import of a `custom module`. • `apic custom-module:delete-export` - Delete an export of a `custom module`. • `apic custom-module:delete-import` - Delete an import of a `custom module`. • `apic custom-module:get-export` - Get an export of a `custom module`. • `apic custom-module:get-export-status` - Get the status of an export of a `custom module`. • `apic custom-module:get-import-status` - Get the status of an import of a `custom module`. For more information, see Using the custom-module commands.
`apic custom-theme`	Manage your `custom themes`.	• `apic custom-theme:create-export` - Create an export of a `custom theme`. • `apic custom-theme:create-import` - Create an import of a `custom theme`. • `apic custom-theme:delete-export` - Delete an export of a `custom theme`. • `apic custom-theme:delete-import` - Delete an import of a `custom theme`. • `apic custom-theme:get-export` - Get an export of a `custom theme`. • `apic custom-theme:get-export-status` - Get the status of an export of a `custom theme`. • `apic custom-theme:get-import-status` - Get the status of an import of a `custom theme`. For more information, see Using the custom-theme commands.
`apic custom-translation`	Manage your `custom translations`.	• `apic custom-translation:create-export` - Create a task to export a `custom translation`. • `apic custom-translation:create-import` - Create a task to import a `custom translation`. • `apic custom-translation:delete-export` - Cancel any ongoing or recently created export tasks. • `apic custom-translation:delete-import` - Cancel any ongoing or recently created import tasks. • `apic custom-translation:get-export` - Streams an export artifact of a `custom translation` back to the provided task ID. • `apic custom-translation:get-export-status` - Get the status of an export of a `custom translation`. • `apic custom-translation:get-import-status` - Get the status of an import of a `custom translation`. For more information, see Using the custom-translation commands.
`apic custom-webserver-page`	Manage your `custom-webserver-page` content.	• `apic custom-webserver-page:delete` - Delete a custom HTML web server error page. • `apic custom-webserver-page:get` - Get the content of a custom HTML web server error page. • `apic custom-webserver-page:set` - Set a custom HTML web server error page by using a valid HTML5 content file. For more information, see Using the custom-webserver-page commands.
`apic drupal-config`	Manage your `drupal-config`.	• `apic drupal-config:delete` - Delete a Drupal config object, or a specific config key. • `apic drupal-config:get` - Get all of the key values for a Drupal config object, or a specific config key value. • `apic drupal-config:list` - List the Drupal config names by prefix, or list all. • `apic drupal-config:set` - Set a new Drupal config key and value, or update an existing config key and value. For more information, see Using the drupal-config commands.

Command	Description	Subcommands
`apic drupal-state`	Manage your `drupal-state` keys and values.	• `apic drupal-state:delete` - Delete a specific Drupal state key and value. • `apic drupal-state:get` - Get a specific Drupal state key value. • `apic drupal-state:set` - Set a new Drupal state key and value, or update an existing state key value. For more information, see Using the drupal-state commands.
`apic entity`	Manage your `entity`.	• `apic entity:count` - A count of entities from a site. For more information, see Using the entity commands.
`apic export-entity`	Manage the export of your content entities.	• `export-entity:create` - Create a new export entity, which is the container for the entity content that you want to export. • `export-entity:add-content` - Adds content to an existing export entity. • `export-entity:get` - Returns a list of the content of a specific export entity. • `export-entity:remove-content` - Removes certain content from a specific export entity. • `export-entity:delete` - Deletes a specific export entity. • `export-entity:launch` - Launches an export entity polling task that creates a .tgz file of all of the entities that are contained in a specific export entity. Can be run with a `--no-poll` option, in which case the task doesn't return a .tgz file, but just returns the task ID. • `export-entity:get-launch-export` - Streams the content of a specific completed `export-entity:launch` task to a .tgz file. • `export-entity:delete-launch-export` - Cancels a currently running `export-entity:launch` task, and deletes any related artifacts. • `export-entity:get-launch-export-status` - Returns the status of a specific `export-entity:launch` task. • `export-entity:list` - Returns a list of all of the export entities within a specific Developer Portal. Each export entity contains a defined list of all of the entity content that will be exported if `export-entity:launch` is run. For more information, see Using the export-entity commands.
`apic factory-reset`	Perform a factory reset of your Developer Portal.	• `apic factory-reset:delete` - Perform a factory reset of your Developer Portal, deleting the portal service and all of its associated Developer Portal sites. Warning: The **factory-reset** command is irreversible. You must ensure that you have backups created before running this command. For more information, see Using the factory-reset command.
`apic forums`	Manage your `forums`.	• `apic forums:disable` - disables the Forum module for a given site. • `apic forums:enable` - enables the Forum module for a given site. For more information, see Using the forums commands.
`apic ip-security-enabled`	Manage your `IP security`.	• `apic ip-security-enabled:update` - Enable or disable the IP security at the portal service level. For more information, see Using the ip-security-enabled command.
`apic maintenance`	Manage your `maintenance` operations.	• `apic maintenance:disable` - Disable your `maintenance` operations. • `apic maintenance:enable` - Enable your `maintenance` operations. • `apic maintenance:rebuild_node_access` - Rebuild the node access table of your `maintenance` operations. • `apic maintenance:search_api_index_rebuild` - Rebuild and re-index the search API index of your `maintenance` operations. • `apic maintenance:search_api_index_status` - Print the search API index status of your `maintenance` operations. • `apic maintenance:status` - Get the current mode of your `maintenance` operations. For more information, see Using the maintenance commands.
`apic memcache`	Manage your `memcache` operations.	• `apic memcache:disable` - Disable the default caching store operations. This sets Drupal to use database as its cache. • `apic memcache:enable` - Enable the default caching store operations. This sets Drupal to use RAM as its cache. • `apic memcache:get` - Get the status of the `memcache enabled` operations. For more information, see Using the memcache commands.
`apic modules`	Manage your `modules`.	• `apic modules:delete` - Delete `modules`. • `apic modules:disable` - Disable `modules`. • `apic modules:enable` - Enable `modules`. • `apic modules:list` - Get a list of your `modules`. For more information, see Using the modules commands.
`apic php-memory`	Manage your `php-memory`.	• `apic php-memory:list` - List the PHP memory limit on the platform. • `apic php-memory:update` - Set the PHP memory limit on the portal platform. For more information, see Using the php-memory commands.
`apic platforms`	Manage your `platforms`.	• `apic platforms:list` - List the platforms of a portal service. For more information, see Using the platforms commands.

Command	Description	Subcommands
`apic product`	Manage your `product`.	• `apic product:add-attachment` - Add an attachment for the given product. • `apic product:add-tag` - Add a tag for the given product. • `apic product:get` - Get a product from a portal service. • `apic product:get-document` - Get a specific entire product document from the portal of the given organization and catalog. • `apic product:list` - List the products on a portal service. • `apic product:set-icon` - Set an icon image for the given product. For more information, see Using the product commands.
`apic queue`	View the tasks in a portal `queue`.	• `apic queue:get` - View the queued and locked platform related tasks for a specific Developer Portal site. • `apic queue:list` - View the queued and locked platform related tasks across all of the Developer Portal sites on a specific portal service. For more information, see Using the queue commands.
`apic role`	Manage your `role` operations.	• `apic role:create` - Create a new Drupal user role. • `apic role:delete` - Delete an unwanted Drupal user role. • `apic role:add-permission` - Add specific permissions to a Drupal user role. • `apic role:remove-permission` - Remove unwanted permissions from a Drupal user role. • `apic role:get` - Get the details of a Drupal user role as well as all the permissions granted to the specific role. • `apic role:list` - List all of the roles. You can filter the list based on the user role as well as the permission using the corresponding flags along with the `role:list` command. Use the `--filter_by_permission` flag to get the list of the roles that have the specified permission. Use the `--role` flag to get the list of permissions granted to the specified role. For more information, see Using the role commands.
`apic security`	Manage your `security`.	• `apic security:clear-bans` - Clear all of the banned user/IP addresses on a portal site. For more information, see Using the security command.
`apic service`	Manage your `service` operations.	• `apic service:list` - List the Portal service currently installed. For more information, see Using the service command.
`apic service-ip-allowlist`	Manage your `service-ip-allowlist`, which enables specific IP addresses to be exempt from being blocked by portal security checks.	• `apic service-ip-allowlist:add` - Add specific IP addresses to the `allowlist`. • `apic service-ip-allowlist:delete` - Delete all of the IP addresses from the `allowlist`. • `apic service-ip-allowlist:list` - List all of the IP addresses that are currently on the `allowlist`. • `apic service-ip-allowlist:remove` - Remove one or more specific IP addresses from the `allowlist`. For more information, see Using the service-ip-allowlist commands.
`apic site`	Manage your `site`.	• `site:cache-rebuild` - Rebuild the cache of a portal site. • `apic site:check` - Run a platform check against a portal site. • `apic site:state` - Obtain the current state of a portal site. • `apic site:login-link` - Get an admin login link for a specific portal site. • `site:create-export` - Create a task to export a .tgz archive file of your entire site configuration. • `site:create-import` - Create a task to import an archive of your entire site configuration. • `site:delete-export` - Cancel any currently running `site:create-export` tasks, and delete any related artifacts. • `site:delete-import` - Cancel any currently running `site:create-import` tasks, and delete any related artifacts. • `site:get-export-status` - Return the status of a specific export task. • `site:get-export` - Stream the content of a specific completed export task to a .tgz file. • `site:get-import-status` - Return the status of a specific import task. Important: If you want to import a site export configuration file, the export file must have been created on the same version of API Connect as the version that you want to import to. For more information, see Using the site commands.
`apic site-config`	Manage your `site-config`.	• `apic site-config:create-export` - Create an export of a `site config`. • `apic site-config:create-import` - Create an import of a `site config`. • `apic site-config:delete-export` - Delete an export of a `site config`. • `apic site-config:delete-import` - Delete an import of a `site config`. • `apic site-config:get-export` - Get an export of a `site config`. • `apic site-config:get-export-status` - Get the status of an export of a `site config`. • `apic site-config:get-import-status` - Get the status of an import of a `site config`. For more information, see Using the site-config commands.
`apic sites`	Manage your `sites`.	• `apic sites:check` - Run a platform check against all portal sites on a portal service. • `apic sites:list` - List the sites of a portal service. • `apic sites:reset-upgrade-attempts` - Reset the portal upgrade attempts. For more information, see Using the sites commands.

Command	Description	Subcommands
`apic themes`	Manage your `themes`.	• `apic themes:delete` - Delete `themes`. • `apic themes:disable` - Disable `themes`. • `apic themes:enable` - Enable `themes`. • `apic themes:list` - Get a list of your `themes`. • `apic themes:set-default` - Set the default theme of the portal. For more information, see Using the themes commands.
`apic twig`	Manage the `twig` debugging operations on a specific portal site.	• `apic twig:debug-enable` - Enable twig debugging for a portal site. • `apic twig:debug-disable` - Disable twig debugging for a portal site. • `apic twig:debug-status` - Get the current state of twig debugging for a specific site. For more information, see Using the twig commands.
`apic user`	Manage some Developer Portal `user` tasks.	• `apic user:add-role` - Add one or more roles to one or more specified user accounts. • `apic user:block` - Block one or more users. • `apic user:information` - Retrieve information about your users. • `apic user:remove-role` - Remove one or more roles from one or more specified user accounts. • `apic user:unblock` - Unblock one or more users. For more information, see Using the user commands.
`apic version`	Get the version of your API Connect toolkit.	• `apic version --mode portaladmin` - Get toolkit version.

- **Using the api commands**
  You can use the **api** commands to get and list the APIs on your Developer Portal service.
- **Using the apic-config commands**
  You can use the **apic-config** commands to get the apic config of your Developer Portal service.
- **Using the application commands**
  You can use the **application** commands to get and list the applications on your Developer Portal service.
- **Using the backups commands**
  You can use the **backups** commands to list the backups on your Developer Portal service.
- **Using the consumer-org commands**
  You can use the **consumer-org** commands to get and list the consumer orgs on your Developer Portal service.
- **Using the content commands**
  You can use the **content** commands to list, import, and export content from your Developer Portal site.
- **Using the custom-module commands**
  You can use the **custom-module** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.
- **Using the custom-theme commands**
  You can use the **custom-theme** commands to create export and import tasks, delete export and import tasks, get the status of an export or import task, and get an export artifact, on your Developer Portal service.
- **Using the custom-translation commands**
  You can use the **custom-translation** commands to create an import or export task that will import or export a .tgz of custom translations for a Developer Portal site. You can also delete the export and import tasks, get the status of an export or import task, and get a custom translation export artifact.
- **Using the custom-webserver-page commands**
  You can use the **custom-webserver-page** commands to customize the web server error pages on your Developer Portal service.
- **Using the drupal-config commands**
  You can use the **drupal-config** commands to list, get the values of, set values, create new, and delete the Drupal configuration objects on your Developer Portal service.
- **Using the drupal-state commands**
  You can use the **drupal-state** commands to store and retrieve information about the state of your Developer Portal system.
- **Using the entity commands**
  You can use the **entity** commands to get the entity count on your Developer Portal service.
- **Using the export-entity commands**
  You can use the **export-entity** commands to manage the export of content entities from your Developer Portal site.
- **Using the factory-reset command**
  You can use the **factory-reset** command to perform a factory reset of your Developer Portal, which will delete the portal service and all of its associated Developer Portal sites.
- **Using the forums commands**
  You can use the **forums** commands to disable or enable the forums on your Developer Portal service.
- **Using the ip-security-enabled command**
  You can use the **ip-security-enabled** commands to toggle IP security on your Developer Portal. When IP security is enabled, modules such as the Drupal Perimeter Defence module, or flood control, will block client IP addresses suspected of malicious behavior, as expected. Banned IP addresses can be cleared by using the `security:clear-bans` command. You might want to turn off IP security if you are performing penetration tests, or if you cannot pass through the client IP address from your external load balancer. Note that IP security is enabled by default on the Developer Portal.
- **Using the maintenance commands**
  You can use the **maintenance** commands to manage the maintenance operations on your Developer Portal service.
- **Using the memcache commands**
  You can use the **memcache** commands to get, enable, and disable the default caching store operations on your Developer Portal service.
- **Using the modules commands**
  You can use the **modules** commands to list, enable, disable and delete the modules on your Developer Portal service.
- **Using the php-memory commands**
  You can use the **php-memory** commands to list or update the PHP memory limits on your Developer Portal.
- **Using the platforms commands**
  You can use the **platforms** commands to list the platforms on your Developer Portal service.
- **Using the product commands**
  You can use the **product** commands to get and list the products on your Developer Portal service.
- **Using the queue commands**
  You can use the **queue** commands to list the queued and locked platform tasks on your Developer Portal site.

- **Using the role commands**
  You can use the **role** commands to complete the full lifecycle of Drupal user roles. This includes creating and deleting of roles, as well as adding and removing permissions to the roles in your Developer Portal service.
- **Using the security command**
  You can use the **security** command to clear all of the banned user/IP addresses on a Developer Portal site.
- **Using the service command**
  You can use the **service** command to list the Developer Portal service from the Developer Portal database.
- **Using the service-ip-allowlist commands**
  You can use the **service-ip-allowlist** commands to add, remove, and list the IP addresses on your Developer Portal `allowlist`. IP addresses that are on the `allowlist` are exempt from being blocked by Developer Portal security checks, for example, load balancer and proxy IPs.
- **Using the site commands**
  You can use the **site** commands to check the site on your Developer Portal service, and to export and import an entire site configuration.
- **Using the site-config commands**
  You can use the **site-config** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.
- **Using the sites commands**
  You can use the **sites** commands to check and list the sites on your Developer Portal service. You can also reset the portal upgrade attempt counter.
- **Using the themes commands**
  You can use the **themes** commands to list, enable, disable, delete, and set the default themes on your Developer Portal service.
- **Using the twig commands**
  You can use the **twig** commands to enable, disable, and check the state of twig debugging on a specific site on your Developer Portal service.
- **Using the user commands**
  You can use the **user** commands to complete some Drupal user management tasks on your Developer Portal, such as adding and removing roles, blocking and unblocking users, and retrieving user information.

Using the api commands

You can use the **api** commands to get and list the APIs on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. List the APIs from a site.
   For example,

   ```
   apic --mode portaladmin api:list --org orgid/name --server management_server --catalog catalogid/name
   ```

   - *`management_server`* is the endpoint URL of the management server (required).
   - *`catalogid/name`* is the ID or name of the catalog that the site belongs to (required).
   - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
   - *`format_type`* is the output format. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.
3. Get an API from a site by using the *`id`* or *`name:version`*.
   For example,

   ```
   apic --mode portaladmin api:get --org orgid/name --server management_server --catalog catalogid/name id/name:version
   ```

   - *`id/name:version`* - The ID or name:version of a specific API (required). For example, `id-of-api-called-example-3` or `example:3.0.0`.
4. Get a specific entire API document from the portal of the provided organization and catalog by using the *`id`* or *`name:version`*.

   ```
   apic --mode portaladmin api:get-document --org orgid/name --server management_server --catalog catalogid/name --format
   format_type  id/name:version
   ```

   For example,

   ```
   apic --mode portaladmin api:get-document --org ibm --server management_server --catalog portal-test --format yaml  intuiz-
   api:1.0.0
   ```

5. Add an attachment for your API within your Developer Portal.
   For example,

```
apic --mode portaladmin api:add-attachment -s management_server --org orgid/name --catalog catalogid/name --
attachment_name attachment.txt --attachment_description "API documentation" mortgage-management-api:1.0.0 ./attachment.txt
Loading File (Large files may take a while)...

Attachment successfully added to api mortgage-management-api:1.0.0.
  This product now has 4 attachments.
```

- `attachment_name` is the name given to the attachment when it is uploaded (required).
- `attachment_description` is the description of the attachment that is displayed to the users.

6. Set an icon for your API within your Developer Portal.
   For example,

```
apic --mode portaladmin api:set-icon -s management_server --org orgid/name --catalog catalogid/name --icon_description
"API icon" mortgage-management-api:1.0.0 ./icon.png
Loading File (Large files may take a while)...

Icon successfully set for api mortgage-management-api:1.0.0
```

- `icon_description` is the icon description to be displayed to users and it is used as an alt text for the image (required).

7. Add a tag (Category) for your API within your Developer Portal.
   For example,

```
apic --mode portaladmin api:add-tag -s management_server --org orgid/name --catalog catalogid/name --tag_name
top_level_element/next_level_element/lower_level_element mortgage-management-api:1.0.0
Successfully set taxonomy tag top_level_element/next_level_element/lower_level_element
  for api mortgage-management-api:1.0.0
```

- `tag_name` is the tag name. For example, `top_level_element/next_level_element` (required).

Using the apic-config commands

You can use the **apic-config** commands to get the apic config of your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Get the apic config of a site.
   For example,

```
apic --mode portaladmin apic-config:get --org orgid/name --server management_server --catalog name/id
```

Using the application commands

You can use the **application** commands to get and list the applications on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
```

```
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. List the applications on a site.
   For example,

```
apic --mode portaladmin application:list --org orgid/name --server management_server --catalog name/id
```

3. Get an application from a site by using application id.
   For example,

```
apic --mode portaladmin application:get --org orgid/name --server management_server --catalog name/id id
```

Using the backups commands

You can use the **backups** commands to list the backups on your Developer Portal service.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

   For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
   For full details of the **apic login** command, see Logging in to a management server.

2. Get the availability zone of the portal service's backups that you want to list:

```
apic availability-zones --org orgid/name --server management_server
```

3. List all the portal services in that availability zone

```
apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
```

4. Get the selected portal service's name

```
apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-NAME
```

5. List the backups of the portal service

```
apic --mode portaladmin backups:list --server management_server --portal_service_name PORTAL-SERVICE-NAME --format json
```

Using the consumer-org commands

You can use the **consumer-org** commands to get and list the consumer orgs on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. List the consumer orgs of a site.
   For example,

   ```
   apic --mode portaladmin consumer-org:list --org orgid/name --server management_server --catalog name/id
   ```

3. Get a consumer org from a site by using org id.
   For example,

   ```
   apic --mode portaladmin consumer-org:get --org orgid/name --server management_server --catalog name/id id
   ```

Using the content commands

You can use the **content** commands to list, import, and export content from your Developer Portal site.

About

The Developer Portal is based on the Drupal content management system. In Drupal, a content entity is an item of content data that is intended to be displayed to site users, such as text, images, and HTML markup. Content entities are grouped into entity types, and most of these entity types are also subdivided into entity subtypes, also known as bundles. The **content** commands enable you to list, import, and export either one type of content entity, or all of the content entity types, at a time. If you want to manage the export of assorted content entity types at the same time, you can use the **export-entity** commands; see Using the export-entity commands for more information.

Procedure

1. Log in as Provider org as seen in the following example.

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.

   For full details of the **apic login** command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. List the content entity types that are exportable from your site by using the following **content:list-types** command. This command returns a list of all of the content entity types that are allowed to be exported from your site. If a type isn't listed in the return, that type is either blocked or isn't a content entity type.

   ```
   apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:list-types
   ```

   Where:
   - ***management_server*** is the endpoint URL of the management server (required).
   - ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
   - ***catalogid/name*** is the ID or name of the catalog that the site belongs to (required).

   Each content entity type can have subtypes, which are known as bundles. These bundles can be used in the **content:list** command, when you want to list a particular bundle type of a content entity. In the following example, **page** is a bundle type of the content entity type **node**.

   ```
   apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog content:list-types
   block_content:
     - basic
   comment:
     - comment
     - comment_forum
   export_entity: {  }
   file: {  }
   import_entity: {  }
   media: {  }
   menu_link_content: {  }
   node:
     - article
     - blog_post
     - faq
     - forum
   ```

```
  - page
shortcut:
  - default
taxonomy_term:
  - forums
  - tags
```

3. List all of the entities in your site for a given content entity type and, if required, bundle by using the following **content:list** command.

   ```
   apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:list --entity_type
   entity_type_name --bundle bundle_name
   ```

   Where:
   - ***entity_type_name*** is the type of content entity that you want to list (required). You can use the **content:list-types** command to find the list of available content entity types.
   - ***bundle_name*** is the name of the bundle type that you want to list (optional).

   The following example lists the content of the **page** bundle type for the **node** content entity. Included in the return is an **Entity ID** for each item in the content list.

   ```
   apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog content:list --entity_type node --
   bundle page
   -
     Title: 'Terms of use'
     Langcode: en
     'Entity ID': '1'
     Bundle: page
     UUID: 75fc430e-fc4d-47e3-bc5f-7f23063716ac
   -
     Title: 'Privacy Policy'
     Langcode: en
     'Entity ID': '2'
     Bundle: page
     UUID: ddff300b-16fe-4d1e-be6f-ce7040131b68
   ```

4. Export your site content entities by using the following **content:create-export** command. This command creates an export task that returns a .tgz file containing the content entities. By default, the command polls the status of the task every 30 seconds until the task is finished, at which point the export file is returned. You can export a specific content entity type, or specific entities within an entity type, or you can generate a .tar file that contains all of the exportable content from your site. Note that exporting all of your site content can take a long time to complete.

   ```
   apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:create-export --
   entity_type entity_type_name --entity_ids entity_ids
   ```

   Where:
   - ***entity_type_name*** is the type of content entity that you want to export (required). If you want to export all of the exportable content from your site, set this option to **all**.
   - ***entity_ids*** is a comma separated list of the entity IDs that you want to export (optional).
   - **--no-poll** is an optional flag meaning that the command won't poll the status of the task, but instead just returns the task ID. This task ID can then be used with the **content:get-export** command to return the export file.

   Note: The command continues to poll until the maximum polling time of 25 minutes is reached. At which point you can use the commands **content:get_export_status** and **content:get-export** to get the status and, if the task has finished, an artifact.
   The following example creates an export task for the **Terms of use** and **Privacy Policy** entity IDs of the **node** content entity.

   ```
   apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog content:create-export --
   entity_type node --entity_ids 1,2
   201 CREATED - Task ID: 8h86b8utjtw51

   Response Code - 202:

   Message(s) -
   The status of this task is: RUNNING

   Response Code - 200:

   Message(s) -
   The status of this task is: FINISHED and the artifact can now be streamed

   Saving File (Large files may take a while)...
   Incoming project saved to content_createExport-20230627114023.tgz
   ```

   The command saves the export file to your running directory. The export .tgz file includes a root.json file that contains an index of all of the entities that are contained in the .tgz file, as well as a *content_entity_type*.json file for each content entity type exported. The *content_entity_type*.json file contains all of the information needed to be able to import those entities into a different Developer Portal site.

5. If you ran the **content:create-export** command with the **--no-poll** option, you can use the following commands to manage your content export.
   - **content:delete-export**
     Cancels any currently running **content:create-export** tasks, and deletes any related artifacts. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:delete-export --
     task_id task_id
     ```

     Where ***task_id*** is the ID of the export task on the queue.
   - **content:get-export**
     Streams the content of a specific completed export task to a .tgz file. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:get-export --
     task_id task_id
     ```

   - **content:get-export-status**
     Returns the status of a specific export task. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:get-export-
     status --task_id task_id
     ```

6. Import your site content entities by using the `content:create-import` command. This command launches an import polling task that polls the status of the task every 30 seconds until the task is finished, at which point a summary of the import is returned. If the command is run with the `--no-poll` option, the task doesn't return the status of the task, but just returns the task ID.
   Important: Before you import any content, make sure that you backup the site that you're importing to, in case content gets overwritten that you weren't expecting.

   ```
   apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:create-import
   export_file_name
   ```

   Where:
   - *`export_file_name`* is the name of the export file that you want to import. You can import .tgz files that were created by using the `content:create-export` or `export-entity:launch` commands.
   - `--no-poll` is an optional flag meaning that the command won't poll the status of the task, but instead just returns the task ID. This task ID can then be used with the `content:get-import-status` command to get the status of the task.

   Note: The command continues to poll until the maximum polling time of 25 minutes is reached. At which point you can use the command `content:get-import-status` to get the status of the task.
   In the following example, the export file from Step 4 is imported into a different Developer Portal site on a different server:

   ```
   apic --mode portaladmin --server my_management_server2 --org my_prod_org --catalog my_prod_catalog content:create-import
   content_createExport-20230627114023.tgz
   Loading File (Large files may take a while)...

   201 CREATED - Task ID: zmaskh7oo6531tty

   Response Code - 202:

   Message(s) -
   The status of this task is: QUEUED

   Response Code - 202:

   Message(s) -
   The status of this task is: RUNNING

   Response Code - 202:

   Message(s) -
   The status of this task is: RUNNING

   Response Code - 200:

   Message(s) -
   2023-10-18 13:36:18: CLI task (content:import) starting.
   2023-10-18 13:36:29: [notice] [1/2] - [node.page:1] "Terms of use" - Updated
   (https://my_management_server2/my_prod_catalog/tsandcs)
    [notice] [2/2] - [node.page:2] "Privacy Policy" - Updated (https://my_management_server2/my_prod_catalog/privacy)
   2023-10-18 13:37:20: CLI task (content:import) completed successfully.
   ```

   Depending on the content imported, the following three types of import can be shown in the import summary messages:
   - `Overridden` - In this case a content entity existed with the same entity ID but not the same UUID, and there was also no reference to it in the synchronization table, so the entity was overridden. Care must be taken when importing entities across different sites until they are in sync with one another, as data can be lost. For example, say you have a blog post about APIs with an entity ID of `50` on a test site, and you wanted to import this post onto your production site. However, the production site already has a blog post with an entity ID of `50` that talks about policies, in which case that post would be overwritten by the blog post about APIs, and be given the imported UUID. The next time that entity ID of `50` is imported, the import type will be `Updated`, because the UUID is now the same.
   - `Updated` - In this case the same content entity, with the same UUID, was found, so its contents were updated with the content from the import file.
   - `Created` - In this case no content entity of this type was found, so a new entity was created, and it was populated with the data from the import file.
7. If you ran the `content:create-import` command with the `--no-poll` option, you can use the following commands to manage your content import.
   - `content:delete-import`
     Cancels any currently running `content:create-import` tasks, and deletes any related artifacts. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:delete-import --
     task_id task_id
     ```

     Where *`task_id`* is the ID of the import task on the queue.
   - `content:get-import-status`
     Returns the status of a specific import task. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name content:get-import-
     status --task_id task_id
     ```

- Using the export-entity commands

Using the custom-module commands

You can use the **custom-module** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

2. Export your custom modules.
The **custom-module:create-export** command creates an export task against the portal of the specified `catalog` and `org`. The command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back.
Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-module:get-export-status** and **custom-module:get-export** to get the status and potentially an artifact.

```
apic --mode portaladmin custom-module:create-export --catalog name/id --org orgid/name --server management_server
```

- The module .tgz is saved to the directory in which you ran the command.
- The saved .tgz has the format `custom_module_createExport-20200217134637.tgz`.
- You can save your exports into your change control management system.

For example,

```
apic --mode portaladmin custom-module:create-export --catalog dev --org ibm --server api.stagingexample.com
```

3. Import your custom modules.
The **custom-module:create-import** command uses the supplied .tgz file to import the custom modules into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.
Note:
   - The higher level folders of the archive can contain only these characters, a-z and 0-9.
   - The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-module:get-import-status** to get the status of the import.
   - If you import a custom module that already exists you overwrite the existing custom module.
   - The Drupal cache is rebuilt in the background after the task is complete. If you want to include the cache rebuild as part of the task, you must include the `--wait` flag.

```
apic --mode portaladmin custom-module:create-import --catalog name/id --org orgid/name --server management_server
/PATH/TO/theme/TGZ --wait
```

Where `--wait` is an optional flag that makes the Drupal cache rebuild part of the task. Otherwise, the cache is rebuilt in the background after the task is finished.
For example,

```
apic --mode portaladmin custom-module:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/custom_module_export_three.tgz
Loading File (Large files may take a while)...

201 CREATED - Task ID: qe91vremj903owve

Using the custom-theme commands

You can use the **custom-theme** commands to create export and import tasks, delete export and import tasks, get the status of an export or import task, and get an export artifact, on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Export your custom themes.
   The **custom-theme:create-export** command creates an export task against the portal of the specified `catalog` and `org`. The command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back.
   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-theme:get-export-status** and **custom-theme:get-export** to get the status and potentially an artifact.

   ```
   apic --mode portaladmin custom-theme:create-export --catalog name/id --org orgid/name --server management_server
   ```

   - The theme .tgz is saved to the directory in which you ran the command.
   - The saved .tgz has the format `custom_theme_createExport-20200217134637.tgz`.
   - You can save your exports into your change control management system.

   For example,

   ```
   apic --mode portaladmin custom-theme:create-export --catalog dev --org ibm --server api.stagingexample.com
   ```

3. Import your custom themes.
   The **custom-theme:create-import** command uses the supplied .tgz file to import the custom themes into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.
   Note:
   - The higher level folders of the archive can contain only these characters, a-z and 0-9.
   - The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-theme:get-import-status** to get the status of the import.
   - If you import a custom theme that already exists you overwrite the existing custom theme.
   - The Drupal cache is rebuilt in the background after the task is complete. If you want to include the cache rebuild as part of the task, you must include the `--wait` flag.

   ```
   apic --mode portaladmin custom-theme:create-import --catalog name/id --org orgid/name --server management_server
   /PATH/TO/theme/TGZ --wait
   ```

   Where `--wait` is an optional flag that makes the Drupal cache rebuild part of the task. Otherwise, the cache is rebuilt in the background after the task is finished.
   For example,

   ```
   apic --mode portaladmin custom-theme:create-import --catalog prod --org ibm --server api.productionexample.com
   C:/users/example/desktop/custom_theme_export_three.tgz
   Loading File (Large files may take a while)...

Using the custom-translation commands

You can use the **custom-translation** commands to create an import or export task that will import or export a .tgz of custom translations for a Developer Portal site. You can also delete the export and import tasks, get the status of an export or import task, and get a custom translation export artifact.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Export your custom translations.
   The **custom-translation:create-export** command creates an export task against the portal of the specified `catalog` and `org`, to export an archive of the custom translations of the site. The command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back. The task ID is printed to the terminal.
   Note:
   - The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-translation:get-export-status** and **custom-translation:get-export** to get the status and potentially an artifact.
   - The translation .tgz archive is saved to the directory in which you ran the command.
   - The saved .tgz has the format `custom_translation_createExport-20210217134637.tgz`.
   - You can save your exports into your change control management system.

   ```
   apic --mode portaladmin custom-translation:create-export --catalog catalogid/name --org orgid/name --server
   management_server
   ```

   - `catalogid/name` is the ID or name of the catalog that the site belongs to (required).
   - `orgid/name` is the ID or name of the provider organization that the catalog belongs to (required).
   - `management_server` is the endpoint URL of the management server (required).
   - `--langcodes` is a comma separated list of the language codes, for example `es,zh-hans`. You can use this option to specify which custom translations to export.
   - `--no-poll` can be used to stop the command from polling the task, and just return the task ID.

   For example:

   ```
   apic --mode portaladmin custom-translation:create-export --catalog dev --org ibm --server api.stagingexample.com
   ```

3. Import your custom translations.
   The **custom-translation:create-import** command uses the supplied .tgz file to create a task to import the custom translations into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error. The task ID is printed to the terminal.

Note:

- The .tgz archive must contain only .po translation files, and nothing else.
- The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-translation:get-import-status** to get the status of the import.
- If you import a custom translation that already exists, the existing custom translation is overwritten.

```
apic --mode portaladmin custom-translation:create-import --catalog catalogid/name --org orgid/name --server
management_server /PATH/TO/MODULE/TGZ
```

- `--no-poll` can be used to stop the command from polling the task, and just return the task ID.

For example:

```
apic --mode portaladmin custom-translation:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/custom_translation_createExport-20210217134637.tgz
```

4. You can run the delete command to cancel any ongoing or recently created import or export tasks. Any temporarily created artifacts will be deleted from the portal filesystem. No custom translations are deleted.
   For example,

   ```
   apic --mode portaladmin custom-translation:delete-export --catalog catalogid/name --org orgid/name --server
   management_server --format json --task_id taskid
   ```

   ```
   apic --mode portaladmin custom-translation:delete-import --catalog catalogid/name --org orgid/name --server
   management_server --format json --task_id taskid
   ```

   - *taskid* is the ID of the import or export task that was created on the queue (required).
   - `--format` is the output format that can be seen if you run the command with debug. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.

   For example:

   ```
   apic --mode portaladmin custom-translation:delete-import --catalog prod --org ibm --server api.productionexample.com  --
   task_id 4hythbptta6z9lyx
   ```

Using the custom-webserver-page commands

You can use the **custom-webserver-page** commands to customize the web server error pages on your Developer Portal service.

The **custom-webserver-page** commands enable you to set, get, and delete custom HTML content for the web server error pages of index, 404, 40x, and 50x. You can embed base64 encoded images, such as .svg and .png, or inline .svg images in your content, but the maximum size of the content of each error page is 8 MB.
Note:

- The custom web server error pages that can be set by using the **custom-webserver-page** commands, are the pages that are returned when the URL of a specific portal site isn't used. For example, if your portal site was https://example.com/myorg/dev, but you went to https://example.com/myorg/deb, then this is when a custom 404 error page is returned. However, if the requested URL matches a portal site, then the web server will use the Drupal error handlers, and will respond according to the Drupal configuration.
- All custom content that you set must conform to the HTML5 specification. If you try to set custom content that doesn't conform to HTML5, it will fail with the following error message:

  ```
  Error: The supplied custom HTML failed validation.
  ```

- Setting and deleting custom web server pages can take several minutes to complete, depending on the size of the content.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

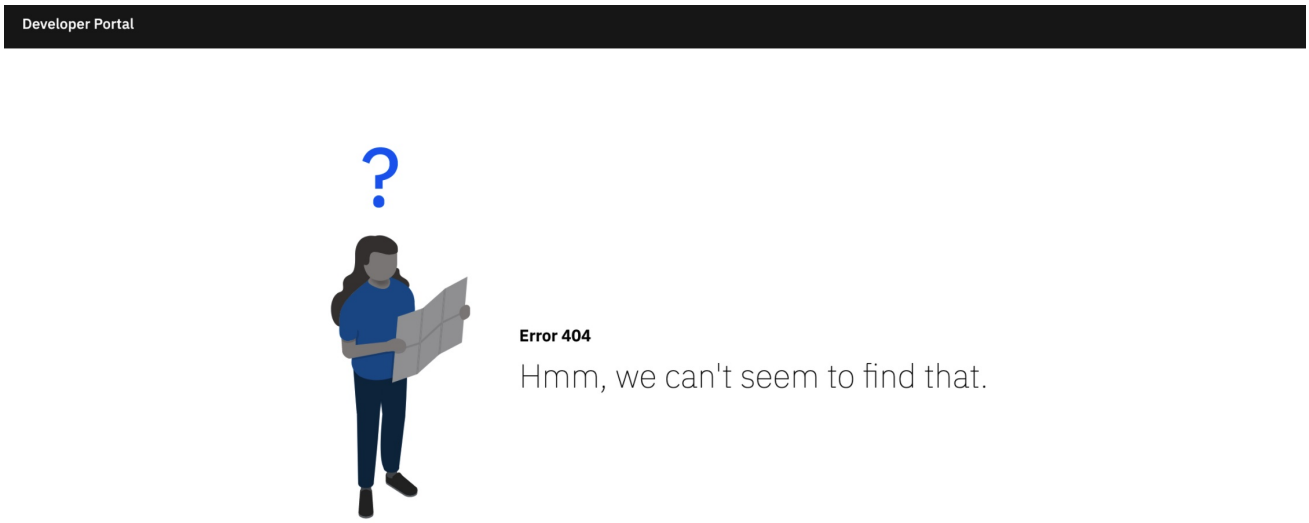
   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Set a custom HTML web server error page on the Developer Portal. The maximum size of the page is 8 MB, and you must ensure that the content conforms to the HTML5 specification, or the **custom-webserver-page:set** command will fail with a validation error.

   ```
   apic --mode portaladmin custom-webserver-page:set --server management_server --portal_service_name portal --page_type
   page_type filename.html
   ```

   - *management_server* is the endpoint URL of the management server (required).
   - *portal* is the name of the portal service (required).
   - *page_type* is the type of web server error page that you want to run the command against (required). Valid values are `index`, `404`, `40x`, or `50x`.
   - *filename* is the name of the HTML file that contains the content for the custom web server error page.

For example, the following screen capture shows a standard 404 web server response:



Then the following **custom-webserver-page:set** command is run:

```
apic --mode portaladmin custom-webserver-page:set --server my.management.server.com --portal_service_name portal --
page_type 404 custom-404.html
Loading File (Large files may take a while)...

Successfully added the custom HTML content for page type 404.
```

The following custom 404 error page is now displayed:

3. Get the custom content of a specific page type and save it to a file named <page_type>-timestamp.html.

   ```
   apic --mode portaladmin custom-webserver-page:get --server management_server --portal_service_name portal --page_type
   page_type
   ```

   For example:

   ```
   apic --mode portaladmin custom-webserver-page:get --server my.management.server.com --portal_service_name portal --
   page_type 404
   Incoming project saved to 404-20211027121830.html
   ```

   If there is no custom content available for the page type, the following error is displayed:

   ```
   apic --mode portaladmin custom-webserver-page:get --server my.management.server.com --portal_service_name portal --
   page_type 50x
   Error: There is currently no custom HTML content for page type 50x.
   ```

4. Delete the custom content of a specific page type. If there is no custom content available for a page type, the error response defaults to the standard web server error page.

   ```
   apic --mode portaladmin custom-webserver-page:delete --server management_server --portal_service_name portal --page_type
   page_type
   ```

   For example:

   ```
   apic --mode portaladmin custom-webserver-page:delete --server my.management.server.com --portal_service_name portal --
   page_type 404
   The custom HTML content for page type 404 has been deleted.
   ```

Using the drupal-config commands

You can use the **drupal-config** commands to list, get the values of, set values, create new, and delete the Drupal configuration objects on your Developer Portal service.

For example, you can use the **drupal-config** commands to disable CSS and JS aggregation to help with twig debug, see Example.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. List all of the available Drupal config for a site.

```
apic --mode portaladmin drupal-config:list --server management_server --catalog catalogid/name --org orgid/name --format
format_type
```

- ***management_server*** is the endpoint URL of the management server (required).
- ***catalogid/name*** is the ID or name of the catalog that the site belongs to (required).
- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
- ***format_type*** is the output format. Can be **json**, **yaml**, **go-template=...**, **go-template-file=...**. Defaults to **yaml**.

For example:

```
apic --mode portaladmin drupal-config:list --server my.management.server.com --org ibm --catalog portal-test --format yaml
admin_toolbar_tools.settings:
  name: admin_toolbar_tools.settings
adminimal_admin_toolbar.settings:
  name: adminimal_admin_toolbar.settings
advagg.settings:
  name: advagg.settings
advagg_css_minify.settings:
  name: advagg_css_minify.settings
advagg_js_minify.settings:
  name: advagg_js_minify.settings
autologout.settings:
  name: autologout.settings
...
```

Note that the example has been reduced as the full response is very large.

3. List a specific Drupal config for a site.

```
apic --mode portaladmin drupal-config:list --server management_server --catalog catalogid/name --org orgid/name --prefix
config_prefix --format format_type
```

- ***config_prefix*** is the prefix of the Drupal config, for example **system**. If omitted, the command returns all config names in the system.

For example:

```
apic --mode portaladmin drupal-config:list --server my.management.server.com --org ibm --catalog portal-test --format yaml
--prefix system.theme
system.theme:
  name: system.theme
system.theme.global:
  name: system.theme.global
```

4. Update a Drupal config key value.

```
apic --mode portaladmin drupal-config:set -server management_server --catalog catalogid/name --org orgid/name  --
config_name config_name --config_key config_key --config_value config_value
```

- ***config_name*** is the name of the Drupal config object, for example **system.site** (required).
- ***config_key*** is the Drupal config key, for example **page.front** (required).
- ***config_value*** is the value to assign to the config key (required).

For example, to set the default theme to **claro**:

```
apic --mode portaladmin drupal-config:set --server my.management.server.com --org ibm --catalog portal-test --config_name
system.theme --config_key default --config_value claro
// Do you want to update default key in system.theme config?: yes.
```

5. Create a new Drupal config key and set the value.

```
apic --mode portaladmin drupal-config:set -server management_server --catalog catalogid/name --org orgid/name  --
config_name config_name --config_key new_config_key --config_value new_config_value
```

For example, to create a new config key and set the value in the **system.site** config object:

```
apic --mode portaladmin drupal-config:set --server my.management.server.com --org ibm --catalog portal-test --config_name
system.site --config_key new_key --config_value new_value
// new_key key does not exist in system.site config. Do you want to create a new config key?: yes.
```

6. Get all of the key values for a Drupal config object.

```
apic --mode portaladmin drupal-config:get --server management_server --catalog catalogid/name --org orgid/name  --format
format_type --config_name config_name
```

For example, to find out what themes are available:

```
apic --mode portaladmin drupal-config:get --server my.management.server.com --org ibm --catalog portal-test --format json
--config_name system.theme
```

```
{
    "admin": "seven",
    "default": "claro",
    "_core": {
        "default_config_hash": "fOjer9hADYYnbCJVZMFZIIM1azTFWyg84ZkFDHfAbUg"
    },
    "defaultplus": "bartisk"
}
```

7. Get the value of a specific key for a Drupal config object.

   ```
   apic --mode portaladmin drupal-config:get --server management_server --catalog catalogid/name --org orgid/name  --format
   format_type --config_name config_name --config_key config_key
   ```

   For example, to find out what the default theme is:

   ```
   apic --mode portaladmin drupal-config:get --server my.management.server.com --org ibm --catalog portal-test --format json
   --config_name system.theme --config_key default
   {
       "system.theme:default": "claro"
   }
   ```

8. Delete a Drupal config object, or a specific config key and its value.

   ```
   apic --mode portaladmin drupal-config:delete --server management_server --catalog catalogid/name --org orgid/name  --
   config_name config_name --config_key config_key
   ```

   - `config_key` is the Drupal config key, for example `page.front` (optional).

   For example, to delete the config key `new_key` and its value:

   ```
   apic --mode portaladmin drupal-config:delete --server my.management.server.com --org ibm --catalog portal-test --
   config_name system.site --config_key new_key
   The config object/value was successfully deleted.
   ```

Example

The following scenario gives an example of how to turn off CSS and JS aggregation to help with twig debug. However, on a production system aggregation should be enabled for performance reasons.

1. Check the settings for performance, which include settings for CSS and JS aggregation:

   ```
   apic --mode portaladmin drupal-config:get --server management_server --catalog catalogid/name --org orgid/name --
   config_name system.performance
   ```

2. Turn off CSS aggregation:

   ```
   apic --mode portaladmin drupal-config:set --server management_server --catalog catalogid/name --org orgid/name --
   config_name system.performance --config_key css.preprocess --config_value 0
   ```

3. Turn off JS aggregation:

   ```
   apic --mode portaladmin drupal-config:set --server management_server --catalog catalogid/name --org orgid/name --
   config_name system.performance --config_key js.preprocess --config_value 0
   ```

4. Then, rebuild the cache:

   ```
   apic --mode portaladmin site:cache-rebuild  --server management_server --catalog catalogid/name --org orgid/name
   ```

When loading the site in a browser, you should now see CSS and JS aggregation is disabled when using development tools for site debug or customization.
Note:

- Disabling aggregation affects site performance, so if the site goes into production remember to turn aggregation back on again.
- Although the settings are shown as `true` or `false`, to set them by using the `drupal-config:set` command, you must apply a value of `1` for `true`, and `0` for `false`.

Using the drupal-state commands

You can use the **drupal-state** commands to store and retrieve information about the state of your Developer Portal system.

Information about the state of your Developer Portal system is stored in the Developer Portal database, and therefore this information is lost if the database is dropped, or the Developer Portal site is re-installed from configuration.

The **drupal-state** commands can be used to set, update, get, or delete a state key value. For example, you can use the **drupal-state** commands to enable and disable maintenance mode for your Developer Portal; for more information, see the scenario How to enable and disable maintenance mode on your Developer Portal.

Warning: Use the **drupal-state** command with caution. This command enables you to modify keys for your Developer Portal site state. Incorrect usage of this command can bring down your Developer Portal, and then require restoring it from a backup.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. Create a new Drupal state key, or update an existing key, and set the value.

```
apic --mode portaladmin drupal-state:set -server management_server --catalog catalogid/name --org orgid/name  --
input_format input_format_type --state_key state_key_name --state_value state_value
```

Where:
- ***management_server*** is the endpoint URL of the management server (required).
- ***catalogid/name*** is the ID or name of the catalog that the site belongs to (required).
- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
- ***input_format_type*** is the input format of the value for the state key. Can be **string**, **integer**, **float**, **boolean**, **json**, or **yaml**. Defaults to **auto**, which means that you can omit this parameter, and the toolkit CLI will decide which format to use.
- ***state_key_name*** is the name of the state key, for example **system.cron_last** (required).
- ***state_value*** is the value to assign to the state key (required).
- **--format** is the output format. Can be **json**, **yaml**, **go-template=...**, **go-template-file=...**. Defaults to **yaml**.

For example, to create a new key called **testKey**, and set the value to **123**:

```
apic --mode portaladmin drupal-state:set -s my.management.server.com -o myorg -c dev-catalog --input_format yaml --
state_key testKey --state_value 123
Successfully set state testKey to the value of 123
```

3. Get the value for a particular Drupal state key.

```
apic --mode portaladmin drupal-state:get --server management_server --catalog catalogid/name --org orgid/name  --format
format_type --state_key state_key_name
```

For example, to get the value of the state key **testKey**:

```
apic --mode portaladmin drupal-state:get -s my.management.server.com -c dev-catalog -o myorg --format yaml --state_key
testKey
testKey: 123
```

4. Delete a specific Drupal state key and its value.

```
apic --mode portaladmin drupal-state:delete --server management_server --catalog catalogid/name --org orgid/name --
state_key state_key_name
```

For example, to delete the state key **testKey** and its value:

```
apic --mode portaladmin drupal-state:delete -s my.management.server.com -c dev-catalog -o myorg --state_key testKey
The key/value was successfully deleted.
```

Related tasks

- Toggling the site in and out of maintenance mode

Using the entity commands

You can use the **entity** commands to get the entity count on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.

For full details of the **apic login** command, see Logging in to a management server.

2. Get the entity count for a site.
   For example,

```
apic --mode portaladmin entity:count --org orgid/name --server management_server --catalog name/id
```

Using the export-entity commands

You can use the **export-entity** commands to manage the export of content entities from your Developer Portal site.

About

The Developer Portal is based on the Drupal content management system. In Drupal, a content entity is an item of content data that is intended to be displayed to site users, such as text, images, and HTML markup. Content entities are grouped into entity types, and most of these entity types are also subdivided into entity subtypes, also known as bundles. The **export-entity** commands enable you to create a predefined list, called an export entity, of all of the content entities that you want to export. You can create multiple export entities, each one containing its own set of assorted entity types. Export entities persist, so you can add content and remove content as required.

If you want to export only one type of content entity, or all of the content entity types, at a time, you can use the **content** commands; see Using the content commands for more information. You also use these commands when you want to import your entity content.

Procedure

1. Log in as Provider org as seen in the following example.

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.

   For full details of the **apic login** command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Create an export entity by using the following **export-entity:create** command. This command creates a container for the entity content that you want to export.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:create --
export_entity_name "export_entity_name"
```

   Where:
   - *management_server* is the endpoint URL of the management server (required).
   - *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
   - *catalogid/name* is the ID or name of the catalog that the site belongs to (required).
   - *export_entity_name* is the name of the export entity that you want to create. Note that this name is not a unique identifier.

   The command returns an ID for the newly created export entity. For example:

```
apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:create --
export_entity_name "Main Content"
[notice] Created new export entity Main Content, id 5
```

   Make a separate note of the ID number that is returned, as you will need this ID for future commands.
3. List all of the export entities that are available for your site by using the following **export-entity:list** command.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:list
```

   The command returns a list of the available export entities, including their ID, and the date and time that they were created. For example:

```
apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:list
-
  id: '5'
  name: 'Main Content'
  created_time: '2023-09-12 15:05:04'
```

4. Add content to an export entity by using the following **export-entity:add-content** command.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:add-content --
export_entity_id export_entity_id --entity_type entity_type_name --entity_ids entity_ids
```

Where:

- *export_entity_id* is the ID of the export entity (required).
- *entity_type_name* is the type of content entity that you want to add to the export entity (required). You can use the `content:list-types` command to find out the type of content entities that are exportable from your site; see Using the content commands.
- *entity_ids* is a comma separated list of the entity IDs that you want to add to the export entity (optional). If you want to add all of the content entities for a particular entity type, you don't need to set any entity IDs.

The following example shows three different types of entity content being added to the export entity `5`:

```
apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:add-content --
export_entity_id 5 --entity_type node --entity_ids 1,2
[notice] Successfully added entity type node - "1, 2" to export entity 5

apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:add-content --
export_entity_id 5 --entity_type block_content --entity_ids 1,2
[notice] Successfully added entity type block_content - "1, 2" to export entity 5

apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:add-content --
export_entity_id 5 --entity_type shortcut --entity_ids 1
[notice] Successfully added entity type shortcut - "1" to export entity 5
```

5. Delete content from an export entity by using the following `export-entity:remove-content` command.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:remove-content
--export_entity_id export_entity_id --entity_type entity_type_name --entity_ids entity_ids
```

Where:

- *export_entity_id* is the ID of the export entity (required).
- *entity_type_name* is the type of content entity that you want to remove (required).
- *entity_ids* is a comma separated list of the entity IDs that you want to remove (optional). If you want to remove all of the content entities for a particular entity type, you don't need to set any entity IDs.

For example, to remove entity ID `1` of the content entity type `shortcut` from the export entity `5`, you can run the following command:

```
apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:remove-content --
export_entity_id 5 --entity_type shortcut --entity_ids 1
[notice] Successfully removed entity type shortcut - "1" from export entity 5
```

6. View the content details of an export entity by using the following `export-entity:get` command. This command returns a list of all of the content entities in a specific export entity ID, and is the entity content that will be exported if the `export-entity:launch` command is run on that ID.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:get --
export_entity_id export_entity_id
```

In the following example, export entity `5` contains four different content entities:

```
apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:get --
export_entity_id 5
- bundle: basic
  id: "1"
  title: No Apps Found [en]
  type: block_content
- bundle: page
  id: "1"
  title: Terms of use
  type: node
- bundle: basic
  id: "2"
  title: No Apis Found [en]
  type: block_content
- bundle: page
  id: "2"
  title: Privacy Policy
  type: node
```

7. Export your content entities by running the following `export-entity:launch` command. This command launches an export entity polling task that creates a .tgz file of all of the entities that are contained in a specific export entity. By default, the command polls the status of the task every 30 seconds until the task is finished, at which point the export file is returned. If the command is run with the `--no-poll` option, the task doesn't return a .tgz file, but just returns the task ID.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:launch --
export_entity_id export_entity_id
```

Where:

- `--no-poll` is an optional flag meaning that the command won't poll the status of the task, but instead just returns the task ID. This task ID can then be used with the `export-entity:get-export` command to return the export file.

Note: The command continues to poll until the maximum polling time of 25 minutes is reached. At which point you can use the commands `export-entity:get_export_status` and `export-entity:get-export` to get the status and, if the task has finished, an artifact.
The `export-entity:launch` command can be run multiple times, and the content of the export entity updated as required by using the `export-entity:add-content` and `export-entity:remove-content` commands.

The following example exports the contents of export entity `5`:

```
apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog export-entity:launch --
export_entity_id 5
201 CREATED - TASK ID: saleo5261k5a2y

Response Code - 202:

Message(s) -
The status of this task is: QUEUED
```

```
Response Code - 200:

Message(s) -
The status of this task is: FINISHED and the artifact can now be streamed

Saving File (Large files may take a while)...
Incoming project saved to export_entity_launchExport-20230912165
```

The command saves the export to your running directory. The export .tgz file includes a root.json file that contains an index of all of the entities that are contained in the .tgz file, as well as a *content_entity_type*.json file for each content entity type exported. The *content_entity_type*.json file contains all of the information needed to be able to import those entities into a different Developer Portal site.

8. If you ran the **export-entity:launch** command with the **--no-poll** option, you can use the following commands to manage your entity export.
   - **export-entity:delete-launch-export**
     Cancels any currently running **export-entity:launch** tasks, and deletes any related artifacts. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:delete-launch-export --task_id task_id
     ```

     Where ***task_id*** is the ID of the export task on the queue.
   - **export-entity:get-launch-export**
     Streams the content of a specific completed **export-entity:launch** task to a .tgz file. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:get-launch-export --task_id task_id
     ```

   - **export-entity:get-launch-export-status**
     Returns the status of a specific **export-entity:launch** task. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name export-entity:get-launch-export-status --task_id task_id
     ```

What to do next

You can import your export entity archive files by using the **content** commands; see Using the content commands for more information.

Related reference

- Using the content commands

Using the factory-reset command

You can use the **factory-reset** command to perform a factory reset of your Developer Portal, which will delete the portal service and all of its associated Developer Portal sites.

Warning: The **factory-reset** command is irreversible. You must ensure that you have backups created before running this command.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
   ```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
   For full details of the **apic login** command, see Logging in to a management server.

2. Output a dry run status of a Developer Portal factory reset:

   ```
   apic --mode portaladmin factory-reset:delete --server management_server --portal_service_endpoint portal_endpoint
   ```

   - ***management_server*** is the endpoint URL of the management server.
   - ***portal_endpoint*** is the URL endpoint of the portal service.

   For example:

   ```
   apic --mode portaladmin factory-reset:delete --server api.stagingexample.com --portal_service_endpoint
   https://api.portal.mystack.com
   ```

3. Perform a factory reset of the Developer Portal, deleting the portal service and all of its associated Developer Portal sites:
   Warning: The **factory-reset** command is irreversible. You must ensure that you have backups created before running this command.

```
apic --mode portaladmin factory-reset:delete --server management_server --portal_service_endpoint portal_endpoint --
execute_reset true
```

- `--execute_reset` must be set to `true` to trigger the Developer Portal reset.

For example:

```
apic --mode portaladmin factory-reset:delete --server api.stagingexample.com --portal_service_endpoint
https://api.portal.mystack.com  --execute_reset true
```

Using the forums commands

You can use the **forums** commands to disable or enable the forums on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Disable the Forum module on your Developer Portal site.
   This command deletes all of the taxonomy terms in the forum vocabulary, and then disables the Forum module.

   ```
   apic --mode portaladmin forums:disable --org orgid/name --server management_server --catalog name/id
   ```

   - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
   - *`management_server`* is the endpoint URL of the management server (required).
   - *`name/id`* is the ID or name of the catalog that the site belongs to (required).

   For example,

   ```
   apic --mode portaladmin forums:disable --org ibm --server api.stagingexample.com --catalog dev
   ```

3. Enable the Forum module on your Developer Portal site.

   ```
   apic --mode portaladmin forums:enable --org orgid/name --server management_server --catalog name/id
   ```

   For example,

   ```
   apic --mode portaladmin forums:enable --org ibm --server api.stagingexample.com --catalog dev
   ```

Using the ip-security-enabled command

You can use the **ip-security-enabled** commands to toggle IP security on your Developer Portal. When IP security is enabled, modules such as the Drupal Perimeter Defence module, or flood control, will block client IP addresses suspected of malicious behavior, as expected. Banned IP addresses can be cleared by using the `security:clear-bans` command. You might want to turn off IP security if you are performing penetration tests, or if you cannot pass through the client IP address from your external load balancer. Note that IP security is enabled by default on the Developer Portal.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For full details of the **apic login** command, see Logging in to a management server.

2. Enable IP security on the Developer Portal:

```
apic --mode portaladmin ip-security-enabled:update --server management_server --portal_service_name portal --enabled true
```

- ***management_server*** is the endpoint URL of the management server.
- ***portal*** is the name of the portal service.
- **--enabled** is set to **true** to enable IP security. Can be set to **false** to disable IP security.

For example:

```
apic --mode portaladmin ip-security-enabled:update --server my.management.server.com --portal_service_name
my_portal_service --enabled true
IP security has been successfully set to true
```

3. Disable IP security on the Developer Portal:

```
apic --mode portaladmin ip-security-enabled:update --server management_server --portal_service_name portal --enabled false
```

Using the maintenance commands

You can use the **maintenance** commands to manage the maintenance operations on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Get the current mode of your maintenance operations.

```
apic --mode portaladmin --server management_server maintenance:status --org orgid/name --catalog catalogid/name
```

- ***mode*** is the toolkit operation mode.
- ***catalogid/name*** is the ID or name of the catalog that the site belongs to (required).
- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
- ***management_server*** is the endpoint URL of the management server (required).

For example,

```
apic --mode portaladmin --server api.stagingexample.com maintenance:status --org ibm --catalog api-connect-catalog-1
```

3. Enable the maintenance mode to make the Developer Portal site inaccessible to everyone apart from an administrator. All other users who enter the site URL will see a maintenance message set by the administrator.

```
apic --mode portaladmin --server management_server maintenance:enable --org orgid/name --catalog catalogid/name
```

4. Disable the maintenance mode to make the Developer Portal site accessible to everyone.

```
apic --mode portaladmin --server management_server maintenance:disable --org orgid/name --catalog catalogid/name
```

5. Rebuild the node access table to prevent users from accessing the nodes to which they do not have access permissions.

```
apic --mode portaladmin --server management_server maintenance:rebuild-node-access --org orgid/name --catalog
catalogid/name
```

6. Rebuild and reindex the search API index to increase the performance and storage space usage.

```
apic --mode portaladmin --server management_server maintenance:search-api-index-rebuild --org orgid/name --catalog
catalogid/name
```

7. Print the search API index status.

```
apic --mode portaladmin --server management_server maintenance:search-api-index-status --org orgid/name --catalog
catalogid/name
```

Using the memcache commands

You can use the **memcache** commands to get, enable, and disable the default caching store operations on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Get the status of all the `memcache enabled` operations.

   ```
   apic --mode portaladmin --server management_server memcache:get --org orgid/name --catalog catalogid/name
   ```

   - *mode* is the toolkit operation mode.
   - *management_server* is the endpoint URL of the management server (required).
   - *catalogid/name* is the ID or name of the catalog that the site belongs to (required).
   - *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).

   For example,

   ```
   apic --mode portaladmin --server api.stagingexample.com memcache:get --org ibm --catalog api-connect-catalog-1
   ```

3. Enable the default caching store operations. This will set Drupal to use the RAM as cache.

   ```
   apic --mode portaladmin --server management_server memcache:enable --org orgid/name --catalog catalogid/name
   ```

4. Disable the default caching store operations. This will set Drupal to use the database as cache.

   ```
   apic --mode portaladmin --server management_server memcache:disable --org orgid/name --catalog catalogid/name
   ```

Using the modules commands

You can use the **modules** commands to list, enable, disable and delete the modules on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. List the modules from a *packagename*.
   For example,

```
apic --mode portaladmin modules:list --org orgid/name --server management_server --catalog name/id --package
packagename1,packagename2
```

3. Enable the *modulename* module. You can upload this module by using the **custom-module:create-import** command. For more information, see Using the custom-module commands.
   For example,

   ```
   apic --mode portaladmin modules:enable --org orgid/name --server management_server --catalog name/id --modules modulename
   ```

   - `management_server` is the endpoint URL of the management server (required).
   - `catalogid/name` is the ID or name of the catalog that the site belongs to (required).
   - `orgid/name` is the ID or name of the provider organization that the catalog belongs to (required).
   - `--package` enables you to filter by project packages. You can use multiple comma separated values.
   - `--status` enables you to filter by extension status. Can be `_ enabled`, `disabled` and/or `'not installed'`. You can use multiple comma separated values.
   - `--custom` enables you to filter your results to only the modules that you have installed on your Developer Portal site.
4. Disable the *modulename* module. If you disable a module, you must also disable all its dependencies.
   For example,

   ```
   apic --mode portaladmin modules:disable --org orgid/name --server management_server --catalog name/id --modules
   modulename,module_lib
   ```

5. Delete the *modulename* module. The module and all its dependencies must be disabled before you can delete them.
   For example,

   ```
   apic --mode portaladmin modules:delete --org orgid/name --server management_server --catalog name/id --modules modulename
   ```

Note that if you want to manage the Forum module, you can use the `forums` commands. For more information, see Using the forums commands.

Using the php-memory commands

You can use the **php-memory** commands to list or update the PHP memory limits on your Developer Portal.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Get the availability zone of the portal service's sites that you want to list:

   ```
   apic availability-zones --org orgid/name --server management_server
   ```

3. List all the portal services in that availability zone:

   ```
   apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
   ```

4. Get the selected portal service's name:

   ```
   apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-
   NAME
   ```

5. List the current PHP memory limits on the Developer Portal platform:

   ```
   apic --mode portaladmin php-memory:list --server management_server --portal_service_name PORTAL-SERVICE-NAME
   ```

   You receive output like this example:

   ```
   Current web memory is set to: 768M
   Current admin memory is set to: 768M
   ```

6. Update the current PHP memory limits on the Developer Portal platform:

   ```
   apic --mode portaladmin php-memory:update --server management_server --portal_service_name PORTAL-SERVICE-NAME --
   memory_value 1024
   ```

   You receive output like this example:

   ```
   Setting php memory limit to 1024M within the database
   Setting php memory limit to 1024M in /var/devportal/storenosync/php.ini
   ```

```
Setting php memory limit to 1024M in /web/local/php_config/php.ini
Done
```

Note: Consider the memory resource limits that are allocated to your Developer Portal pods before you set this value. Setting this value too high can result in the portal pods restarting because the containers request more memory than is allowed by Kubernetes. Setting the value too low can result in the internal portal processes failing because of lack of available memory.

Using the platforms commands

You can use the **platforms** commands to list the platforms on your Developer Portal service.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Get the availability zone of the portal service's platforms that you want to list:

   ```
   apic availability-zones --org orgid/name --server management_server
   ```

3. List all the portal services in that availability zone

   ```
   apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
   ```

4. Get the selected portal service's name

   ```
   apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-NAME
   ```

5. List the platforms of the portal service

   ```
   apic --mode portaladmin platforms:list --server management_server --portal_service_name PORTAL-SERVICE-NAME --format json
   ```

Using the product commands

You can use the **product** commands to get and list the products on your Developer Portal service.

1. Log in as Provider org as seen in the following example.

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Get a list of products from a site.

For example,

```
apic --mode portaladmin product:list --org orgid/name --server management_server --catalog catalogid/name
```

- *management_server* is the endpoint URL of the management server (required).
- *catalogid/name* is the ID or name of the catalog that the site belongs to (required).
- *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
- *format_type* is the output format. Can be **json**, **yaml**, **go-template=...**, **go-template-file=...**. Defaults to **yaml**.

3. Get a product from a site by using the *id* or *name:version*.

   For example,

   ```
   apic --mode portaladmin product:get --org orgid/name --server management_server --catalog catalogid/name id/name:version
   ```

   - *id/name:version* - The ID or name:version of a specific product (required). For example, **id-of-product-called-example-3** or **example:3.0.0**.

4. Get a specific entire product document from the portal of the provided organization and catalog by using the *id* or *name:version*.

   ```
   apic --mode portaladmin product:get-document --org orgid/name --server management_server --catalog catalogid/name --format
   format_type  id/name:version
   ```

   For example,

   ```
   apic --mode portaladmin product:get-document --org ibm --server my.management.server.com --catalog portal-test --format
   yaml  intuiz-product:1.0.0
   ```

5. Add an attachment for your product within your Developer Portal.

   For example,

   ```
   apic --mode portaladmin product:add-attachment -s management_server --org orgid/name --catalog catalogid/name --
   attachment_name attachment.txt --attachment_description "Product documentation" awesome-sleek-soft-chips-product:1.0.0
   ./attachment.txt
   Loading File (Large files may take a while)...

   Attachment successfully added to product awesome-sleek-soft-chips-product:1.0.0.
     This product now has 2 attachments.
   ```

   - *attachment_name* is the name given to the attachment when it is uploaded (required).
   - *attachment_description* is the description of the attachment that is displayed to the users.

6. Set an icon for your product within your Developer Portal.
   For example,

   ```
   apic --mode portaladmin product:set-icon -s management_server --org orgid/name --catalog catalogid/name --icon_description
   "product icon" awesome-sleek-soft-chips-product:1.0.0 ./icon.png
   Loading File (Large files may take a while)...

   Icon successfully set for product awesome-sleek-soft-chips-product:1.0.0
   ```

   - *icon_description* is the icon description to be displayed to users and it is used as an alt text for the image (required).

7. Add a tag (Category) for your product within your Developer Portal.
   For example,

   ```
   apic --mode portaladmin product:add-tag -s management_server--org orgid/name --catalog catalogid/name --tag_name
   top_level_element/next_level_element/lower_level_element awesome-sleek-soft-chips-product:1.0.0
   Successfully set taxonomy tag top_level_element/next_level_element/lower_level_element
     for product api-connect-cassin-llc-awesome-sleek-soft-chips-product:1.0.0
   ```

   - *tag_name* is the tag name. For example, *top_level_element/next_level_element* (required).

Using the queue commands

You can use the **queue** commands to list the queued and locked platform tasks on your Developer Portal site.

1. List the queued and locked platform tasks for a specific Developer Portal site, including Developer Portal creates, restores, upgrades, snapshots, and cron jobs. An empty response means that there are currently no queued tasks for this Developer Portal.
   a. Log in as Provider org as seen in the following example.

      ```
      apic login --server management_server --realm provider/identity_provider --username provider_username --password
      provider_password
      ```

      You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

      ```
      apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
      ```

      For example,

      ```
      apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
      total_results: 2
      results:
        - title: API Manager User Registry
          realm: provider/default-idp-2
        - title: Corporate LDAP user registry
          realm: provider/corporate-ldap
      ```

      The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.

For full details of the **apic login** command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

b. Run the following **queue:get** command:

```
apic --mode portaladmin queue:get --server management_server  --org orgid/name --catalog catalogid/name
```

- ***management_server*** is the endpoint URL of the management server (required).
- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
- ***catalogid/name*** is the ID or name of the catalog that the site belongs to (required).

2. List the queued and locked platform related tasks for all of the Developer Portal sites on a specific portal service, including Developer Portal creates, restores, upgrades, snapshots, and cron jobs. An empty response means that there are currently no queued tasks.
   a. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username cloud_username --password
cloud_password
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.

   b. Run the following **queue:list** command:

```
apic --mode portaladmin queue:list --server management_server  --portal_service_name  portal_service_name
```

- ***portal_service_name*** is the name of the portal service (required).

Related information

- Toolkit CLI reference documentation

Using the role commands

You can use the **role** commands to complete the full lifecycle of Drupal user roles. This includes creating and deleting of roles, as well as adding and removing permissions to the roles in your Developer Portal service.

1. Log in as Provider org as seen in the following example.

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Get the details of a specific Drupal user role and all of the permissions granted to the role.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:get role
```

- ***mode*** is the toolkit operation mode.
- ***management_server*** is the endpoint URL of the management server (required).
- ***catalogid/name*** is the ID or name of the catalog that the site belongs to (required).

- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
- ***role*** is the name or label of the Drupal user role (required).

For example,

```
apic --mode portaladmin -server management-platform-api --org ibm --catalog api-connect-catalog-1 role:get portal_cli_blog
portal_cli_blog:
label: 'Portal CLI Blog'
perms:
  - 'access content'
  - 'access shortcuts'
```

The command returns the Drupal user role under the **portal_cli_blog** label as well as the permissions granted to the role.

3. List all of the Drupal user roles.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:list
```

List the Drupal user roles based on user permissions assigned to the role.

For example,

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:list --
filter_by_permission=role_permission
```

- ***--filter_by_permission*** flag is used to filter the list based on specific permission (optional).
- ***role_permission*** is the permissions granted to a specific role.

List the Drupal user roles based on a specific role.
For example,

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:list --role=role
```

- ***--role*** flag is used to filter the list based on specific role (optional).

4. Create a new Drupal user role.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:create --machine_name
machine_name --human_readable_name human_readable_name
```

Note: The command must include a *machine_name* and a *human_readable_name*.

- The *machine_name* is used by Drupal to refer to the role and must contain only lowercase letters, numbers, and underscores.
- The *human_readable_name* is displayed on the UI and can contain other characters such as spaces.

For example,

```
apic --mode portaladmin --server management-platform-api --org ibm --catalog api-connect-catalog-1 role:create --
machine_name "portal_cli_blog" --human_readable_name "Portal CLI Blog"
```

5. Delete an unwanted Drupal user role.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:delete role
```

For example,

```
apic --mode portaladmin --server management-platform-api --org ibm --catalog api-connect-catalog-1 role:delete
portal_cli_blog
```

If you try to delete a role that does not exist, you will get an error indicating that the specific user role doses not exist.
For example,

```
  - [error]  Unable to load the user_role: no_role
```

6. Add permissions to a Drupal user role using the **permissions** flag. You can add multiple permissions to a role using a comma separated list within a single command call.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:add-permission role --
permissions=role_permissions
```

- ***role_permissions*** is the permissions granted to a specific role (required).

For example,

```
apic --mode portaladmin --server management-platform-api --org ibm  --catalog api-connect-catalog-1 role:add-permission
portal_cli_blog --permissions="access comments,access content,access shortcuts"
```

If you try to add permissions to a role that does not exist, you will get an error indicating that the permission is fake.
For example,

```
- [error]  Permission(s) not found: fake permission
```

7. Remove unwanted permissions from a Drupal user role using the **permissions** flag. You can delete multiple permissions from a role using a comma separated list within a single command call.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name role:remove-permission role -
-permissions=role_permissions
```

For example,

```
apic --mode portaladmin --server management-platform-api --org ibm --catalog api-connect-catalog-1 role:remove-permission
portal_cli_blog --permissions="access comments"
```

If you try to remove permissions from a role that does not exist, you will get an error indicating that the permission does not exist.
For example,

```
 - [error]  Permission(s) not found: perm not on role
```

Using the security command

You can use the **security** command to clear all of the banned user/IP addresses on a Developer Portal site.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Clear all of the user and IP addresses that are currently banned on a particular portal site:

   ```
   apic --mode portaladmin security:clear-bans --server management_server --catalog catalogid/name --org orgid/name
   ```

   - *`management_server`* is the endpoint URL of the management server.
   - *`catalogid/name`* is the ID or name of the catalog that the site belongs to.
   - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to.

   For example:

   ```
   apic --mode portaladmin security:clear-bans --server my.management.server.com --catalog portal-test --org ibm
   [notice] All bans cleared.
   ```

Note: You can also manage banned IP addresses by using the Developer Portal UI. For more information, see Managing banned IP addresses.

Using the service command

You can use the **service** command to list the Developer Portal service from the Developer Portal database.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Get the availability zone of the portal service's sites that you want to list.

   ```
   apic availability-zones --org orgid/name --server management_server
   ```

   - `apic service:list` - List the Portal service currently installed.
   - `-s, --server` *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry.
   - `--org` *orgid*
   - `--catalog` *catalog id*.
   - `--debug`. If you need debug information.

3. List the installed Developer Portal service.

   ```
   apic --mode portaladmin service:list -s management_server --portal_service_name PORTAL-SERVICE-NAME --format json
   ```

Using the service-ip-allowlist commands

You can use the **service-ip-allowlist** commands to add, remove, and list the IP addresses on your Developer Portal `allowlist`. IP addresses that are on the `allowlist` are exempt from being blocked by Developer Portal security checks, for example, load balancer and proxy IPs.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Add one or more IP addresses to the `allowlist`:

   ```
   apic --mode portaladmin service-ip-allowlist:add --server management_server --portal_service_name portal --ips
   "list_of_ips"
   ```

   - *`management_server`* is the endpoint URL of the management server.
   - *`portal`* is the name of the portal service.
   - *`list_of_ips`* is a comma separated list of the IP addresses that you want to add to the `allowlist`.

   For example:

   ```
   apic --mode portaladmin service-ip-allowlist:add --server my.management.server.com --portal_service_name my_portal_service
   --ips "123.456.34.56,123.456.46.67"
   Successfully added IP: 123.456.34.56.
   Successfully added IP: 123.456.46.67.
   ```

3. Delete all of the IP addresses that are currently on the `allowlist`:

   ```
   apic --mode portaladmin service-ip-allowlist:delete --server management_server --portal_service_name portal
   ```

4. List all of the IP addresses that are currently on the `allowlist`:

   ```
   apic --mode portaladmin service-ip-allowlist:list --server management_server --portal_service_name portal
   ```

5. Remove one or more IP addresses from the `allowlist`:

   ```
   apic --mode portaladmin service-ip-allowlist:remove --server management_server --portal_service_name portal --ips
   "list_of_ips"
   ```

Using the site commands

You can use the **site** commands to check the site on your Developer Portal service, and to export and import an entire site configuration.

About

You can use the **site** commands to check the health of a portal site, rebuild the cache of a site, and display the login link for an admin account of a site. You can also use them to export the configuration settings for an entire Developer Portal site, and import those settings into another site. For example, you could use the export and import commands to replicate the configuration of a test site into a production site.
Important: If you want to import a site export configuration file, the export file must have been created on the same version of API Connect as the version that you want to import to.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
   ```

```
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Check the site on your portal service. This command checks the file system, database, and API Manager on your portal site, which might identify platform-related problems on your portal site.

```
apic --mode portaladmin site:check  --server management_server --catalog catalogid/name --org orgid/name --format
format_type
```

   - *management_server* is the endpoint URL of the management server (required).
   - *catalogid/name* is the ID or name of the catalog that the site belongs to (required).
   - *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
   - *format_type* is the output format. Can be **json**, **yaml**, **go-template=...**, **go-template-file=...**. Defaults to **yaml**.
3. Rebuild the cache of a specific portal site.

```
apic --mode portaladmin site:cache-rebuild  --server management_server --catalog catalogid/name --org orgid/name
```

   For example:

```
apic --mode portaladmin site:cache-rebuild --server management_server --org ibm --catalog portal-test
[success] Cache rebuild complete.
```

4. Display the state of a portal site associated with a particular organization and catalog. This command is useful as a general health check of the site.

```
apic --mode portaladmin site:state --server management_server --catalog catalogid/name --org orgid/name --format
format_type
```

```
apic --mode portaladmin site:state --server my.management.server.com --org ibm --catalog portal-test --format json
{
    "alias": "ibm.portal-test.my.management.server.com",
    "check_state": "OK: 200",
    "content_refresh_required": false,
    "known_to_apim": 1,
    "platform": "platform_devportal_9_x_10_99_99_99_20210922_2000",
    "snapshot_first_requested": "0000-00-00 00:00:00",
    "snapshots_failed_processing_since_last_success": 0,
    "snapshots_requested_since_last_received": 0,
    "state": "INSTALLED",
    "subscribed_to_webhooks": true,
    "url": "my.management.server.com/ibm/portal-test",
    "uuid": "cc0ad766-e372-4988-9d45-744eb8d381de.1cd9dc41-b08d-xyz"
}
```

5. Log in to your Developer Portal admin with a link. This command displays a one time login link for the admin account for your Developer Portal site that is specified by the catalog and organization.

```
 apic --mode portaladmin site:login-link  --server management_server --org ibm --catalog portal-test
sample output:
https://my.portal.server.com/ibm/portal-test/user/reset/1/12345678901/ABCde1f2gH3ijKL-
4M_NOPqrs5TU6VWxy7ZABCDEFg7h8/new/login
```

6. Export your entire site configuration by using the following **site:create-export** command. This command creates an export task that returns a .tgz file containing the site configuration. By default, the command polls the status of the task every 10 seconds until the task is finished, at which point the export file is returned. Note that exporting all of your site configuration can take a long time to complete.

```
apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name site:create-export
```

   Where:
   - **--no-poll** is an optional flag meaning that the command won't poll the status of the task, but instead just returns the task ID. This task ID can then be used with the **site:get-export** command to return the export file.

   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **site:get_export_status** and **site:get-export** to get the status and, if the task has finished, an artifact.
   For example:

```
apic --mode portaladmin --server my_management_server --org my_org --catalog my_catalog site:create-export
201 CREATED - Task ID: vfg6b8utjtw51

Response Code - 202:

Message(s) -
The status of this task is: QUEUED

Response Code - 202:

Message(s) -
The status of this task is: RUNNING

Response Code - 202:

Message(s) -
The status of this task is: RUNNING

Response Code - 200:
```

```
Message(s) -
The status of this task is: FINISHED and the artifact can now be streamed

Saving File (Large files may take a while)...
Incoming project saved to site_createExport-20231013154023.tgz
```

The command saves the export file to your running directory. The export .tgz file includes a site-content.tgz file, and a site-config.tgz file. The export file will also include a site-custom-themes.tgz, or a site-custom-modules.tgz file, or both, depending on whether the site contains any custom themes or custom modules.

7. If you ran the **site:create-export** command with the **--no-poll** option, you can use the following commands to manage your site export.
   - **site:delete-export**
     Cancels any currently running **site:create-export** tasks, and deletes any related artifacts. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name site:delete-export --
     task_id task_id
     ```

     Where ***task_id*** is the ID of the export task on the queue.
   - **site:get-export**
     Streams the content of a specific completed export task to a .tgz file. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name site:get-export --
     task_id task_id
     ```

   - **site:get-export-status**
     Returns the status of a specific export task. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name site:get-export-status -
     -task_id task_id
     ```

8. Import your site configuration by using the **site:create-import** command. This command launches an import polling task that polls the status of the task every 10 seconds until the task is finished, at which point a summary of the import is returned. If the command is run with the **--no-poll** option, the task doesn't return the status of the task, but just returns the task ID.
   Important:
   - If you want to import a site export configuration file, the export file must have been created on the same version of API Connect as the version that you want to import to.
   - The **site:create-import** command changes taxonomy term IDs. This can affect configurations that reference specific IDs. Since the IDs are not preserved as part of import or export, it is necessary to review and adjust these configurations after the import to ensure they work correctly.

   ```
   apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name site:create-import
   export_file_name
   ```

   Where:
   - ***export_file_name*** is the name of the export file that you want to import. You can import .tgz files that were created by using the **site:create-export** command.
   - **--no-poll** is an optional flag meaning that the command won't poll the status of the task, but instead just returns the task ID. This task ID can then be used with the **site:get-import-status** command to get the status of the task.

   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **site:get-import-status** to get the status of the task.
   In the following example, the export file from Step 6 is imported into a production Developer Portal site on a different server:

```
apic --mode portaladmin --server my_management_server2 --org my_prod_org --catalog my_prod_catalog site:create-import
site_createExport-20231013154023.tgz
Loading File (Large files may take a while)...

201 CREATED - Task ID: 1z8e9zthfkhwdxh2

Response Code - 202:

2023-10-11 10:52:38: CLI task (site:import) completed successfully.
```

The message section provides detailed information about the import as the configuration is being imported.

9. If you ran the `site:create-import` command with the `--no-poll` option, you can use the following commands to manage your content import.
   - `site:delete-import`
     Cancels any currently running `site:create-import` tasks, and deletes any related artifacts. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name site:delete-import --
     task_id task_id
     ```

     Where *`task_id`* is the ID of the import task on the queue.
   - `site:get-import-status`
     Returns the status of a specific import task. For example:

     ```
     apic --mode portaladmin --server management_server --org orgid/name --catalog catalogid/name site:get-import-status -
     -task_id task_id
     ```

Using the site-config commands

You can use the **site-config** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username cloud_username --password
   cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. Export your site configs.
The **site-config:create-export** command creates an export task against the portal of the specified **catalog** and **org**. The command then polls the status of the task until it has **FINISHED** and the artifacts are streamed back.
Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **site-config:get-export-status** and **site-config:get-export** to get the status and potentially an artifact.

```
apic --mode portaladmin site-config:create-export --catalog name/id --org orgid/name --server management_server
```

- The site config .tgz is saved to the directory in which you ran the command.
- The saved .tgz has the format **site_config_createExport-*20200217134637*.tgz**.
- You can save your exports into your change control management system.

For example,

```
apic --mode portaladmin site-config:create-export --catalog dev --org ibm --server api.stagingexample.com
```

3. Import your site configs.
The **site-config:create-import** command uses the supplied .tgz file to import the site configs into the portal of the specified **catalog** and **org**. The command then polls the status of the task until the task has either **FINISHED** successfully, or failed because of an error.
Note: The higher level folders of the archive can contain only these characters, a-z and 0-9.
Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **site-config:get-import-status** to get the status of the import.

```
apic --mode portaladmin site-config:create-import --catalog name/id --org orgid/name --server management_server
/PATH/TO/SITE_CONFIG/TGZ
```

For example,

```
apic --mode portaladmin site-config:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/site_config_createExport-20200217134637.tgz
```

4. You can run the delete command to cancel any ongoing or recently created import or export tasks. Any temporarily created artifacts will be deleted from the portal filesystem.
For example,

```
apic --mode portaladmin site-config:delete-export --catalog name/id --org orgid/name --server management_server --format
json --task_id string
```

```
apic --mode portaladmin site-config:delete-import --catalog name/id --org orgid/name --server management_server --format
json --task_id string
```

Using the sites commands

You can use the **sites** commands to check and list the sites on your Developer Portal service. You can also reset the portal upgrade attempt counter.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For full details of the **apic login** command, see Logging in to a management server.

2. Get the availability zone of the portal service's sites that you want to list.

```
apic availability-zones --org orgid/name --server management_server
```

3. List all the portal services in that availability zone.

```
apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
```

4. Get the selected portal service's name.

```
apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-NAME
```

5. Check the sites on your portal service. This command checks the file system, database, and API Manager on all your portal sites, which might identify platform-related problems on one or more of your portal sites.

```
apic --mode portaladmin sites:check --server management_server --portal_service_name PORTAL-SERVICE-NAME --format yaml
```

6. List the sites of the portal service.

```
apic --mode portaladmin sites:list --server management_server --portal_service_name PORTAL-SERVICE-NAME --format json
```

7. Reset the portal upgrade attempts. The following command resets the upgrade attempt counter within the portal, so that failed upgrades can be retried.

```
apic --mode portaladmin sites:reset-upgrade-attempts --server management_server --portal_service_name PORTAL-SERVICE-NAME
```

Using the themes commands

You can use the **themes** commands to list, enable, disable, delete, and set the default themes on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. List the themes from a *packagename*.
For example,

```
apic --mode portaladmin themes:list --org orgid/name --server management_server --catalog catalogid/name --package packagename1,packagename2
```

- *management_server* is the endpoint URL of the management server (required).
- *catalogid/name* is the ID or name of the catalog that the site belongs to (required).
- *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
- `--package` enables you to filter by project packages. You can use multiple comma separated values.
- `--status` enables you to filter by extension status. Can be `enabled`, `disabled` and/or `'not installed'`. You can use multiple comma separated values.
- `--custom` enables you to filter your results to only the themes that you have installed on your Developer Portal site.

3. Enable the *themename* theme. You can upload this theme by using the **custom-theme:create-import** command. For more information, see Using the custom-theme commands.
For example,

```
apic --mode portaladmin themes:enable --org orgid/name --server management_server --catalog catalogid/name --themes themename
```

- `--themes` is the name of the theme, and can be multiple comma separated values (required).

4. Disable the *themename* theme.
For example,

```
apic --mode portaladmin themes:disable --org orgid/name --server management_server --catalog catalogid/name --themes themename,theme_lib
```

5. Delete the *themename* theme. The theme and all its dependencies must be disabled before you can delete them.
For example,

```
apic --mode portaladmin themes:delete --org orgid/name --server management_server --catalog catalogid/name --themes themename
```

6. Set the *themename* theme to be the default theme. The theme must exist and be enabled for it to be set as a default theme.
For example,

```
apic --mode portaladmin themes:set-default --org orgid/name --server management_server --catalog catalogid/name themename
```

- *themename* is the name of the theme to set as default.

Using the twig commands

You can use the **twig** commands to enable, disable, and check the state of twig debugging on a specific site on your Developer Portal service.

Note: Twig debugging should not be left enabled on production sites, as it causes performance issues, and can affect the caching on the site.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Enable twig debugging for a portal site.

   ```
   apic --mode portaladmin twig:debug-enable --server management_server --org orgid/name --catalog catalogid/name
   ```

   - `management_server` is the endpoint URL of the management server (required).
   - `orgid/name` is the ID or name of the provider organization that the catalog belongs to (required).
   - `catalogid/name` is the ID or name of the catalog that the site belongs to (required).

   For example:

   ```
   apic --mode portaladmin twig:debug-enable --server my.management.server.com --org ibm --catalog portal-test
   Setting twig debug to true for site my.management.server.com/ibm/portal-test.
   Rebuilding cache for my.management.server.com/ibm/portal-test so twig debug changes can take affect.
   ```

3. Disable twig debugging for a portal site.

   ```
   apic --mode portaladmin twig:debug-disable --server management_server --org orgid/name --catalog catalogid/name
   ```

   For example:

   ```
   apic --mode portaladmin twig:debug-disable --server my.management.server.com --org ibm --catalog portal-test
   Setting twig debug to false for site my.management.server.com/ibm/portal-test.
   Rebuilding cache for my.management.server.com/ibm/portal-test so twig debug changes can take affect.
   ```

4. Get the current state of twig debugging for a specific site.

   ```
   apic --mode portaladmin twig:debug-status --server management_server --org orgid/name --catalog catalogid/name
   ```

   For example:

   ```
   apic --mode portaladmin twig:debug-status --server my.management.server.com --org ibm --catalog portal-test
   The current state of twig debugging is true for my.management.server.com/ibm/portal-test.
   ```

Using the user commands

You can use the **user** commands to complete some Drupal user management tasks on your Developer Portal, such as adding and removing roles, blocking and unblocking users, and retrieving user information.

About

In the Developer Portal, user management tasks can be completed by using the Developer Portal UI (see People), or by using the toolkit CLI as described in the following instructions. You can use these toolkit CLI commands to help you facilitate the user management process. For example, you could integrate these commands into your CI/CD processes, to find out information about inactive users that need to be notified of account deletion.

Procedure

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

2. Retrieve information about your Developer Portal users by using the **user:information** command. Due to the large number of users that might exist in your Developer Portal site, this command includes a default pagination limit of 50 users, with an offset of 0, but these defaults can be changed by using the optional flags. You can also use the optional flags to filter what user information is returned.

   ```
   apic --mode portaladmin user:information --server management_server --org orgid/name --catalog catalogid/name
   ```

   Where:
   - *`management_server`* is the endpoint URL of the management server (required).
   - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
   - *`catalogid/name`* is the ID or name of the catalog that the site belongs to (required).

   For example:

   ```
   apic --mode portaladmin user:information --server my.management.server.com --org ibm --catalog portal-test
   total: 2
   offset: 0
   limit: 2
   users:
     - uid: '9'
       name: 'portal1'
       mail: 'corg-email+1@ibm.com'
       roles:
         - 'authenticated'
       status: 'active'
       apic_state: 'enabled'
       last_login: '01/11/2024 12:25:40'
       user_registry: '/consumer-api/user-registries/349aa966-a081-4f10-a104-084c353bd08e (portal-ci Catalog 1 Catalog User
   Registry)'
       consumer_orgs:
         - '/consumer-api/orgs/d22714f4-89e0-48a2-b5a3-94e7f1043eaf (portal-ci Grant - Stokes - Practical Rustic Metal Chair
   Consumer Organization)'
         - '/consumer-api/orgs/b6251379-5b43-433f-a64e-c93cdae6e085 (portal-ci Krajcik, Jacobson and Kihn - Tasty Sleek Metal
   Mouse Consumer Organization)'
     - uid: '10'
       name: 'portal2'
       mail: 'corg-email+2@ibm.com'
       roles:
         - 'authenticated'
       status: 'active'
       apic_state: 'enabled'
       last_login: '01/01/1970 00:00:00'
       user_registry: '/consumer-api/user-registries/349aa966-a081-4f10-a104-084c353bd08e (portal-ci Catalog 1 Catalog User
   Registry)'
       consumer_orgs:
         - '/consumer-api/orgs/d22714f4-89e0-48a2-b5a3-94e7f1043eaf (portal-ci Grant - Stokes - Practical Rustic Metal Chair
   Consumer Organization)'
         - '/consumer-api/orgs/b6251379-5b43-433f-a64e-c93cdae6e085 (portal-ci Krajcik, Jacobson and Kihn - Tasty Sleek Metal
   Mouse Consumer Organization)'
   ```

   The following user information is returned by default:
   - `uid`- The unique Drupal ID that identifies the user entity.
   - `name` - The name of the user.
   - `mail` - The email address of the user.
   - `roles` - The current active Drupal user roles that the user has assigned to them.
   - `status` - The Drupal status of the user. Valid values are `active` or `blocked`.
   - `apic_state` - The current status of the user account. Valid values are:
     - `enabled` - The account is activated.
     - `pending` - The account is created, but not activated.
     - `pending_approval` - The account is created, but is waiting for approval before it can be activated.
   - `last_login` - The last time the user logged into the Developer Portal UI. If the user hasn't logged into the UI since creating their account, the time defaults to `01/01/1970 00:00:00`, which is the start of UNIX time.
   - `user_registry` - The user registry that the account is in. The entry contains both its unique identifier, and its human readable name.
   - `consumer_orgs` - A list of the consumer organizations that the user is in. The list contains both the unique identifier, and the human readable name, of the organizations.

   You can use the following optional command flags to filter what user information is returned, and control the pagination:
   - `--apic-state` - A comma-separated list of the user account states (string).
   - `--consumer-org` - A comma-separated list of consumer organization URLs (string). The users that are returned can be in one or more of the organizations listed, and you can find the consumer organization URLs by using the **consumer-org:list** command.

- `--format` - The output format of the return (string). Valid values are `json`, `yaml`, `octet-stream`, `go-template=template_name`, or `go-template-file=file_name`. Defaults to `yaml`.
- `--limit` - Limit the number of user results returned (int32). Default is 50 user results.
- `--login-after` - Filter the return to those users who last logged in after the provided date (string). The date must be in the format of `MM-DD-YYY` or `MM-DD-YY HH:MM:SS`.
- `--login-before` - Filter the return to those users who last logged in before the provided date (string). The date must be in the format of `MM-DD-YYY` or `MM-DD-YY HH:MM:SS`.
- `--mail` - A comma-separated list of user email addresses (string).
- `--names` - A comma-separated list of user names (string).
- `--offset` - Offset the user results that are returned (int32). For example, if there are 100 users in your Developer Portal site, and you want to return the user information for users 51 to 100, you can set the `--offset` option to `50`.
- `--role` - A comma-separated list of Drupal user roles (string).
- `--status` - The Drupal status of the user. Valid values are `'active'` or `'blocked'`.
- `--uid` - A comma-separated list of unique Drupal user IDs.

3. Add one or more roles to one or more specified user accounts. You must provide one or more of the email address, user name, or unique Drupal ID of the user accounts that you want to update.

   ```
   apic --mode portaladmin user:add-role --server management_server --org orgid/name --catalog catalogid/name --role role_name --names user_names
   ```

   Where:
   - *`role_name`* is a comma-separated list of the name of the Drupal user roles that you want to add (required). Note that the role must already exist in the Developer Portal.
   - `--names` is a comma-separated list of user names.
   - `--mail` is a comma-separated list of user email addresses.
   - `--uid` is comma-separated list of unique Drupal IDs of users.

   For example:

   ```
   apic --mode portaladmin user:add-role --server my.management.server.com --org ibm --catalog portal-test --role administrator --names portal1
   [success] Added administrator role to portal1
   ```

4. Remove one or more roles from one or more specified user accounts. You must provide one or more of the email address, user name, or unique Drupal ID of the user accounts that you want to update.

   ```
   apic --mode portaladmin user:remove-role --server management_server --org orgid/name --catalog catalogid/name --role role_name --names user_names
   ```

   Where:
   - *`role_name`* is a comma-separated list of the name of the Drupal user roles that you want to remove (required).
   - `--names` is a comma-separated list of user names.
   - `--mail` is a comma-separated list of user email addresses.
   - `--uid` is comma-separated list of unique Drupal IDs of users.

   For example:

   ```
   apic --mode portaladmin user:remove-role --server my.management.server.com --org ibm --catalog portal-test --role administrator --names portal1
   [success] Removed administrator role from portal1
   ```

5. Block one or more Developer Portal users. You must provide the names of the users that you want to block.

   ```
   apic --mode portaladmin user:block --server management_server --org orgid/name --catalog catalogid/name --names user_names
   ```

   Where:
   - `--names` is a comma-separated list of user names.

   For example:

   ```
   apic --mode portaladmin user:block --server my.management.server.com --org ibm --catalog portal-test --names portal1
   [success] Blocked user(s): portal1
   ```

   When a blocked user tries to log in to their Developer Portal account, an error message is displayed indicating that they are unable to sign in.

6. Unblock one or more Developer Portal users. You must provide the names of the users that you want to unblock.

   ```
   apic --mode portaladmin user:unblock --server management_server --org orgid/name --catalog catalogid/name --names user_names
   ```

   Where:
   - `--names` is a comma-separated list of user names.

   For example:

   ```
   apic --mode portaladmin user:unblock --server my.management.server.com --org ibm --catalog portal-test --names portal1
   [success] Unblocked user(s): portal1
   ```

Scenarios that use the Portal CLI

Here are some scenarios of how you can use the Portal commands in the toolkit CLI to accomplish tasks that are more complex to complete, or not possible in the Developer Portal UI.

- **Exporting and importing custom themes and site configuration**
  You can use the portal commands in the toolkit CLI to replicate changes from one Developer Portal instance to another. You might want to use these commands to copy your themes or a configuration change, from a staging environment to a production environment.
- **How to enable and disable maintenance mode on your Developer Portal**
  You can use the Portal commands in the toolkit CLI to enable and disable maintenance mode on your Developer Portal site.

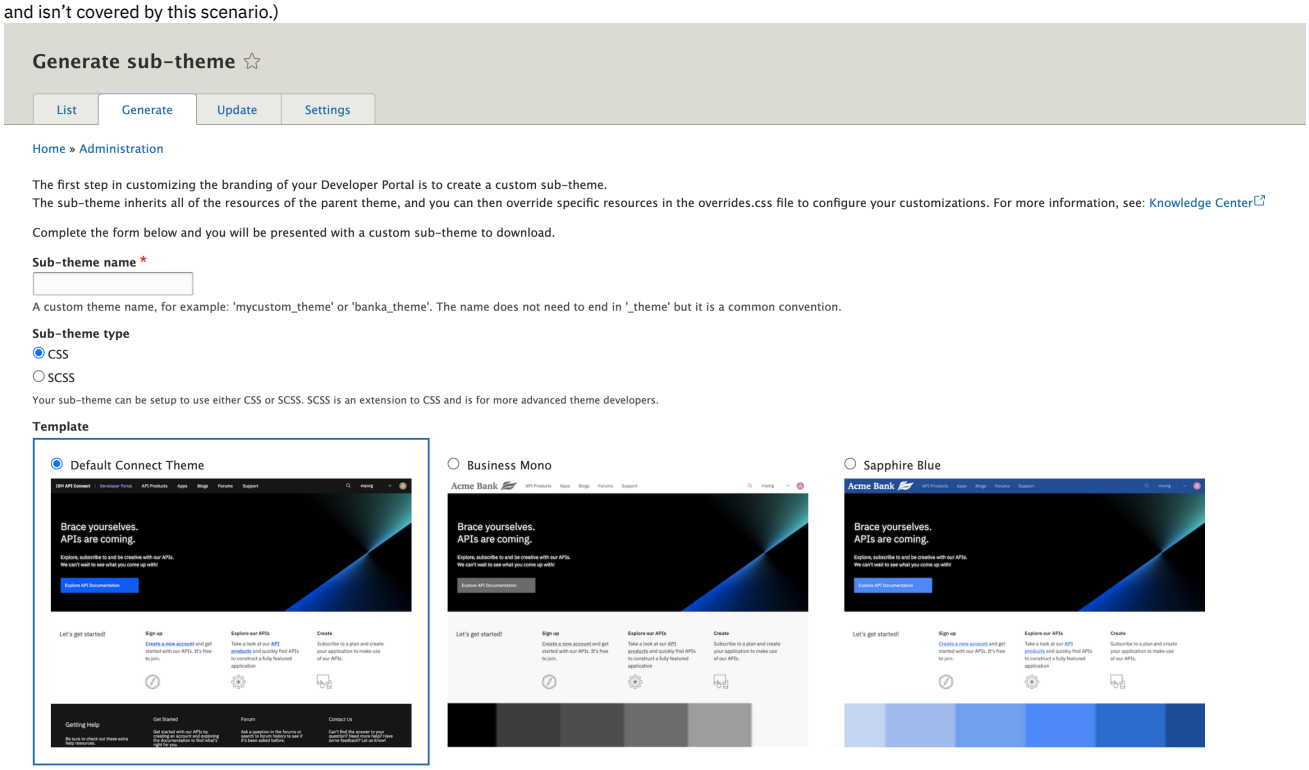
Exporting and importing custom themes and site configuration

You can use the portal commands in the toolkit CLI to replicate changes from one Developer Portal instance to another. You might want to use these commands to copy your themes or a configuration change, from a staging environment to a production environment.

Before you begin

To complete this scenario, you must have a staging Developer Portal and a production Developer Portal enabled. You must have administrator access, and the permission `settings:manage`, to both to complete this scenario. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this scenario



In this scenario, on your staging Developer Portal, you create a theme and make some configuration changes. Then, you use the toolkit CLI to replicate the changes on your production Developer Portal.

This scenario takes you through the following steps:

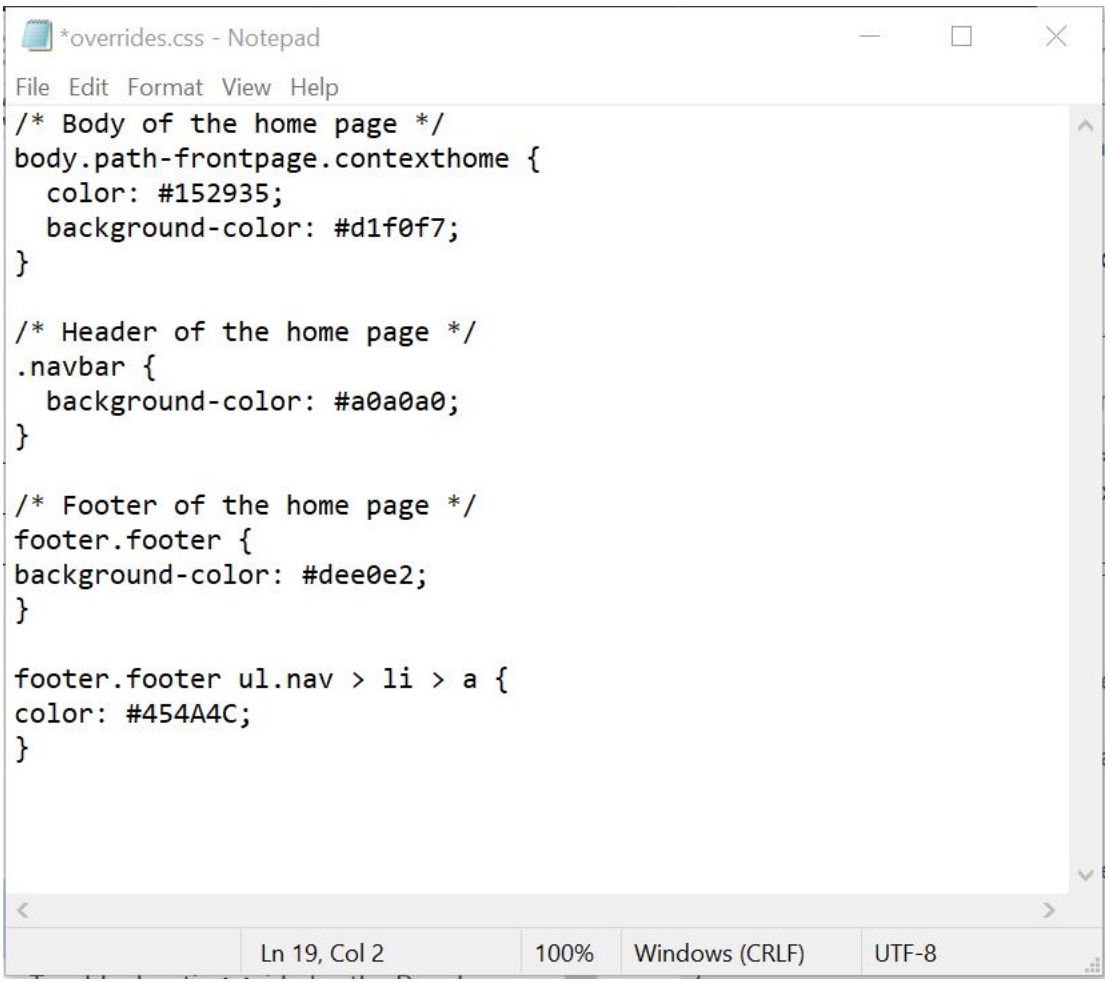
1. Create a custom theme on the staging Developer Portal.
2. Add a field to an application content type to change the `site-config` on the staging Developer Portal.
3. Use the `cli` to export the custom themes and `site-config` on the staging Developer Portal.
4. Use the `cli` to import the custom themes and `site-config` on the production Developer Portal.

Create a custom theme on the staging Developer Portal

1. Log in to your staging Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Appearance > Generate sub-theme. The `Generate sub-theme` window is displayed.
4. Enter a Sub-theme name, and select CSS for the Sub-theme type. (If you prefer, you can select SCSS, but this extension to CSS is for advanced theme developers, and isn't covered by this scenario.)

5. Select the Default template to base your `sub-theme` on. You can create a `sub-theme` based on a color template. However, for this scenario you use the default connect_theme template.
6. Click Generate.
7. Download the generated `sub-theme` to a location of your choice, and extract all the files from the .zip file.

On your computer, navigate to the files that you extracted. Find the overrides.css file in here banka_theme/banka_theme/css/overrides.css. You can now customize the overrides.css file.

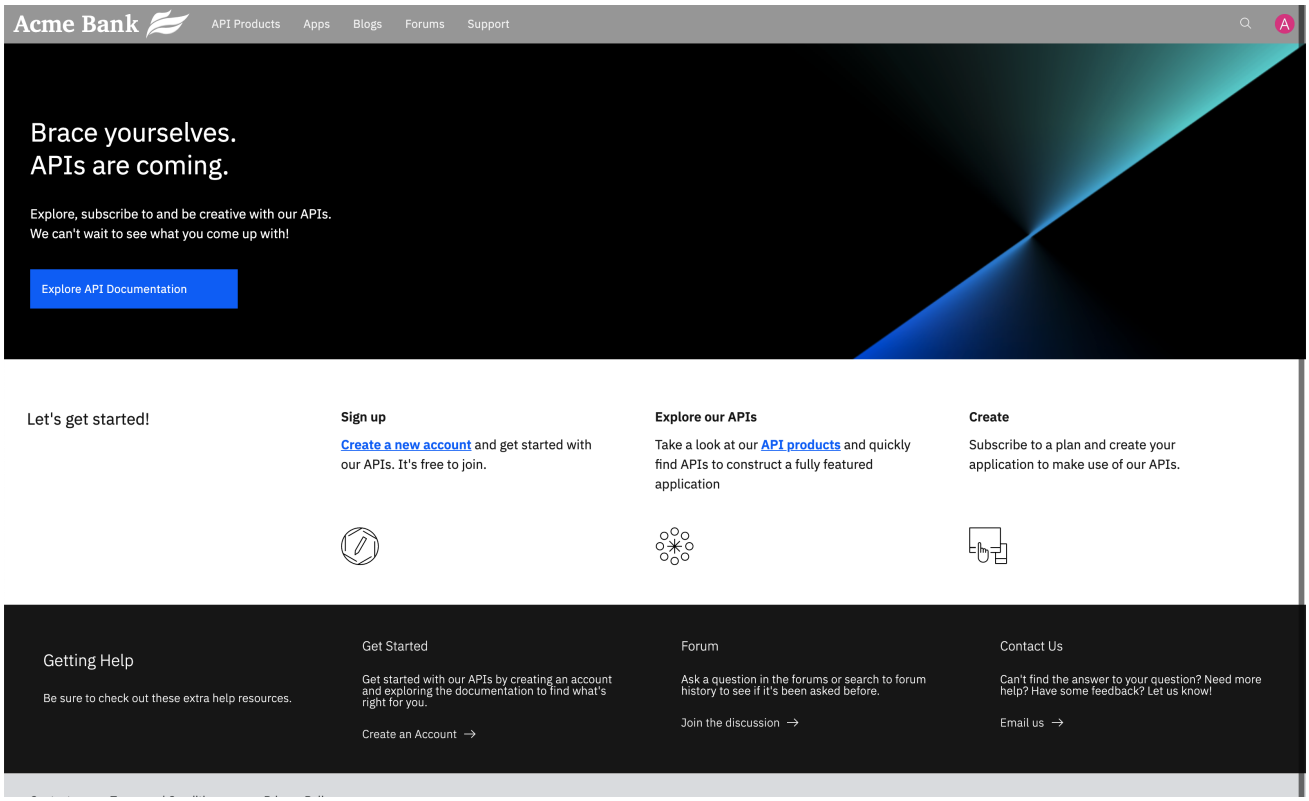


1. Open the overrides.css file in your chosen editor.
2. Customize your `sub-theme` by entering the following elements into the overrides.css file:

```
/* Body of the home page */
body.path-frontpage.contexthome {
  color: #152935;
  background-color: #d1f0f7;
}

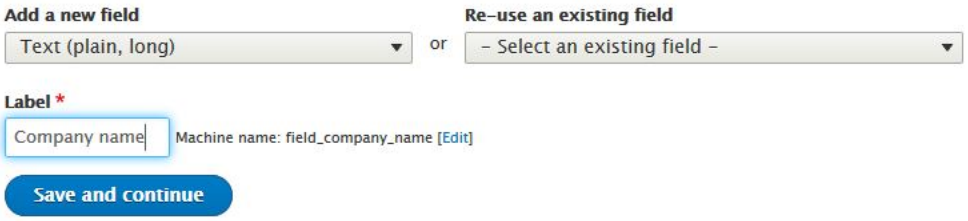
/* Header of the home page */
.navbar {
  background-color: #a0a0a0;
}

/* Footer of the home page */
footer.footer {
background-color: #dee0e2;
}



footer.footer ul.nav > li > a {
color: #454A4C;
}
```

3. Save the overrides.css file.



You can now install and enable your customized theme.

1. After you finish updating the overrides.css file, compress all the theme files back into the .zip **`sub-theme`** file that you downloaded originally.
2. In the Developer Portal, click Appearance > Install new theme. The **`Install new theme`** window is displayed.
3. In Upload a module or theme archive to install click Browse, and navigate to your newly updated compressed theme file.
4. Click Install to install the theme onto your site.
5. Click Enable newly added themes, and find your new theme in the list of **`Disabled themes`**. Click Enable and set as default to set your new custom **`sub-theme`** as the default theme for your site.
6. Return to the Developer Portal home page by clicking Back to site. You can now see your custom theme.

Add a field to an application content type to change the `site-config` on the staging Developer Portal

1. Log in to your staging Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Structure > Content types > Application > Manage fields.
4. Click + Add field.
5. In **`Add a new field`**, select Text (plain, long). Enter `Company name` as the label title.

6. Click Save and continue.
7. Leave the **`Allowed number of values`** set to 1 and click Save field settings.
8. Click Save field settings. You can now see your new field.

Use the toolkit CLI to export the custom themes and `site-config` on the staging Developer Portal

1. Log in to the management server.

   `apic login --server` ***`management_server`*** **`--realm`** ***`realm`*** **`--username`** ***`org_username`*** **`--password`** ***`org_password`***

   For example,

   `apic login -s manager.stagingexample.com --realm provider/default-idp-2 --username ibm --password Qwerty123£`

   For more information about variable options, see Logging in to a management server.

2. Export your custom themes.
   The **custom-theme:create-export** command creates an export task against the portal of the specified **`catalog`** and **`org`**. The command then polls the status of the task until it has **`FINISHED`** and the artifacts are streamed back.
   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-theme:get-export-status** and **custom-theme:get-export** to get the status and potentially an artifact.

   `apic --mode portaladmin custom-theme:create-export --catalog` ***`name/id`*** **`--org`** ***`name/id`*** **`--server`** ***`management_server`***

- The theme .tgz is saved to the directory in which you ran the command.
- The saved .tgz has the format `custom_theme_createExport-20200217134637.tgz`.
- You can save your exports into your change control management system.

For example,

```
apic --mode portaladmin custom-theme:create-export --catalog dev --org ibm --server manager.stagingexample.com
```

3. Export your site config.
   The **site-config:create-export** command creates an export task against the portal of the specified `catalog` and `org`, the command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back.

```
apic --mode portaladmin site-config:create-export --catalog name/id --org name/id --server management_server
```

- The site config .tgz is saved to the directory in which you ran the command.
- The saved .tgz has the format `site_config_createExport-20200217134637.tgz`.
- You can save your exports into your change control management system.

For example,

```
apic --mode portaladmin site-config:create-export --catalog dev --org ibm --server manager.stagingexample.com
```

Note: For troubleshooting issues related to `site-config` export or import, see Why am I having migration issues with non identical environments?.

Use the toolkit CLI to import the custom themes and `site-config` on the production Developer Portal

1. Log in to the management server.

```
apic login --server management_server --realm realm --username org_username --password org_password
```

For example,

```
apic login -s manager.productionexample.com --realm provider/default-idp-2 --username ibm --password Qwerty123£
```

For more information about variable options, see Logging in to a management server.

2. Import your custom themes.
   The **custom-theme:create-import** command uses the supplied .tgz file to import the custom themes into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.
   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-theme:get-import-status** to get the status of the import.

```
apic --mode portaladmin custom-theme:create-import --catalog name/id --org name/id --server management_server
/PATH/TO/THEME/TGZ
```

For example,

```
apic --mode portaladmin custom-theme:create-import --catalog prod --org ibm --server manager.productionexample.com
C:/users/example/desktop/custom_theme_createExport-20200217134637.tgz
```

3. Import your site config.
   The **site-config:create-import** command uses the supplied .tgz file to import the site config into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.

```
apic --mode portaladmin site-config:create-import --catalog name/id --org name/id --server management_server
/PATH/TO/CONFIG/TGZ
```

For example,

```
apic --mode portaladmin site-config:create-import --catalog prod --org ibm --server manager.productionexample.com
C:/users/example/desktop/site_config_createExport-20200217134637.tgz
```

What you did in this scenario

In this scenario, you created a theme and changed the configuration on your staging Developer Portal. Then, you used the toolkit CLI to replicate the changes on to your production Developer Portal.

You can now see the changes that you made on your production Developer Portal.

- **Exporting and importing custom themes and site configuration by using the Portal Admin API**
  The platform REST APIs for IBM® API Connect provide complete access to the capability of the platform. So, you can use the toolkit CLI to replicate changes from one Developer Portal instance to another. However, if the toolkit CLI was not available for some reason, you can use the Portal Admin API.

Exporting and importing custom themes and site configuration by using the Portal Admin API

The platform REST APIs for IBM® API Connect provide complete access to the capability of the platform. So, you can use the toolkit CLI to replicate changes from one Developer Portal instance to another. However, if the toolkit CLI was not available for some reason, you can use the Portal Admin API.

Before you begin

To complete this scenario, you must have a staging Developer Portal and a production Developer Portal enabled. You must have administrator access, or the permission **settings:manage**, to both to complete this scenario. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

Also, you must download and install the toolkit. For more information, see Installing the toolkit.

About this scenario

In this scenario, you use the toolkit to obtain some authentication. Then, on your staging Developer Portal, you create a theme and make some configuration changes. Then, you use the Portal Admin API to replicate the changes on your production Developer Portal.

This scenario takes you through the following steps:

1. Obtaining the client ID and secret, and a bearer token.
2. Create a custom theme on the staging Developer Portal.
3. Add a field to an application content type to change the **site-config** on the staging Developer Portal.
4. Use the Portal Admin API to export the custom themes and **site-config** on the staging Developer Portal.
5. Use the Portal Admin API to import the custom themes and **site-config** on the production Developer Portal.

Obtaining the client ID and secret, and a bearer token.

From your toolkit:

1. Obtaining the client ID and secret.
   a. Obtain the list of administrator scoped providers to determine the correct realm to use:

      ```
      apic identity-providers:list --scope admin --server <management_server>
      ```

      For example,

      ```
      apic identity-providers:list --scope admin --server api.stagingexample.com
      ```

      The following example depicts some possible output.

      ```
      default-idp-1
      ```

   b. Run **apic login**, complete the details:

      ```
      apic login --server management_server --realm cloud_realm --username admin_username --password admin_password
      ```

      For example,

      ```
      apic login -s api.stagingexample.com --realm provider/default-idp-1 --username admin --password Qwerty123£
      ```

   c. Log in to cloud manager, and register an app. Make a new file locally and call it **app1.json**. Then, copy into it the following code snippet:

      ```
      {
        "name": "app1",
        "client_id": "app1id",
        "client_secret": "app1secret",
        "client_type": "toolkit"
      }
      ```

   d. Run the registration create command:

      ```
      apic registrations:create --server management_server app1.json
      ```

      For example,

      ```
      apic registrations:create --server api.stagingexample.com app1.json
      ```

      The following example depicts some possible output.

      ```
      app1    [state: enabled]    https://api.stagingexample.com/api/cloud/registrations/d2b7572f-3406-42a7-bdcc-85f177860df7
      ```

2. Now, you can get a bearer token from the provider org.
   a. To obtain a list of provider realms:

      ```
      apic identity-providers:list --scope provider --server management_server
      ```

      For example,

      ```
      apic identity-providers:list --scope provider --server api.stagingexample.com
      ```

      The following example depicts some possible output.

      ```
      default-idp-2
      ```

   b. Run **apic login**, complete the details:

      ```
      apic login --server management_server --realm provider_realm --username org_username --password org_password
      ```

      For example,

      ```
      apic login -s api.stagingexample.com --realm provider/default-idp-2 --username ibm --password Qwerty123£
      ```

   c. Create an HTTP request to obtain an access token:

      ```
      curl -k -X POST -d '{"username": "org_username", "password": "org_password", "realm": "provider/default-idp-2",
      "client_id": "app_id", "client_secret": "app_secret", "grant_type": "password"}' -H 'Content-Type: application/json'
      -H 'Accept: application/json' https://management_server/api/token
      ```

For example,

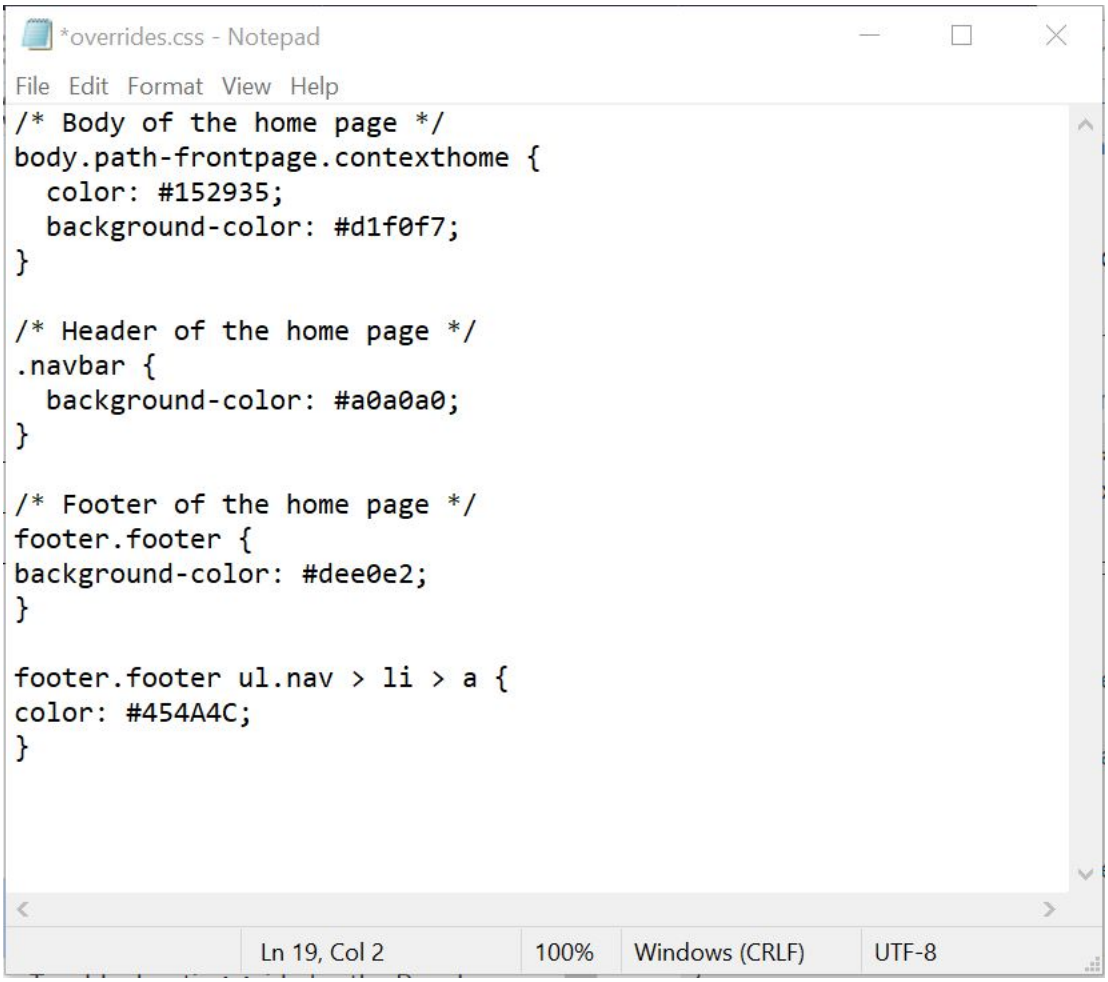
```
curl -k -X POST -d '{"username": "steve", "password": "T****8", "realm": "provider/default-idp-2", "client_id": "app1id", "client_secret": "app1secret", "grant_type": "password"}' -H 'Content-Type: application/json' -H 'Accept: application/json' https://api.stagingexample.com/api/token
```

The following example depicts some possible output.

```
{
    "access_token":
"eyJhbGciOiJSUzI1NiIsInR5cCI6IkpXVCIsImtpZCI6IjBDQkI2Mjg5MkU4QUNFNEIzNDZCQzcyNDMxMUY0QzE4NTU2MUE4NjkifQ.eyJqdGkiOiJlNDY2M2U4MC0wMzlkLTRiNDUtYmFjZC04NjA2MDcwZDIwODIiLCJuYW1lc3BhY2UiOiJiMTU4YjdhYy1kMTEzLTQxNDctODE1OS05ZDliNGViZjE3ZGE6ZjdhY2IwNzMtYzU4ZC00ZjhkLWIwZDYtMGNlM2YwYjIyYmNmOmZjMWRlOTE2LWI1NDAtNDE4MS1iZTJiLWM4ZGU0NGVlYTMzZiIsImF1ZCI6Ii9hcGkvY2xvdWQvcmVnaXN0cmF0aW9ucy9kMmI3NTcyZi0zNDA2LTQyYTctYmRjYy04NWYxNzc4NjBkZjciLCJzdWIiOiIvYXBpL3VzZXItcmVnaXN0cmllcy9iMTU4YjdhYy1kMTEzLTQxNDctODE1OS05ZDliNGViZjE3ZGEvZjdhY2IwNzMtYzU4ZC00ZjhkLWIwZDYtMGNlM2YwYjIyYmNmL3VzZXJzL2ZjMWRlOTE2LWI1NDAtNDE4MS1iZTJiLWM4ZGU0NGVlYTMzZiIsImlzcyI6IklCTSBBUEkgQ29ubmVjdCIsImV4cCI6MTU5MTcyMzU5NSwiaWF0IjoxNTkxNjk0Nzk1LCJncmFudF90eXBlIjoicGFzc3dvcmQiLCJ1c2VyX3JlZ2lzdHJ5X3VybCI6Ii9hcGkvdXNlci1yZWdpc3RyYXRpb25zIiwic2NvcGUiOiJvcGVuaWQiLCJyZWFsbSI6InByb3ZpZGVyL2RlZmF1bHQtaWRwLTIiLCJ1c2VybmFtZSI6InRqIiwiaWRfdG9rZW4iOiJleUpoYkdjaU9pSlNVekkxTmlJc0luUjVjQ0k2SWtwWFZDSXNJbXRwWkNJNklqVXhRamN4T0RCRU9ESkRNME5HUXpWQlFrSkZPREZHUkRjd05VWTFOekl3TkRBek5FTXpNalFpZlEuZXlKbWFYSnpkRjl1WVcxbElqb2lWR1ZxWVhOMmFXNXBaaXdpYkdGemRGOXVZVzFsSWpvaVUyRnFhWFFpTENKMWMyMyVnlYMmxrSWpvaVl6aG1NREF4T1RjdFlqQXhZaTAwWkRnd0xXSXhObU10TURjMk1UUTNaR0pqT1RFMklpd2lkWE5sY201aGJXVWlPaUowYWljc0ltVnRZV2xzSWpvaWRHVnFZWE4yYVc1cExuTmhhbWwwUUdsaWJTTWpiMjBpTENKcFlYUWlPakUxT1RFMk9UUTNPVFY5LlVuRWhRaTFMTDFzcmlrUE9ReGR0Tkx3SG5iQ24yNnF1U2F5Y2N4WFh0SWstc2YxZEp0T2RaM2k5c2lZdWxkZ0QxV2dueG0wT0UwaVhrRE1kLThsUFVuVzJqc3NaYno4ak5faXlJVWhmVEZsNmVUNER6WTV6WkJiUmJjYzJZUXlneXQxYnBOOFZnRlJKbm01S2xidUhTXzBkV3BJbVdJeU51em5ndjlhTk9VaVFMVTdCdlpNS0xLQmt6US1tMGRVSFdzZi1mRlB2cVE5MVUxTy14MVZ4MDBnSHFEQXZlM0VyWExlZm14dGYwalVTY0prcUdjUXVvcE9yNDRNdGcyVUJIRXJhUWpadmlMb0JwUlNja25uX1hnRXpZVXdzeUUzQ2d6SC1sRjhJa2Q4VGtqT0tELUc3YmJoRWlZcUhxdnJxVTk0Z18tZ05KbEE0MEZ2b2xnV25GQSIsInNjb3BlcyI6WyJjbG91ZDp2aWV3IiwiY2xvdWQ6bWFuYWdlIiwicHJvdmlkZXItb3JnOnZpZXciLCJwcm92aWRlci1vcmc6bWFuYWdlIiwicHJvdmlkZXIiLCJvcmc6bWFuYWdlIiwicHJvdmlkZXIiLCJvcmc6cmFmdHM6dmlldyIsInByb2R1Y3QtZHJhZnRzOmVkaXQiLCJhcGktZHJhZnRzOnZpZXciLCJvcmc6bWFuYWdlIiwicHJvdmlkZXIiLCJvcmc6cmFmdHM6dmlldyIsInByb2R1Y3QtZHJhZnRzOnZpZXciLCJjaGlsZDp2aWV3IiwiY2hpbGQ6Y3JlYXRlIiwiY2hpbGQ6bWFuYWdlIiwicHJvdmlkZXIi
```

7. Download the generated **sub-theme** to a location of your choice, and extract all the files from the .zip file.

On your computer, navigate to the files that you extracted. Find the overrides.css file in here banka_theme/banka_theme/css/overrides.css. You can now customize the overrides.css file.

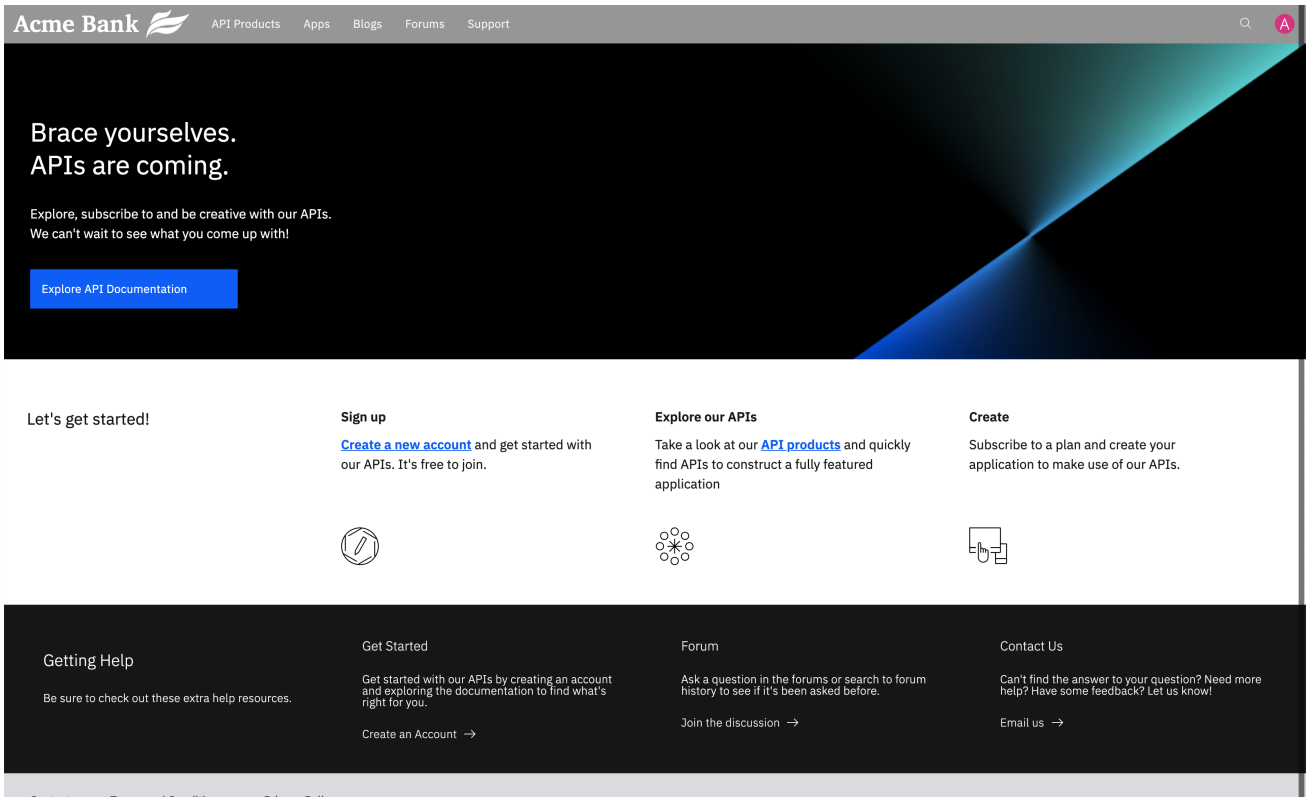


1. Open the overrides.css file in your chosen editor.
2. Customize your **sub-theme** by entering the following elements into the overrides.css file:

```
/* Body of the home page */
body.path-frontpage.contexthome {
  color: #152935;
  background-color: #d1f0f7;
}

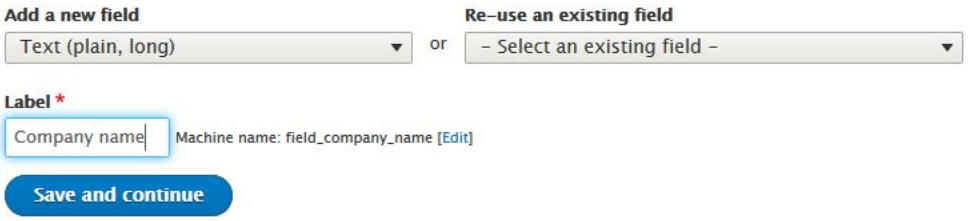
/* Header of the home page */
.navbar {
  background-color: #a0a0a0;
}

/* Footer of the home page */
footer.footer {
background-color: #dee0e2;
}



footer.footer ul.nav > li > a {
color: #454A4C;
}
```

3. Save the overrides.css file.



You can now install and enable your customized theme.

1. After you finish updating the overrides.css file, compress all the theme files back into the .zip **sub-theme** file that you downloaded originally.
2. In the Developer Portal, click Appearance > Install new theme. The **Install new theme** window is displayed.
3. In Upload a module or theme archive to install click Browse, and navigate to your newly updated compressed theme file.
4. Click Install to install the theme onto your site.
5. Click Enable newly added themes, and find your new theme in the list of **Disabled themes**. Click Enable and set as default to set your new custom **sub-theme** as the default theme for your site.
6. Return to the Developer Portal home page by clicking Back to site. You can now see your custom theme.

Add a field to an application content type to change the `site-config` on the staging Developer Portal

1. Log in to your staging Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Structure > Content types > Application > Manage fields.
4. Click + Add field.
5. In **`Add a new field`**, select Text (plain, long). Enter `Company name` as the label title.

6. Click Save and continue.
7. Leave the **`Allowed number of values`** set to 1 and click Save field settings.
8. Click Save field settings. You can now see your new field.

Use the Portal Admin API to export the custom themes and `site-config` on the staging Developer Portal

1. Export your custom themes.
   a. Create the export job by using this command:

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/export'
```

   For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/custom-theme/export'
```

   The following example depicts some possible output.

```
status: 201
message:
  stdout: >-
    /catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/f09602a2-a0e4-40dc-a82d-d1af326ad092/custom-
```

```
theme/export/85z2m39znojolv2s/status
  stderr: ''
errors: []
```

b. You can check the status of the export job by starting the `/status` endpoint.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN"  -H 'Accept: application/yaml'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/export/<task_id>/status'
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/custom-theme/export/85z2m39znojolv2s/status'
```

Here is an example of some possible output:

```
{
  "status": 200,
  "message": {
    "stdout": "The status of this task is: FINISHED and the artifact can now be streamed"
  },
  "errors": []
}
```

c. You can now download the custom theme file onto your machine.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/export/<task_id>' -o <theme_name>
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/custom-theme/export/85z2m39znojolv2s' -o mytheme.tgz
```

Note: When you use the `curl` commands to download files, if you do not specify an output with `-o`, it incorrectly prints the output as binary onto the terminal screen.

d. On Mac and Linux® machines, you can verify that you have a valid theme export `.tgz` file by starting the tar `t --list` argument.

```
tar -tvf <theme_name>
```

For example,

```
tar -tvf mytheme.tgz
```

Here is an example of some possible output:

```
drwxrwsr-x  0 aegir  aegir       0  9 Jun 13:40 ./
drwxr-sr-x  0 aegir  aegir       0  9 Jun 13:40 emerald_theme_css/
-rw-r--r--  0 aegir  aegir       7  9 Jun 13:40 emerald_theme_css/emerald_theme_css.theme
-rw-r--r--  0 aegir  aegir   29224  9 Jun 13:40 emerald_theme_css/screenshot.png
-rw-r--r--  0 aegir  aegir     442  9 Jun 13:40 emerald_theme_css/composer.json
-rw-r--r--  0 aegir  aegir     599  9 Jun 13:40 emerald_theme_css/emerald_theme_css.info.yml
-rw-r--r--  0 aegir  aegir    1150  9 Jun 13:40 emerald_theme_css/favicon.ico
-rw-r--r--  0 aegir  aegir    5932  9 Jun 13:40 emerald_theme_css/logo.svg
-rw-r--r--  0 aegir  aegir      61  9 Jun 13:40 emerald_theme_css/emerald_theme_css.libraries.yml
drwxr-sr-x  0 aegir  aegir       0  9 Jun 13:40 emerald_theme_css/css/
-rw-r--r--  0 aegir  aegir   47249  9 Jun 13:40 emerald_theme_css/css/overrides.css
```

2. Export your site config.

a. Create the export job by using this command:

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/export'
```

For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/config/export'
```

The following example depicts some possible output.

```
{
    "status": 201,
    "message": {
        "stdout": "/catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/f09602a2-a0e4-40dc-a82d-
d1af326ad092/config/export/5cylgk55ciiwn190/status",
        "stderr": ""
    },
    "errors": []
}
```

b. You can check the status of the export job by starting the `/status` endpoint.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/export/<task_id>/status'
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/config/export/5cylgk55ciiwn190/status'
```

Here is an example of some possible output:

```
{
  "status": 200,
  "message": {
    "stdout": "The status of this task is: FINISHED and the artifact can now be streamed"
  },
  "errors": []
}
```

c. You can now download the site-config file onto your machine.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/export/<task_id>' -o <config_name>
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/config/export/5cy1gk55ciiwn190' -o myconfig.tgz
```

Note: When you use the `curl` commands to download files, if you do not specify an output with `-o`, it incorrectly prints the output as binary onto the terminal screen.

d. On Mac and Linux machines, you can verify that you have a valid theme export `.tgz` file by starting the tar `t --list` argument. The `head -n 10` option returns the first 10 lines of the result.

```
tar -tvf <config_name> | head -n 10
```

For example,

```
tar -tvf myconfig.tgz | head -n 10
```

The following example depicts some possible output, which should be a list of yaml files:

```
-rw-rw-r--  0 aegir  aegir 393 11 Jun 15:54 block.block.bartik_page_title.yml
-rw-rw-r--  0 aegir  aegir 577 11 Jun 15:54 filter.format.plain_text.yml
-rw-rw-r--  0 aegir  aegir 256 11 Jun 15:54 captcha.captcha_point.consumerorg_invite_user_form.yml
-rw-rw-r--  0 aegir  aegir 741 11 Jun 15:54 block.block.emerald_theme_css_account_menu.yml
-rw-rw-r--  0 aegir  aegir 488 11 Jun 15:54 field.field.node.application.apic_hostname.yml
-rw-rw-r--  0 aegir  aegir 460 11 Jun 15:54 field.storage.node.apic_catalog_id.yml
-rw-rw-r--  0 aegir  aegir 545 11 Jun 15:54 field.field.user.user.apic_user_registry_url.yml
-rw-rw-r--  0 aegir  aegir 427 11 Jun 15:54 language.content_settings.shortcut.default.yml
-rw-rw-r--  0 aegir  aegir 460 11 Jun 15:54 field.storage.node.api_soapversion.yml
-rw-rw-r--  0 aegir  aegir 148 11 Jun 15:54 captcha.captcha_point.node_product_form.yml
```

Use the Portal Admin API to import the custom themes and `site-config` on the production Developer Portal

Note: If you are importing your custom theme onto a new server, then before you continue, follow step 1 of this tutorial to obtain a new token to authenticate with your second server. If you are using the same server, and are importing the theme into a new catalog, then the current TOKEN remains valid for the rest of the steps.
Note: Import the custom theme before you import the site config. This order is because the site config contains information about the default theme, and so your custom theme must exist on the portal when the site config is imported so that it can be set upon import.

1. Import your custom themes.
   a. On the production catalog, import the custom theme onto the production catalog `prod` by using the following command.

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml' -H 'Content-Type:
application/octet-stream' 'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/import' --data-
binary @<path_to_theme_file>
```

For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml' -H 'Content-Type:
application/octet-stream' 'https://api.productionexample.com/portal/catalogs/ibm/prod/custom-theme/import' --data-
binary @/Users/steve/PortaladminCLI/mytheme.tgz
```

The following example depicts some possible output.

```
status: 201
message:
  stdout: >-
    /catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/56f3d4ca-8be2-48f7-8f91-3d654c2b91f2/custom-
theme/import/vtscpucj08i0hfo6/status
  stderr: ''
errors: []
```

   b. You can check the status of the import job by starting the `/status` endpoint on this command:

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/import/<task_id>/status'
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://api.productionexample.com/portal/catalogs/ibm/prod/custom-theme/import/vtscpucj08i0hfo6/status'
```

The following example depicts some possible output.

```
{
  "status": 200,
  "message": {
    "stdout": "2020-06-09 13:00:59: CLI task (custom_theme:import) starting.\n2020-06-09 13:00:59: Importing custom
theme emerald_theme_css\n2020-06-09 13:01:18: CLI task (custom_theme:import) completed successfully.",
    "stderr": ""
  },
```

```
  "errors": []
}
```

2. Import your site config.
   a. Import the existing site-config onto the production catalog `prod` by using this command:

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json' -H 'Content-Type:
application/octet-stream' 'https://<management_server>/portal/catalogs/<org>/<catalog>/config/import' --data-binary
@<path_to_config_import>
```

   For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json' -H 'Content-Type:
application/octet-stream' 'https://api.productionexample.com/portal/catalogs/ibm/prod/config/import' --data-binary
@/Users/steve/PortaladminCLI/myconfig.tgz
```

   The following example depicts some possible output.

```
{
  "status": 201,
  "message": {
      "stdout": "/catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/56f3d4ca-8be2-48f7-8f91-
3d654c2b91f2/config/import/kzyozx4v5sfa8la5/status",
      "stderr": ""
  },
  "errors": []
}
```

   b. You can check the status of the config import job by starting the `/status` endpoint:

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/import/<task_id>/status'
```

   For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://api.productionexample.com/portal/catalogs/ibm/prod/config/import/kzyozx4v5sfa8la5/status'
```

   The following example depicts some possible output.

```
{
  "status": 200,
  "message": {
      "stdout": "2020-06-11 15:42:55: CLI task (site_config:import) starting.\n2020-06-11 15:43:29: CLI task
(site_config:import) completed successfully.",
      "stderr": ""
  },
  "errors": []
}
```

What you did in this scenario

In this scenario, you created a theme and changed the configuration on your staging Developer Portal. Then, you used the Portal Admin API to replicate the changes on to your production Developer Portal.

You can now see the changes that you made on your production Developer Portal.

How to enable and disable maintenance mode on your Developer Portal

You can use the Portal commands in the toolkit CLI to enable and disable maintenance mode on your Developer Portal site.

Before you begin

To complete this Portal CLI scenario, you must have a Developer Portal enabled. You must also have administrator access to this site, and the permission **`settings:manage`**, to complete this scenario. The tutorial Creating the Portal explains how to enable the portal if you haven't enabled it already.

For more information about using the toolkit CLI with the Developer Portal, see Getting started with the Portal CLI commands.

Important: Maintenance mode is designed for short-term site maintenance; it is not meant for long-term usage. While a site is in maintenance mode, the database is not updated with new content from API Manager.

About this scenario

In this scenario, you use the toolkit CLI to enable, and then disable, maintenance mode on your Developer Portal site.

The scenario takes you through the following steps:

1. Log in to the management server as a Provider organization by using the toolkit CLI
2. Use the toolkit CLI to enable maintenance mode
3. Use the toolkit CLI to disable maintenance mode

Log in to the management server as a Provider organization by using the toolkit CLI

- Log in to the toolkit CLI as a Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_endpoint_url --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that your administrator created after API Connect was installed, the names are determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

Use the toolkit CLI to enable maintenance mode

- Run the following command to enable maintenance mode on your Developer Portal:

```
apic --mode portaladmin drupal-state:set --server management_server --org orgid/name --catalog catalogid/name --state_key
system.maintenance_mode  --input_format integer --state_value 1
```

Where:
  - *management_server* is the endpoint URL of your management server (required).
  - *catalogid/name* is the ID or name of the catalog that your site belongs to (required).
  - *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
  - `--state_key` is the name of the state key (required). Must be set to `system.maintenance_mode`.
  - `--input_format` is the input format of the value of the state key. Must be set to `integer` for configuring the maintenance mode.
  - `--state_value` is the value to assign to the state key (required). Set to `1` to enable maintenance mode.

For example, to enable maintenance mode for a Developer Portal in the `myOrg` organization, and in the `dev` catalog:

```
apic --mode portaladmin drupal-state:set --server my.management.server.com --org myOrg --catalog dev --state_key
system.maintenance_mode  --input_format integer --state_value 1
Successfully set state system.maintenance_mode to the value of 1.
```

The Developer Portal site is now inaccessible to everyone apart from an administrator. All other users who enter the site URL will see a maintenance message set by the administrator.

Use the toolkit CLI to disable maintenance mode

- Run the following command to disable maintenance mode on your Developer Portal:

```
apic --mode portaladmin drupal-state:set --server management_server --org orgid/name --catalog catalogid/name --state_key
system.maintenance_mode  --input_format integer --state_value 0
```

Where:
  - *management_server* is the endpoint URL of your management server (required).
  - *catalogid/name* is the ID or name of the catalog that your site belongs to (required).
  - *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
  - `--state_key` is the name of the state key (required). Must be set to `system.maintenance_mode`.
  - `--input_format` is the input format of the value of the state key. Must be set to `integer` for configuring the maintenance mode.
  - `--state_value` is the value to assign to the state key (required). Set to `0` to disable maintenance mode.

For example, to disable maintenance mode for a Developer Portal in the `myOrg` organization, and in the `dev` catalog:

```
apic --mode portaladmin drupal-state:set --server my.management.server.com --org myOrg --catalog dev --state_key
system.maintenance_mode  --input_format integer --state_value 0
Successfully set state system.maintenance_mode to the value of 0.
```

Your Developer Portal site is now accessible to everyone again.

What you did in this scenario

In this scenario, you used the toolkit CLI to put your Developer Portal site into maintenance mode, and to turn maintenance mode off again.

Troubleshooting guide for the Developer Portal

Use this guide to help you diagnose and resolve Developer Portal issues in IBM® API Connect. For example, why is the Developer Portal not connecting to the Management server, why is my site not created, and why can't I log in?

About

The following sections provide advice about how to diagnose and resolve some common problems. This information can help you to identify whether a specific IBM API Connect Version 10 component is failing, whether it's an environmental problem, and whether you should raise a support request. Some advice includes reviewing specific log files so you can narrow down the source of the problem.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

1. Why is the Developer Portal not connecting to the Management server?
2. Why is my Developer Portal site not being created?
3. Why can't I register a user?
4. Why can't I login?
5. Why are changes to Products not appearing in the Developer Portal?
6. Why am I having problems with my Developer Portal user interface?
7. Why am I having problems with my Kubernetes system?
8. #rapim_portal_troubleshoot__backup
9. Why am I having problems installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal?
10. Are my upgrade issues related to custom Drupal modules or themes?
11. Why am I having migration issues with non identical environments?

Why is the Developer Portal not connecting to the Management server?

Problems with connecting to the Management server can be due to connectivity or TLS issues. You should check the following areas:

- Can the Management server actually reach the Developer Portal?
- Is SSL passthrough enabled or required on any load balancer that sits between the Management server and the Developer Portal? For more information, see JWT security on Kubernetes and OpenShift.

If you need to open a Service Request, include the following information:

- The IBM API Connect MustGather Information.
- Details of the date and time that the connection attempts were made.

Why is my Developer Portal site not being created?

If you are having problems creating a site, you should take the following actions to help diagnose the issue:

1. Tail the nginx container log to confirm that the site create request reached the portal, for example:

   ```
   kubectl logs rb93d4fb118-apic-portal-nginx-7c7b464fb6-vvx5m
   ```

2. Look in the container log for a site create request, for example:

   ```
   POST /portal-service-configuration-create HTTP/1.1" 200
   ```

   a. If you don't find a site create request in the log, then the create request is not reaching the Developer Portal from the Management. Follow the instructions in Why is the Developer Portal not connecting to the Management server? to diagnose the connectivity issues.
   b. If a site create request is in the log, then further diagnostics can be found in the admin pod log, for example:

      ```
      kubectl logs -f rb93d4fb118-apic-portal-www-p4bhj -c admin
      ```

      Look in the admin pod log for messages that refer to `create_site`, as well as the name of the site.

Why can't I register a user?

If you are having problems registering a user, take the following actions to help diagnose the issue:

- The user registration links in the emails are only valid for 24 hours, so check that the system time is correctly configured across all of the pods.
- If emails aren't being received, check that the email server is correctly configured; see Configuring an email server for notifications. Also, if possible, check whether other emails such as publish approval alerts or password reset emails are being received.

If you need to open a Service Request, please take the following steps:

1. Note which user registry type is being used, such as Local User Registry (LUR), or LDAP user registry.
2. Enable the debug REST server and method trace in the Developer Portal UI. Click Configuration > Development > IBM Development on the administrator dashboard. Then select the Enable method entry / exit trace and Enable API Manager REST interface debug check boxes. Click Save configuration.
3. Re-create the issue, making a note of the time, the username, and any messages displayed on the screen.
4. Gather the web container log for the www pod, for example:

   ```
   kubectl logs portal-apic-portal-www-zhqxf web > web.log
   ```

5. Gather all of the Management server logs and the logs for the user registry type that is being used; see IBM API Connect MustGather Information for details.

Why can't I login?

If users are having problems with logging in to the Developer Portal, please take the following steps before opening a Service Request:

1. Note which user registry type is being used, such as Local User Registry (LUR), or LDAP user registry.
2. Enable the debug REST server and method trace in the Developer Portal UI. Click Configuration > Development > IBM Development on the administrator dashboard. Then select the Enable method entry / exit trace and Enable API Manager REST interface debug check boxes. Click Save configuration.

3. Recreate the issue, making a note of the time, the username, and any messages printed to the screen.
4. Gather the web container log for the www pod, for example:

```
kubectl logs portal-apic-portal-www-zhqxf web > web.log
```

5. Gather all of the Management server logs and the logs for the user registry type that is being used; see IBM API Connect MustGather Information for details.

Why are changes to Products not appearing in the Developer Portal?

To determine whether the problem is with the Portal server (either the nginx or the www pod), the Management server, or the network, please make the following diagnostic checks.

Portal nginx pod

1. Tail the nginx pod log on the Portal, for example:

```
kubectl logs -f portal-apic-portal-nginx-866c977c4c-n9gbf
```

2. Make a publish request to the Catalog (note that the request must be a Publish or Retire operation, not a Stage operation).
3. In the log being tailed, see if the following message appears:

```
...POST /event-create...
```

If the POST message appears in the nginx log, then the publish webhook that was sent from the Management server did arrive at the Portal. If there is an error message in place of a POST message, then the problem is likely to be with the nginx pod. If there is no message at all, then it's likely that the webhook from the Management server is not reaching the Portal and there is a network problem.

Portal www pod

1. Tail the www pod admin container log on the Portal, for example:

```
kubectl logs -f portal-apic-portal-www-dtbzw -c admin
```

2. Make a publish request to the Catalog (note that the request must be a Publish or Retire operation, not a Stage operation).
3. In the log being tailed, see if the following message appears:

```
Received webhook event 'product_lifecycle' for catalog
```

If no such message appears, it suggests that the webhook is either not arriving at the Portal, or not getting beyond the nginx pod (see the previous section Portal nginx pod). Any errors that the admin container has in processing the webhook will be logged in the www pod admin container log.

Management server apim pod

1. Tail the apim pod log on the Management server, for example:

```
kubectl logs -f apiconnect-apim-v2-86b464c4f5-4cx6r
```

2. Make a publish request to the Catalog (note that the request must be a Publish or Retire operation, not a Stage operation).
3. In the log being tailed, see if there any error messages.

Search for the word 'sending', you should see the message `webhook: sending successful` if the webhook is sent, or error messages indicating why if the webhook is not sent.

Why am I having problems with my Developer Portal user interface?

If you are having user interface (UI) problems, make the following checks:

- Try clearing the cache from your browser, try using private browsing, and try using different browsers - see whether there are any differences in behavior.
- Check your browser window size and screen resolution, and try increasing and decreasing the settings.
- Investigate the browser developer tools console and network tabs, as they might provide some diagnostic clues.
- Try clearing the Drupal caches from within the Developer Portal; see Clearing the server caches for details.

If you need to open a Service Request, along with the IBM API Connect MustGather Information logs, also include details of the time and date when the problem was reproduced. In addition, an export of the browser developer tools console and network output would be helpful.

Why am I having problems with my Kubernetes system?

Kubernetes provides a DNS server as one of the pods in the kube-system namespace (unless you have configured your Kubernetes setup differently), and sometimes this DNS server can silently fail. When the Portal www or db pods restart, they check that their own hostname and IP address is in the service that is defined for the pod. If the DNS server is down, this check fails. An indication that the DNS server is down is seeing the following log lines printed endlessly in the admin or db containers:

```
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:54: service-ready:
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:54: service-all:
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:54: Waiting for sleep in service all check. Pid(s) 352  Seconds
24
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:59: Finished waiting for sleep in service all check. Pid(s)
352  Seconds 29
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:28:01: WARNING 5: r4c09b98d02-apic-portal-admin-all doesn't
include this pod or r4c09b98d02-apic-portal-director does. Checking again in 5 seconds.
```

To fix this problem, delete the DNS pod in the kube-system namespace to force it to restart, for example:

```
kubectl -n kube-system delete pod kube-dns-b76db4f7f-n4lvt
```

Where *kube-dns-b76db4f7f-n4lvt* is the full name of the DNS pod.
Note: To find out the full name of the DNS pod in your Kubernetes system, run the following command:

```
kubectl -n kube-system get pods
```

This command will return data like the following example:

```
$ kubectl -n kube-system get pods
NAME READY STATUS RESTARTS AGE
default-http-backend-5bccfbdc8-mjnnb 1/1 Running 0 4d
etcd-minikube 1/1 Running 0 4d
kube-addon-manager-minikube 1/1 Running 0 4d
kube-apiserver-minikube 1/1 Running 0 4d
kube-controller-manager-minikube 1/1 Running 0 4d
kube-dns-6f4fd4bdf-7zslq 3/3 Running 0 4d
kube-proxy-mddmj 1/1 Running 0 4d
kube-registry-proxy-99qml 1/1 Running 0 4d
kube-registry-v0-zt8pv 1/1 Running 0 4d
kube-scheduler-minikube 1/1 Running 0 4d
kubernetes-dashboard-77d8b98585-dczcs 1/1 Running 0 4d
nginx-ingress-controller-57bcfc76d6-z775d 1/1 Running 0 4d
storage-provisioner 1/1 Running 0 4d
tiller-deploy-587df449fb-bpwhq 1/1 Running 0 4d
```

Why am I having problems installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal?

From IBM API Connect 10.0.3.0, the Developer Portal is based on the Drupal 9 content management system. If you want to install Drupal 8 custom modules or sub-themes into the Drupal 9 based Developer Portal, you must ensure that they are compatible with Drupal 9, including any custom code that they contain, and not using any deprecated APIs, for example. There are tools available for checking your custom code, such as drupal_check on GitHub, which checks Drupal code for deprecations.

For example, any Developer Portal sites that contain modules or sub-themes that don't contain a Drupal 9 version declaration will fail to upgrade, and errors like the following output will be seen in the `admin` logs:

```
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: emeraldgreen
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for emeraldgreen
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Found themes incompatible with
Drupal 9: emeraldgreen rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: /tmp/restore_site.355ec8 is NOT
Drupal 9 compatible
...
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_1
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for custom_mod_1
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_2
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for custom_mod_2
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Found modules incompatible with
Drupal 9: emeraldgreen rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: site1.com is NOT Drupal 9
compatible
```

To fix version compatibility errors, all custom modules and sub-themes should declare a `core_version_requirement` key in their *.info.yml file that indicates Drupal 9 compatibility. For example:

```
name: Example module
type: module
description: Purely an example
core: 8.x
core_version_requirement: '^8 || ^9'
package: Example module

# Information added by Drupal.org packaging script on 2020-05-31
version: '8.x-1.3'
project: 'example_module'
datestamp: 1590905415
```

This example specifies that the module is compatible with all versions of Drupal 8 and 9. For more information, see Let Drupal know about your module with an .info.yml file on the drupal.org website.
If you have a backup of a site that you need to restore and are getting the version compatibility error, but the module or theme *.info.yml file cannot be changed easily, then you can modify the site backup.

To modify the site backup, extract the it, edit the relevant files inside it, and then tar the backup file again. Note that this procedure will overwrite the original backup file, so ensure that you keep a separate copy of the original file before you start the extraction. For example:

1. `mkdir /tmp/backup`
2. `cd /tmp/backup`
3. `tar xfz path_to_backup.tar.gz`
4. Edit the custom module and theme files to make them Drupal 9 compatible, and add the correct `core_version_requirement` setting.
5. `rm -f path_to_backup.tar.gz`
6. `tar cfz path_to_backup.tar.gz`
7. `cd /`
8. `rm -rf /tmp/backup`

Are my upgrade issues related to custom Drupal modules or themes?

To enhance the functionality of your Drupal site, you might install additional modules or themes that are not provided by IBM. While these custom or third-party components can offer extended capabilities, they might also impact the core features and introduce compatibility issues during upgrades. Additionally, these modules or themes might not align with the newer versions of Drupal or IBM API Connect modules or might contain bugs or vulnerabilities.

Note: IBM Support does not cover issues caused by third-party components or custom modules or themes.
If your customization is causing upgrade failures, consider the following steps:
Note: Always ensure that your custom modules and themes are compatible with the target upgrade version before proceeding.

1. Back up your customization and site configuration using the exporting feature. For more information, Exporting and importing custom themes and site configuration.
2. Temporarily switch themes - set the site theme to `connect_theme` and the admin theme to `claro`.
3. Disable or temporarily remove the problematic modules.
4. Proceed with the upgrade.
5. Reapply and retest your customization after a successful upgrade

For more information about locating your custom modules and themes, see How to find your custom modules and themes on your Developer Portal.
For more information about upgrading your Developer Portal, see Preparations for upgrading your Developer Portal to Drupal 11.

Why am I having migration issues with non identical environments?

When exporting and importing custom themes and site configurations, ensure that the source and target Drupal environments are as closely identical as possible. Diverse environments might often cause migration failures or unexpected behavior. Always ensure that the configurations, enabled or disabled modules, or themes on both environments are identical and the database schema on the target environment is up to date.

You can review each environment in Admin > Reports > Status report.

For more information about exporting or importing custom themes and site configuration, see Exporting and importing custom themes and site configuration.

Migrating your Developer Portal from Version 5 to Version 10

Guidance on how to migrate a Developer Portal site from IBM® API Connect version 5, to IBM API Connect version 10.

In IBM API Connect version 10, the Developer Portal is based on the open source Drupal 9 content management software, which enables more advanced, flexible and powerful customization capabilities. However, in IBM API Connect version 5 the Developer Portal is based on Drupal 7. The migration tooling in Version 10 creates a new Developer Portal site, and migrate all the associated APIs and Products, user information and subscriptions over. However, customizations such as modules and themes cannot be automatically migrated, as the Drupal 9 baseline is very different to Drupal 7. For more information about upgrading from a Drupal 7 baseline to a Drupal 9 baseline, see Upgrading Drupal in the Drupal documentation.

The following sections take you through the migration process for the Developer Portal, and provide guidance on how to manually migrate any specific customizations to Drupal 9.

- Migration process for the Developer Portal
- Portal Delegated User Registries
- Custom themes
- Custom modules
- Custom Rules
- Custom content types and fields
- Advanced theme development
- Changing the page layout
- Changing the front page
- Features no longer available in the Developer Portal

Note: The ability to migrate is available only from IBM API Connect Version 5.0.8.7 onwards. If your deployment is at an earlier version, you must upgrade before migrating. For information about upgrading in Version 5, seeUpgrading your API Connect cloud. For more information about the supported versions for migration, see Migrating a Version 5 deployment.
Note: In Version 5, it was possible, though not recommended, to modify files on the Developer Portal server directly. For more information, see Developer Portal best practices for administrators. However, in Version 10, you should not make any system changes. Do not use the **kubectl exec** command to make changes inside the Developer Portal containers. Make any customizations on your Developer Portal by using the UI or CLI. Do not run a **kubectl exec** command on any Developer Portal containers unless asked to by IBM.

Migration process for the Developer Portal

The migration process for the Developer Portal migrates all of the following information to Version 10 for each site in your cluster:

- User information (if Portal Delegated User Registry is enabled, the process is slightly different; see Portal Delegated User Registries).
- Products and APIs.
- Consumer organizations.
- Applications.
- Subscriptions.

For information about the main migration process, see Migrating a Version 5 deployment.

Portal Delegated User Registries

In IBM API Connect Version 5, if Portal Delegated User Registry (PDUR) was selected for a Catalog, the user management was delegated from the management server to the Developer Portal. The site administrator within the Portal then performed the configuration of user registries, and the management server recorded that the delegation had taken place, and stored a record of the users that existed in the Catalog. However, the management service maintained no information about the configuration of the

specific registries or how users mapped to them. In IBM API Connect Version 10, all user registry configuration takes place in the management server, and PDUR is no longer needed. Therefore, to migrate the PDUR user registries and users from v5 to v10, configuration information must be gathered from both the management server and the Portal node.

If your IBM API Connect Version 5 Developer Portal uses Portal Delegated User Registry (PDUR), you must first export the user information that is stored in the Version 5 Developer Portal local database. This user information can then be fed into the migration tooling so that the correct user registries can be created in the newer version of API Connect.

For more information about how to export the PDUR information from v5, see Exporting Portal Delegated User Registry user information. For more information about the migration process in v10, see Migration steps with PDUR.

Custom themes

If your Version 5 Developer Portal is using a custom theme, you'll need to create the custom theme again for the Drupal 9 baseline. Start by creating a sub-theme of the new Version 10 Developer Portal site by using the theme generator, and then manually customize the sub-theme to your specifications for Drupal 9 by using Cascading Style Sheets (CSS), or Sass CSS (SCSS). Note that using SCSS in your theme makes it far simpler to change colors. We've also added a color template theme generator, which means you can quickly generate a base color theme on which to build your customized site branding. For more information, see Creating a sub-theme.

Note, directly editing the API Connect theme is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.

Other useful resources:

- Tutorial: Creating a custom theme for the Developer Portal - takes you through how to use the theme generator, customize a theme, and install a custom theme.
- Changing the site logo - how to change your site logo.
- Changing the shortcut icon - how to change the shortcut icon (favicon).
- Creating sub-themes - Drupal documentation about creating a sub-themes.
- Theming differences between Drupal 6, 7 & 8 - Drupal documentation about theming differences.

Custom modules

If your Version 5 Developer Portal is using any custom modules, you will need to create these custom modules again for the Drupal 9 baseline. For more information on writing custom modules, see Extend.

Other useful resources:

- Creating custom modules - Drupal documentation about creating custom modules.
- Getting started creating custom modules - Drupal documentation giving background information and prerequisites needed for custom module development.
- Understanding hooks - Drupal documentations about hooks.
- Drupal API hooks - Drupal documentation about the hooks that are available.

Custom Rules

If your Version 5 Developer Portal is using any custom Rules, you will need to create them as custom modules for the Drupal 9 baseline. You cannot export the Drupal 7 Rules, and then import them into the Drupal 9 baseline, as the events and actions are implemented in a different way. For more information about custom modules, see the Custom modules section.

Custom content types and fields

If your Version 5 Developer Portal is using any custom content, you will need to create this content again for the Drupal 9 baseline.

For information about creating custom content types, see the following topics:

- Creating content types
- Adding fields to content types
- Adding custom fields to user records

Advanced theme development

If your Version 5 Developer Portal is using modified content type templates, you must create these templates again for the Drupal 9 baseline. In Drupal 9 the templates are Twig files that define the actual HTML output for a particular piece of content. You can override a Twig template by copying the original template into the templates folder of your custom sub-theme, and then editing the template to your specification. The Developer Portal then uses your template in preference to the original one. For more information, see Applying a modified content type template, and Creating a sub-theme. You can also follow a guided example of how to create a new theme, see Tutorial: Creating a custom theme for the Developer Portal.

Note:
Modifying Twig templates allows very fine-grained control over the structure of pages. However, it also means you might miss new features and defect fixes that are made to the original templates, as your Developer Portal is using your overrides instead of the originals. So, if you override a template, it is your responsibility to check the templates in the latest API Connect Version 10 releases, and to ensure that any equivalent changes that are needed to your overrides to maintain functional equivalence are made.

Changing the page layout

If your Version 5 Developer Portal is using a different page layout, you will need to create this layout again for the Drupal 9 baseline. The page layout is defined by configuring which blocks appear in which regions. Blocks are controlled by using the Structure > Block layout options on the Developer Portal administrator dashboard.

For information about how to configure the page layout, see Adding and changing the blocks displayed on Developer Portal pages.

Changing the front page

If your Version 5 Developer Portal is using a different front page, you will need to create this front page again for the Drupal 9 baseline. The front page is configured from the Structure > Pages options on the Developer Portal administrator dashboard.

For information about how to configure the front page, see Configuring the front page, and Adding custom pages.

Further options that you might want to consider when designing your front page include:

- Change the banner block content or image: Changing the front page banner block.
- Display featured API Products by creating a featured content block: Changing the front page Featured Content block.
- Create custom blocks with your own HTML content: Adding and changing the blocks displayed on Developer Portal pages.
- Set up the social block to include your organization Twitter feed: Integrating X data into the social block.

Features no longer available in the Developer Portal

The following features that are available in IBM API Connect Version 5, are not available in IBM API Connect Version 10:

- Security questions can now be created inside an OpenID Connect provider.
- Two-factor authentication can now be performed inside an OpenID Connect provider.
- Support tickets - Currently, no Drupal 9 equivalent module is available.

Upgrading your Developer Portal from Drupal 10 to Drupal 11

The Developer Portal is based on the open source Drupal content management system. From API Connect 10.0.10.0, Drupal 10 is upgrading to Drupal 11.

Starting with API Connect 10.0.10.0, all the existing Developer Portal sites are upgraded to Drupal 11, and all new sites that you create must be based on Drupal 11. Therefore, all modules and themes on your Developer Portal site is compatible with Drupal 11. The core modules and themes are automatically made compatible as part of the upgrade.
Note: If your Developer Portal sites contain any custom modules or themes, either written in-house or contributed by the Drupal community, it is your responsibility to ensure that they are Drupal 11 compatible before the upgrade.
For more information about how to prepare your Developer Portal sites for the upgrade to Drupal 11, see the following topics:

- How to find your custom modules and themes on your Developer Portal.
- Prepare your Developer Portal for the update for Drupal 11.
- Upgrade your custom modules to be Drupal 11 compliant.

Upgrading from older versions of API Connect v10

If you are upgrading to API Connect 10.0.10.0 from 10.0.8.0, your Developer Portal sites are first upgraded to Drupal 10.4 and then to Drupal 11. This is because upgrading to Drupal 11 requires your site to be on at least Drupal 10.3.
Note: If you are in the category where a double upgrade occurs, your Developer Portal sites are going to take double the time to upgrade compared to your normal experience. This time consumption occurs because the upgrade from Drupal 10 to Drupal 11 is a major upgrade. Therefore, when you are planning your maintenance window for upgrading your API Connect deployment to 10.0.10.0, you need to be aware of the extended time frame. To shorten your upgrade window, consider removing the Developer Portal sites that you do not need.

Further reading

For more information about upgrading the Developer Portal to Drupal 11, see the following links:

- Deprecation checking and correction tools.
- Deprecated modules and themes.
- List of APIs deprecated and now removed from Drupal 11.

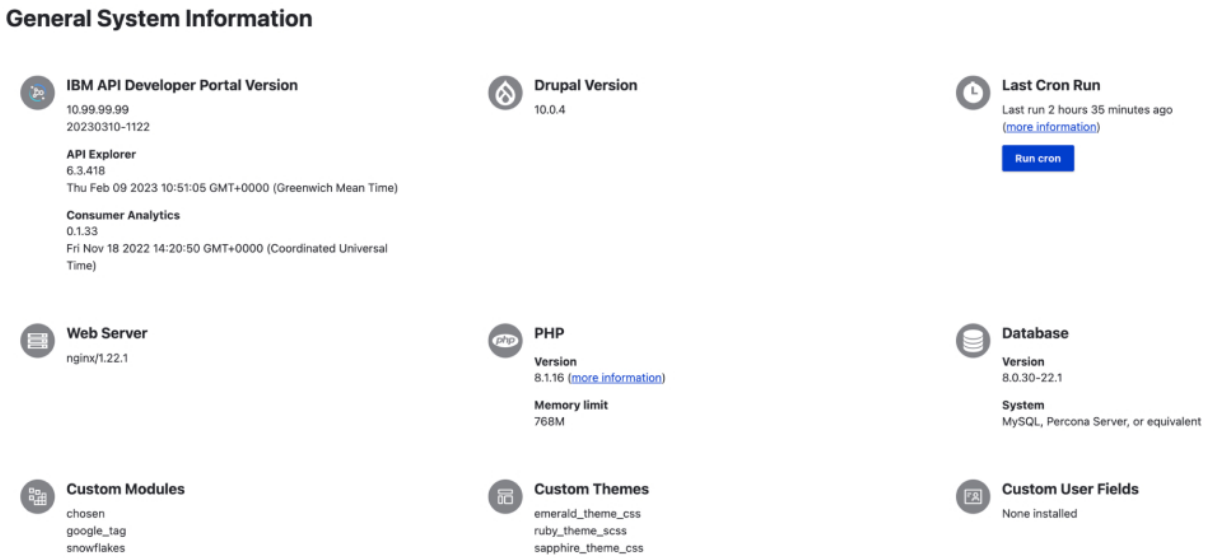
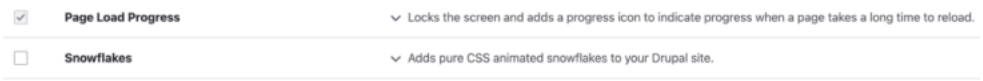
- **Preparations for upgrading your Developer Portal to Drupal 11**
  Make all the custom modules and themes in your Developer Portal are Drupal 11 compatible before you start the upgrade process.
- **Upgrading to class-based hooks in Drupal 11**
  Starting with Drupal 11, you can define hooks as class-based attributes that align with modern PHP practices to improve the ease of maintenance.

How to find your custom modules and themes on your Developer Portal



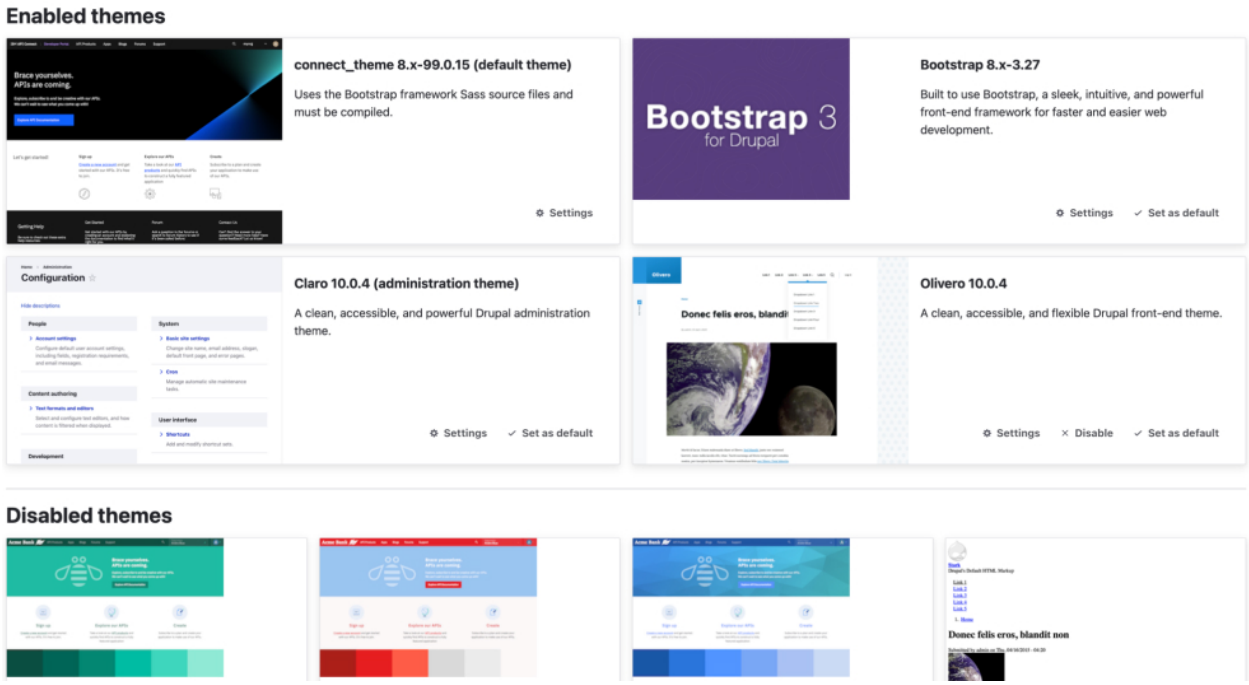
Guidance on how to find what custom modules and themes you installed on your Developer Portal.

The Developer Portal within API Connect comes with built-in modules and themes that you can use to customize your site. You can extend your customizations by installing external custom modules and themes, or even ones written by yourself. If you are unsure which custom modules and themes are installed on your Developer Portal, you can use one of the following methods to find out.



1. Method 1. Developer Portal admin status report (recommended)
2. Method 2. Developer Portal toolkit CLI
3. Method 3. Developer Portal container

Method 1. Developer Portal admin status report (recommended)



1. Log in to your Developer Portal as the administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Manage > Reports > Status report.
   - The custom modules and themes are listed in the Custom Modules and Custom Themes sections at the end of the page.

4. Check which of your custom modules are enabled or disabled by clicking Manage > Extend.
   - The enabled modules are displayed with a selected checkbox, and the disabled ones are not selected as seen in the following example.

5. Check which of your custom themes are enabled or disabled by clicking Manage > Appearance.
   - Find your themes that are categorized into Enabled and Disabled sections.

Method 2. Developer Portal toolkit CLI

Use the **`custom-module:create-export`** and **`custom-theme:create-export`** commands to extract your custom modules and themes into a compressed file.

The compressed file includes a list of your custom modules and themes. For more information about using the Developer Portal toolkit CLI and all the other features it offers, see Overview of the Developer Portal command-line tool.

1. To list your modules, implement the following steps:
   a. Log in to the Developer Portal toolkit CLI as a provider organization.
   b. Run the following **`custom-module:create-export`** command against the Developer Portal.

```
apic custom-module:create-export --mode portaladmin [flags]
```

   c. Specify the appropriate **`org`** and **`catalog`** name.

For example,

```
❯ SERVER=myserver.ibm.com
❯ apic login -s $SERVER -r provider/default-idp-2 -u steve
Warning: Using default toolkit credentials.
Enter your API Connect credentials
Password?
Logged into myserver.ibm.com successfully

❯ apic -s $SERVER -m portaladmin custom-module:create-export -o ibm -c api-connect-catalog-1
201 CREATED - Task ID: x8jupowmktkf8f2r

Response Code - 202:

Message(s) -
The status of this task is: QUEUED

Response Code - 200:

Message(s) -
The status of this task is: FINISHED and the artifact can now be streamed

Saving File (Large files may take a while)...
Incoming project saved to custom_module_createExport-20230322143819.tgz
```

After the command has run, extract your compressed export to see the modules inside. Or use **tar** directly as shown in the following example.

```
❯ tar --exclude='*/*' -tvf custom_module_createExport-20230322143819.tgz
drwxr-sr-x aegir/aegir       0 2023-03-22 12:05 chosen/
drwxr-sr-x aegir/aegir       0 2023-03-22 12:05 google_tag/
drwxr-sr-x aegir/aegir       0 2023-03-22 12:05 snowflakes/
```

2. To check which one of your custom modules are enabled or disabled, implement the following steps:
   a. Run the following **modules:list** command to print the list of installed modules.

   ```
   apic modules:list --mode portaladmin [flags]
   ```

   b. Search for your custom modules from the result.
   For example,

   ```
   ❯ SERVER=myserver.ibm.com
   ❯ apic -s $SERVER -m portaladmin modules:list -o ibm -c api-connect-catalog-1 --no-core
   .
   .
   .
   chosen:
     package: 'User interface'
     display_name: 'Chosen (chosen)'
     status: Disabled
     version: 3.0.5
   google_tag:
     package: Statistics
     display_name: 'Google Tag Manager (google_tag)'
     status: Enabled
     version: 8.x-1.6
   snowflakes:
     package: 'User interface'
     display_name: 'Snowflakes (snowflakes)'
     status: Enabled
     version: 2.0.1
   .
   .
   ```

3. To list your custom themes, implement the following steps:
   a. Log in to the Developer Portal toolkit CLI as a provider organization.
   b. Run the following **custom-theme:create-export** command against the Developer Portal.

   ```
   apic custom-theme:create-export --mode portaladmin [flags]
   ```

   c. Specify the appropriate **org** and **catalog** name.
   For example,

   ```
   ❯ SERVER=myserver.ibm.com
   ❯ apic login -s $SERVER -r provider/default-idp-2 -u steve
   Warning: Using default toolkit credentials.
   Enter your API Connect credentials
   Password?
   Logged into api.fyre-ci-136264-master.fyre.ibm.com successfully

   ❯ apic -s $SERVER -m portaladmin custom-theme:create-export -o ibm -c api-connect-catalog-1
   201 CREATED - Task ID: oh595vuywxsz3526

   Response Code - 202:

   Message(s) -
   The status of this task is: QUEUED

   Response Code - 200:

   Message(s) -
   The status of this task is: FINISHED and the artifact can now be streamed

   Saving File (Large files may take a while)...
   Incoming project saved to custom_theme_createExport-20230322143856.tgz
   ```

After the command has run, extract your compressed export to see the themes inside. Or use `tar` to view the contents directly as shown in the following example.

```
❯ tar --exclude='*/*' -tvf custom_theme_createExport-20230322143856.tgz
drwxr-sr-x aegir/aegir       0 2023-03-22 14:36 emerald_theme_css/
drwxr-sr-x aegir/aegir       0 2023-03-22 14:36 ruby_theme_scss/
drwxr-sr-x aegir/aegir       0 2023-03-22 14:36 sapphire_theme_css/
```

4. To check which of your custom themes are enabled or disabled, implement the following steps:
   a. Run the following `themes:list` command to print the list of installed themes.

   ```
   apic themes:list --mode portaladmin [flags]
   ```

   b. Search for your custom themes from the result.
   For example,

   ```
   ❯ SERVER=myserver.ibm.com
   ❯ apic -s $SERVER -m portaladmin themes:list -o ibm -c api-connect-catalog-1 --no-core
   bootstrap:
     package: Bootstrap
     display_name: 'Bootstrap (bootstrap)'
     status: Enabled
     version: 8.x-3.27
   .
   .
   .
   emerald_theme_css:
     package: Bootstrap
     display_name: 'emerald_theme_css (emerald_theme_css)'
     status: Disabled
     version: null
   ruby_theme_scss:
     package: Bootstrap
     display_name: 'ruby_theme_scss (ruby_theme_scss)'
     status: Disabled
     version: null
   sapphire_theme_css:
     package: Bootstrap
     display_name: 'sapphire_theme_css (sapphire_theme_css)'
     status: Disabled
     version: null
   ```

Method 3. Developer Portal container

If you are unable to access the Developer Portal settings or the Developer Portal toolkit CLI, check the Developer Portal container running within your Kubernetes or Red Hat OpenShift environment.

Note: You need access to the Developer Portal Kubernetes pods to be able to perform these steps.

1. Use `kubectl` or `oc` for Red Hat OpenShift environment to obtain a shell to the Developer Portal running container.

   Your Developer Portal sites are located within the `portal-www` pod in the `admin` container within the namespace that your Developer Portal subsystem is deployed to as seen in the following example.

   ```
   ❯ kubectl get pods -n apic | grep www
   portal-014179b4-www-0     2/2     Running     0          8d

   ❯ kubectl exec -n apic -it portal-014179b4-www-0 -c admin -- bash
   bash-4.4$
   ```

2. After you access the container, use the command `list_sites -a` to obtain the site alias for your Developer Portal. For example,

   ```
   bash-4.4$ list_sites -a
   daae4642-b1e2-4fd8-a5a7-77a68ed812ef.944dce4f-bbad-41ce-b166-aa2c9f8c4b17 => ibm.api-connect-catalog-1.portal.fyre-ci-
   136264-master.fyre.ibm.com (INSTALLED)
   daae4642-b1e2-4fd8-a5a7-77a68ed812ef.c560c004-852d-42c3-ae4e-797144a857af => ibm.api-connect-catalog-2.portal.fyre-ci-
   136264-master.fyre.ibm.com (INSTALLED)
   ```

   The Developer Portal `portal.fyre-ci-136264-master.fyre.ibm.com/ibm/api-connect-catalog-1` has the site alias `ibm.api-connect-catalog-1.portal.fyre-ci-136264-master.fyre.ibm.com`.

3. After you identify the Developer Portal that you want to look at, use the alias string within a `find` command to list your modules and themes, as shown in the following example.

   ```
   bash-4.4$ find /web/platforms/devportal*/sites/myserver.ibm.com/modules -mindepth 1 -maxdepth 1 -type d -exec basename {}
   \;
   chosen
   google_tag
   snowflake

   bash-4.4$ find /web/platforms/devportal*/sites/ibm.api-connect-catalog-1.portal.fyre-ci-136264-master.fyre.ibm.com/themes
   -mindepth 1 -maxdepth 1 -type d -exec basename {} \;
   emerald_theme_css
   ruby_theme_scss
   sapphire_theme_css
   ```

4. To check which of your custom modules and themes are enabled or disabled, implement the following sub-steps:
   a. Use the `drush` command-line tool within the container to print the list of installed modules and themes for your Developer Portal.
   b. Then, use the site alias that you obtained earlier to run the following `drush` command and find your custom modules and themes.

   ```
   bash-4.4$ drush @myserver.ibm.com pml --no-core
   Running: drush -y @daae4642-b1e2-4fd8-a5a7-77a68ed812ef-944dce4f-bbad-41ce-b166-aa2c9f8c4b17 pml --no-core
   ```

```
 --------------------------------- ------------------------------------------------------------------------------------------
- ---------- -----------------
  Package                          Name
Status     Version
 --------------------------------- ------------------------------------------------------------------------------------------
- ---------- -----------------
  User                             Account Field Split (account_field_split)

  Bootstrap                        emerald_theme_css (emerald_theme_css)
Disabled
  Bootstrap                        ruby_theme_scss (ruby_theme_scss)
Disabled
  Bootstrap                        sapphire_theme_css (sapphire_theme_css)
Disabled
```

Results

By using one of the three methods discussed in the topic, you managed to successfully list the custom modules and themes installed on your Developer Portal. This also allowed you to see which of these custom modules and themes are enabled or disabled.

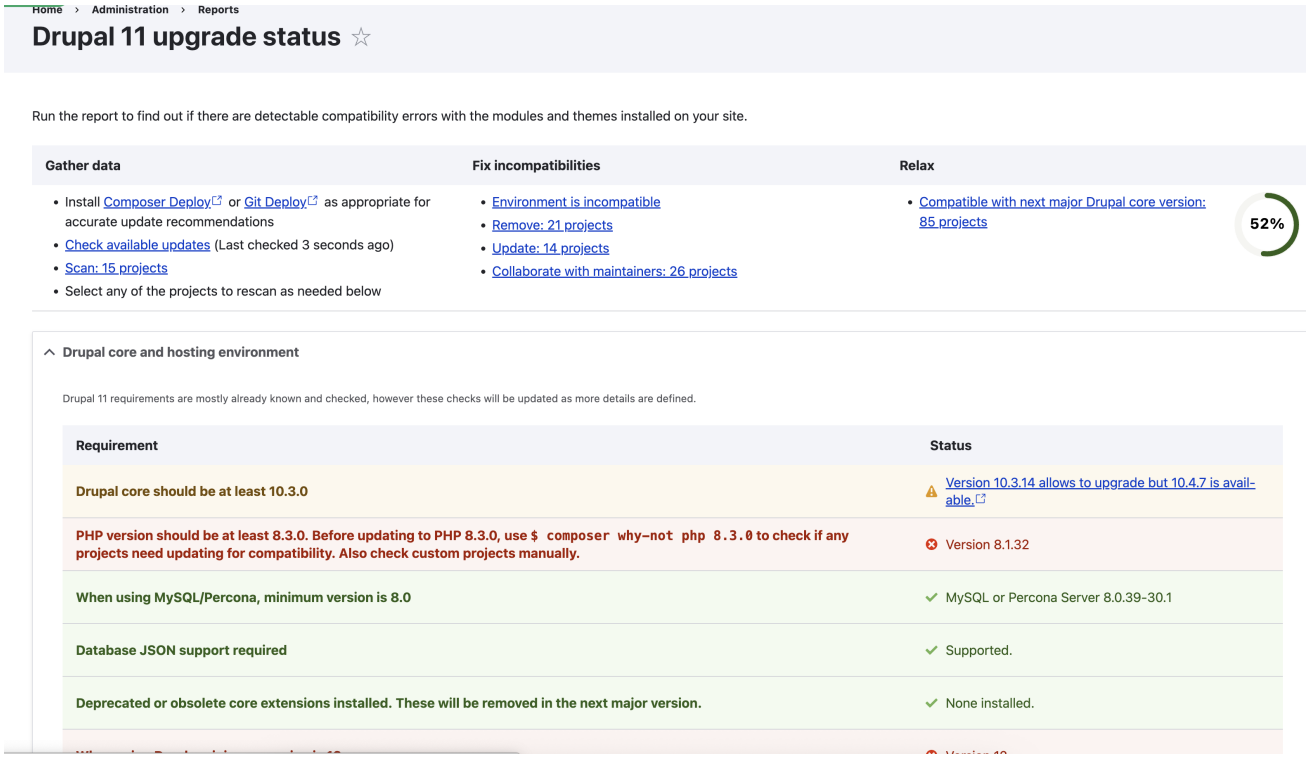
1. Method 1. Developer Portal admin status report (recommended)
2. Method 2. Developer Portal toolkit CLI
3. Method 3. Developer Portal container

Next steps

Ensure that you keep your custom modules and themes up to date, and remove deprecated code within your own written custom modules and themes. If you are not using a custom module or theme, consider removing it. This helps mitigate problems when you want to migrate or upgrade your Developer Portal.

Preparations for upgrading your Developer Portal to Drupal 11

Make all the custom modules and themes in your Developer Portal are Drupal 11 compatible before you start the upgrade process.

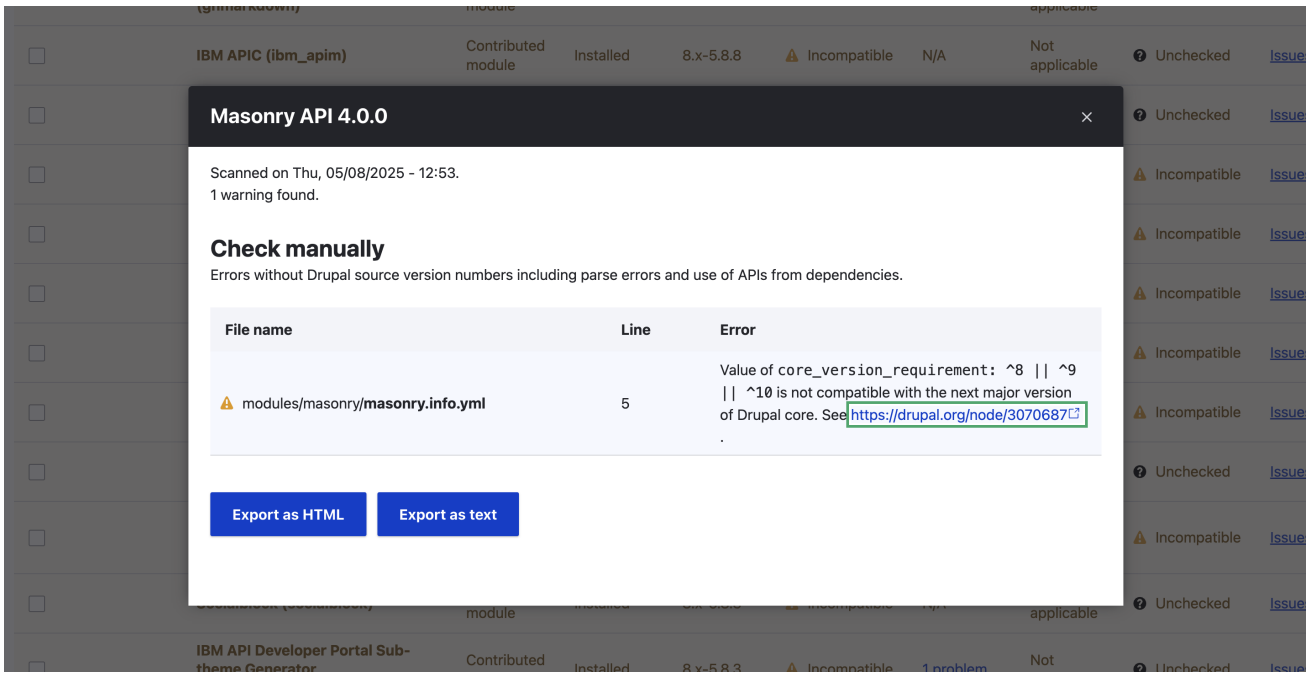


If your Developer Portal contains custom modules and themes that are written by yourself or downloaded from elsewhere, ensure that they are Drupal 11 compatible before you start the upgrade process. This action can help create a seamless IBM® API Connect upgrade experience. For more information about your modules and themes compatibility, download the **`Upgrade status`** module from Upgrade status in the Drupal documentation.

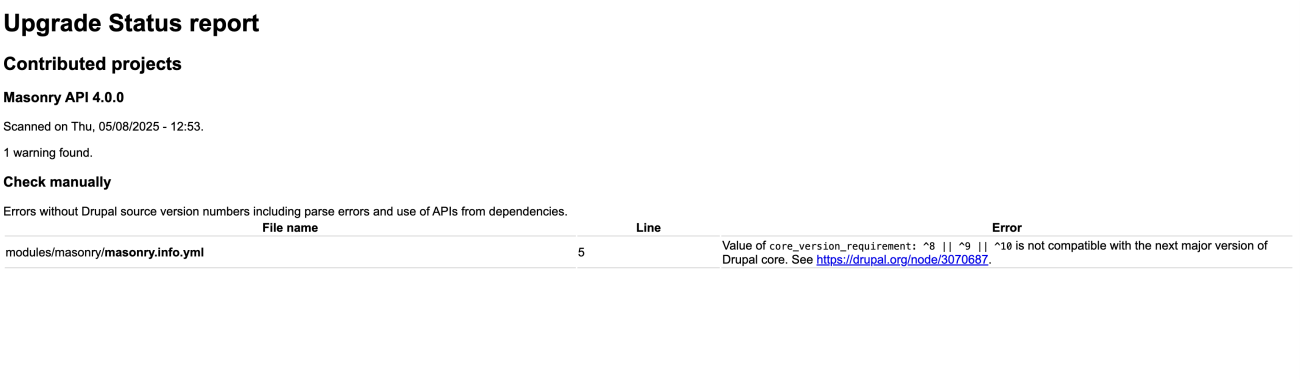
Note: Before you start the upgrade, check the status of your modules and themes and if they are in use. Remove the ones that you do not use.
For more information about how to prepare your Developer Portal for the Drupal 11 upgrade, see the following steps:

1. Installing the upgrade status module
2. Upgrading your module to be Drupal 11 compatible
3. Import your module into your Developer Portal
4. Verifying that your module is Drupal 11 compatible

Installing the upgrade status module



1. Log in to your Developer Portal as the administrator.
2. Install the Upgrade Status module. For more information about how to install the Upgrade Status, see Installing custom modules.
3. When you finish your Upgrade Status installment, click Admin > Reports > Upgrade-status.



You can ignore the Drupal core and hosting environment section as this area is managed by IBM API Connect and gets resolved when the upgrade is complete.
Important: Your custom modules and themes must be PHP 8.3 compatible before you upgrade to Drupal 11, and you are responsible for doing the upgrade. For troubleshooting issues related to the Drupal upgrade, see Are my upgrade issues related to custom Drupal modules or themes?.
The list of projects displayed on the Drupal 11 upgrade status page are the ones that are not compatible with Drupal 11. The **`Upgrade status`** module categorizes these projects into different sections. For example, Remove, Update, Collaborate with maintainers.

Note: When you upgrade IBM API Connect, the Drupal 11 compatibility is automatically given to the modules and themes that you have not created or installed manually.

4. If you find your custom modules and themes on the Drupal 11 upgrade status page, select your custom modules and themes and then click Scan selected to reveal what changes are needed to make them Drupal 11 compatible. If your custom module or theme requires updates, you see a link to the corresponding themes or custom modules once the scan completed. For example, the following image demonstrates the process of scanning an installed custom module, named **`Masonry API`**.
Note: For the **`Upgrade status`** module to identify all the Drupal 11 compatibility issues in your custom modules and themes, you must enable the custom modules and themes before scanning it.

5. Click Export as HTML to get a clear view.

Upgrade Status report

Contributed projects

Masonry API 4.0.0

Scanned on Thu, 05/08/2025 - 12:53.

1 warning found.

Check manually

Errors without Drupal source version numbers including parse errors and use of APIs from dependencies.

File name	Line	Error
modules/masonry/**masonry.info.yml**	5	Value of `core_version_requirement: ^8 || ^9 || ^10` is not compatible with the next major version of Drupal core. See https://drupal.org/node/3070687.

6. Add the new version in the info.yml file and change the code for the deprecated functions to upgrade your module and make it compatible with Drupal 11.
7. When your module becomes compatible with Drupal 11, import your updated module by reinstalling it using the Developer Portal UI. For more information about how to install custom modules, see Installing custom modules.
8. Return to Upgrade status report page and rescan the module to verify that your module is Drupal 11 compatible.

Upgrading your module to be Drupal 11 compatible

This module is an example of how you can read the report and fix your code to make it compatible with Drupal 11.

1. Add the new version into the info.yml file. Keep Drupal/Core/Extension/Extension List as it is still present in Drupal 9 and Drupal 10, and add on support for Drupal 11.
   Note: If any custom modules use deprecated APIs that are not compatible with Drupal 11, it is your responsibility to make it compatible with Drupal 11. For troubleshooting issues related to the Drupal upgrade, see Are my upgrade issues related to custom Drupal modules or themes?.
2. When you make a change to the module, modify the version number as shown in the following example.

Before

```
 name: 'IBM APIC Portal - custom icons'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of custom product icons'
package: 'Custom'
core_version_requirement: ^9 || ^10
version: 1.0.1
project: 'custom_icons'
dependencies:
  - ibm_apim
```

After

```
name: 'IBM APIC Portal - custom icons'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of custom product icons'
package: 'Custom'
core_version_requirement: ^9 || ^10 || ^11
version: 1.0.2
project: 'custom_icons'
dependencies:
  - ibm_apim
```

Import your module into your Developer Portal

Import the module by using Developer Portal Toolkit CLI. For more information about how to use the Developer Portal CLI, see Getting started with the Portal CLI commands.

For example,

```
❯ apic login -s $SERVER -r provider/default-idp-2 -u steve Warning: Using default toolkit credentials. Enter your API Connect credentials Password? Logged into api.fyre-ci-134466-master.fyre.ibm.com successfully ❯ apic -s $SERVER -m portaladmin custom-module:create-import -o ibm -c api-connect-catalog-2 /tmp/custom_icons.zip Loading File (Large files may take a while)... 201 CREATED - Task ID: wp5fhmm9l74pmkw1 Response Code - 202: Message(s) - The status of this task is: QUEUED Response Code - 202: Message(s) - The status of this task is: RUNNING Response Code - 200: Message(s) - 2023-02-27 14:39:38: CLI task (custom_module:import) starting. 2023-02-27 14:39:40: Deleting existing custom module /var/aegir/platforms/devportal-9.x-10.0.5.2-20230105-1720/sites/ibm.api-connect-catalog-2.portal.fyre-ci-134466-master.fyre.ibm.com/modules/custom_icons 2023-02-27 14:39:40: Importing custom module custom_icons 2023-02-27 14:40:25: CLI task (custom_module:import) completed successfully.
```

Alternatively, import your updated module by installing it again using the Developer Portal UI. For more information about how to install custom modules, see Installing custom modules.

Verifying that your module is Drupal 11 compatible

The updated module is now imported into the Developer Portal. Return to the Upgrade status report page to rescan the module. When it becomes compatible with Drupal 11, it appears at the end of the page.

Workbench (workbench)	Contributed module	Installed	8.x-1.4	✓ Compatible	N/A	Up to date	✓ Compatible	Issues	N/A
IBM APIC Portal - custom icons (custom_icons)	Contributed module	Installed	1.0.0	✓ Compatible	No problems found	Not applicable	? Unchecked	Issues	N/A
Snowflakes (snowflakes)	Contributed module	Uninstalled	2.0.1	✓ Compatible	3 problems	Not applicable	? Unchecked	Issues	N/A

Results

You used the **`Upgrade status`** module to identify and fix the Drupal 11 compatibility problems with your custom modules and themes. However, this process might not cover everything that you need to be ready for the upgrade to Drupal 11. Drupal 11 requires PHP 8.3, so you might need to change your custom modules and themes to support it. Remember to keep your custom modules and themes up to date, and to remove deprecated code within your own written custom modules and themes.

Upgrading to class-based hooks in Drupal 11

Starting with Drupal 11, you can define hooks as class-based attributes that align with modern PHP practices to improve the ease of maintenance.

Although the traditional procedural hooks that are defined as functions in the .module files still supports backward compatibility, use **`class-based`** syntax for Drupal 11. The suggested directory for defining hook classes is src/Hook/. For more information, see Drupal 11.1.0 release blog.

Important:

- Hooks are now annotated with the **`#[Hook]`** PHP attribute to indicate their role in the system.
- You cannot convert all hooks to class-based definitions. Some older or low-level hooks must remain as procedural functions.
- Before converting hooks, consult the official API documentation to ensure compatibility.

The following sections provide examples of the most common updates that you might need to make. However, you must check the deprecation lists for Drupal and PHP to ensure that you cover all the scenarios in your Developer Portal sites.

Notable changes the update brings

Some of the key changes in Drupal 11 include:

- The Drupal 11 upgrade comes with a major Symfony upgrade version. Drupal 10 used Symfony 6, and Drupal 11 now uses Symfony 7. If you are using any Symfony, ensure that they are not deprecated. For more information, see https://symfony.com/doc/current/setup/upgrade_major.html.
- The default Drush version is now Drush 13. If you are writing Drush commands in your custom modules, you must ensure that the commands are Drush 13 compatible.

Note:

- The custom modules and themes must be compatible with Drupal 11. For more information about finding the custom modules and themes on your Developer Portal, see How to find your custom modules and themes on your Developer Portal.
- For troubleshooting issues related to the Drupal upgrade, see Are my upgrade issues related to custom Drupal modules or themes?.
- It is your responsibility to check the deprecation lists for Drupal and PHP to ensure that you cover all scenarios in your Developer Portal sites.

For more information about making your custom modules compatible with Drupal 11, see the following links:

- Deprecation checking and correction tools.
- Deprecated modules and themes.
- List of APIs deprecated and now removed from Drupal 11.
- Symfony Upgrade Guide.
- Drush 13 commands.

Developer Portal tutorials

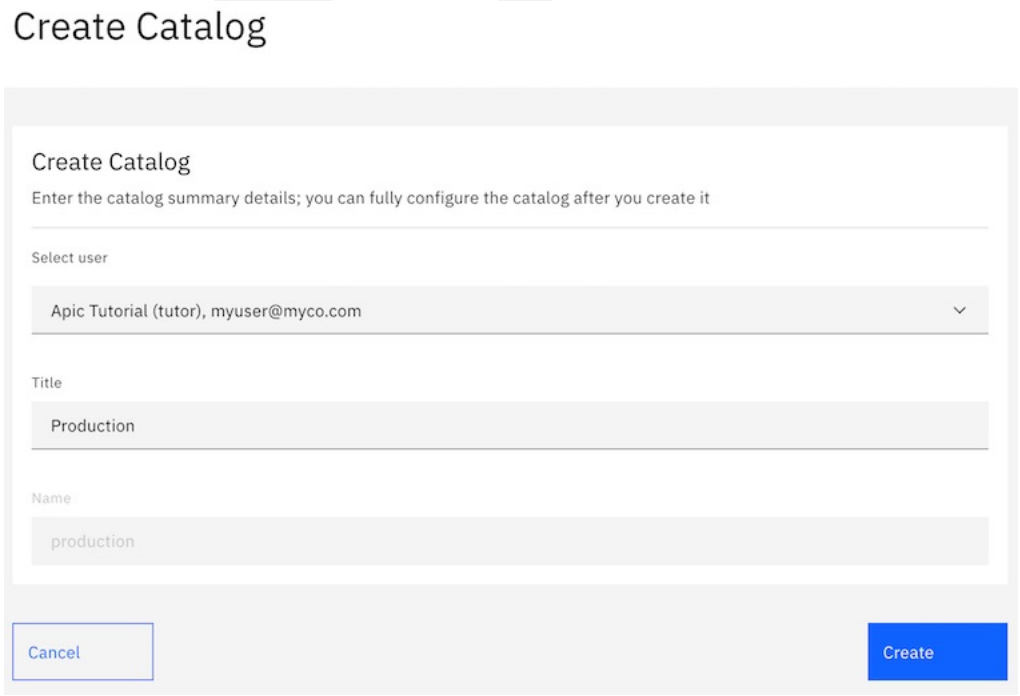
Tutorials for using the Developer Portal.

The following guided examples help you through some of the most common user scenarios in the Developer Portal, as well as some of the more complex areas.

Developer Portal tutorials by category
For API consumers Create an Application
User authentication Adding a field to the sign up form Adding validation to a field on the sign up form Adding a field group to group fields in a content type
Getting started configuring the Developer Portal Creating the Portal Creating a private Portal site Customizing themes

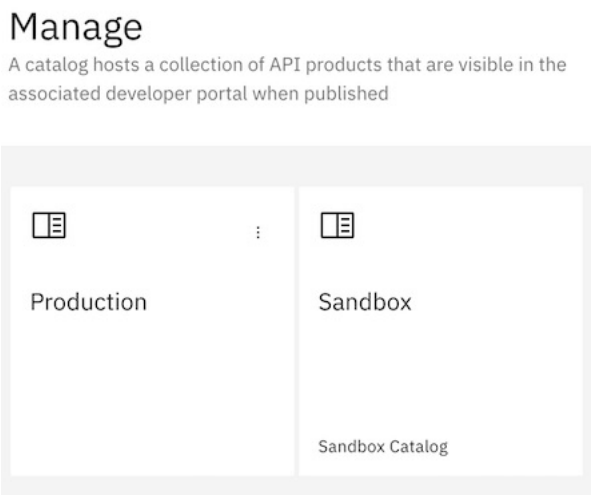
Developer Portal tutorials by category
Advanced customization Changing the front page Grouping products by category Adding a custom block to the front page Adding a custom block to a page other than the front page Using avatars Using image optimization Adding a Back to top button Creating a drop-down menu link Displaying blog posts on the front page Displaying tweets on the front page Changing the profile page to display firstname lastname, instead of username Using a custom weighting sort order on the product list page Configuring the RobotsTxt file Configuring the SecurityTxt file Synchronizing application credentials with an external server

Tutorial: Creating the Developer Portal



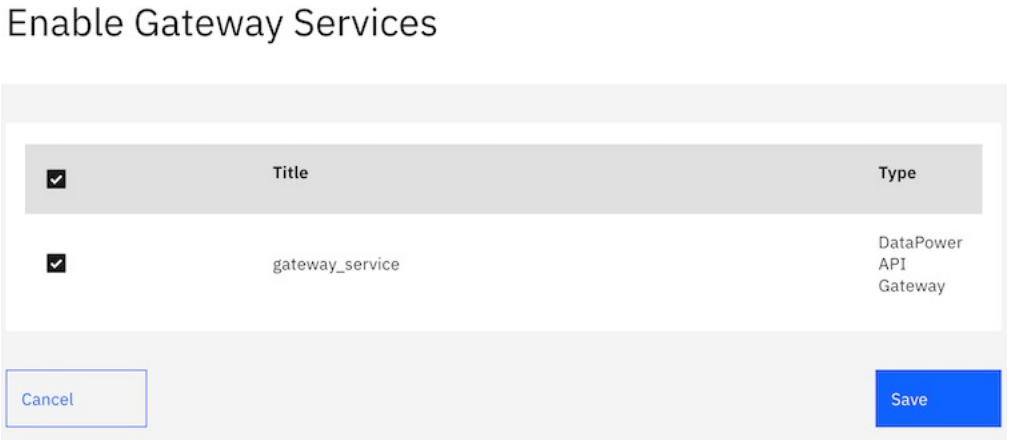
About this task

In this tutorial, you are going to complete the following lessons.

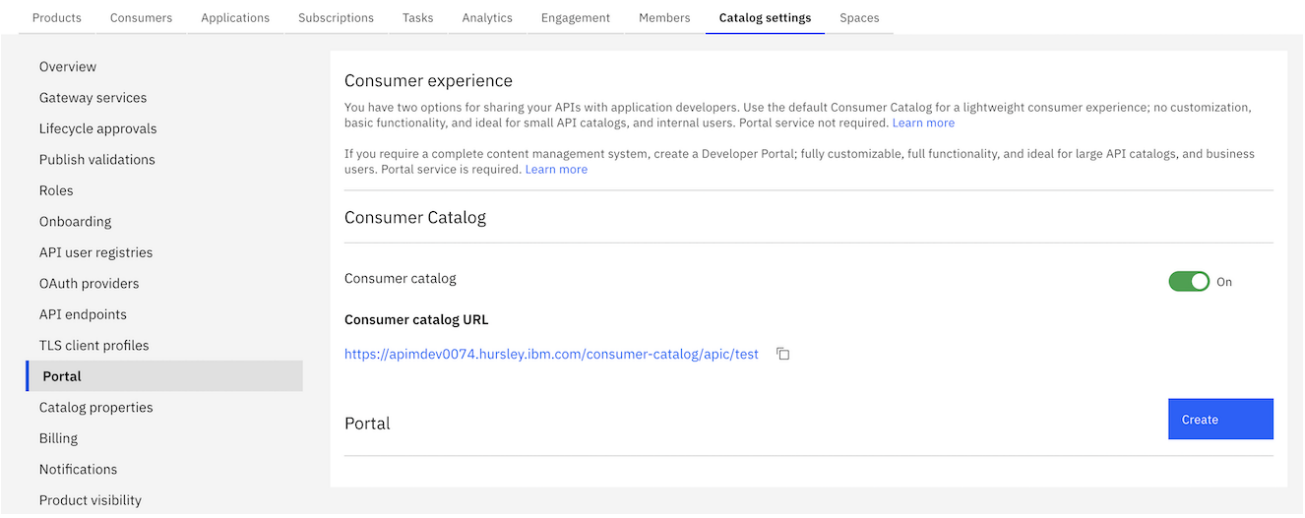


Enabling the Developer Portal through the API Manager

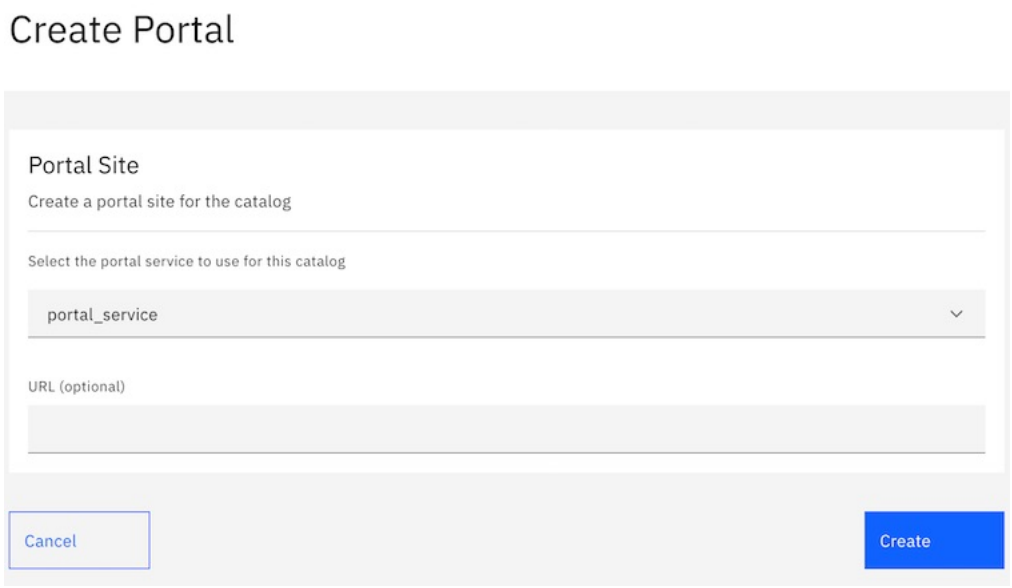
To create an administrator account, complete the following steps.



1. Log in to the API Manager
2. Click Manage, then click Add, and select Create catalog.
3. Select the owner from the **`Select user`** list and then enter a **`Title`** for your catalog. For example `Production`.



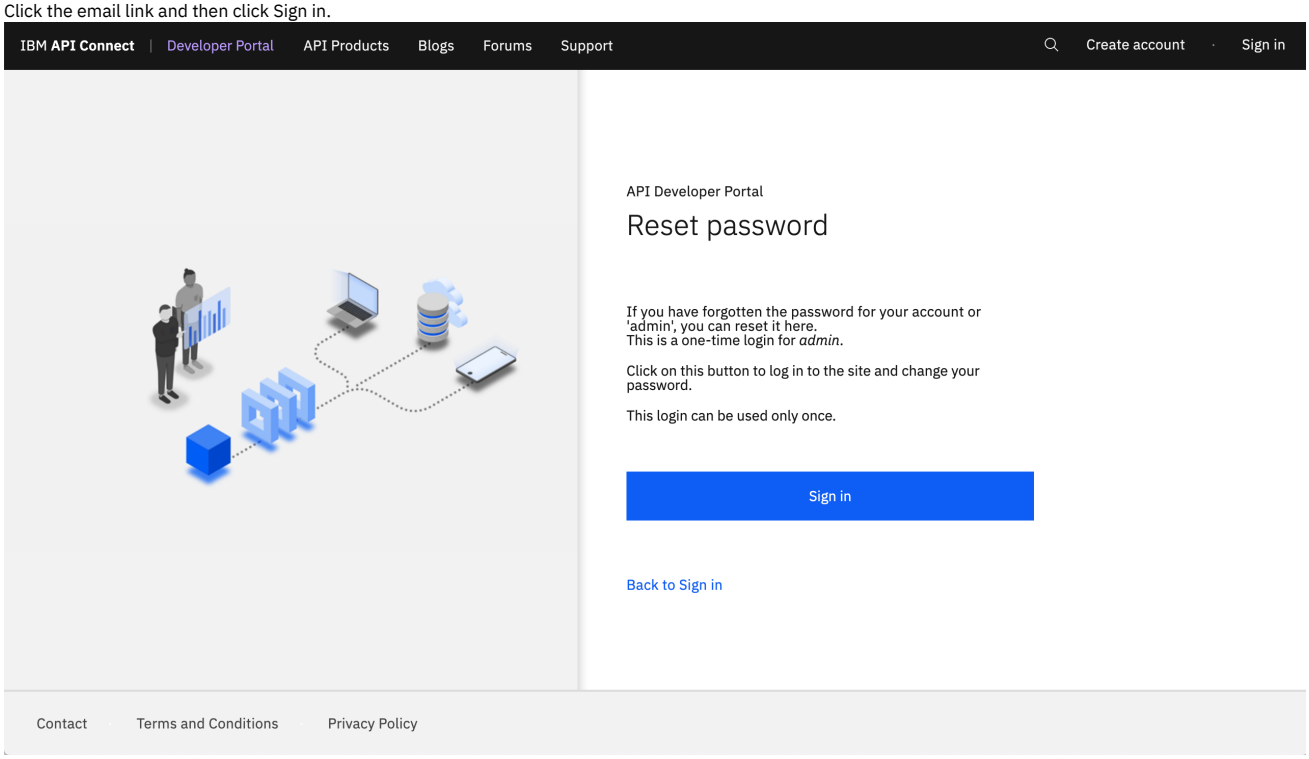
4. Click Create. The Manage page appears.



5. Click the tile that corresponds to your new catalog, for example **`Production`**.
6. Click Catalog settings.
7. Click Gateway Services. If the message **`You currently don't have any gateway services`** is displayed, click Edit, select the configured gateway service, and click Save.

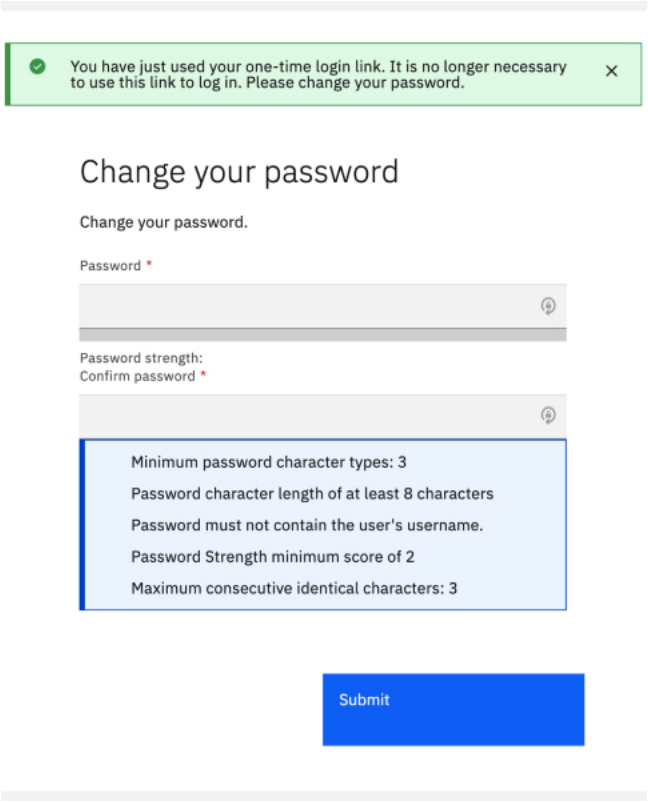
8. Click Portal.
9. Click Create.

10. Select a portal service to use. Click Create.



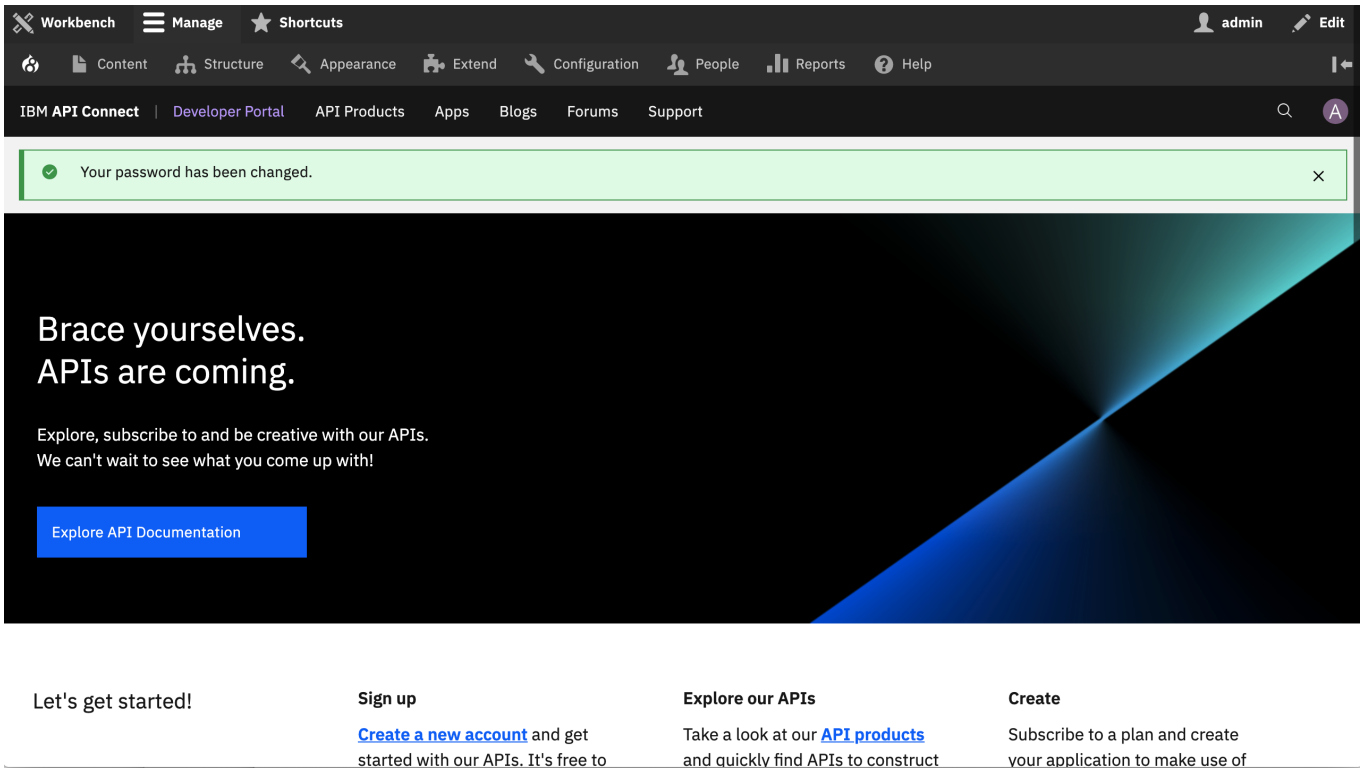
After a few minutes, you receive an email with a link to your Developer Portal site for that catalog. The link is a single use only link for the administrator account.

Administrator (admin),



Your Developer Portal site has been created. You can log in as the 'admin' user by using the following one-time log in link. After you have logged in with the following link, you must change the password for the 'admin' user account immediately.

https://portal.apidemo.demo.ibm.com/tutorial/production/user/reset/1/1591727237/h26vxzf2e51UqqK7vf10LNbHiVEC5VQ_AZAoKCYH72C/new/login



11. Click the email link and then click Sign in.

12. Change the password and then click Submit.

The portal site for the Production catalog is now active. The admin account cannot create applications or subscriptions. Create a new account to complete those tasks.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Enabled a Developer Portal site and created an administrator account.

Note: To make sure that the required content is displayed, it is crucial to publish your product containing APIs to the appropriate catalog.

What to do next

- Create a Developer Account and Application

Related information

- Importing an API

Tutorial: Creating a private Developer Portal site

You can create a private version of the Developer Portal so that only the authenticated users can access content on the site. You might want to do this if you want to restrict public access to your content unless they are logged in.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this tutorial, you are going to restrict access for all the content to authenticated users only. This gives access to all users from **Content Author** to **Superuser**, as they are all required to authenticate to access their roles. You will then add the login form to the home page, so that public users will be able to view the public home page that contains the login form only.

This tutorial takes you through the following steps:

1. Export your configuration settings.
2. Restrict all permissions to authenticated users.
3. Restrict blocks to authenticated users.
4. Add login form to the home page.

Export your configuration settings

In case you make an error, or want to revert all of the changes made during this tutorial, you can back up your configuration settings to your machine before you make any changes.

The tutorial Exporting and importing custom themes and site configuration provides further details on how to export your configuration settings using the Developer Portal CLI.

Restrict all permissions to authenticated users

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to People > Permissions.
3. Clear all check boxes that are associated with **ANONYMOUS USER**.
4. Click **Save permissions** at the end of the page.

Restrict blocks to authenticated users

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Block layout.
3. Find the row that is labeled **Main menu** and click **Configure**.
4. Find the setting **Roles** under the category **Visibility**.
5. Check the box **Authenticated user**.
6. Click **Save block**.
7. Repeat from step 3 for the **Footer menu**.
8. Click **Save block**.

Add login form to the home page

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Pages.
3. Click **Edit** on the **Welcome** page.
4. Navigate to Panels > Content.
5. Click **Add new block**.
6. Find and click **User login**, under the **FORMS** section.
7. Clear the **Display title** check box.
8. Click **Add block**.
9. Rearrange the new login block so that it is underneath the **Welcome Banner**.
10. Click **Update and save**.

What you did in this tutorial

On your Developer Portal, you restricted access for all the content to authenticated users only. Now when you access your home page as an unauthenticated user, you see that the login form appears underneath the welcome banner. Navigating to other URLs on the site presents an **unauthorized** page to appear.

When you log in, the login form disappears from the home page and you are able to access all of the pages that are visible to your role.

Tutorial: Creating Accounts and Applications on the Developer Portal

This tutorial shows you how to create a developer account and register an application on the Developer Portal.

Before you begin

You must have a Developer Portal installed, and created and published at least one API product.

If you do not have a Developer Portal available, complete the tutorial Creating a Developer Portal.

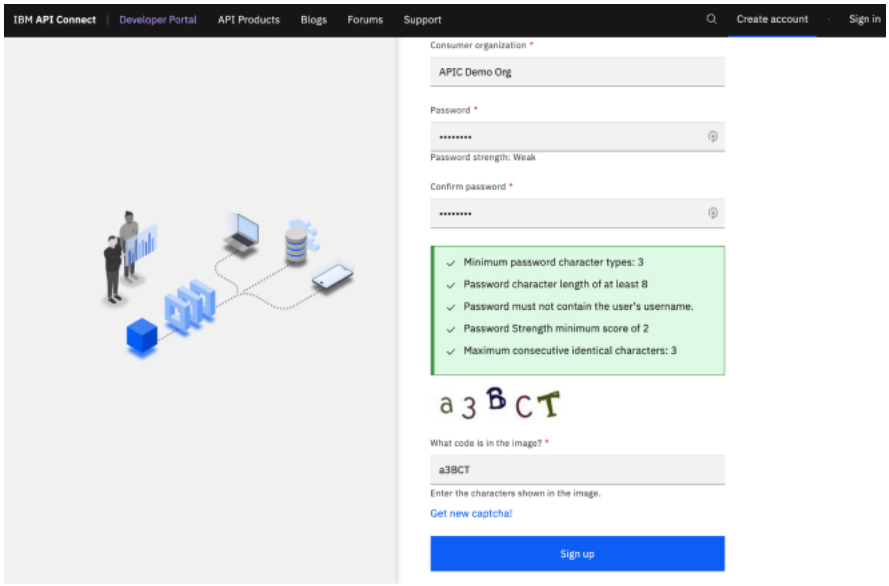
If you don't have an API product available, you can download one of the following APIs, and then import and activate it:

- If your Sandbox catalog uses a DataPower® Gateway (v5 compatible) (as one of the gateways, or as the only gateway), download the findbranch.txt file to your local filesystem. Rename this file `findbranch.yaml`.
- If your Sandbox catalog uses a DataPower API Gateway, download the findbranch_v6.txt file to your local filesystem. Rename this file `findbranch.yaml`.

For more information about importing an API, see Adding a REST API by importing an OpenAPI definition file.

About this task

In this tutorial you are going to complete the following lessons:



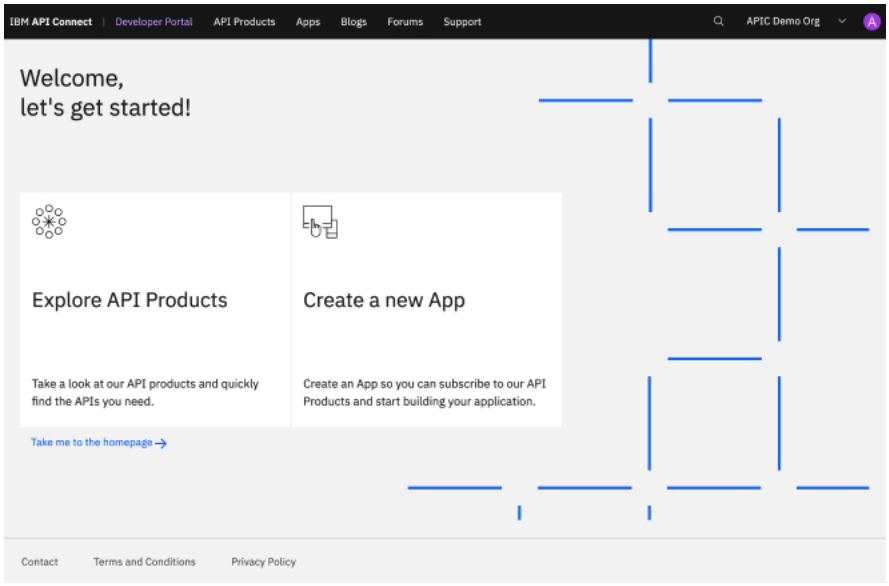
- Creating a developer account in the Developer Portal
- Creating a developer application in the Developer Portal
- Testing the Branches API in the Developer Portal

Note: The administrator account cannot create an App, or register to an App. To create or register to an App, you must have a developer account. A developer account that has been assigned administrator privileges can create and register Apps.

Creating a developer account in the Developer Portal

Take the following steps to create a developer account:

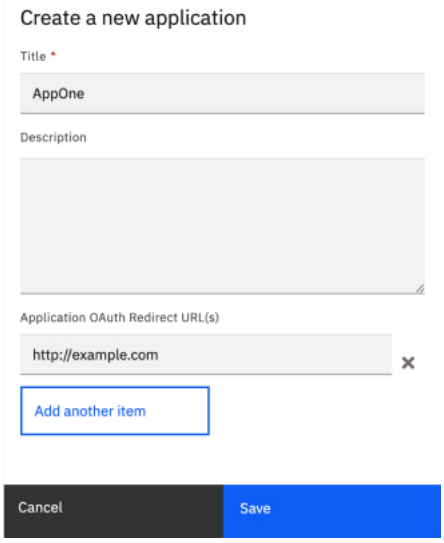
1. Follow the instructions provided on Creating a Developer Portal and open the Developer Portal.
2. Click Create account. If the Create account link is not visible, log out as Admin from the Developer Portal first, go to the home page of the Developer Portal, and click Create account.
   Note: Your email is used as your user name for the Developer Portal. The email address must be different from the address used for creating the administrator account.
3. Complete the sign up form. The email address you provide must be functional. Click Sign up. A confirmation message is sent to the email address provided in the form.



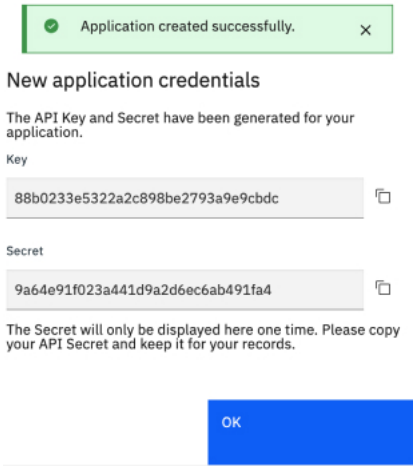
4. Click the account activation link in the confirmation email to activate your account.
5. To use the Developer Portal, click Sign in and sign in with the user credentials you specified.

Creating a Developer Portal Application

To create and register a new App:



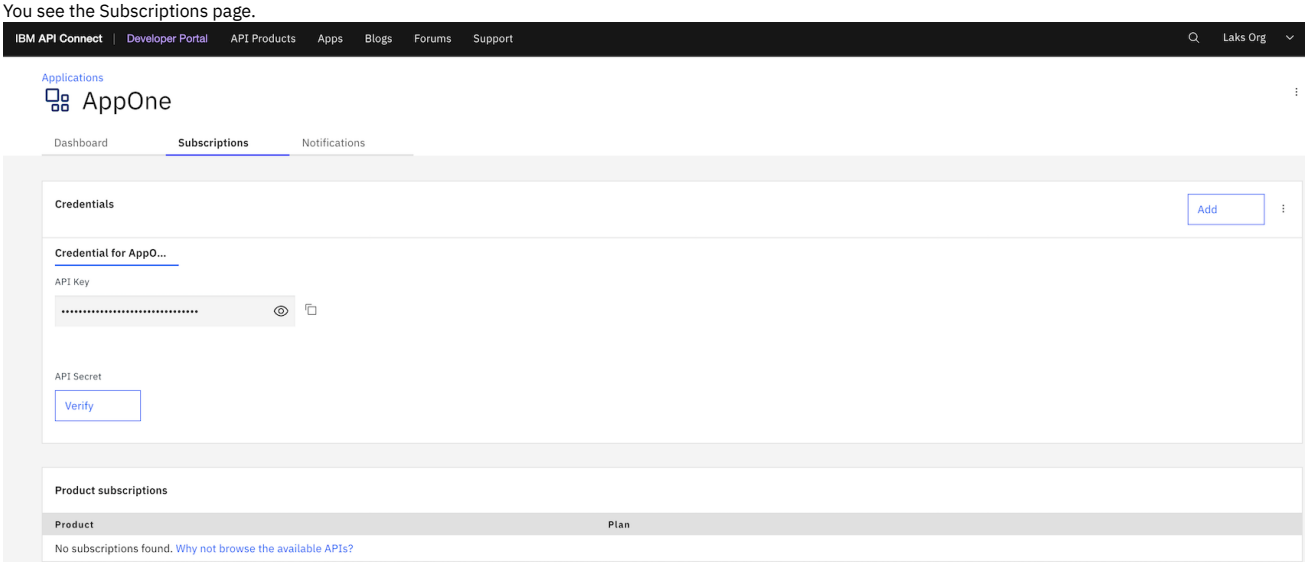
1. In the Developer Portal, click Create a new App.
   Note: You cannot register new applications if you are logged in as the administrator.



2. Enter the following values for the application that is being registered.

Table 1. Values for registering the application

Field Name	Value
Title	`AppOne`
Application OAuth Redirect URL(s)	`http://example.com`

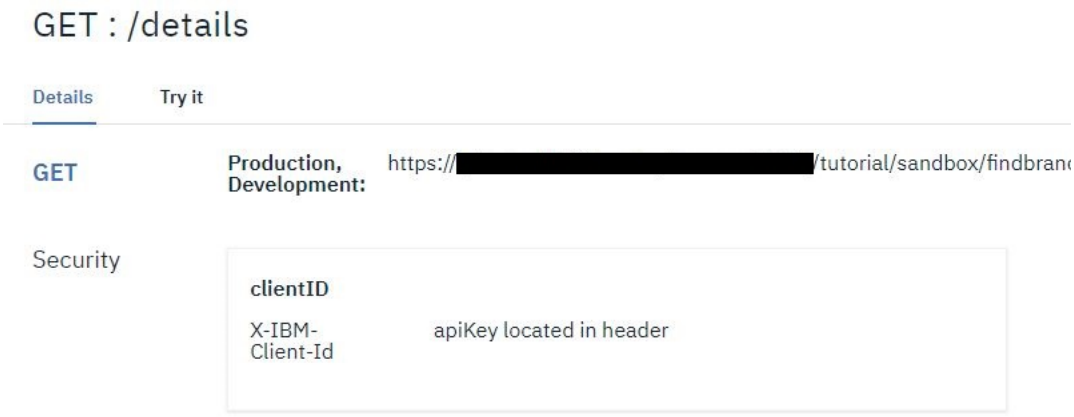


3. Click Save.
4. Copy the key and secret values for the new app. Click OK.

5. Click OK.

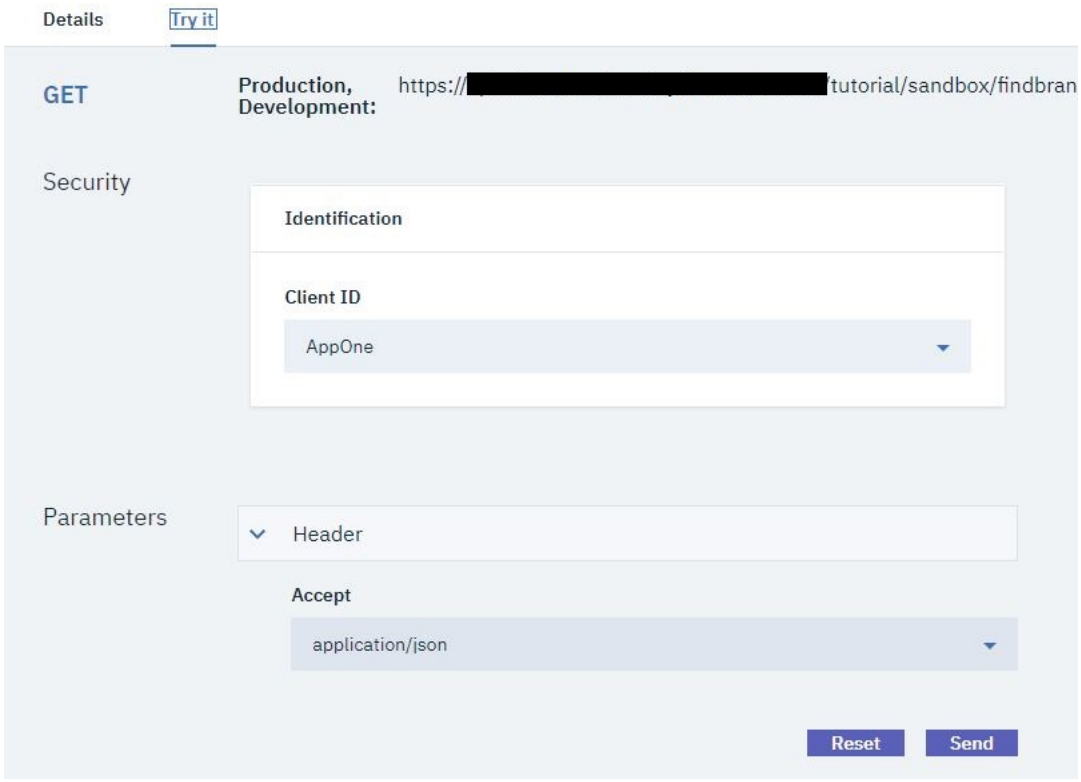
You see the Subscriptions page.

Subscribing to an API in the Developer Portal



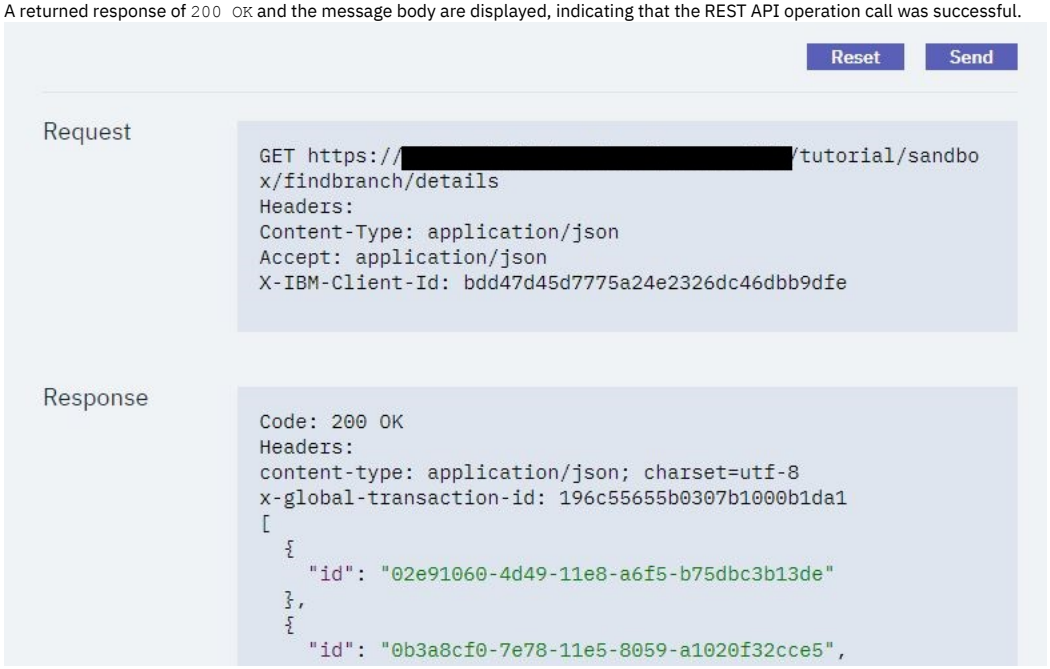
1. Click API Products.
2. In the Name field, enter `FindBranch` and click on the *product name* .
3. Under Plans, click Select.
4. Under the Application heading, click AppOne.
5. Under Subscribe, click Next to confirm the subscription.
6. Under Summary, click Done after confirming the subscription details.

To view the current subscription details of your application, perform the following steps:



1. Under Apps, select AppOne.
2. Click Subscription.

Testing An API in the Developer Portal



1. Click API Products in the Developer Portal dashboard.
2. Click a Product, such as FindBranch auto product , then select the FindBranch API from the list.
3. Click GET /details.

4. Click Try it.

5. Click Send.
   Note: If no response is received, navigate to the URL that is displayed at the beginning of the Try this operation section, in a new browser tab. Accept the security certificate, and then call the operation again.
6. A returned response of `200 OK` and the message body are displayed, indicating that the REST API operation call was successful.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a developer account in the Developer Portal.
- Created and registered a new App, and subscribed it to a Plan.
- Tested an API in the Developer Portal.

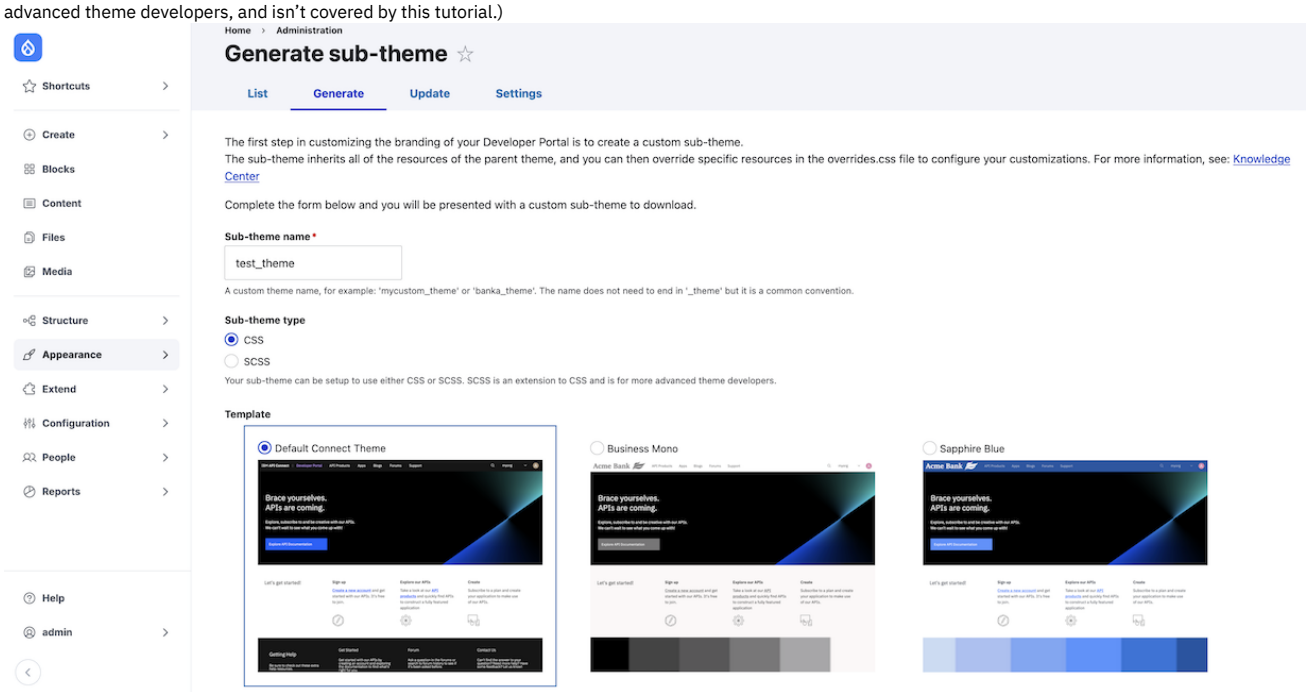
Tutorial: Creating a custom theme for the Developer Portal

Customize the appearance of your Developer Portal home page by generating a subtheme, configuring the overrides.css file, and installing the newly customized theme.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.
Important: You're not permitted to include any IBM® API Connect code within any custom themes that you create.

About this tutorial



The way to create a custom theme is to create a custom subtheme of the standard API Connect theme that the Developer Portal uses by default. The subtheme inherits all of the resources of the parent theme, and you can then override specific resources to configure the required customizations.

This tutorial takes you through the following lessons:

1. Creating a subtheme by using the theme generator.
2. Customizing the overrides.css file.
3. Installing and enabling your customized theme.

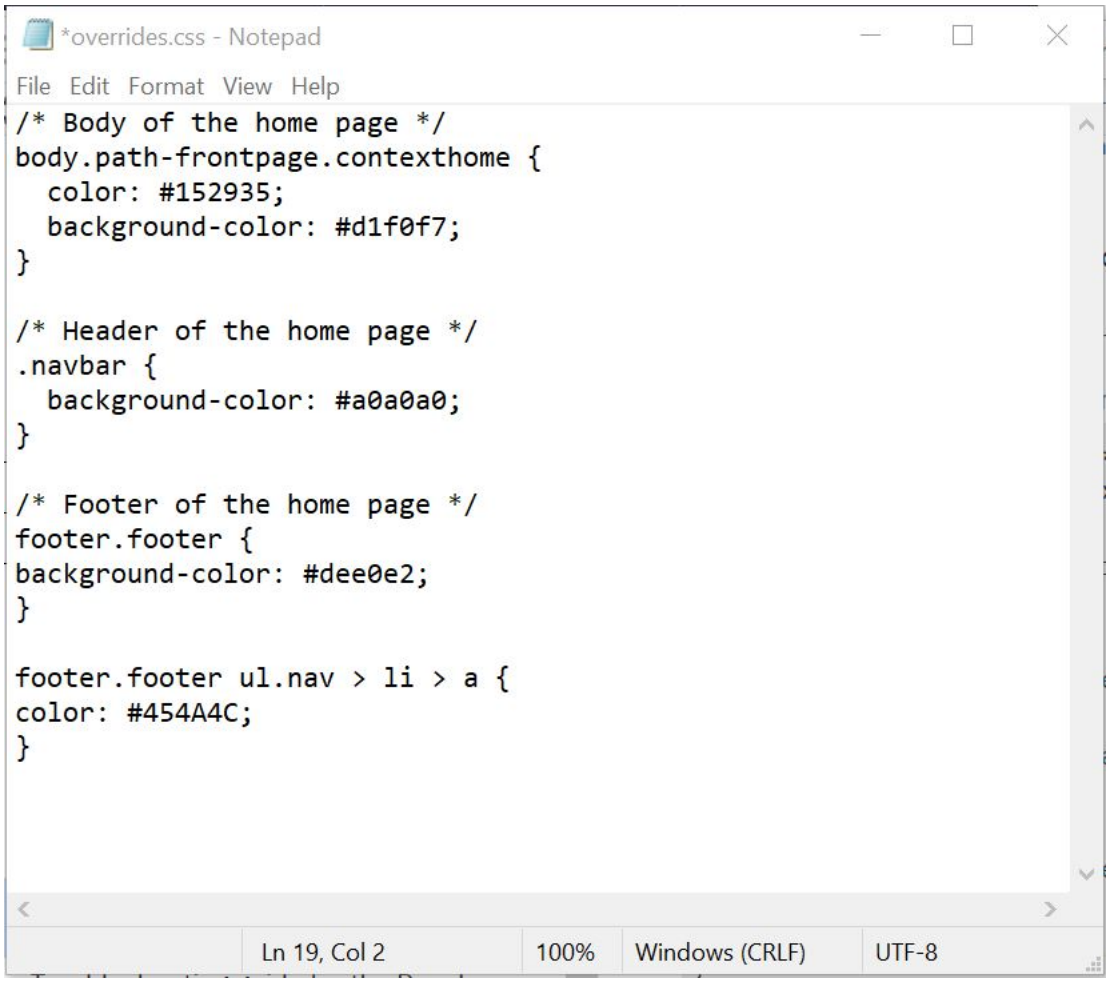
Creating a subtheme

1. Log in to your Developer Portal as an administrator.
2. Click Appearance > Generate sub-theme. The Generate subtheme window is displayed.
3. Under the Generate tab, enter a Sub-theme name, and select CSS for the Sub-theme type. (If you prefer, you can select SCSS, but this extension to CSS is for advanced theme developers, and isn't covered by this tutorial.)

4. Select the Default template to base your `sub-theme` on. You can create a subtheme based on a color template. However, for this tutorial you use the Default Connect Theme template.
5. Click Generate.
6. Download the generated subtheme to a location of your choice, and extract all the files from the .zip file.
   Note: The generated subtheme is available to download for 24 hours.

Customizing the overrides.css file

On your computer, navigate to the files that you extracted. Find the overrides.css file in here: <extract_folder>/css/overrides.css. You can now customize the overrides.css file.

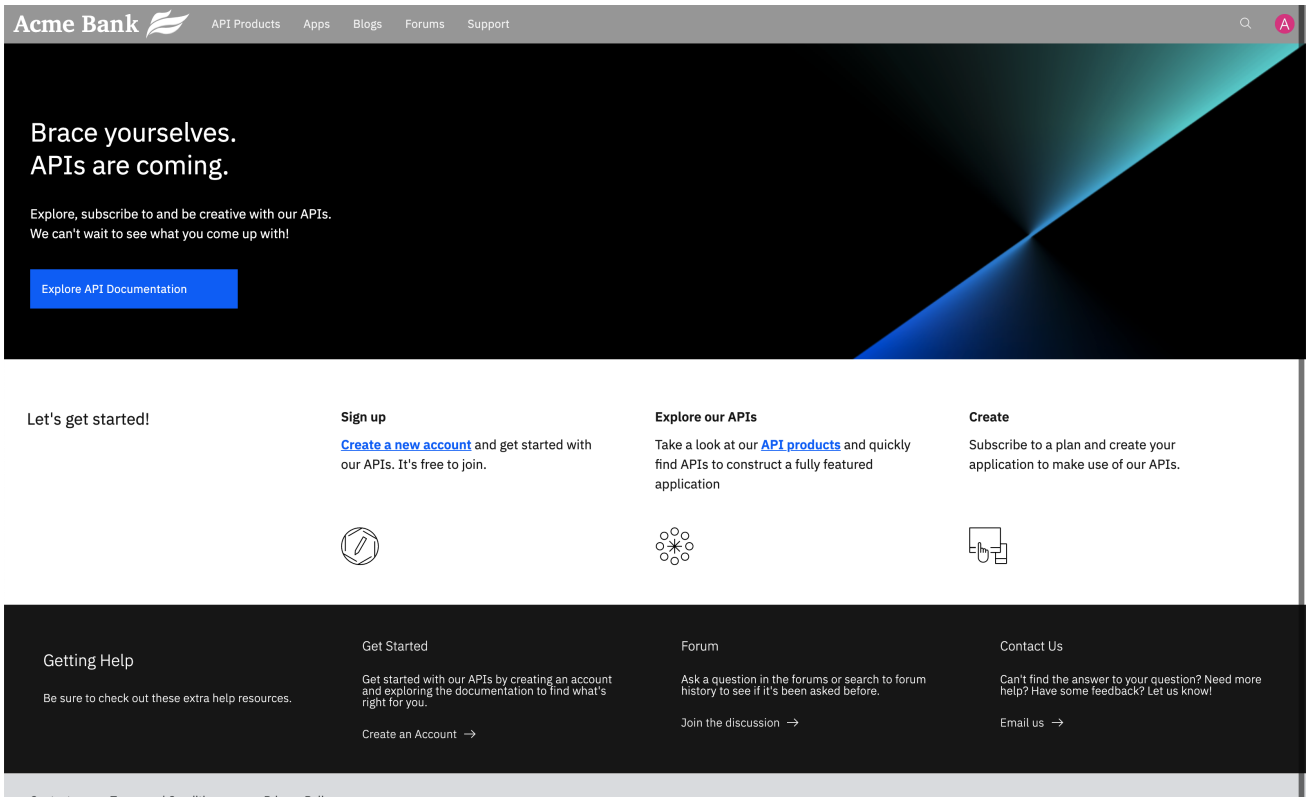


1. Open the overrides.css file in your chosen editor.
2. Customize your subtheme by entering the following elements into the overrides.css file:

```
/* Body of the home page */
body.path-frontpage.contexthome {
  color: #152935;
  background-color: #d1f0f7;
}

/* Header of the home page */
.navbar {
  background-color: #a0a0a0;
}

/* Footer of the home page */
footer.footer {
background-color: #dee0e2;
}
```



```
footer.footer ul.nav > li > a {
color: #454A4C;
}
```

3. Save the overrides.css file.

Installing and enabling your customized theme

1. After updating the overrides.css file, compress all the theme files back into the .zip subtheme file that you downloaded originally.
   Note: You can also include your own custom logo and favicon in your theme files, and these are then included as part of your theme when it is installed. These files must use the naming convention logo.svg, and favicon.ico, respectively. You can also change your logo and favicon later. For more information, see Changing the site logo and Changing the shortcut icon.
2. In the Developer Portal, click Appearance > + Add new theme. The **Add new theme** window is displayed.
3. In Upload a module or theme archive, click Browse, and navigate to your newly updated compressed theme file.
4. Click Continue to install the theme onto your site.
5. Click Enable newly added themes, and find your new theme in the list of Disabled themes. Click Enable and set as default to set your new custom subtheme as the default theme for your site.
6. Return to the Developer Portal home page by clicking Back to site. You can now see your custom theme.

What you did in this tutorial

In this tutorial, you completed the following tasks:

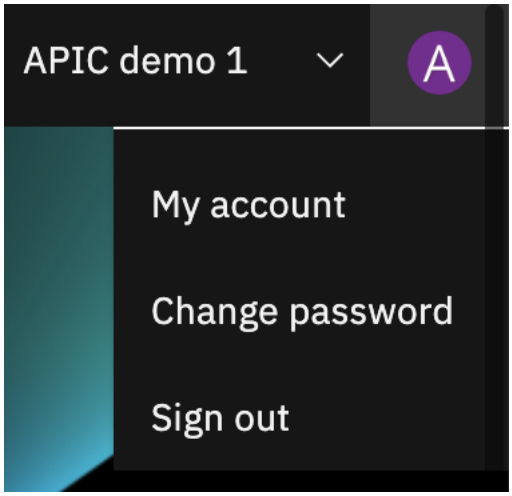
- Created a subtheme of your Developer Portal site by using the theme generator.
- Configured some customized home page elements in the overrides.css file of your subtheme.
- Uploaded and installed your customized theme in your Developer Portal site.
- Successfully customized the appearance of your Developer Portal home page.

Tutorial: Using avatars

You can use an avatar generator to better represent the branding of your site, and add a sense of community for your users, than the default name initial that is provided in the Developer Portal.

Before you begin

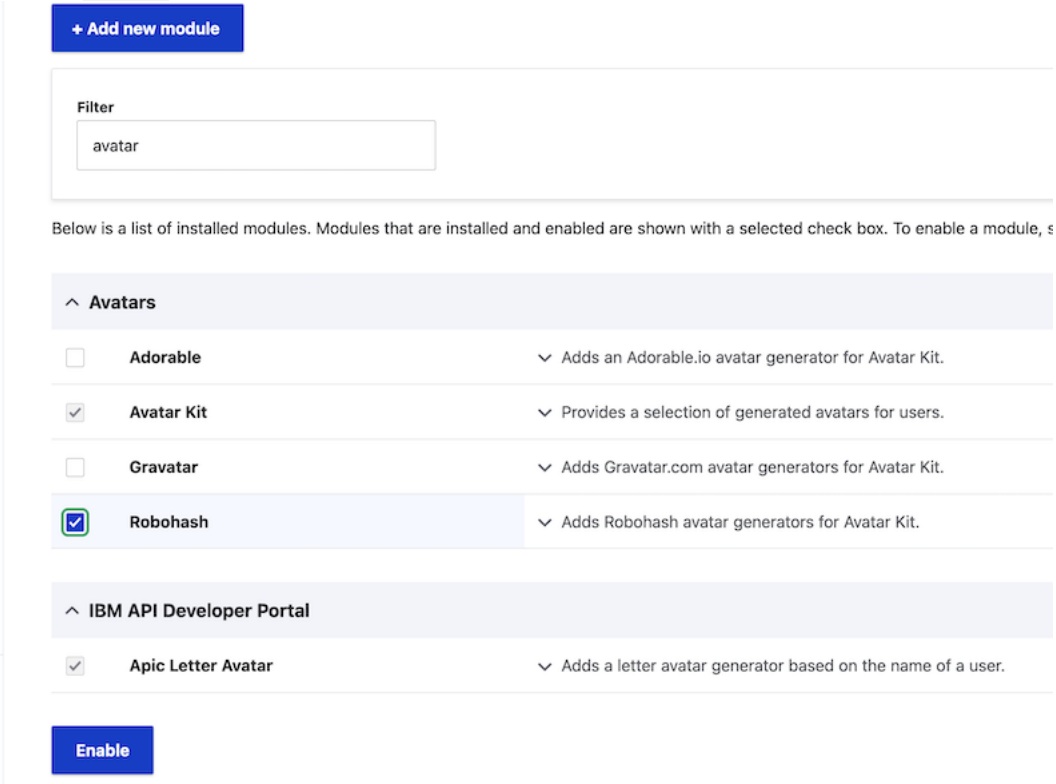
You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.



About this tutorial

In this task, you add the **Robohash** avatar generator to your Developer Portal site, and assign it as the primary avatar generator for all users.

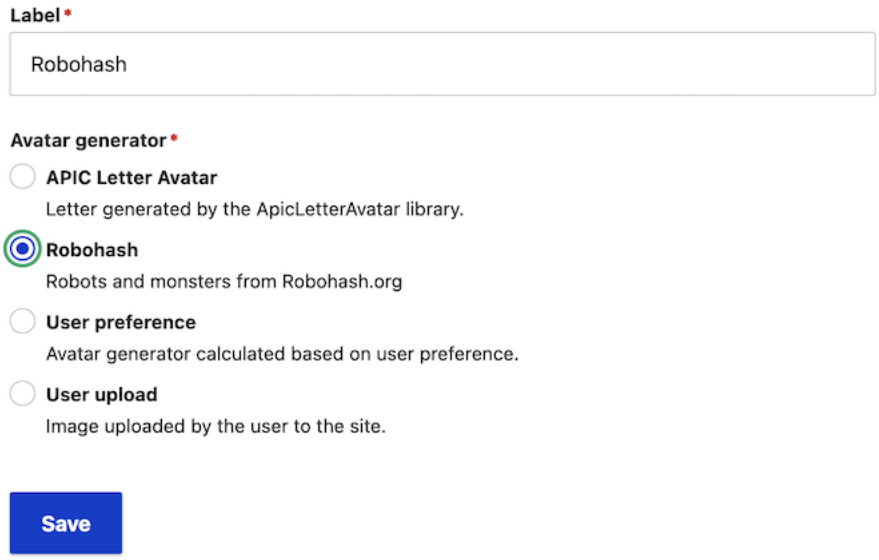
This tutorial takes you through the following steps:



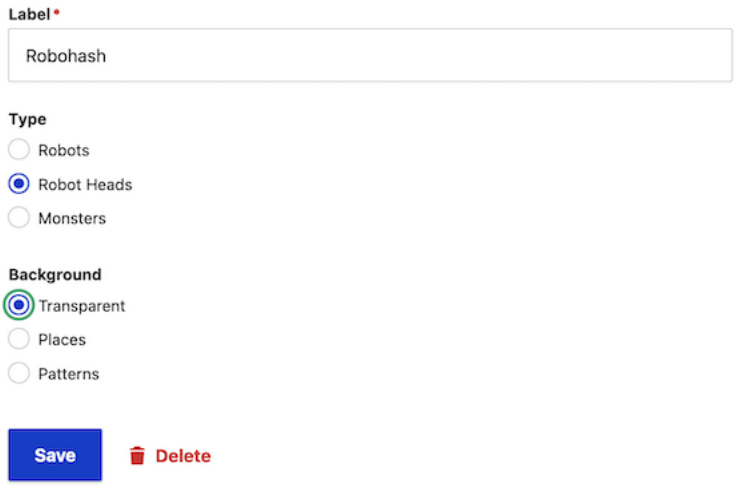
1. Enable the Robohash avatar generator.
2. Set Robohash as the preferred avatar generator for your site.
3. Configure the permissions for the Robohash avatar generator.

The avatar of the admin user displays like this before the block is added.

Enable the `Robohash` avatar generator



1. Log in to your Developer Portal as an administrator.
2. Click Extend > Extend.
3. In the Filter field, enter `avatar` to view the list of all the available avatar modules.
4. Select the **`Robohash`** checkbox and click Enable to enable the selected avatar module.



When the module is enabled, you receive a **`Module Robohash has been enabled`** message.

Set `Robohash` as the preferred avatar generator for your site

1. Navigate to Configuration > People > Avatar settings.
2. Click + Add avatar generator.
3. Enter `Robohash` as the label.
4. Select Robohash from the Avatar generator options.
5. Click Save.

6. The **`Edit avatar generator Robohash`** page opens. Select the following options:
   - **`Type: Robot Heads`**
   - **`Background: Transparent`**

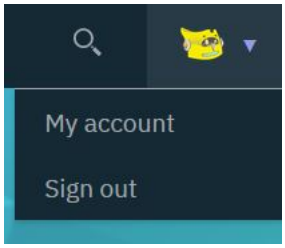
7. Click Save.
8. The Avatar Kit settings page opens. Under the Avatar Generator column, drag **`Robohash`** to be first in the list, and select the **`Enabled`** checkbox.
9. Click Save configuration to save the changes.

You have now set **`Robohash`** as the preferred avatar generator for your site.

Configure the permissions for the `Robohash` avatar generator

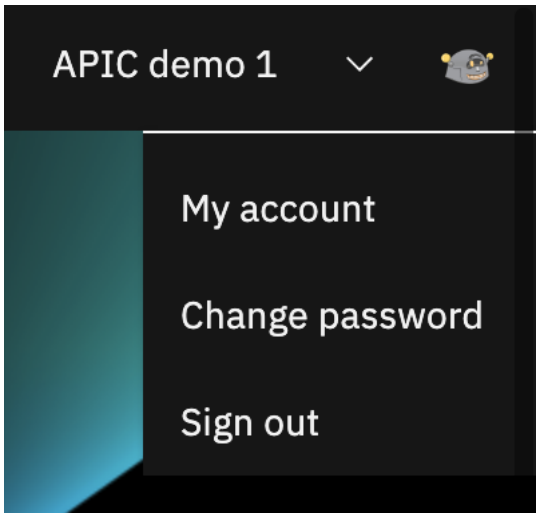
The default setting for the **`Robohash`** avatar generator is to generate avatars for users with **`superuser`** access only. In this example, the permissions are changed so that all **`authenticated users`** can access **`Robohash`**.

1. Navigate to People > People and click the Permissions tab.
2. Find **`Use Robohash`** under the permission type **`Avatar Kit`** and select the Authenticated user checkbox to enable the avatar generator for all authenticated users.
   Note: Once you select the Authenticated user checkbox, all the checkboxes for this user type are automatically selected because all of those users have the same permissions as an authenticated user, or higher.



Permission	Anonymous user	Authenticated user	Forum Moderator	Content Author	Administrator	Superuser
Automated Logout						
Administer Autologout	☐	☐	☐	☐	☑	☑
Change own logout threshold	☐	☐	☐	☐	☑	☑
Avatar Kit						
Administer Avatar Kit *Warning: Give to trusted roles only; this permission has security implications.* Manage settings for Avatar Kit.	☐	☐	☐	☐	☑	☑
Use *APIC Letter Generator* User can select *APIC Letter Generator* avatar generator.	☐	☑	☑	☑	☑	☑
Use *Robohash* User can select *Robohash* avatar generator.	☐	☐	☐	☐	☐	☑
Use *User upload* User can select *User upload* avatar generator.	☐	☑	☑	☑	☑	☑

3. Click Save permissions to save the changes.



What you did in this tutorial

The avatars of all users now have the **robohash** avatar.

You can check that the avatar of the admin user has changed by looking at your site page.

You can check that the avatars of other users have changed by finding their published content and looking for their avatar. Or, you can navigate to Manage > People, click a user, and see their avatar on their profile page.

What to do next

You can disable the **robohash** avatar generator.

1. Navigating to Extend > Disable module.
2. Search for **avatar** in the filter text box.
3. Check **Robohash**, click Disable
4. Click Disable.

You can also disable the **robohash** avatar generator by clearing it within Configuration > People > Avatar settings, or, reducing its preference by dragging it to a different order in the list. Click Save configuration.

Tutorial: Using image optimization

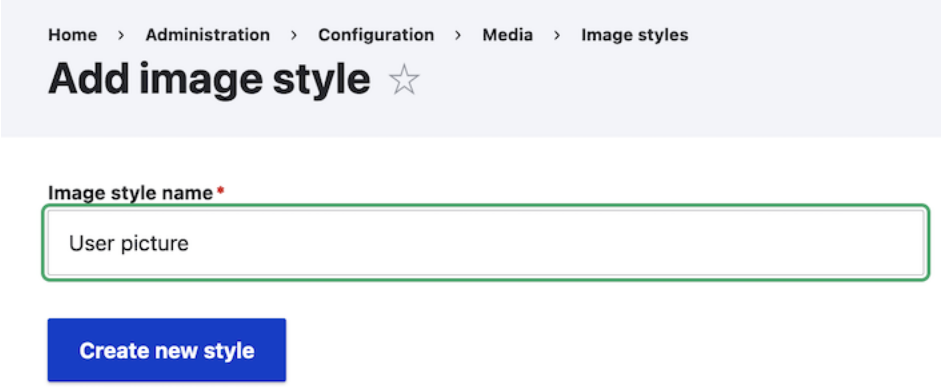
You can use image optimization on your Developer Portal site to enhance the use of images.

Optimized images do not overload your website and significantly increase its performance compared to using the original images. Your customer satisfaction and brand reputation improve with fast-loading and trimmed visual assets. Automatic optimization can save time and effort on editing and content moderation.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial



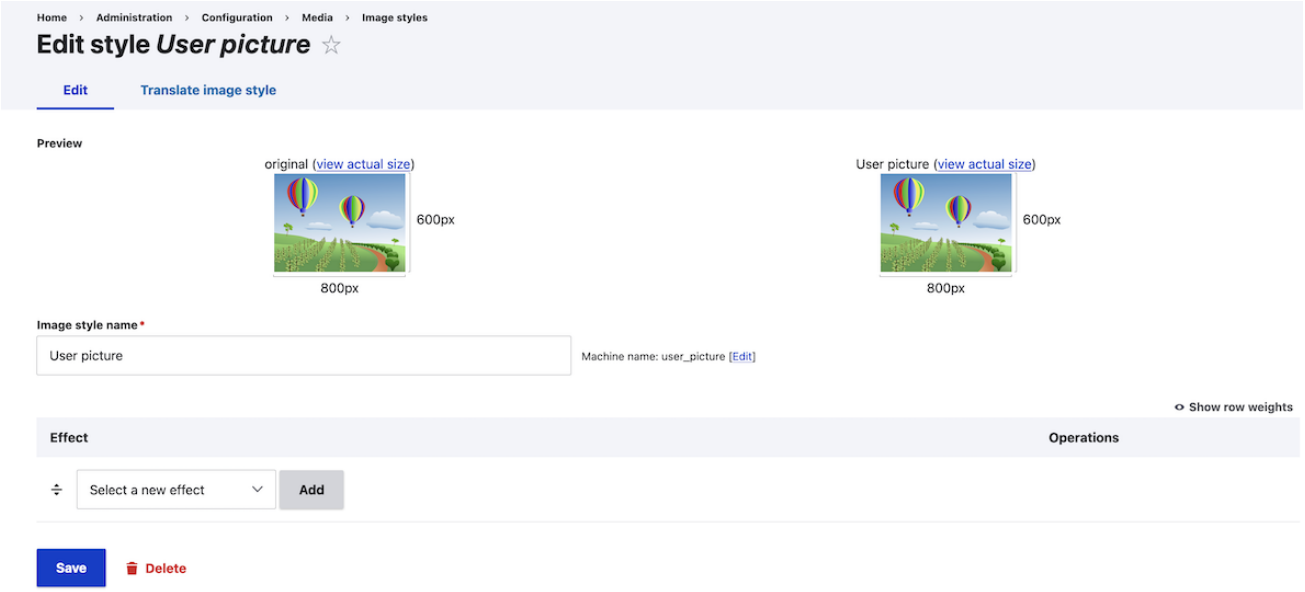
In this task, you create an image style that is called `User picture`, and give it a scale and crop effect. Then, use the `User picture` as the **`Picture`** field in the user account.

This tutorial takes you through the following steps:

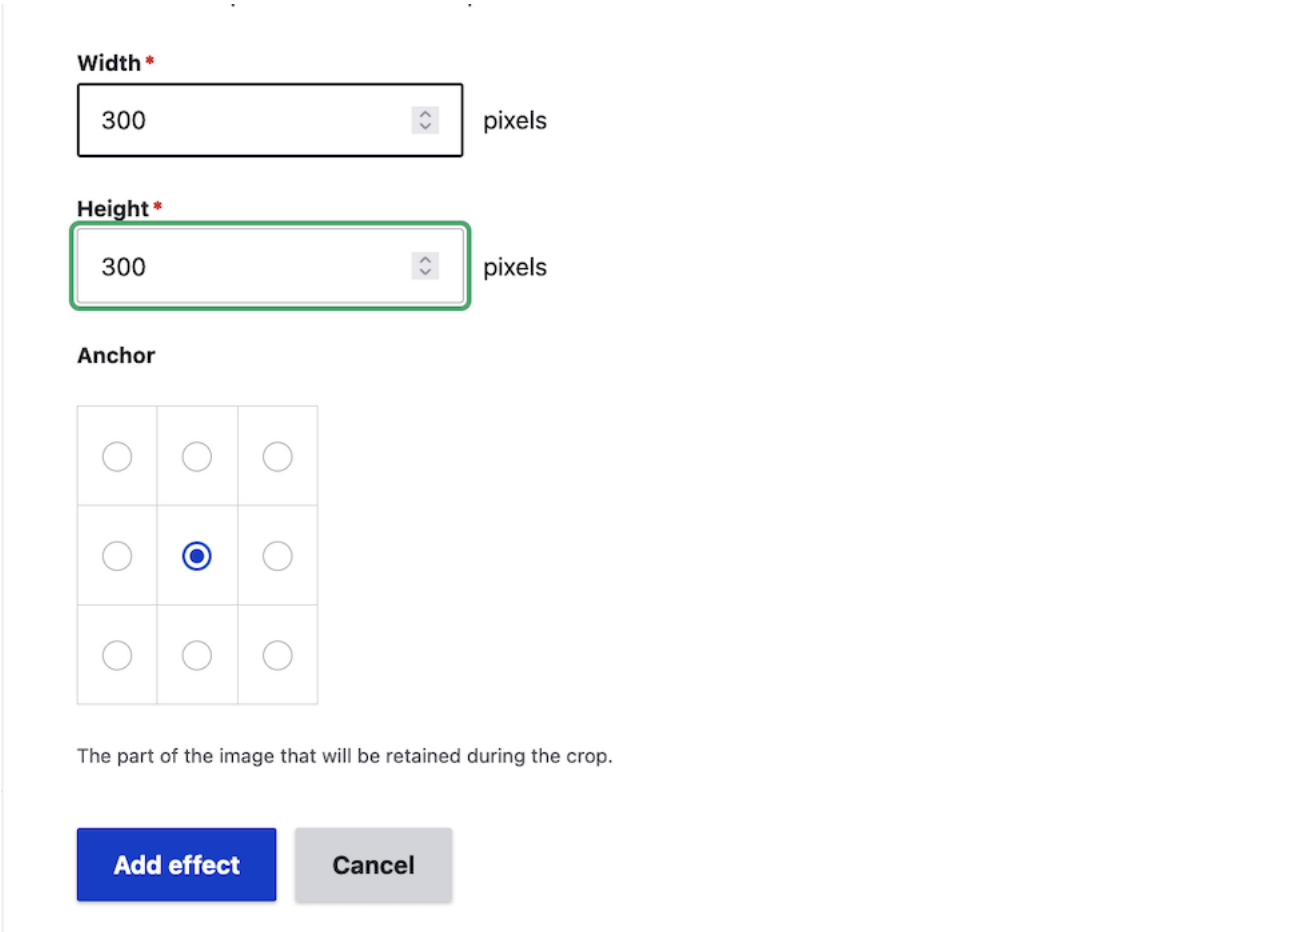
1. Create the image style **`User picture`**.
2. Edit the image style **`User picture`**.
3. Assign **`User picture`** to the **`picture`** option in **`Account settings`**.

Create the image style `User picture`

1. Log in to your Developer Portal as an administrator.
2. Navigate to Configuration > Media > Image styles.
3. Click + Add image style.
4. Enter `User picture` in the **`Image style name`** field. Click Create new style



You created the image style **`User picture`**. You can edit the **`User picture`** as required. For more information, see Edit the image style User picture.

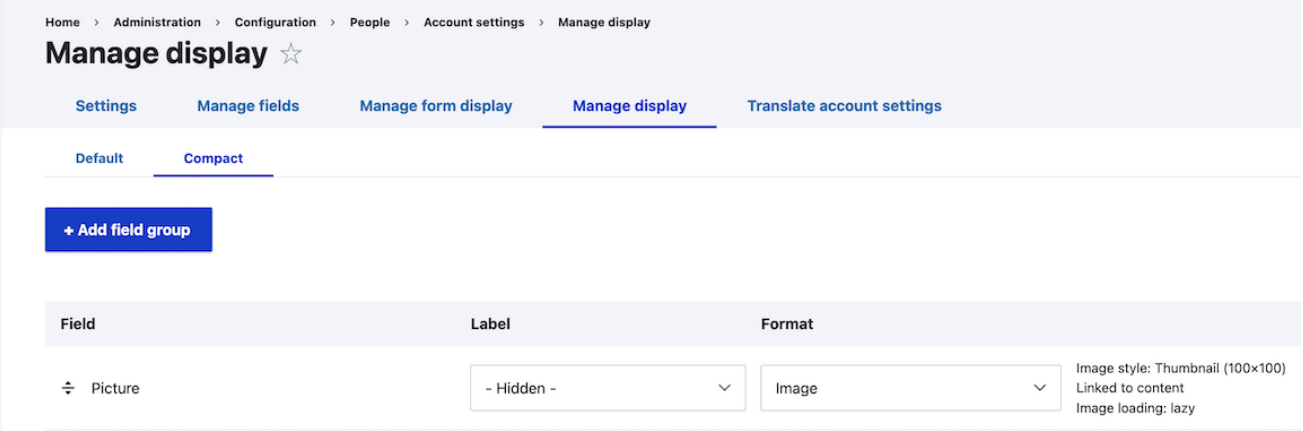


Edit the image style `User picture`

When you edit this style, you choose the width and height settings. Also, the part of the picture to retain during the crop, for example, the center.

1. Navigate to Configuration > Media > Image styles.
2. Click Edit on the **`User picture`** style name.

3. Under **`Effect`**, select **`Scale and crop`** from the list and click Add.
4. Enter `300` in the **`Width`** and **`Height`** boxes. Leave the **`Anchor`** as the middle setting.
5. Click Add effect.



6. Click Save to save the changes.

You edited the image style **`User picture`**.

Assign `User picture` to the `picture` option in `Account settings`

1. Navigate to Configuration > People > Account settings and click the Manage display tab.
2. Click the Compact tab.

3. On the **`Picture`** row, click .
4. Select **`User picture`** from the **`Image style`** list.
5. Click Update
6. Click Save to save the changes .

You set the **`User picture`** image style for all accounts.

What you did in this tutorial

You changed your account settings so that if the user displays a picture it is within the limits of the image style **`User picture`**.

To check the picture used by a user, go to People, click a user, and see their picture on their profile page. Right-click the image, then click **`View image info`**, you can see that the dimensions are scaled.

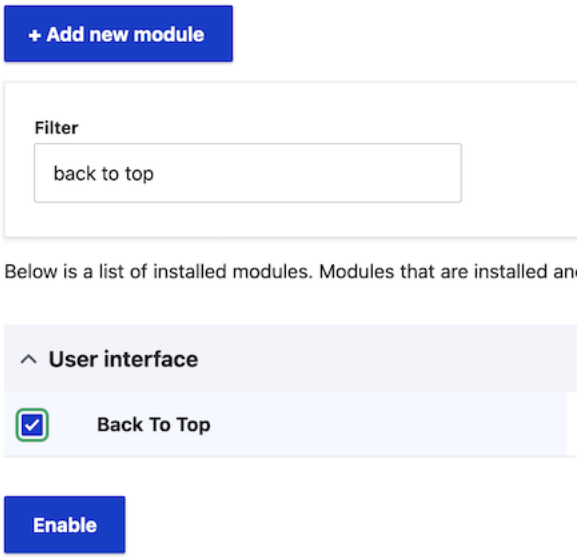
Type:	JPEG Image
Size:	29.95 KB (30,667 bytes)
Dimensions:	620px × 413px (scaled to 240px × 160px)
Associated Text:	Profile picture for user apicdemo1

Tutorial: Adding a Back to top button

You might want to add a Back to top button, as a navigation enhancement to help your Developer Portal users get back to the top of the page that they are viewing, instead of scrolling.

Before you begin

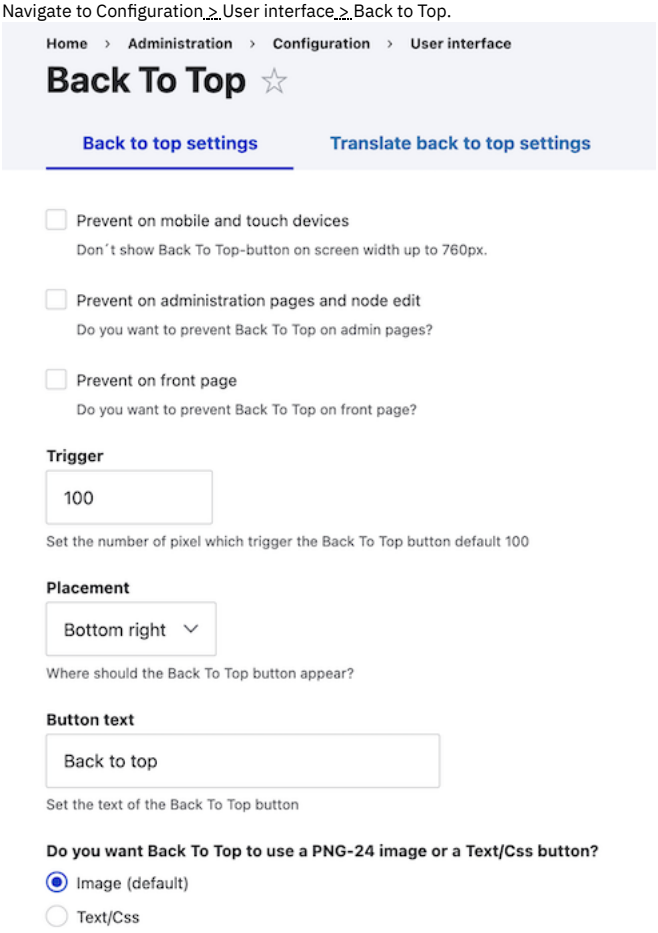
You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.



About this tutorial

In this tutorial, you add a Back to top button to your Developer Portal.

Enable the `Back to top` module



Before you begin, ensure that the **`Back to top`** module is installed and enabled:

1. Log in to your Developer Portal as an administrator.
2. Navigate to Extend > Extend.
3. Enter `back to top` in the **`Filter`** field.
4. Under **`User interface`**, select the **`Back To Top`** checkbox and click Enable.

Configure the `Back to top` module

1. Navigate to Configuration > User interface > Back to Top.

2. Change any settings as required, or keep the default values.
3. Click Save configuration to save the changes.

You now have a Back to Top button.

What you did in this tutorial

You added a Back to Top button, as a navigation enhancement to help your users get back to the beginning of a page that they are viewing, instead of scrolling.

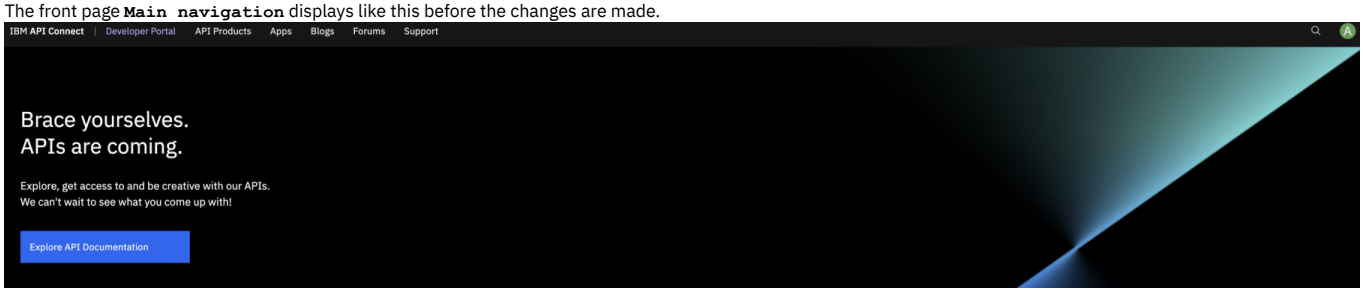
Tutorial: Creating a drop-down menu link

You can create and use drop-down menus, or nested menus, to enhance the use of your Developer Portal .

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

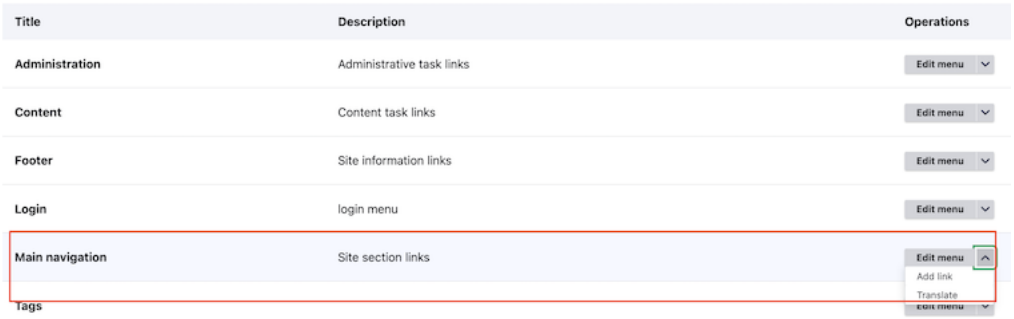
About this tutorial



In this tutorial, you create a drop-down menu link on the **`Main navigation`** menu.

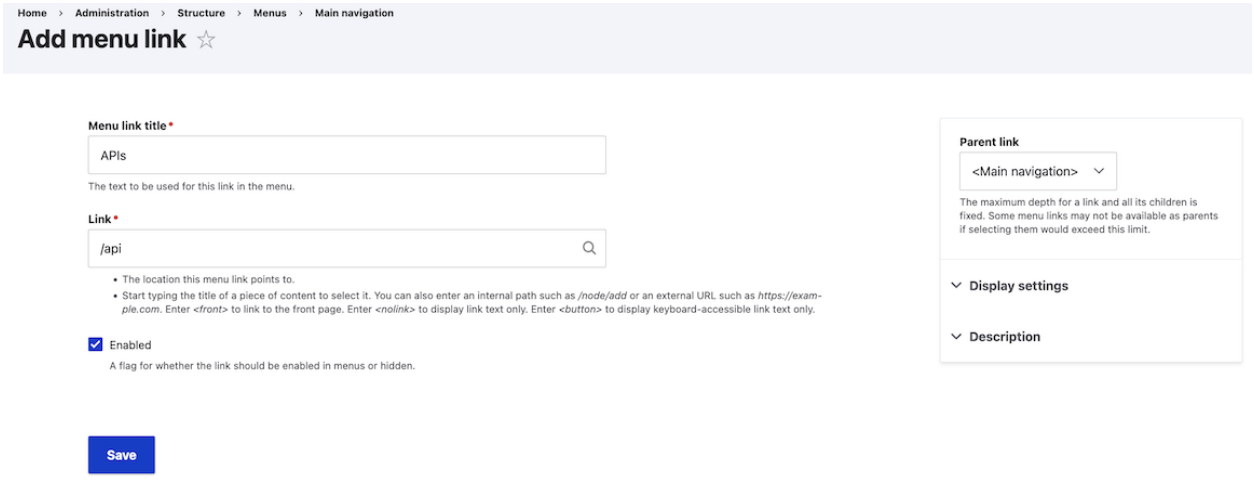
Note:
Although drop-down menu links can be created in the Developer Portal, the drop-down menu doesn't expand by default. To make the drop-down menu expand, you need to use the **`Superfish`** module.

This tutorial takes you through the following steps:



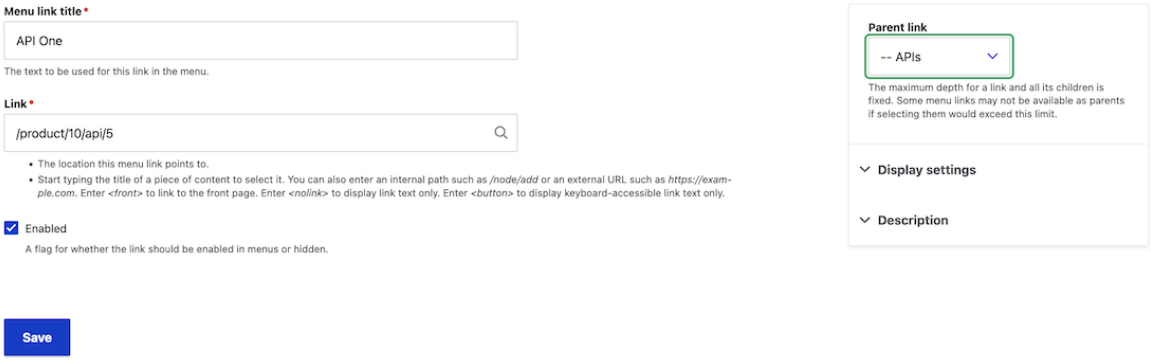
1. Add menu links to the main navigation menu.
2. Make the drop-down menu expand by using the Superfish module.

The front page **`Main navigation`** displays like this before the changes are made.

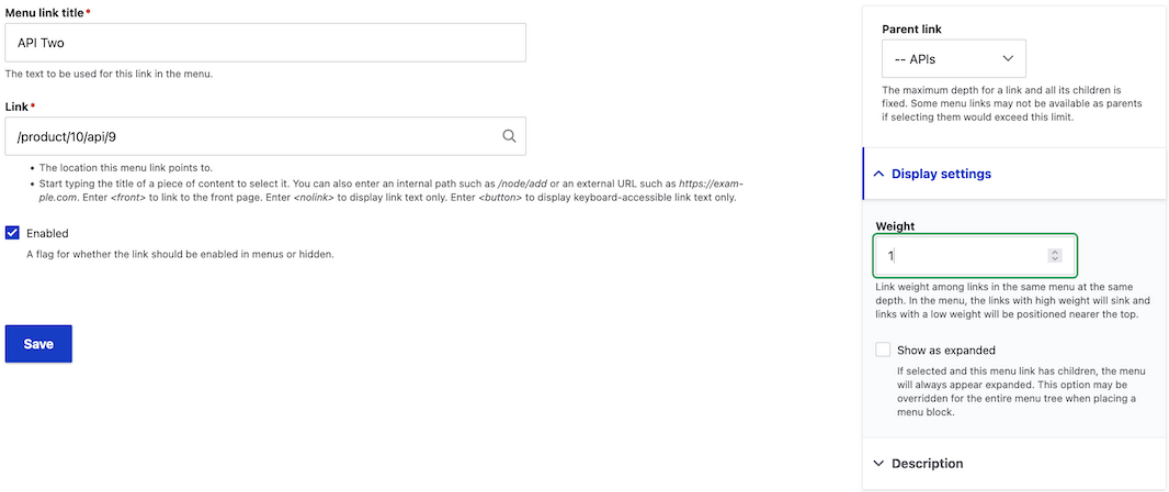


Add menu links to the main navigation menu

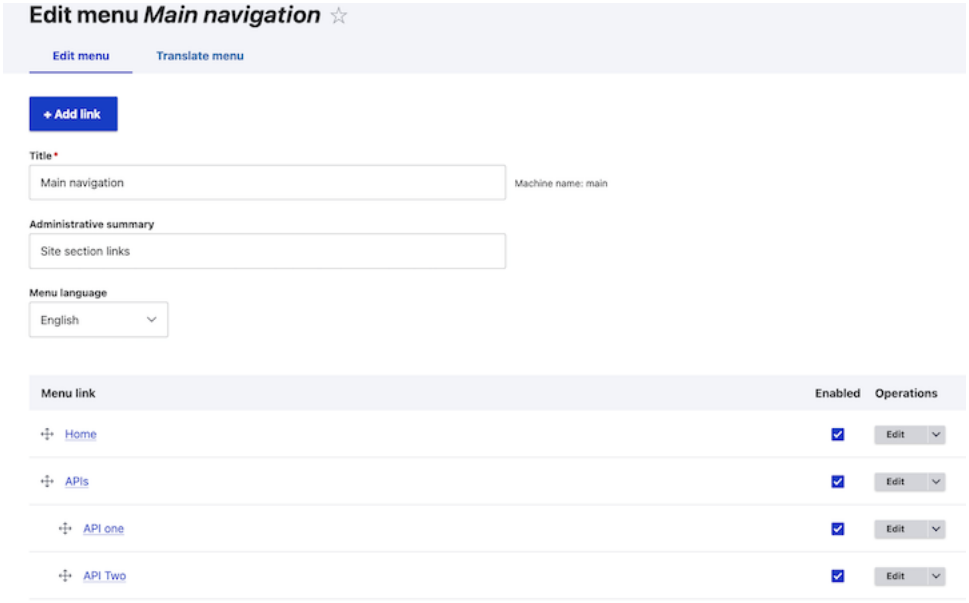
1. Log in to your Developer Portal as an administrator.
2. Navigate to Structure > Menus.
3. From the title list, find **`Main navigation`**. Click the arrow icon beside Edit menu and select Add link.



4. Complete the following steps to add a new menu link:
   a. In the **`Menu link title`** field, enter `APIs`.
   b. In the **`Link`** field, enter `/api`.
   c. Under Display settings, select the Show as expanded checkbox.
   d. Click Save to save the changes.



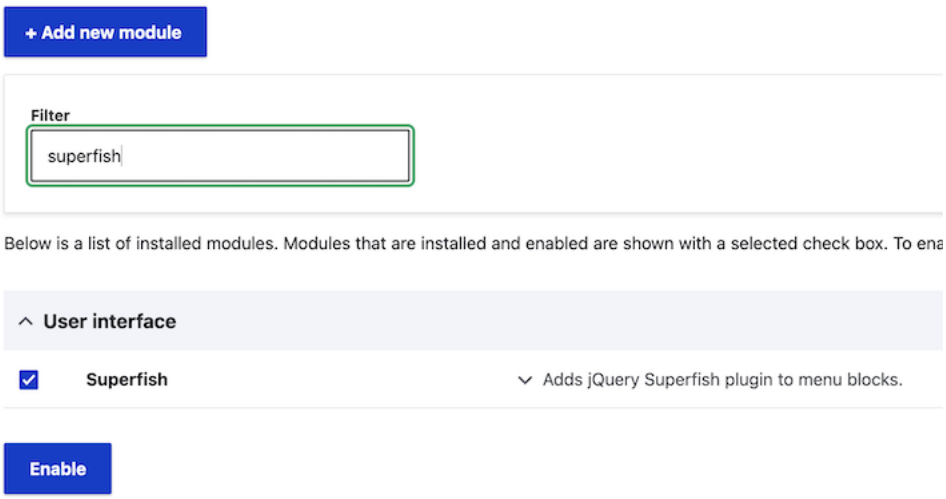
Important: Ensure Show as expanded checkbox is selected as this is the parent link for the submenu links.



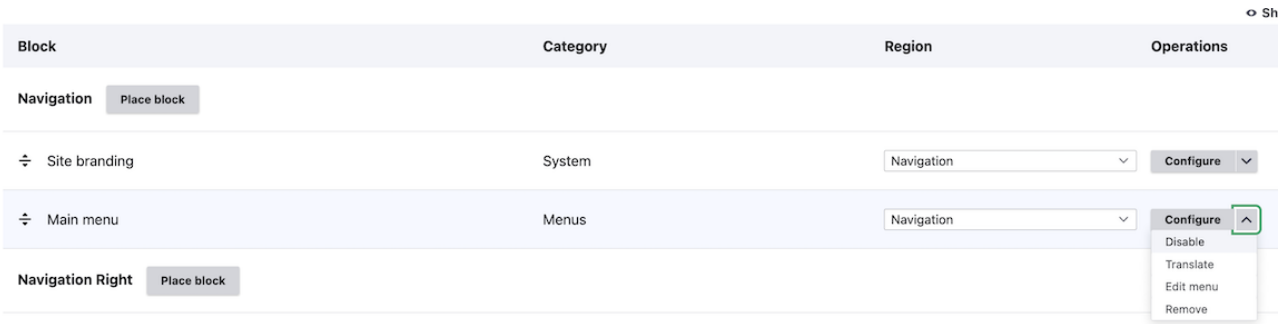
5. Complete the following steps to add another menu link to the main navigation menu:
   a. On the Edit menu Main navigation page, click +Add link.
   b. In the **`Menu link title`** field, enter `API One`.
   c. In the **`Link`** field, enter `/product/10/api/5`.
   d. Under Parent link, select -- APIs.
   e. Click Save to save the changes.

6. Complete the following steps to add another menu link to the main navigation menu:
   a. On the Edit menu Main navigation page, click +Add link.
   b. In the **`Menu link title`** field, enter `API Two`.
   c. In the **`Link`** field, enter `/product/10/api/9`.
   d. Under Parent link, select -- APIs.
   e. Under Display settings, select `1`in the Weight field.
   f. Click Save.

7. The hierarchy of the menu links now looks like this:

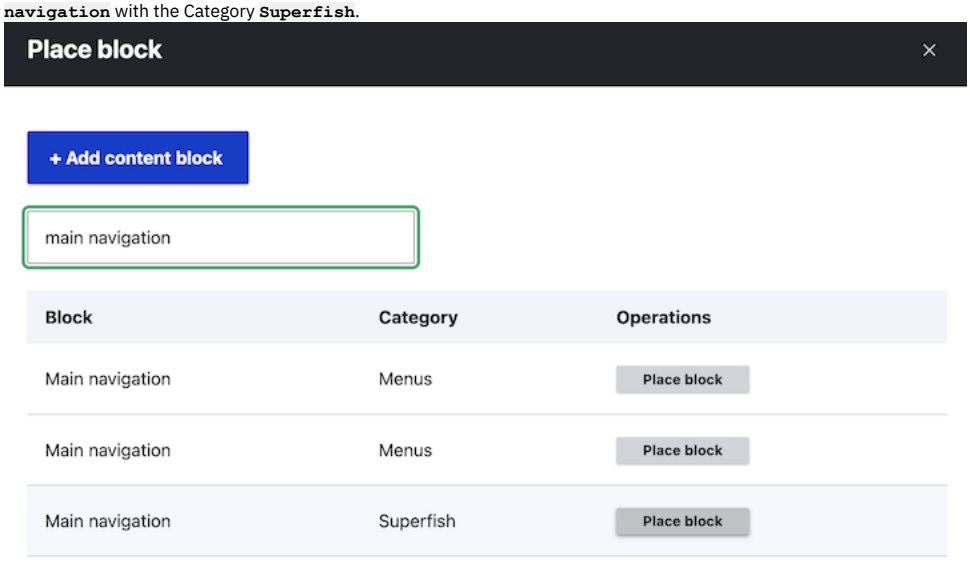


8. Navigate to the home page. The **`APIs`** menu link that you added to the main navigation menu does appear, but the submenus links don't expand when you hover over it.

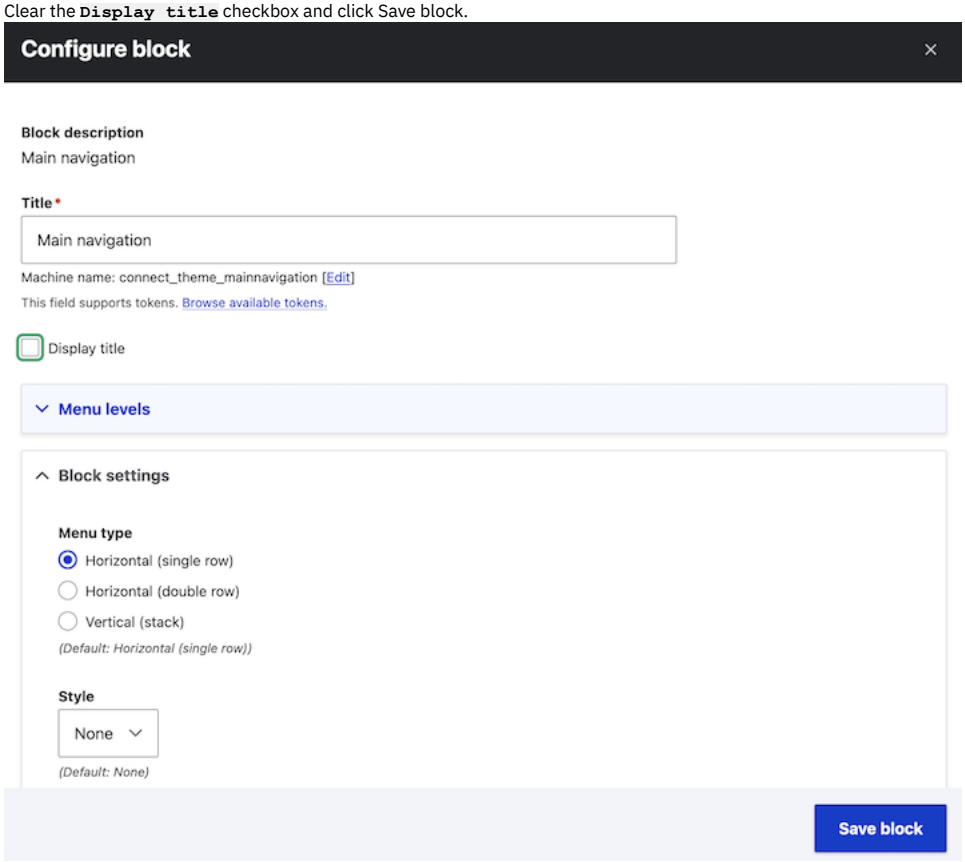


Make the drop-down menu expand by using the Superfish module

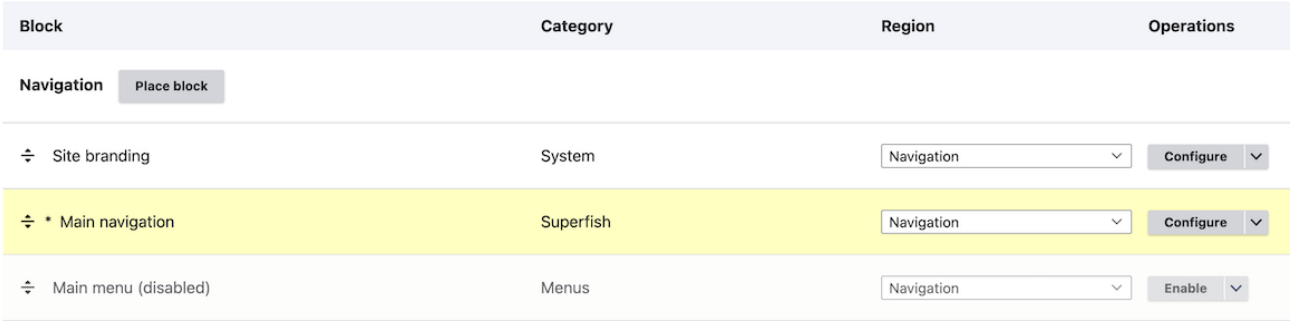
To make the drop-down menu expand when you hover over it, you need to use the **`Superfish`** module and configure the **`Block Layout`**.



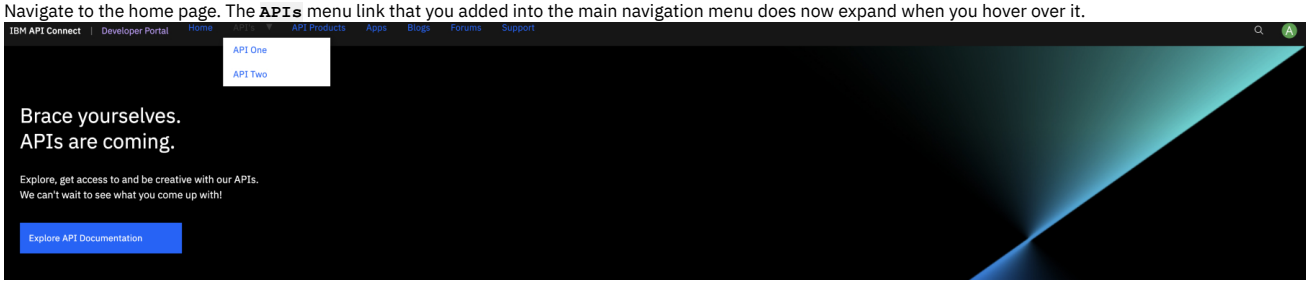
1. Navigate to Extend > Extend.
2. In the **`Filter`** field, enter `superfish` and select the **`Superfish`** checkbox.
3. Click Enable to enable the module.



4. Navigate to Structure > Block layout.
5. Under Block, find **`Main menu`**, click the arrow icon beside Configure, and select Disable.



6. Click Place block for Navigation and search for `main navigation` in the box. The filtered results might show two or more options. Click Place block for the **`Main navigation`** with the Category **`Superfish`**.



7. Clear the **`Display title`** checkbox and click Save block.

8. Drag **`Main navigation`** to be under **`Site branding`**.

9. Click Save blocks to save the changes.
10. Navigate to the home page. The **`APIs`** menu link that you added into the main navigation menu does now expand when you hover over it.

What you did in this tutorial

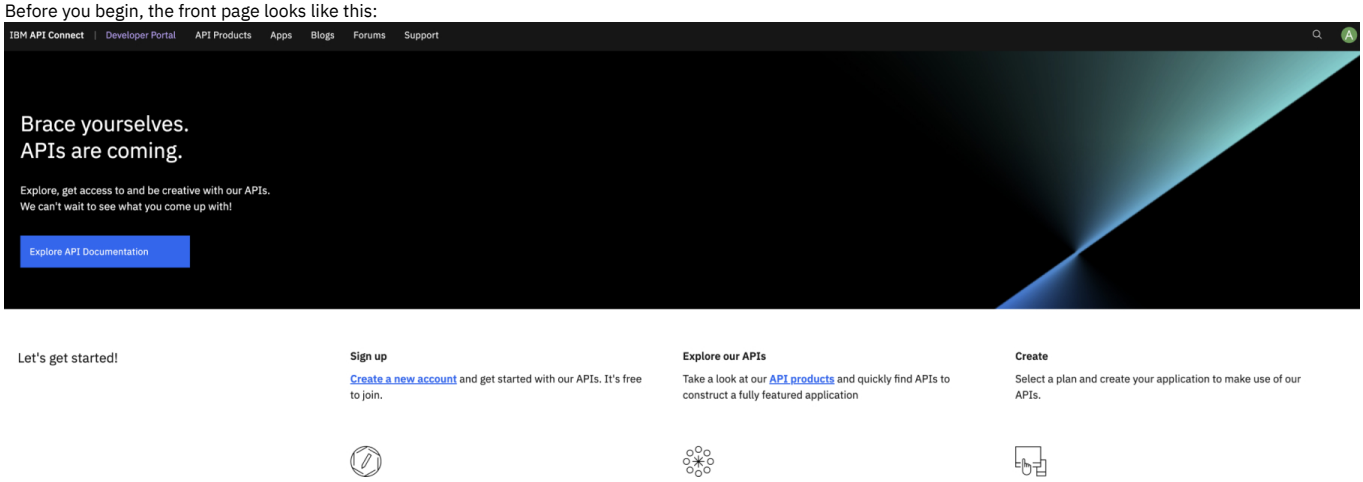
You created a drop-down menu link on the **`Main navigation`** menu.

What to do next

You can consider any other uses of the drop-down menu to enhance your users experience on your Developer Portal.

Tutorial: Displaying blog posts on the front page

You can customize the appearance of the front page of your Developer Portal to display recent blog posts. You might use the blog posts to provide your users with information, such as service availability or marketing campaigns.



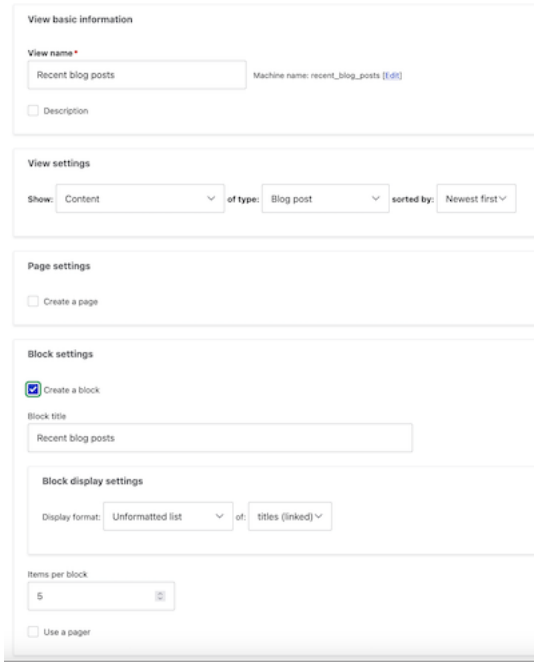
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this task, you create a view, customize that view to show blog posts, then embed that view on the front page of your Developer Portal site.

Before you begin, the front page looks like this:



This tutorial takes you through the following steps:

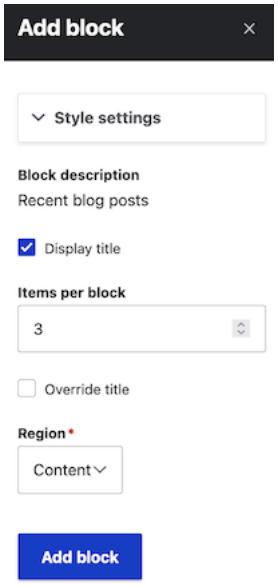
1. Create a view.

2. Customize the view.
3. Embed the view on the front page of your Developer Portal.

Create a view

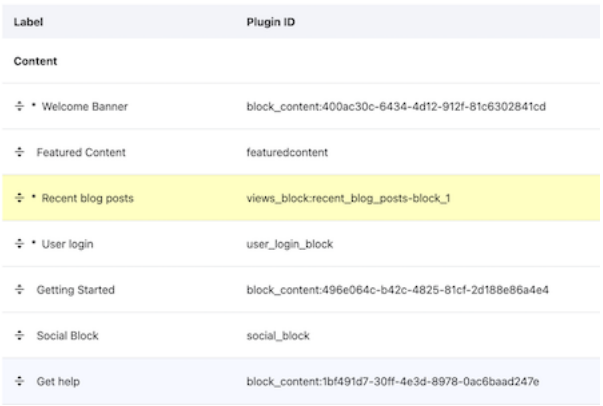
1. Log in to your Developer Portal as an administrator.
2. Navigate to Structure > Views.
3. Click +Add view.
4. In the **View name** field, enter a name for your view, for example Recent Blog posts.
5. Under **View settings**, select the options as follows:
   - Show - **Content**
   - of type - **Blog post**
   - sorted by - **Newest first**
6. Under Block settings, select the **Create a block** checkbox and choose the number of blog posts that you want to display.

7. Click Save and edit.



Customize the view

You are now on the page where you can edit your view.

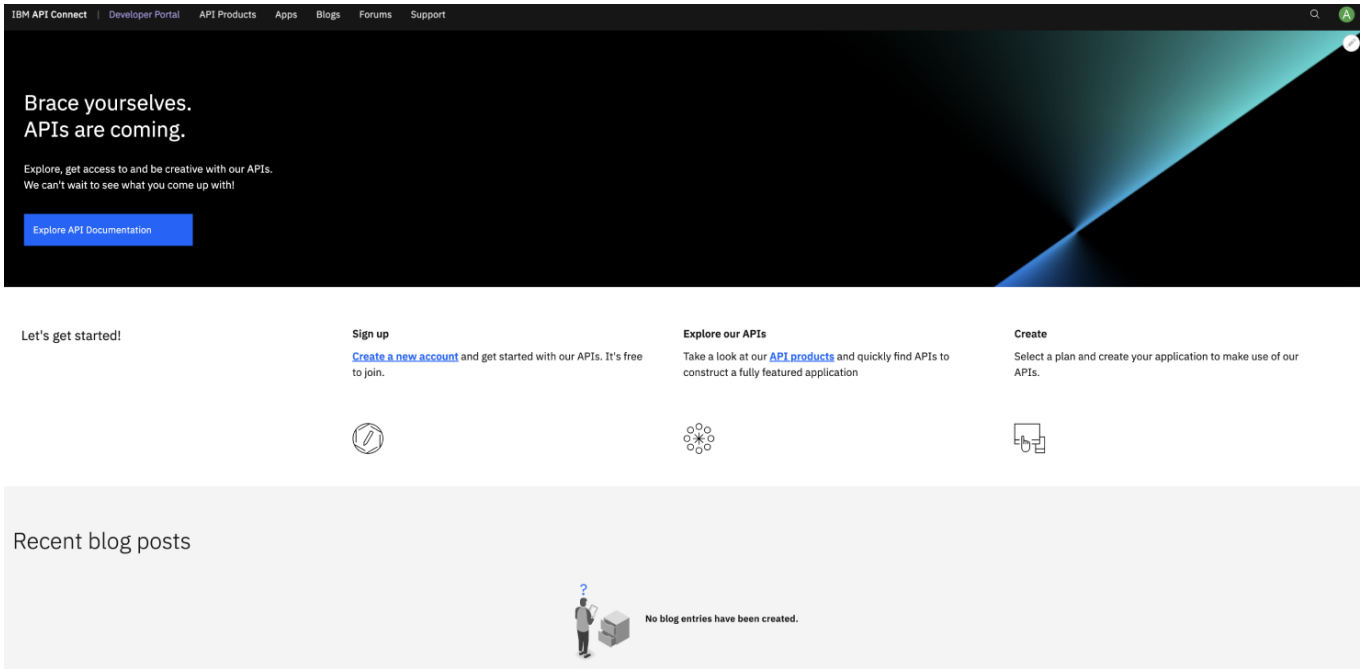


1. If you are not on the edit view page, navigate to Structure > Views, find the name of the view that you created, and click Edit.
2. In the **Format** section, click Unformatted list.
3. Select **Bootstrap List Group**, then click Apply.
4. Select Content: Title from the **Title field** list, then click Apply.
5. Click Save.

Embed the view on the front page of your Developer Portal

1. Navigate to Structure > Pages.
2. From the list of labels, find **welcome** and click Edit.
3. Navigate to Panels > Content.
4. Click Add new block.
5. Under **LISTS (VIEWS)**, select your new block.
6. Select the number of **Items per block**, then click Add block.

7. You can now rearrange the position of the blog post on the front page.



Label	Plugin ID
Content	
* Welcome Banner	block_content:400ac30c-6434-4d12-912f-81c6302841cd
Featured Content	featuredcontent
* Recent blog posts	views_block:recent_blog_posts-block_1
* User login	user_login_block
Getting Started	block_content:496e064c-b42c-4825-81cf-2d188e86a4e4
Social Block	social_block
Get help	block_content:1bf491d7-30ff-4e3d-8978-0ac6baad247e

8. Click Update and save.

What you did in this tutorial

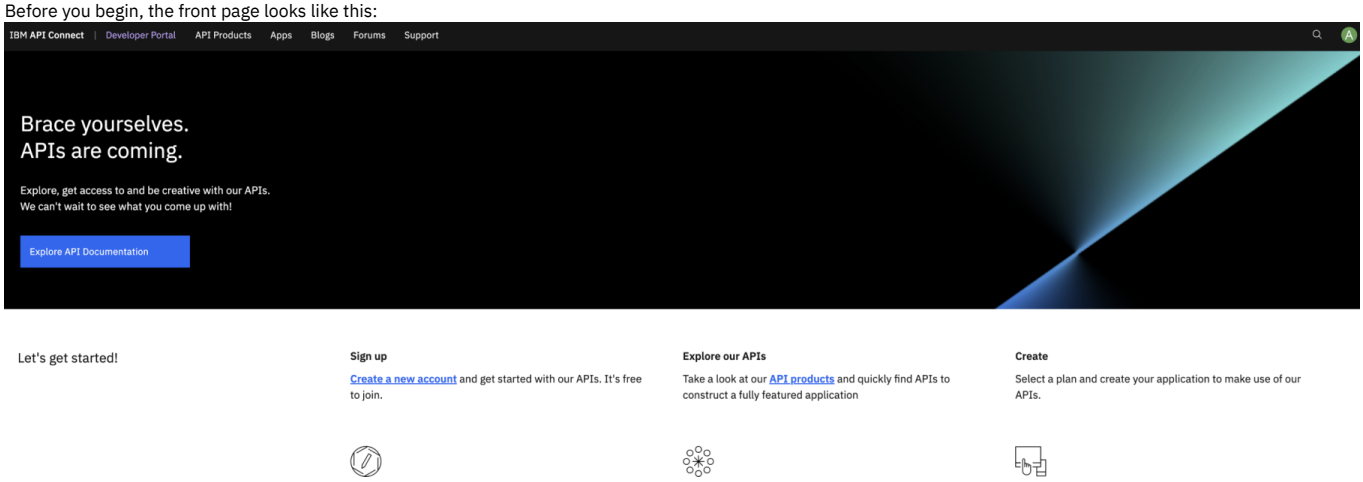
You can check that the view you created appears on the front page of your site page.

What to do next

You can edit your view at any time by navigating to Structure > Views and selecting your view by its name. You can also modify or delete the view's layout on the front page by navigating back to the layout section of your page under Structure > Pages.

Tutorial: Displaying tweets on the front page

You can customize the appearance of the front page of your Developer Portal to display recent tweets. You might use the tweets to provide your users with information, such as service availability or marketing campaigns.



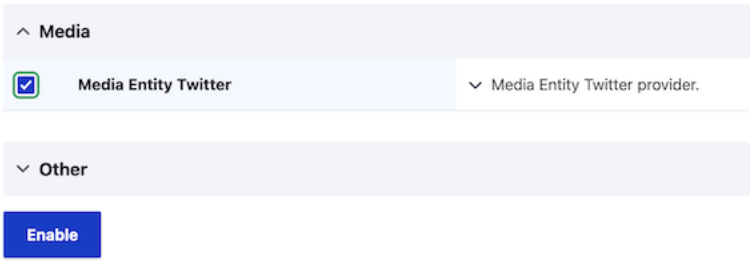
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this task, you create a view, customize that view to show tweets, then embed that view on the front page of your Developer Portal site.

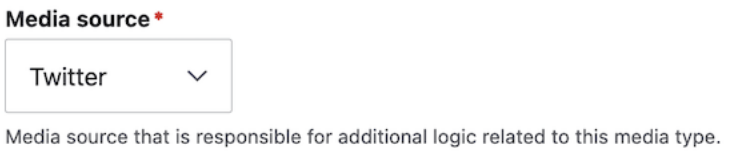
Before you begin, the front page looks like this:



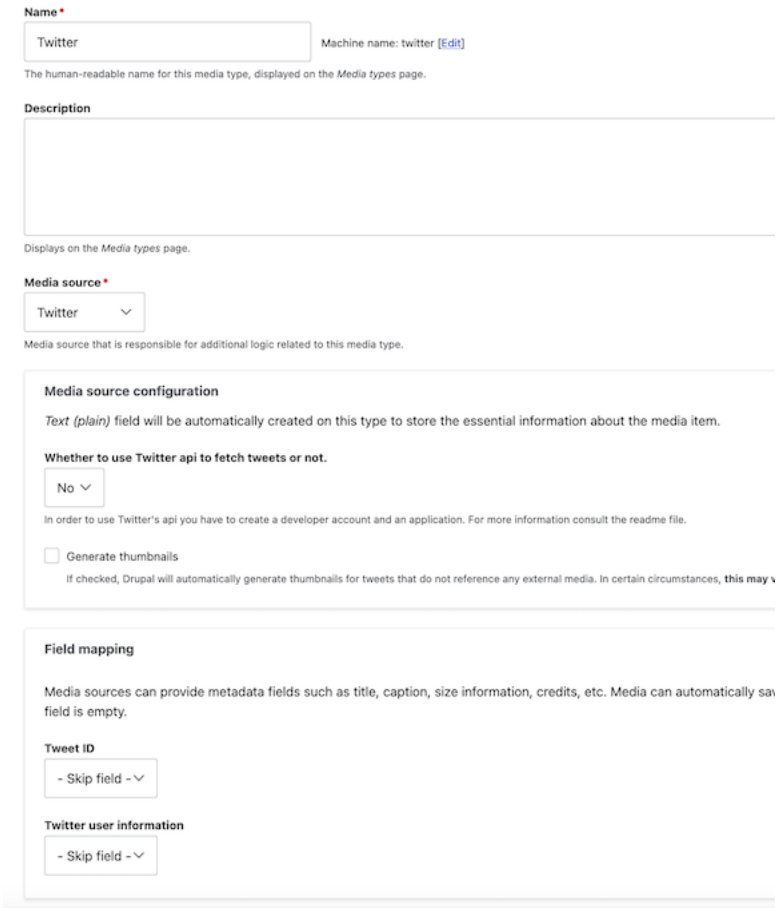
This tutorial takes you through the following steps:

1. Enable the Media entity Twitter module.
2. Create an entity called Twitter to store the tweets.
3. Add media items.
4. Create a carousel view.
5. Customize the carousel view.
6. Embed the carousel view on the front page of your Developer Portal.

Enable the `Media entity twitter` module

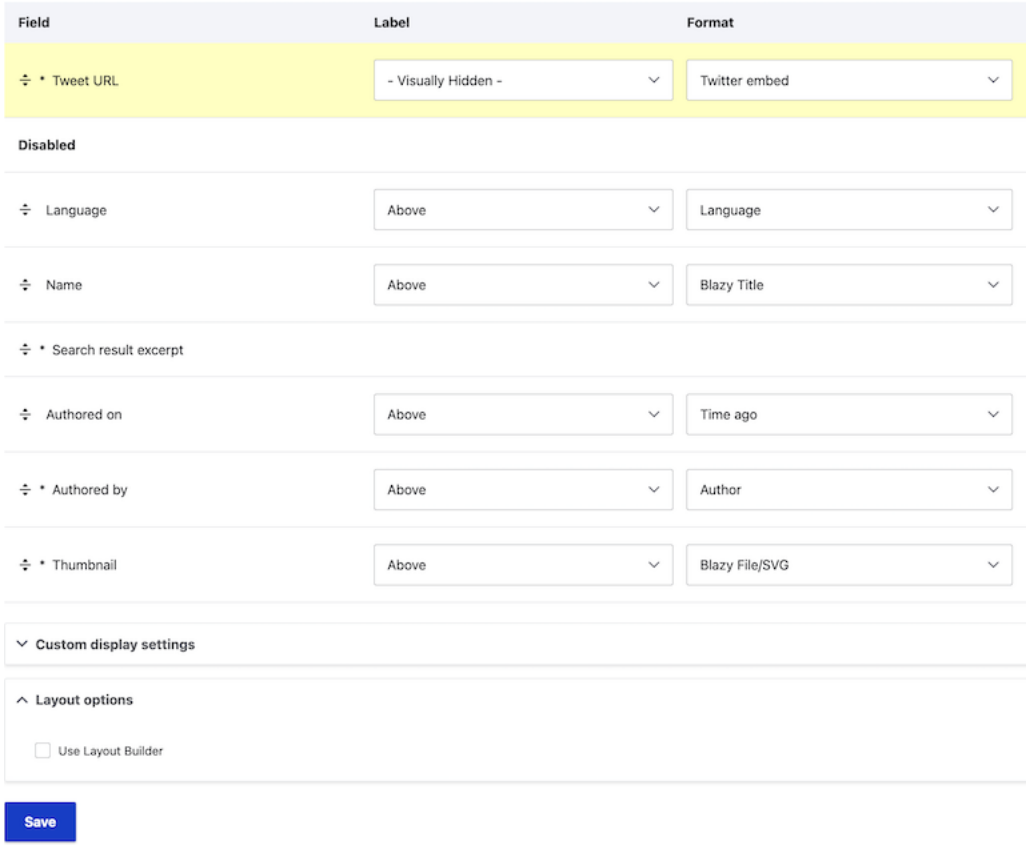


1. Log in to your Developer Portal as an administrator.
2. Click Extend > Extend, and enter `media` in the Filter field.
3. Under the Media section, find Media Entity Twitter and click Enable to enable the **`Media entity twitter`** module.



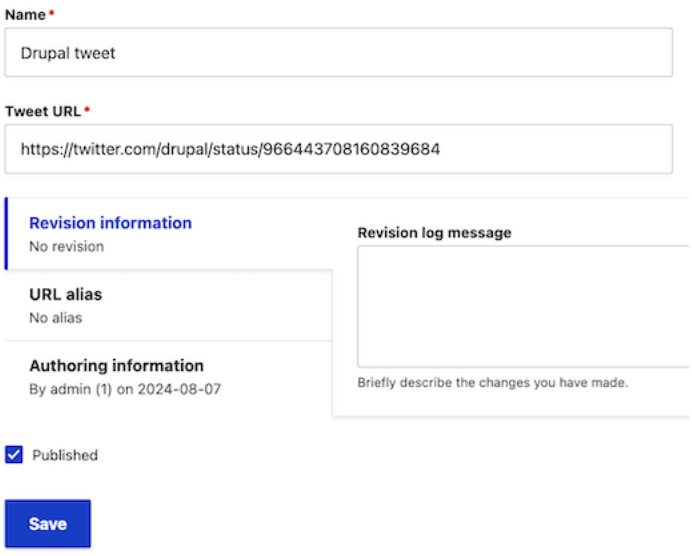
Create an entity called `Twitter` to store the tweets

1. Navigate to Structure > Media types.
2. Click +Add media type.
3. In the Name field, enter Twitter.



4. From the Media source list, select Twitter.

5. Under the Media source configuration section, ensure that **`Whether to use Twitter api to fetch tweets or not`** value is set to No.
6. Under the Field Mapping section, ensure that the **`Tweet ID`** and **`Twitter user information`** sections are set to - Skip field -.

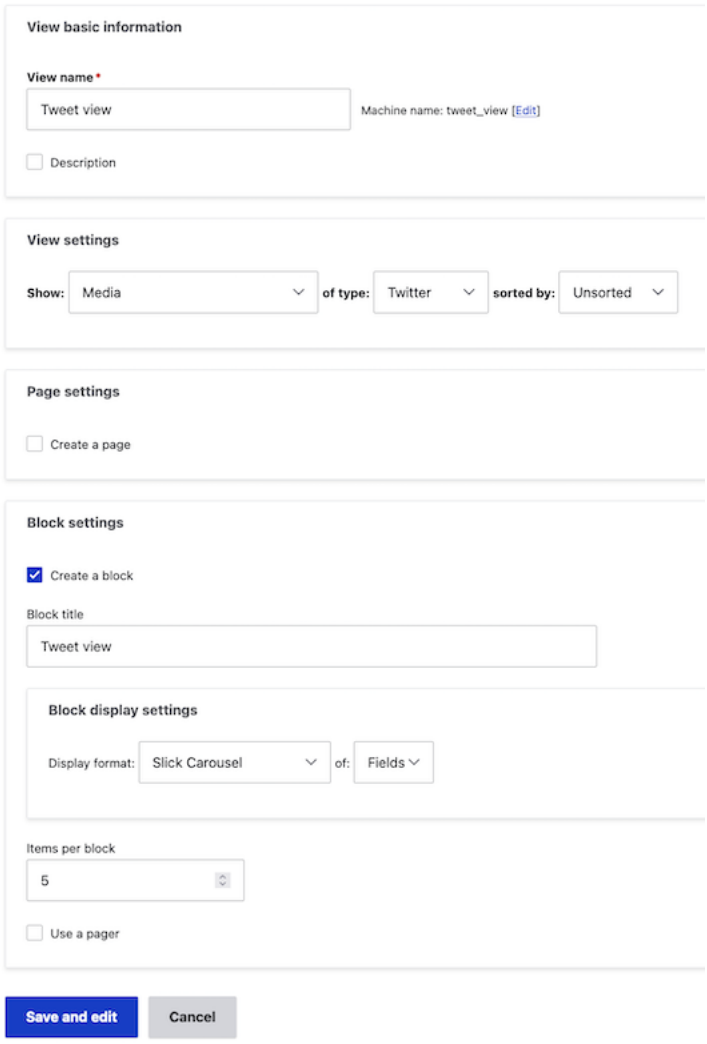


7. Click Save.
8. Select Manage Display from the list next to Edit for the new **`Twitter`** media type.
9. From the Format list of **`Tweet URL`**, select Twitter embed.
10. Ensure that the Authored on, Authored by, and Thumbnail fields are in the Disabled section.

11. Click Save.

Add media items

1. Click Media > +Add media > Twitter.
2. In the Name field, enter a name for the media, for example Drupal Tweet.
3. In the Tweet URL field, enter a URL, for example, `https://twitter.com/drupal/status/966443708160839684`.



4. Click Save.
5. Repeat these steps to add more tweets, you need at least 2 to make a carousel view.

Create a carousel view

1. Navigate to Structure > Views.
2. Click +Add view.
3. In the View name field, enter a name for your view, for example Tweet view.
4. Under View Settings, select the options as follows:
   - **show**: Media

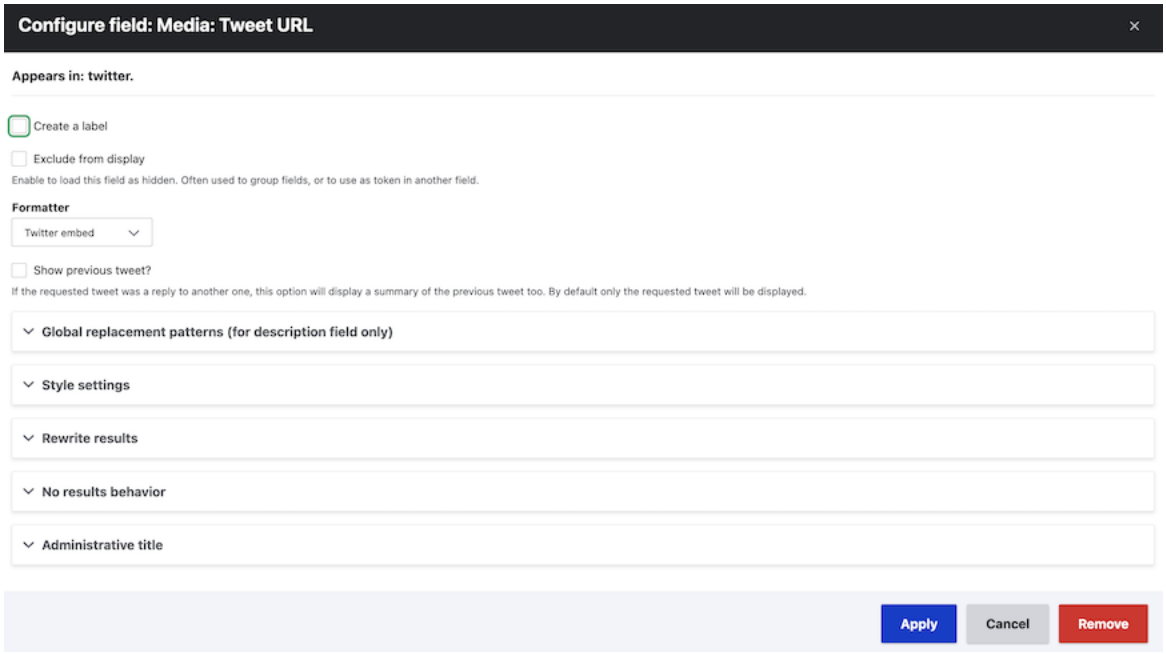
- **`of type`**: Twitter
- **`sorted by`**: Unsorted

5. In the Block Settings section, select the Create a block checkbox.
6. Ensure that the Display format is selected as Slick Carousel of fields.

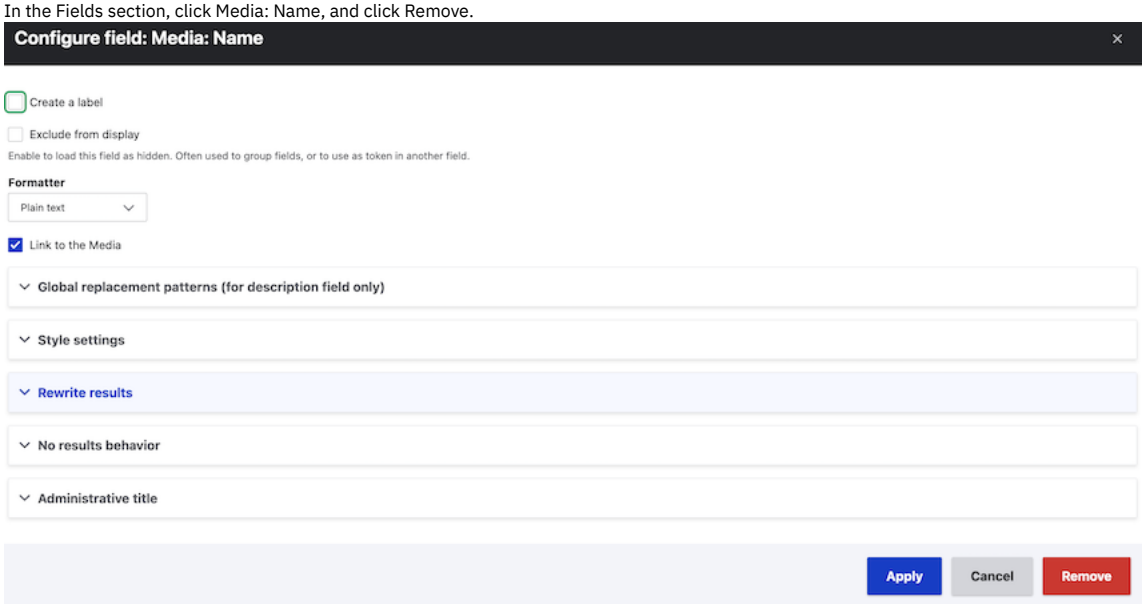
7. Click Save and edit.

Customize the carousel view

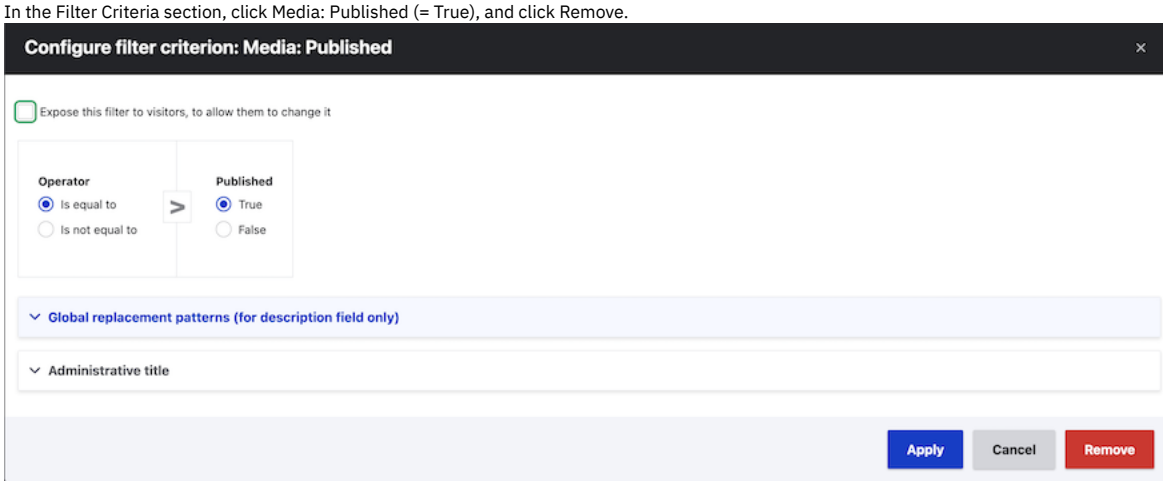
You are now on the page where you can edit your view.



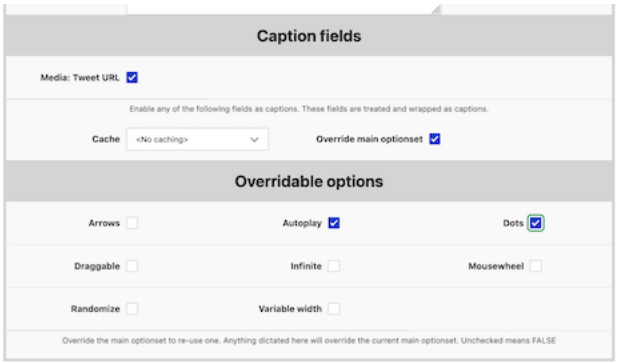
1. If you are not the edit view page, navigate to Structure > Views, find the name of the view that you created, and click Edit.
2. In the Title section, click Tweet view and enter <none> in the **`Title`** field, and click Apply.



3. In the Fields section, click Add and then search for tweet.
4. Select the check box for Tweet URL and click Add and configure fields.

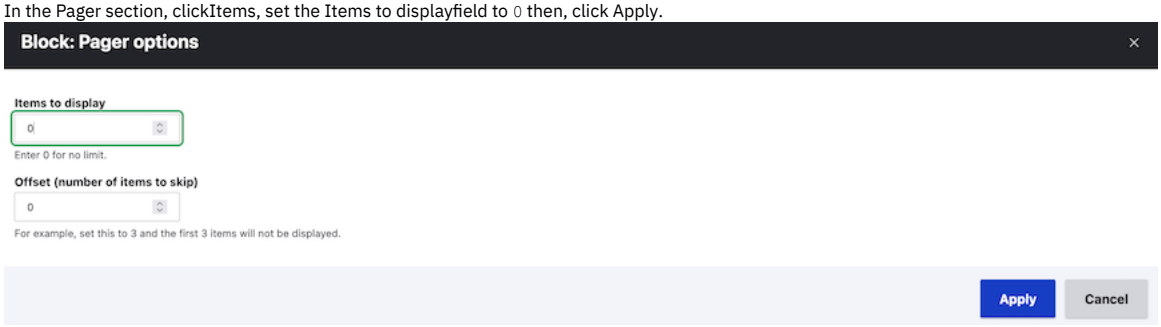


5. From Formatter, select Twitter embed and click Apply.

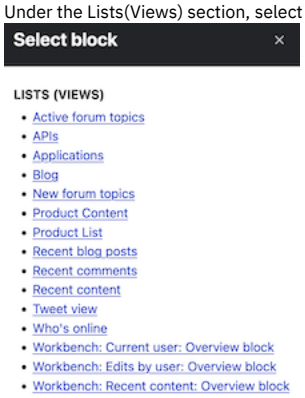


6. In the Fields section, click Media: Name, and click Remove.

7. In the Filter Criteria section, click Media: Published (= True), and click Remove.



8. In the Format section, click Settings next to Slick Carousel.
9. From the Skin Main list, select Default.
10. In the Caption Fields section, select Media: Tweet URL and Override main optionset checkboxes.
11. In the Overridable Options section, select the Autoplay and Dots checkboxes, and click Apply.

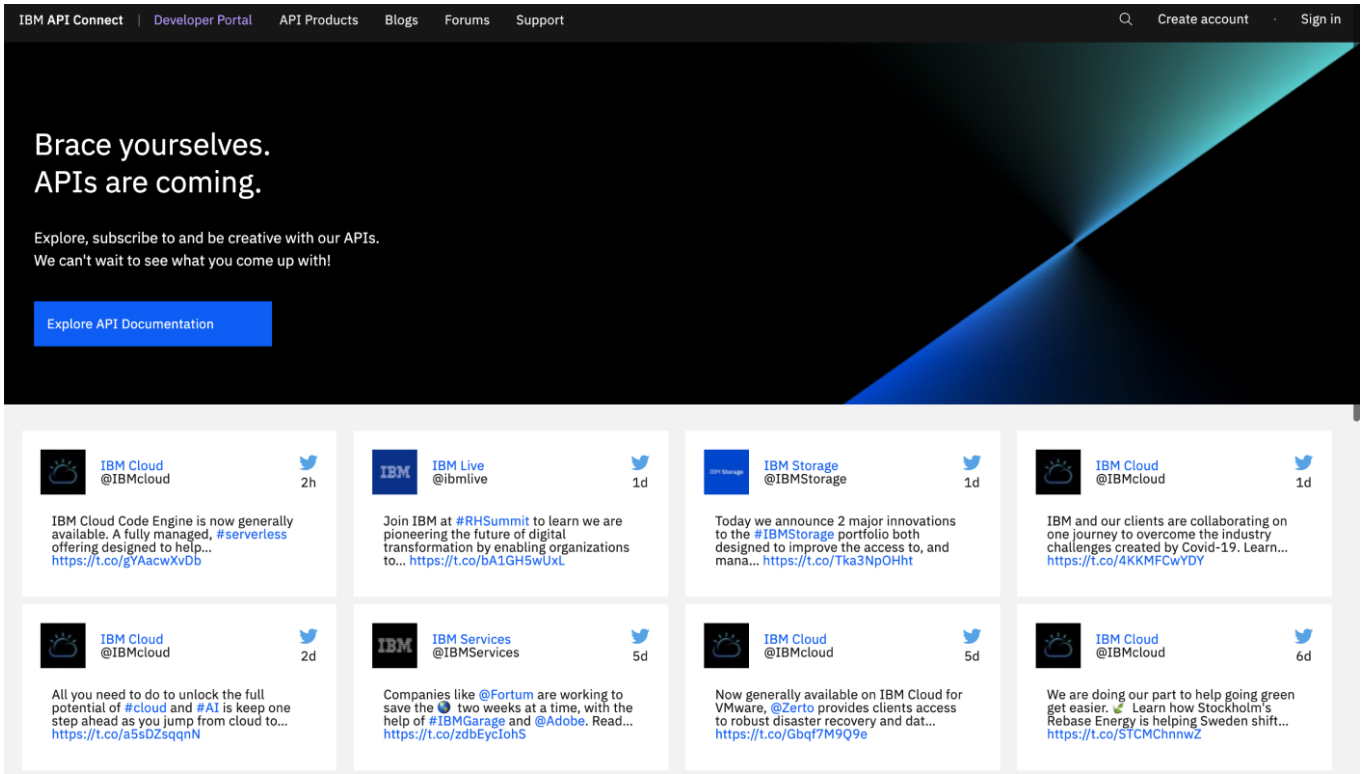


12. In the Pager section, clickItems, set the Items to displayfield to `0` then, click Apply.

13. Click Save.

Embed the view on the front page of your Developer Portal

1. Navigate to Structure > Pages.
2. Find the **`welcome`** label and click Edit.
3. In the Variants section, click Panels, then Content.
4. Click Add new block.
5. Under the Lists(Views) section, select your new block.



6. Clear the Display title checkbox and click Add block.
7. You can now rearrange the position of your tweet view on the front page.

Label	Plugin ID	Region	Operations
Content			
Welcome Banner	block_content:ae26695d-f6fc-4f0e-adda-5d575506bd23	Content	Edit
Featured Content	featuredcontent	Content	Edit
Recent blog posts	views_block:recent_blog_posts-block_1	Content	Edit
Tweet view	views_block:tweet_view-block_1	Content	Edit
Getting Started	block_content:9328e92b-6efe-40fc-971f-d8eb0171912b	Content	Edit
Social Block	social_block	Content	Edit
Get help	block_content:7958fc33-e61d-4c9a-ae61-9b47f02acec8	Content	Edit

8. Click Update and save.

What you did in this tutorial

You can check that the view you created appears on the front page of your site page.

What to do next

You can edit your view at any time by navigating to Structure > Views and selecting your view by its name. You can also modify or delete the view's layout on the front page by navigating back to the layout section of your page under Structure > Pages.

You can also integrate your Twitter data dynamically. For more information, see the links below.

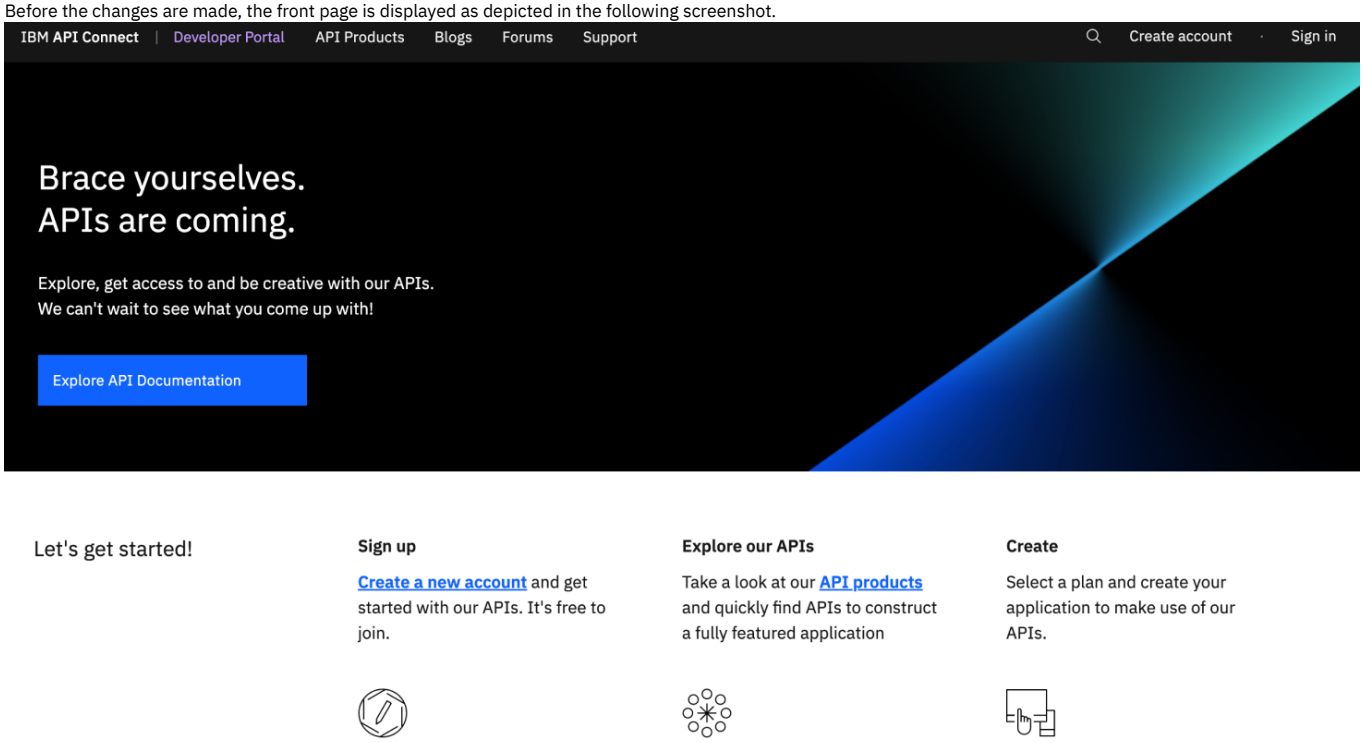
Tutorial: Changing the front page of your Developer Portal

You can create and arrange content in your Developer Portal to provide a front page that aligns with your brand, and help your users discover your APIs.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.



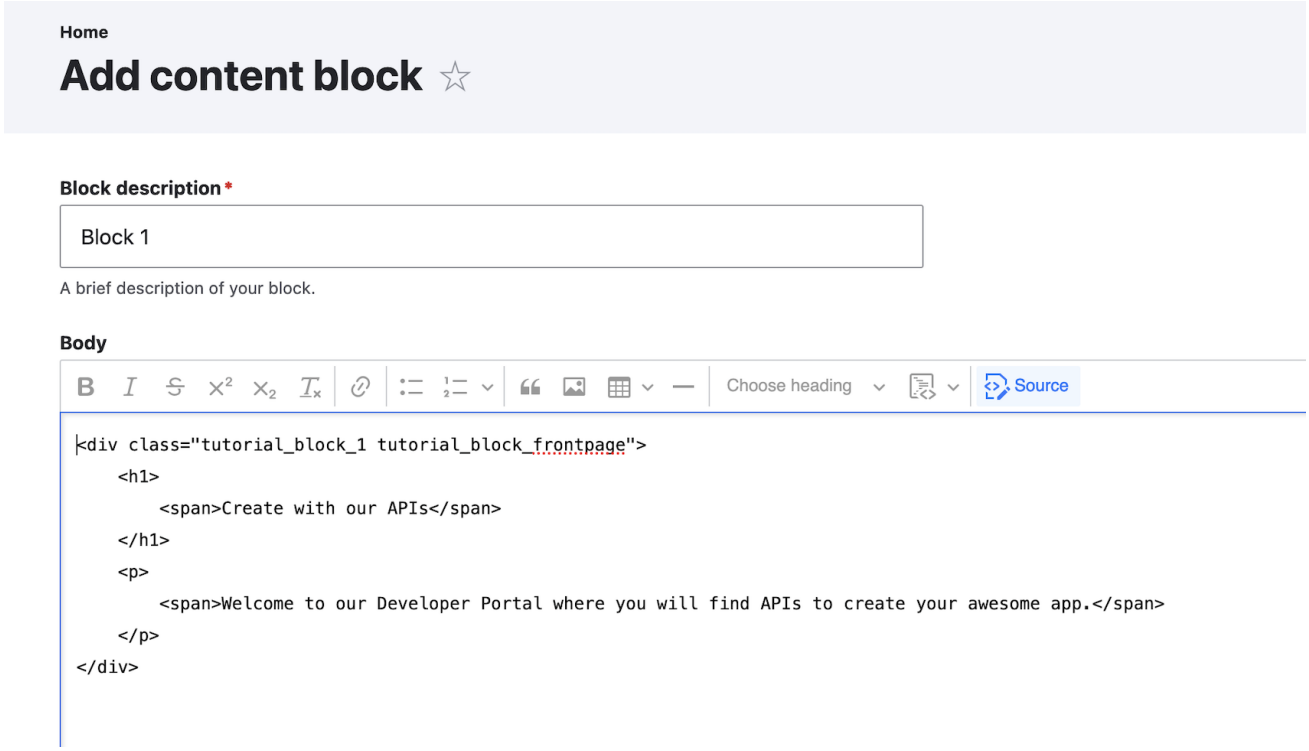
About this tutorial

In this tutorial, you create some content for a page, and then change the front page to be your new page.

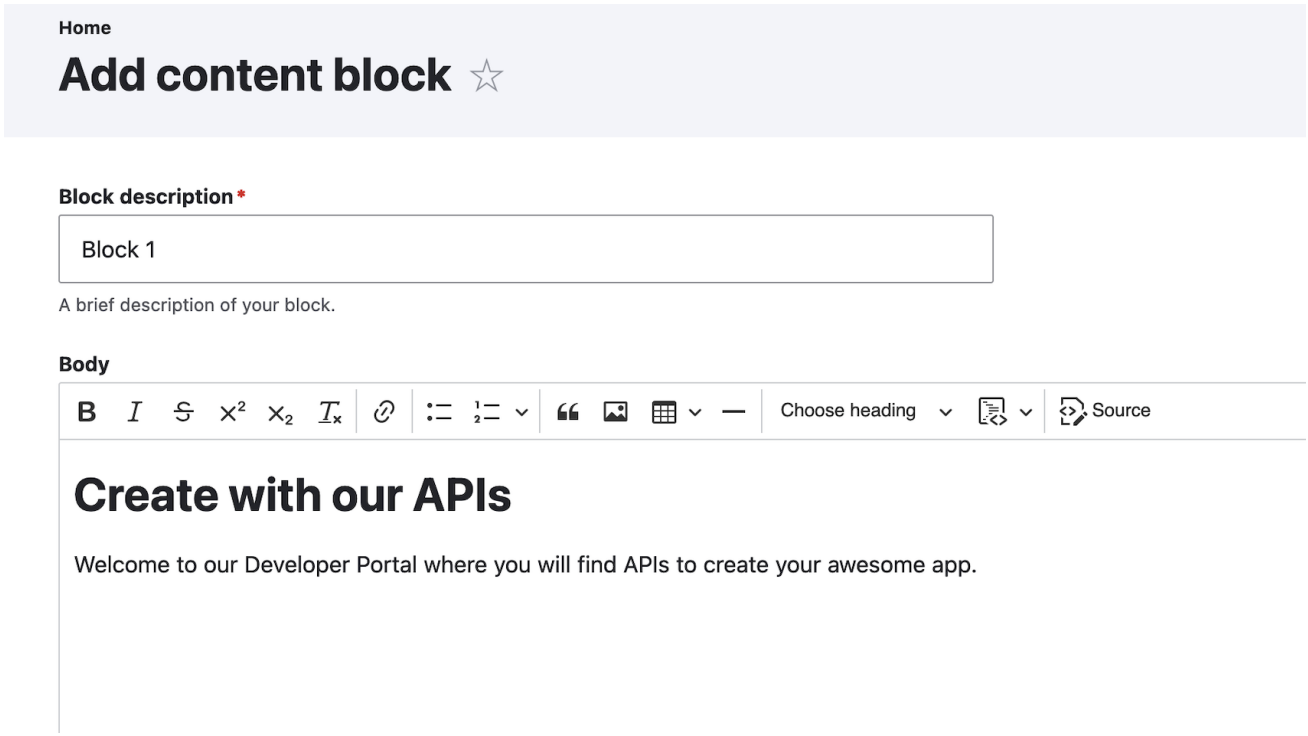
This tutorial takes you through the following steps:

1. Creating some custom blocks.
2. Create and configure a page.
3. Adding the custom blocks to the page.
4. Changing the front page to be your new page.

Before the changes are made, the front page is displayed as depicted in the following screenshot.



Creating some custom blocks



1. Log in to your Developer Portal as an administrator.
2. Navigate to Content > Blocks and click +Add content block.
3. Enter `Block 1` in the Block description.
4. In the body area, click Source, then enter the following HTML:

```
<div class="tutorial_block_1 tutorial_block_frontpage">
<h1><span>Create with our APIs</span></h1>

<p><span>Welcome to our Developer Portal where you will find APIs to create your awesome app.</span></p>
</div>
```

5. Check what the block looks like by clicking Source again.
   A

   Note: This block uses no inline-styling. Instead, it allows your theme to decide how it is rendered. The advantage of this set up is that you can easily change the rendering without modifying existing content in the database. Any styling that is required can be added to a custom theme. For more information, see Tutorial: Creating a custom theme for the Developer Portal.
6. Click Save.
   You have created `Block 1`.

7. Repeat steps 3 to 7 to create `Block 2`, `Block 3`, and `Block 4`.
   a. Enter `Block 2` in the Block description. In the body area, click Source, then enter the following HTML:

```
<div class="tutorial_block_2 tutorial_block_frontpage">
<p class="text-align-center">Explore and subscribe to our APIs.<br />
See what you come up with!</p>

<p class="text-align-center"> </p>

<div class="bannerButtonRow text-align-center"><a class="button cta-btns--white__btn"
```

```
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.devportal.doc_product">Explore API
Documentation</a></div>
</div>
```

b. Enter `Block 3` in the Block description. In the body area, click Source, then enter the following HTML:

```
<div class="tutorial_block_3">
<p class="text-align-center"><a
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.devportal.doc_user_register">Create a
new account</a> and get started with our APIs. It's free to join.</p>
</div>
```

c. Enter `Block 4` in the Block description. In the body area, click Source, then enter the following HTML:

```
<div class="block-get-help">
<div class="get_help">
<div class="column col1">
<h3>Getting Help</h3>

<div>Be sure to check out these extra help resources.</div>
</div>

<div class="column col2">
<h4>Get Started</h4>

<div>Get started with our APIs by creating an account and exploring the documentation to find what's right for you.
</div>

<div><a href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.devportal.doc_user_register">

</div>
</div>
</div>
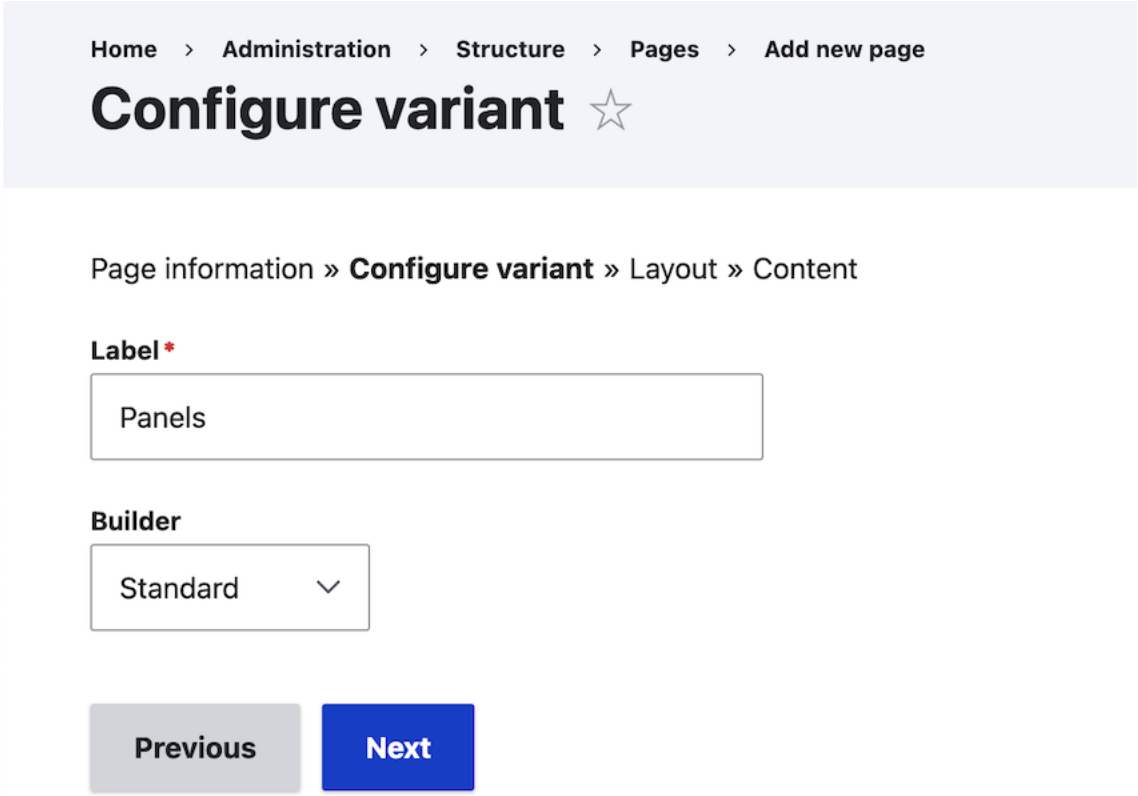
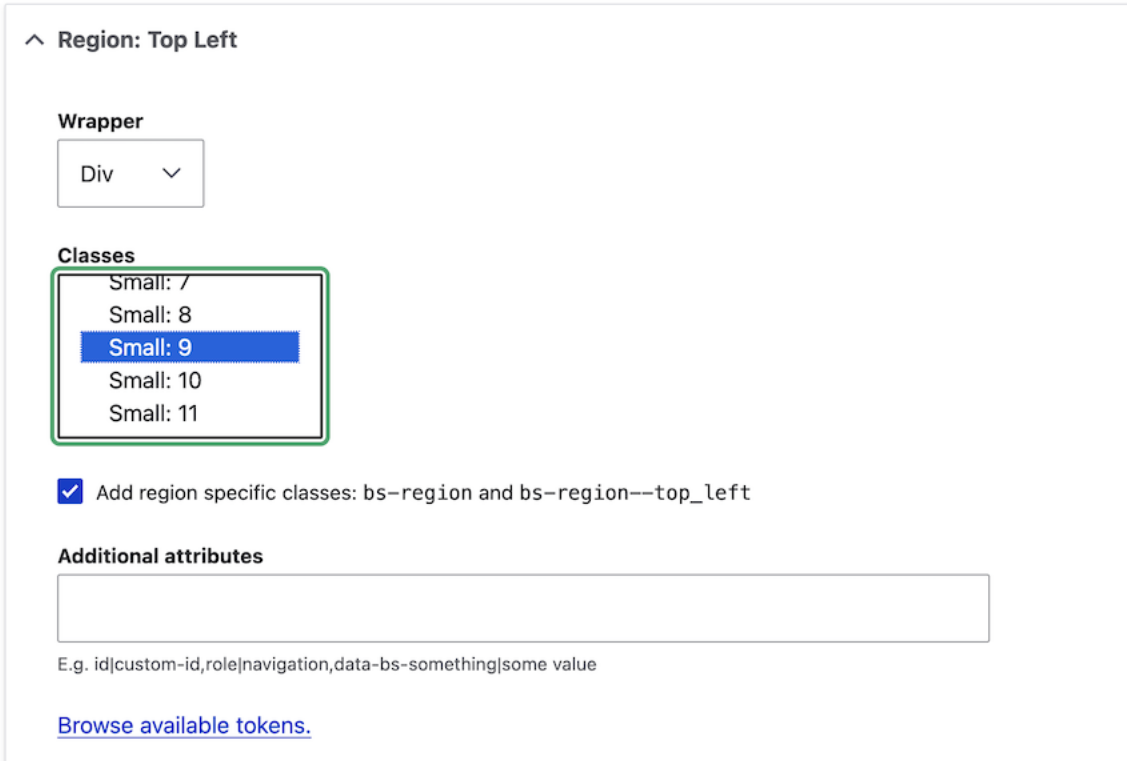
```

8. You can see the new blocks on the Content blocks page. If you are not on the Content blocks page, navigate to Content > Blocks to see the new blocks.

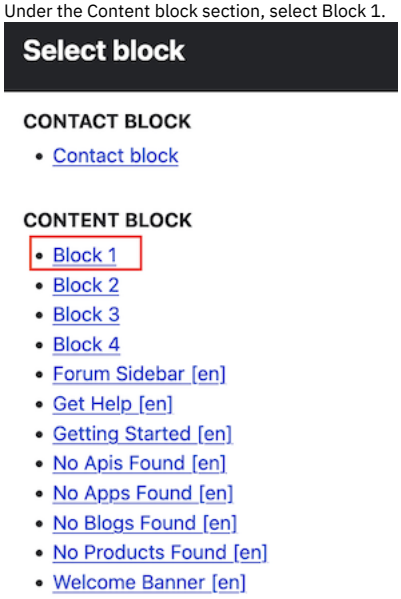


Create and configure a page

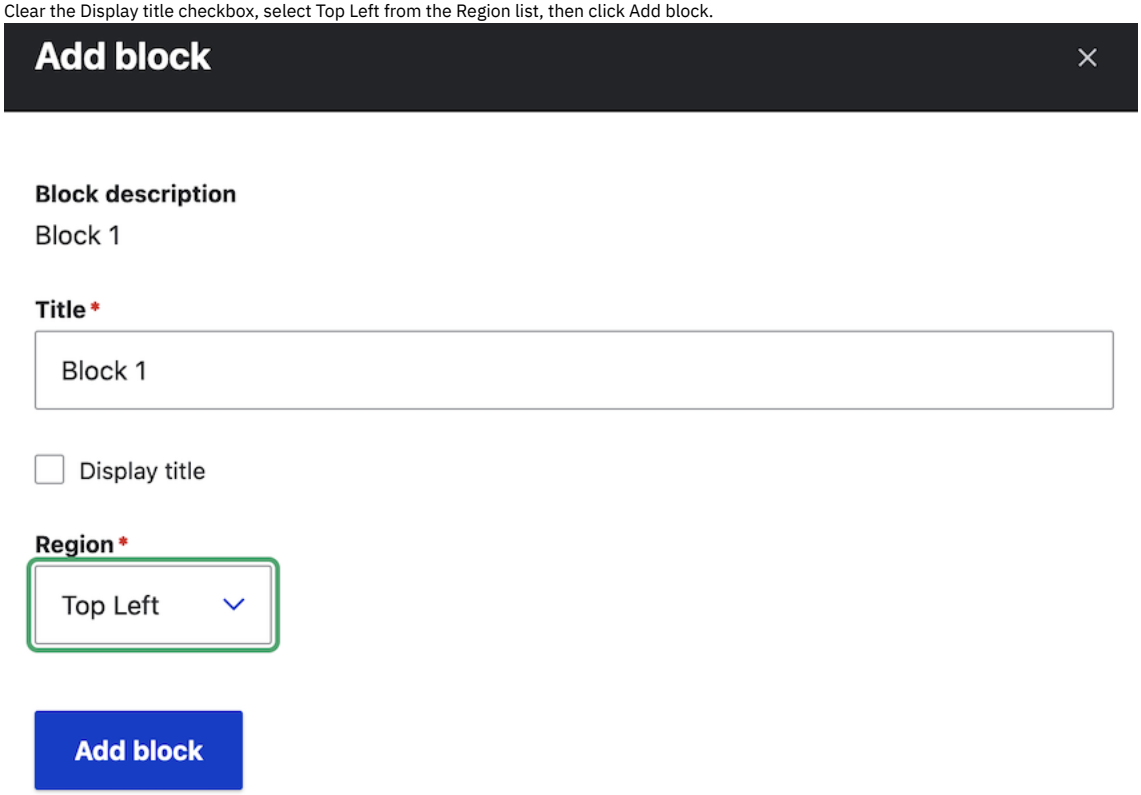


1. Navigate to Structure > Pages, click Add page.

2. In the Administrative title field, enter `Portal home`.
3. In the Path field, enter `newhome`.
4. From Variant type, select **`Panels`**.
5. Ensure all other checkboxes are clear.
6. Click Next.
7. Accept the defaults of `Panels` for Labels, and Standard for Builder, click Next.



8. From Layout, select Two column bricks and click Next.
9. Keep all settings except for the following:
   - Top Left, set Classes to Small:9
   - Top Right, set Classes to Small:3
   - Bottom Left, set Classes to Small:4
   - Bottom Right, set Classes to Small:8



10. Click Next.

Adding the custom blocks to the page

1. Leaving Page title blank, click Add new block.
2. Under the Content block section, select Block 1.

3. Clear the Display title checkbox, select Top Left from the Region list, then click Add block.

You added Block 1, repeat steps 1 to 3 to add Block 2, Block 3, and Block 4:

   a. For Block 2, select Top Right from the Region list.
   b. For Block 3, select Bottom Left from the Region list.
   c. For Block 4, select Bottom Right from the Region list.

4. Click Finish.
5. Click Update and save.

Changing the front page to be your new page

Note: In this tutorial, you create a new page and swap it with the default. If errors are made, the default page is still available as a backup.

1. Navigate to Structure > Pages.
2. Click the newhome URL link for your new Portal home page, check that your page looks as designed.

3. Navigate to Configuration > System > Basic site settings.
4. In Front Page region, set Default front page field to /newhome.
5. Click Save configuration.

What you did in this tutorial

The front page of your Developer Portal is now changed and laid out with the blocks of content that you specified.

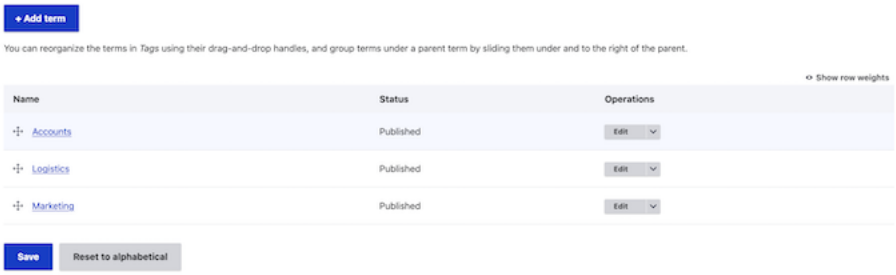
What to do next

You can add further branding by adding content to your custom blocks such as images, or try to use one of the provided custom blocks such as the Featured Content Block. By default this block is in English, you might want to consider adding versions in other languages.

Tutorial: Grouping products by category

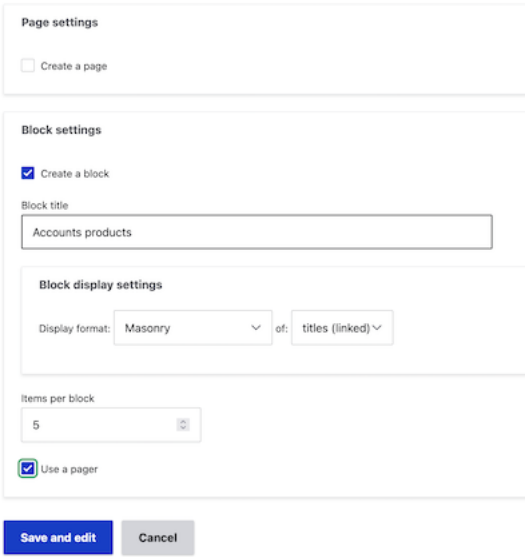
You can configure the Developer Portal so that products are displayed in groups according to the category that they are tagged with.

You can use the **`Views`** module to fetch content from your Developer Portal site, such as lists of products, and present the content to users in different formats. You can combine multiple views on a new page to display whatever content you want.



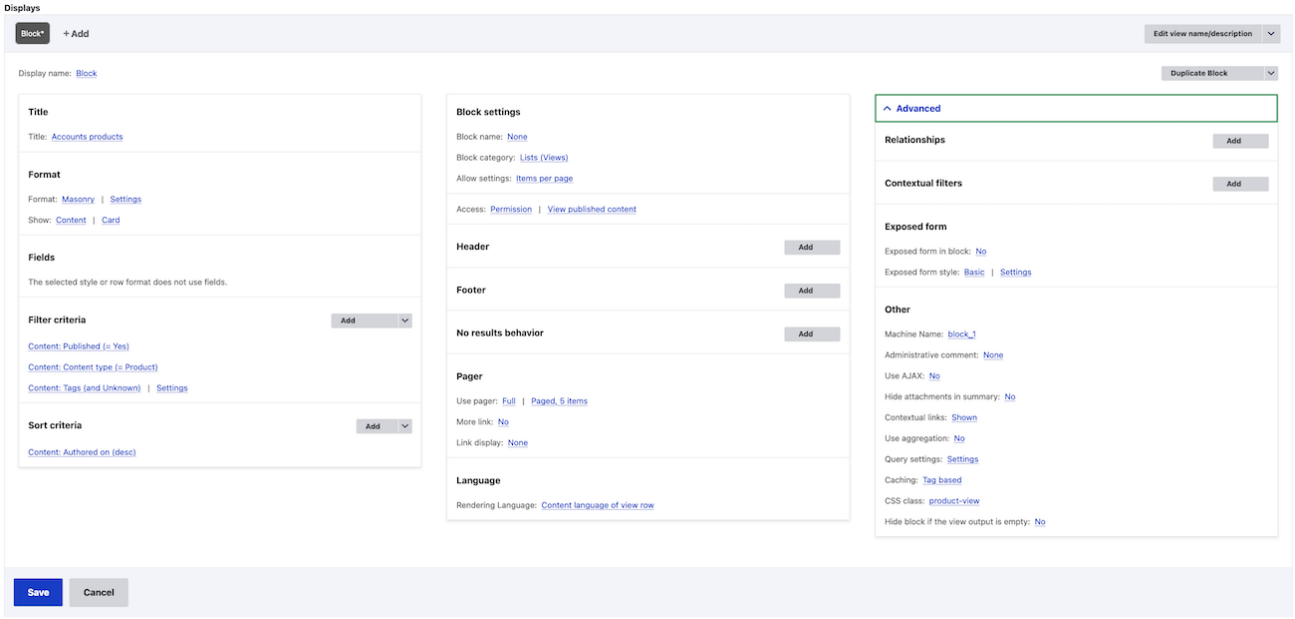
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

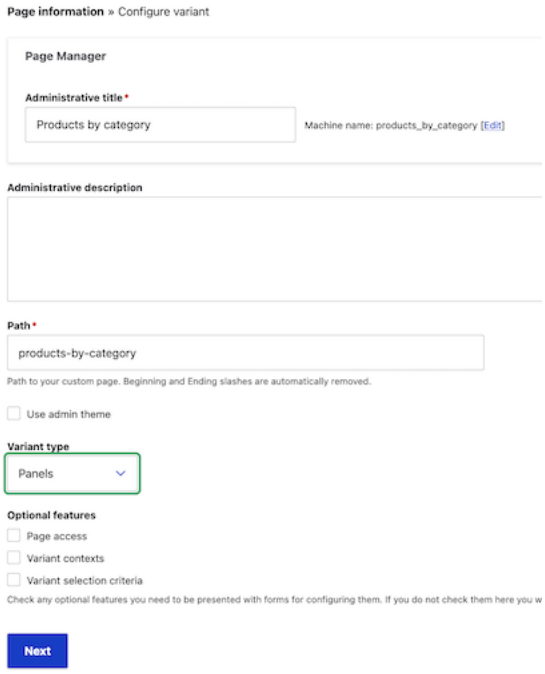


About this tutorial

In this tutorial you create three views in the Developer Portal, each one is configured to display a list of products according to their category. You then create a new page to show the views, where you see products that are grouped by category.

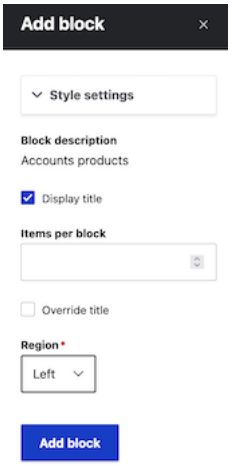


1. Log in to your Developer Portal as an administrator.
2. Create three new taxonomy tags.
    a. Navigate to Structure > Taxonomy.
    b. Under **`Vocabulary name`**, find Tags and click the arrow near to List terms .
    c. Click Add terms.
    d. In the **`Name`** field, enter `Accounts` and click Save.
    e. In the **`Name`** field, enter `Logistics` and click Save.
    f. In the **`Name`** field, enter `Marketing` and click Save.
    g. To show the list of new tags, navigate to Structure > Taxonomy, find Tags vocabulary, and click List terms.



3. Create a view to display products with the **`Accounts`** category.
   a. Navigate to Structure > Views > +Add view.
   b. In the **`View name`** field, enter `Accounts products`.
   c. In the **`View Settings`** section, select the following options:
      - **`Show`**: Content
      - **`of type`**: Product
      - **`sorted by`**: Newest first
   d. In **`Page settings`** section, ensure that the Create a page checkbox is clear.
   e. In **`Block settings`** section, select the Create a block checkbox, and enter `Accounts products` in the **`Block title`** field.
   f. Ensure that the **`Block Display Settings`** section has the following default options:
      - **`Display format`**: Masonry
      - **`of: tiles (linked)`**
   g. Select the Use a pager checkbox.

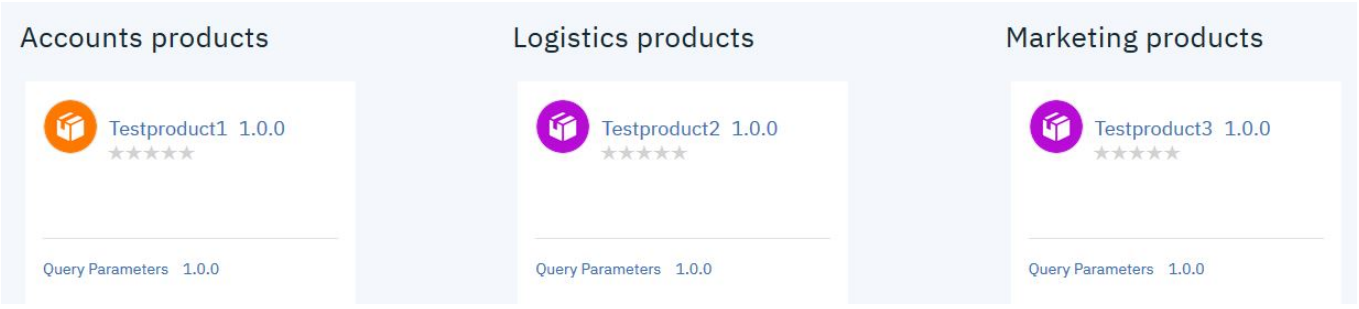
   h. Click Save and edit.
4. Configure the view block settings.
   a. In the **`Format`** section, click the Fields link next to the **`Show`** label.
   b. In the dialog box, select Content and click Apply.
   c. From the View mode list, select Card and click Apply.
   d. In the **`Filter Criteria`** section, click Add.
   e. In the **`Search`**field, enter `tag`, select the **`Tags (apic_tags)`** option from the list, and click Add and configure filter criteria.
   f. In the next dialog box, select the **`Tags`** and **`Client-side hierarchical`** options, then click Apply and continue.
   g. Under **`Operator`**, select Is all of, and from the **`Select terms from vocabulary Tags`** list, select Accounts, and click Apply.
   h. Under **`Advanced`**, click the None link next to the **`CSS class`** label.
   i. If you are using the default API connect theme, then enter the CSS class name `product-view` and click Apply. If you have your own css class that you want to use, then enter its name in here instead.
   j. Click Save to save all the changes.



5. Create a view for the Logistics products.
    a. Select Structure > Views.
    b. Navigate to the **`Accounts products`** view. Click the arrow next to Edit and select Duplicate.
    c. In the **`View name`** field, enter `Logistics products`, update the machine name, and click Duplicate.
    d. In the **`Title`** section, click Accounts products.
    e. In the **`Title`** field, enter `Logistics products` and click Apply.
    f. In the **`Filter Criteria`** section, click the Content: Tags: (=Accounts) link.
    g. From the Select terms from vocabulary Tags list, select Logistics and click Apply.
    h. Click Save to save all the changes.
6. Repeat step 5 to create a view for the Marketing products.
7. Next, create a page to display the views.
    a. Navigate to Structure > Pages.
    b. Click +Add page.
    c. In the **`Administrative title`** field, enter `Products by category`.
    d. In the **`Path`** field, enter `products-by-category`.
    e. From the Variant type list, select Panels and click Next.

    f. Change the **`Label`** value to `Products grouped by category`.
    g. From the Builder list, select **`Standard`** and click Next.
    h. From the Layout list, select Three column then click Next.
    i. Leave all the defaults on the next page and click Next.
    j. Click Add new block.
    k. From the Lists (views) section, select Accounts products .
    l. Ensure that Display tile checkbox is selected and **`Region`** is set to Left.

m. Click Add block.



n. Click Add new block. Select **`Logistics products`** view from the list and set the **`Region`** to Middle, click Add block.
o. Click Add new block. Select **`Marketing products`** view from the list and set the **`Region`** to Right, click Add block.
p. Enter `Products grouped by category` in the **`Page title`** field, and click Finish.

8. From your API Manager, create three new products, or update existing ones, to give each one a category value of either Accounts, Logistics, or Marketing. Publish each of the products to the catalog with the configured Developer Portal.
9. Check that the **`Products grouped by category`** page shows your published products by category.
   a. Select Structure > Pages.
   b. Click the **`/products-by-category`** path link.
   c. You are redirected to the **`/products-by-category`** page and can see the products that you assigned to these categories.

What you did in this tutorial

You created three new views in the Developer Portal, and configured each one to display a list of products according to their category. You then created a new page to show the views.

Tutorial: Adding a field to the sign-up form

You might want to collect and store additional information about your Developer Portal users. For example, you might want to collect a department name, employee ID, or similar data when a user registers for an account on the portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this tutorial, you will add a Department code field to the Sign up form. This field is required for all portal users.

This tutorial takes you through the following steps:

1. Adding a field to a user entity.
2. Adding the new field to the Sign up form.
3. Testing the new field.

Adding a field to a user entity

1. Log in to your Developer Portal as an administrator.
2. Navigate to Configuration > People > Account settings and click the Manage fields tab.

You are on the **`Manage fields`** tab.

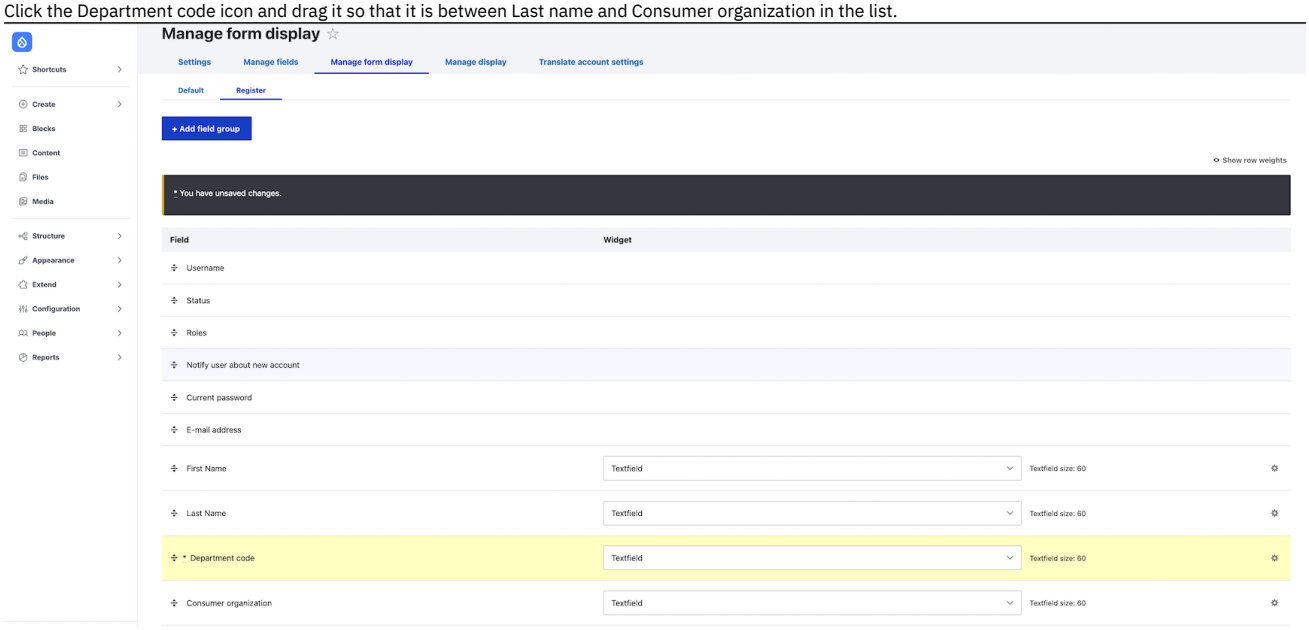
1. Click + Create a new field.
2. From the Choose a type of field list, select Plain text, and click Continue.
3. In the **`Label`** field enter, `Department code`, and select Text (plain).
4. Click Continue.

You are on the **`Department code settings for user`** page.

1. Accept the defaults of **`Maximum length`** (255) and **`Allowed number of values`** (Limited: 1).
2. Click Save settings.

You are on the **`Manage fields`** page. Check that **`Department code`** is a listed field.

1. Under **`Label`**, find **`Department code`** and click Edit.
2. Add some help text. This is information that is displayed to the user to assist them completing the field on a form. Examples or links to further information are useful here. We are going to add an example in this tutorial.
3. Add `Example department code: DEP123.` into the **`Help text`** field.
4. Select the Required field checkbox.
5. Click Save settings.



The field has now been created. You are back on the **`Manage fields`** tab.

Adding the new field to the Sign up form

1. Navigate to Configuration > People > Account settings and click the Manage form display tab.

You are on the Manage form display tab. These tabs, one for each form, show the fields that are displayed from the user entity, and in which order.

1. Switch to the Register tab. Notice that initially the new **`Department code`** field is underneath the **`Disabled row`** in the page. This means that it isn't shown on the form.
2. Click the Department code icon and drag it so that it is between Last name and Consumer organization in the list.

3. Click Save.

Testing the new field

1. Sign out as the Admin user.
2. Click Create a new account.
3. Observe that the `Department code` field is now part of the sign up form.

What you did in this tutorial

You added a Department code field to the Sign up form, then tested the form to make sure that the `Department code` field is now part of the sign up form.

In reality, you would need to add this configuration in such a way that it is available for all sites. To achieve this you would include the configuration in your custom module. For more information, see this Drupal documentation.

You might want to add extra validation to the Department code field on the Sign up form. For more information, see Tutorial: Adding validation to a field on the sign-up form.

Tutorial: Adding validation to a field on the sign-up form

You might want to add extra validation to a field to help your Developer Portal users. For example, you might want to validate a department name, employee ID, or similar data when a user registers for an account on the portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. You must have completed the tutorial about Adding a field to the sign up form, where you added a Department code field to the Sign-up form.

About this tutorial

In this tutorial, you add some validation to the Department code field on the Sign-up form. This is a required field for all portal users and is a string of the format `DEPnnn`, where `DEP` is the string prefix and `nnn` is a three-digit number, for example, `DEP123`. The validation is done by using a custom module that is already available in IBM APIC Portal - addons. However, for more information, see Custom module development: creating a module skeleton.

This tutorial takes you through the following steps:

1. Cloning and packaging the validation module.
2. Installing and enabling the validation module.
3. Testing the validation in the sign up form.

Look at the files that we will use in this link IBM APIC Portal - addons.

- user_field_example.info.yml - this is the metadata for the module, defining things like the name and version, and containing other important information that is required by Drupal to import and enable the module.

```
name: 'IBM APIC Portal - user field example'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of validating a custom user field'
package: 'Custom'
core_version_requirement: ^8 || ^9 || ^10 || ^11
version: 1.0.0
project: 'user_field_example'
dependencies:
  - ibm_apim
  - auth_apic
```

- user_field_example.module - this contains a validation function and adds this to the Sign-up form by using the `hook_form_alter` function.

```
<?php
use Drupal\Core\Form\FormStateInterface;

/**
 * Implementation of hook_form_alter() to alter the Sign up form
 */
function user_field_example_form_alter(&$form, FormStateInterface $form_state, $form_id) {
  if ($form_id === 'user_register_form' ) {
      $form['#validate'][] = 'user_field_example_validate_department_code';
  }
}

/**
 * Validate the Department code field on the Sign up form.
 *
 * Valid entry = DEPnnn
 *   where n = single figure digit.
 */
function user_field_example_validate_department_code($form, &$form_state) {
  $dept_code = $form_state->getValue('field_department_code')[0]['value'];
  $valid = preg_match('/^DEP\d{3}$/', $dept_code);
  if (!$valid) {
    $form_state->setErrorByName('field_department_code', t('Invalid department code.'));
  }
}
```

Cloning and packaging the validation module

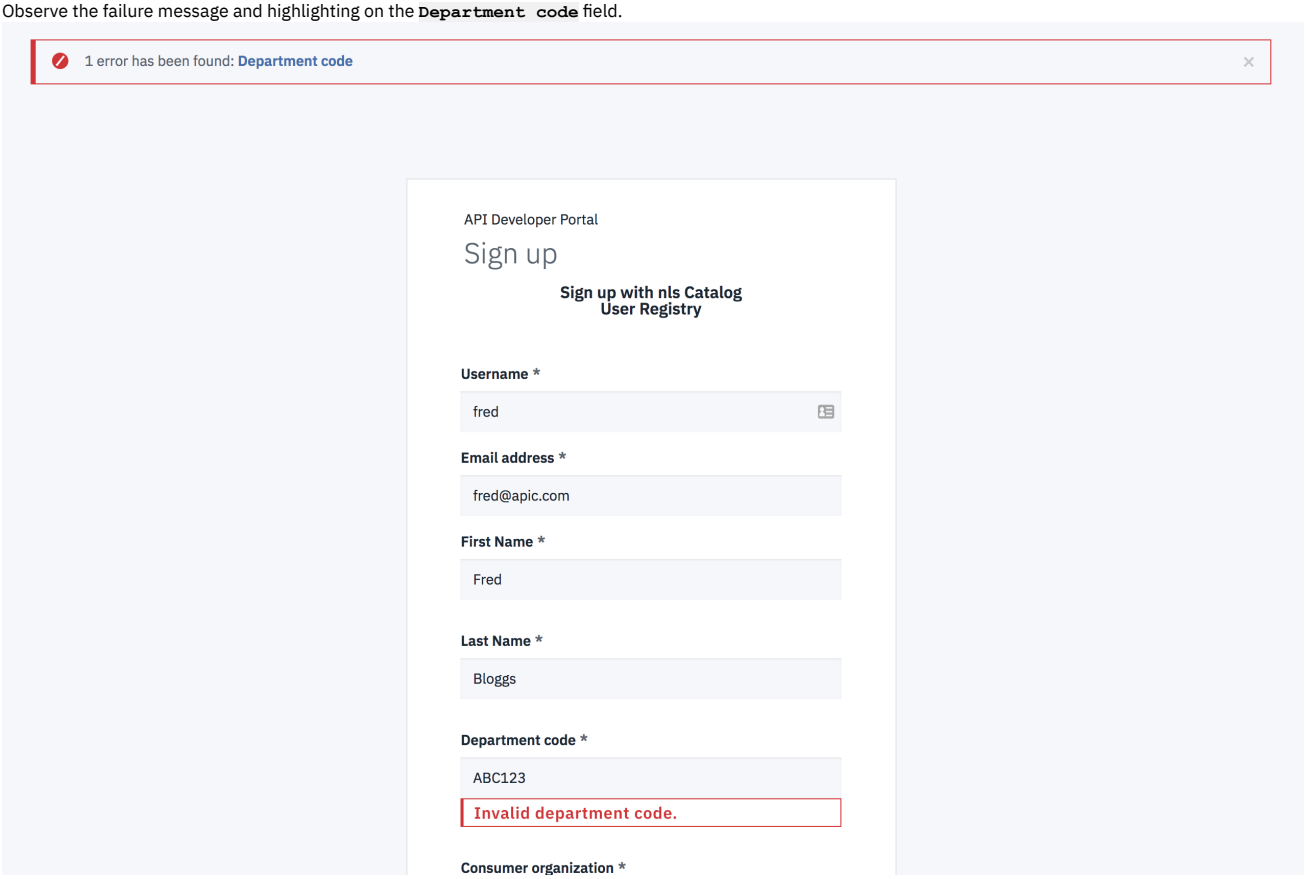
Validation is added to the **`Department code`** field on the Sign-up form by using a custom module.

1. Clone the custom module. Here is an example command if you are using Mac and Linux:

   ```
   git clone https://github.com/ibm-apiconnect/devportal-addons
   ```

2. Package up the custom module.

   ```
   cd devportal-addons/apic_v10/modules
   tar -czf user_field_example.tgz user_field_example/
   ```



Installing and enabling the validation module

1. Log in to your Developer Portal as an administrator.
2. Click Extend > Extend.
3. Click + Add new module.
4. Under the Upload a module or theme archive section, click Browse file.
5. Browse to and select **`user_field_example.tgz`**, the packaged custom module that you created earlier. Click Open.
6. Click Continue.
7. Click the Enable newly added modules link.
8. Enter the `IBM APIC Portal - user field example` in the filter box.
9. Select the **`IBM APIC Portal - user field example`** checkbox.
10. Click Enable.

The module is now installed and enabled.

Testing the validation in the sign-up form

1. Sign out as the Admin user.
2. Click Create a new account.
3. Enter necessary details in all the fields, set **`Department code`** to **`ABC123`**.
4. Click Sign up.
5. Observe the failure message and highlighting on the **`Department code`** field.

6. Change the **`Department code`** field to **`DEP245`**, reenter the password and click **`Sign up`** to see that a valid code is accepted.

What you did in this tutorial

You added some validation to the Department code field on the Sign-up form, then tested the form to ensure that the **`Department code`** field accepts only codes in the format of **`DEPnnn`**.

In reality, you would need to add this configuration in such a way that it is available for all sites. To achieve this availability, you would include the configuration in your custom module. For more information, see Drupal custom modules.

Tutorial for Adding a field group to group fields in a content type

You might want to change how your user account pages are displayed when you have lots of fields.

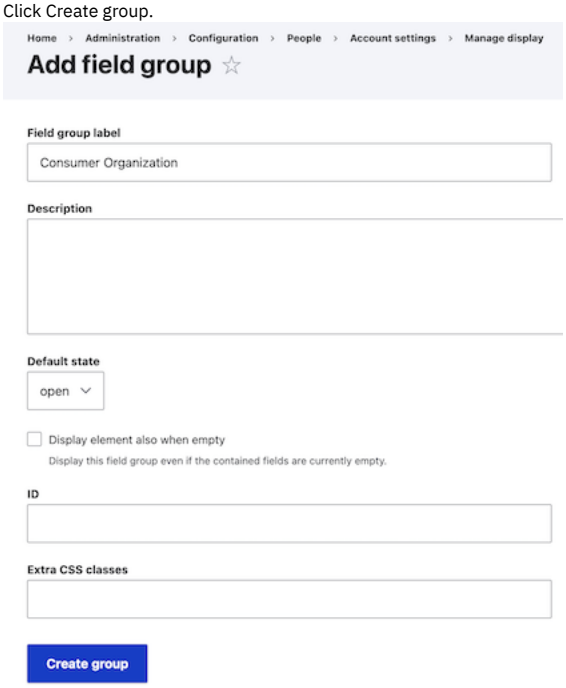
If you have many fields for one of your content types, for example, a user, then you can group some of these fields together while demonstrating them to other users, or when these fields are being edited inside a user form.

Using the field groups, you can create a parent field that contains other fields, set up as children, within that group. The **`Fieldgroup`** forms come with default HTML wrappers such as vertical tabs, horizontal tabs, accordions, fieldsets, or div wrappers.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

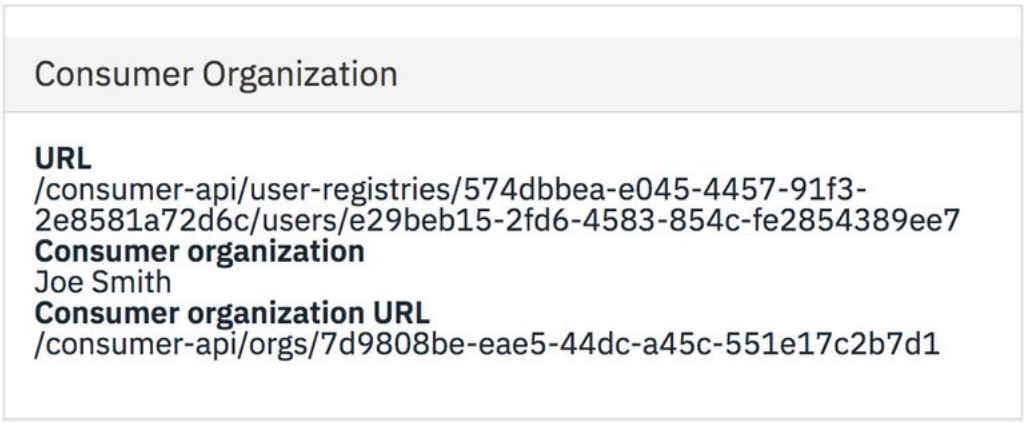
Overview



You can create field groups for various groups of user information. These groups can then be seen under the users own section on the account view and edit pages.

This tutorial takes you through the following steps:

1. Adding a field group called Consumer Organization to the user account display.
2. Adding a field group called Personal Details to the user form display.



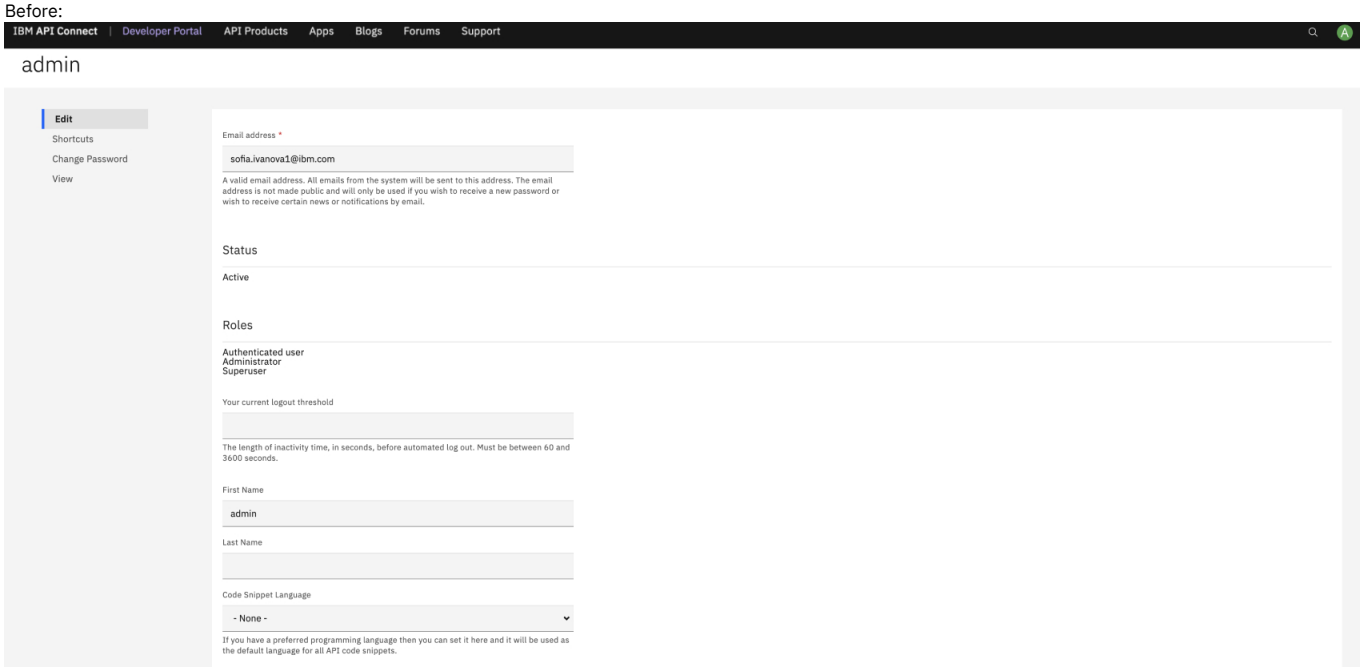
Adding a field group called Consumer Organization to the user account display

1. Log in to your Developer Portal as an administrator.
2. Navigate to Configuration > People > Account settings > Manage display.
3. Click + Add field group.
4. From the Add a new group list, select Tab.
5. In the **`Label`** field, enter `Consumer Organization`.
6. Click Save and continue.
7. From the Default state list, select **`open`**. This sets the tab to be expanded by default.
8. Click Create group.

When the group is created, you can assign fields to that group and rearrange the group on the page. To rearrange the group, on the Manage Display page, drag any group and drop is under your desired field.
Note: The **`Weight`**, **`Parent`**, and **`Region`** fields are hidden by default. Click Show row weights to view these fields.
For example, let's assume that you have created a new group that is named Consumer organization and want to add Consumer organization URL to it. You can do so by dragging the Consumer organization URL group and dropping it under Consumer organization.

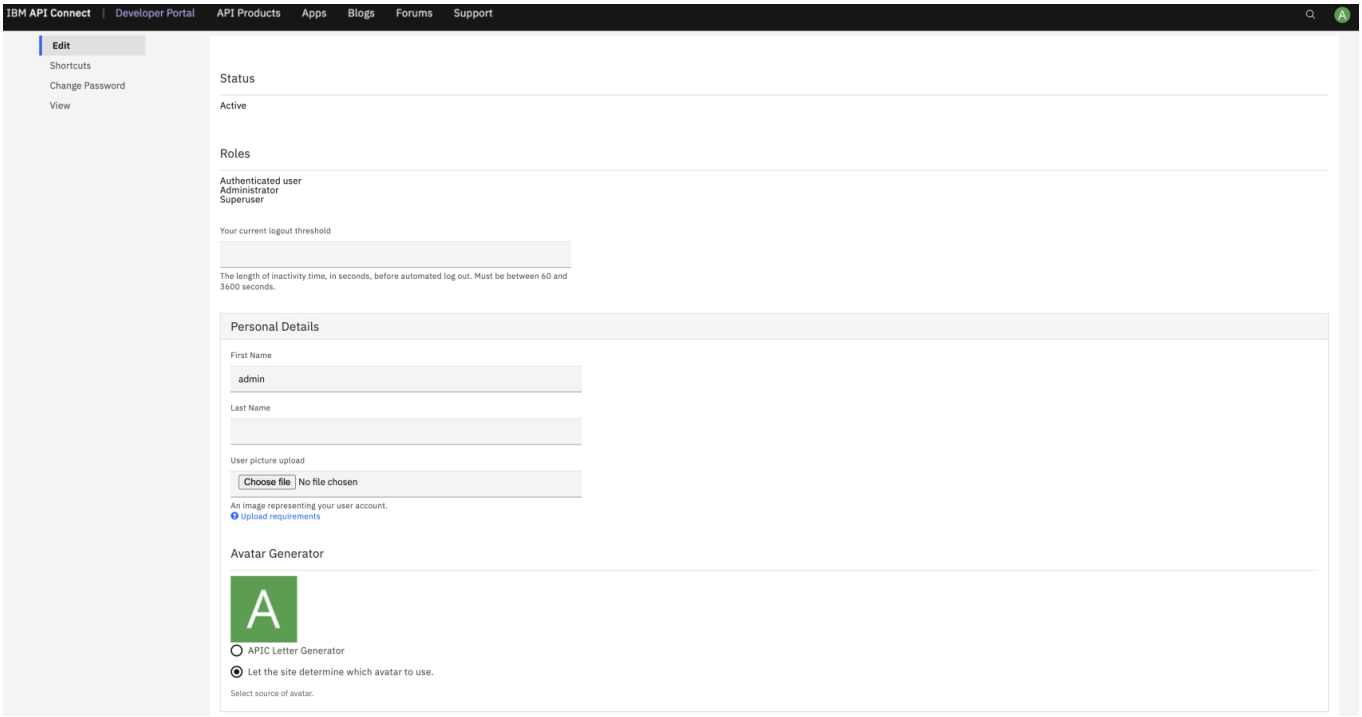
You can view the new group of fields on the account page of a user as depicted in the following image.

Adding a field group called Personal Details to the user form display



1. Navigate to Configuration > People > Account settings > Manage form display.
2. Click + Add field group.
3. From the Add a new group list, select Tab.
4. In the Label field, enter `Personal Details`.
5. Click Save and continue.
6. From the Default state list, select Open. This sets the tab to be expanded by default.
7. Click Create group.

Again, when the group is created, you can assign fields to that group and then rearrange the group on the page as you require. After you create the group, you are redirected to the Manage Display page.



To rearrange the group, on the Manage Display page, drag any group and drop is under your desired field.

You and your user can now see the new grouped section when you edit their account.

Before:

After:

What you did in this tutorial

You have successfully created field groups for various groups of user information, and presented them to the user in its own section on the account view and edit pages.

You can check whether your field groups are applied, by viewing the profile of another user. Do this check by finding any other users published content and clicking the associated avatar. Or, from the Administrator dashboard you can click People and then click a user. You can see the new Consumer Organization field group on their profile page. If you then click **`Edit`** for the user, you can see the Personal Details field group.

What to do next

You can edit the user displays anytime by navigating back to Configuration > People > Account settings > Manage display or Manage form display.

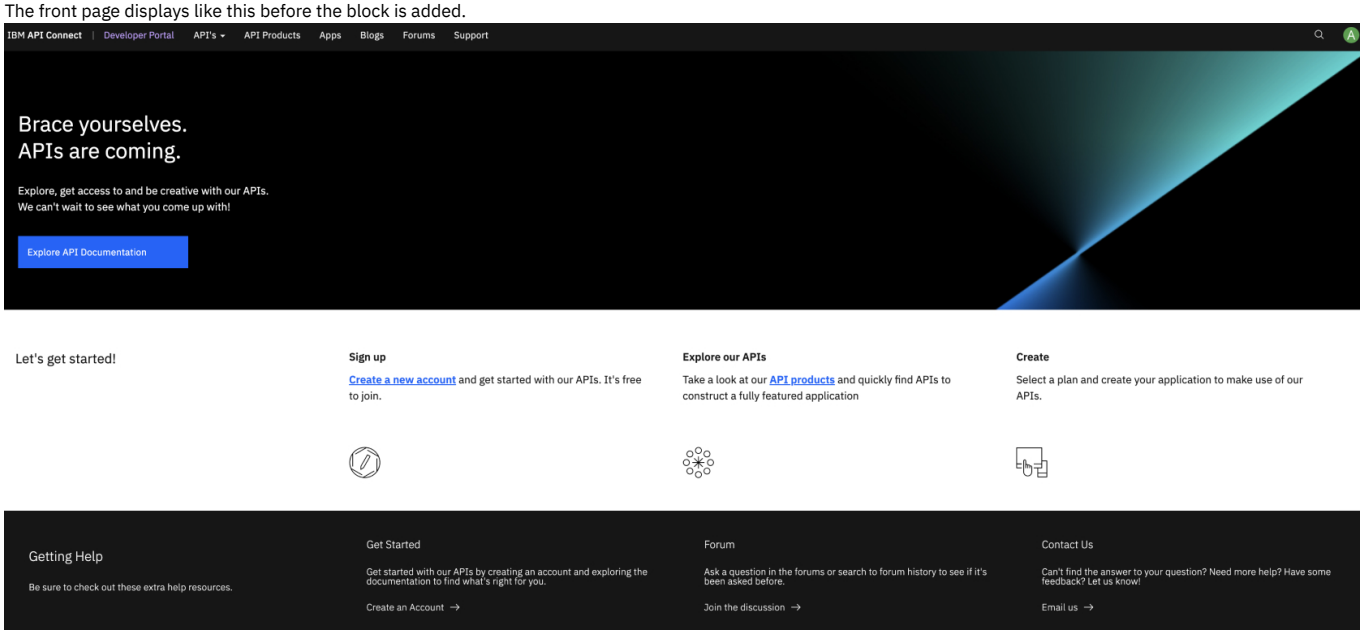
You can delete the field group by clicking the Delete button in the field group row on either of these pages. You can also modify the type of group it is, for example, vertical tabs, horizontal tabs, accordions, and field sets.

Tutorial: Adding a custom block to the front page

You can customize the appearance of the front page of your Developer Portal by adding a custom block. Blocks are boxes of content that are rendered into an area, or region, of a web page such as the Products page or Apps page that can be displayed in regions, such as footer or sidebar, on your page.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so. The tutorial Adding a custom block to a page other than the front page explains how to add a custom block to any other page.

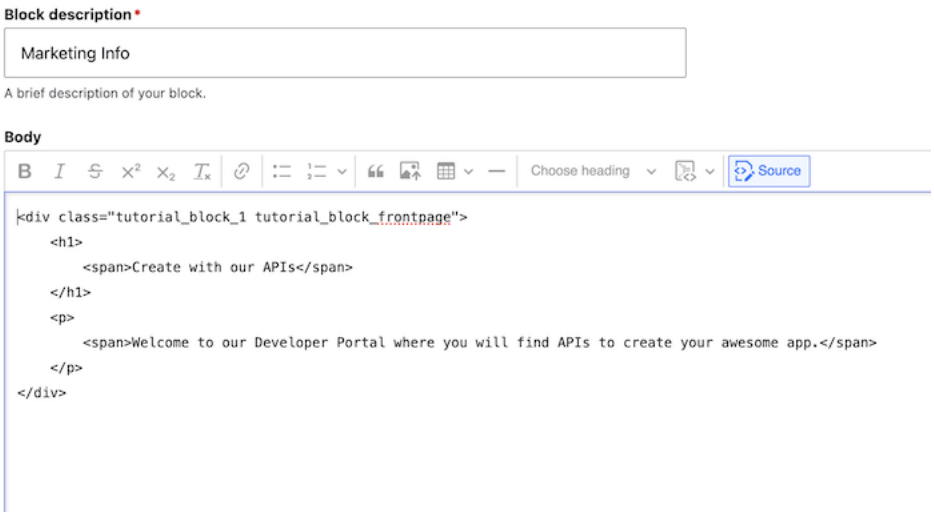


About this tutorial

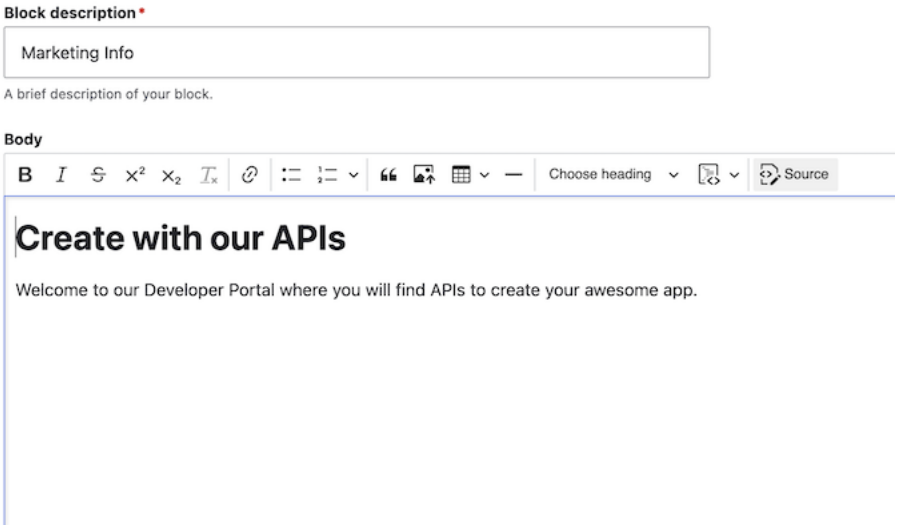
In this tutorial, you create a block that contains a marketing announcement and add it to the front page of your Developer Portal.

This tutorial takes you through the following steps:

1. Creating a custom block
2. Adding the custom block to the front page.



The front page displays like this before the block is added.

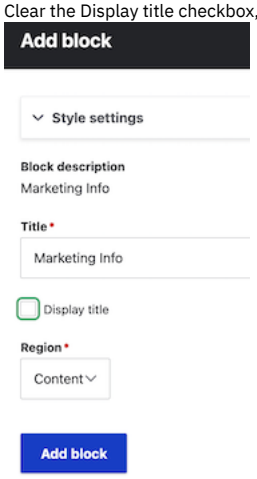


Creating a custom block

1. Log in to your Developer Portal as an administrator.
2. Click Blocks, then click + Add content block.
3. In the **`Block description`**, enter `Marketing Info`.
4. In the body area, click Source, then enter this HTML:

```
<div class="tutorial_block_1 tutorial_block_frontpage">
<h1><span>Create with our APIs</span></h1>
<p><span>Welcome to our Developer Portal where you will find APIs to create your awesome app.</span></p>
</div>
```

5. To see a preview of the block, click Source again.

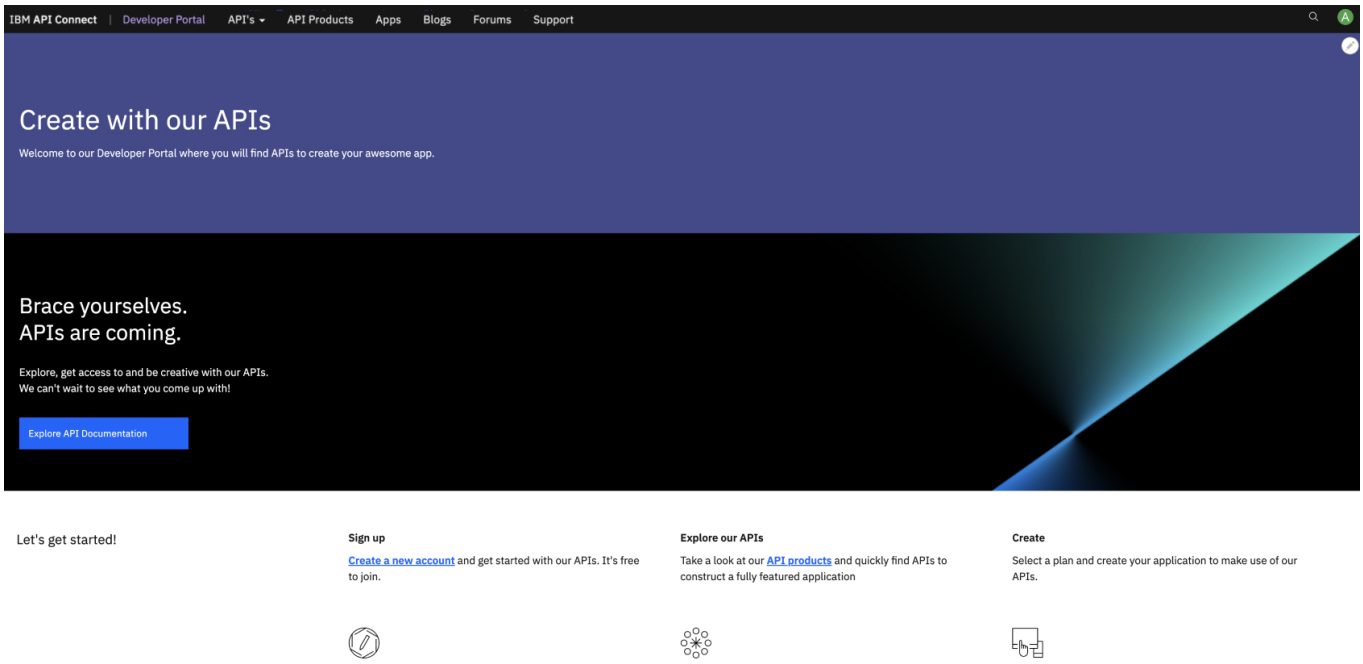


Note: This block uses almost no inline-styling, instead it allows your theme to decide how it is rendered. The advantage of this set up is that you can easily change the rendering without modifying existing content in the database. Any styling that is required can be added to a custom theme. For more information, see Tutorial: Creating a custom theme for the Developer Portal.

6. Click Save.

You have now created the custom block.

Adding the custom block to the front page



1. Navigate to Structure > Pages.
2. Find the **`Welcome`** label and click Edit.
3. Under Variants, click Panels > Content.
4. Click Add new block.
5. Under Content block, click **`Marketing Info`**.
6. Clear the Display title checkbox, keep Content in the **`Region`** list, and click Add block.

7. The **`Marketing Info`** label is now placed before the **`Welcome banner`** label. Click Update and save.

What you did in this tutorial

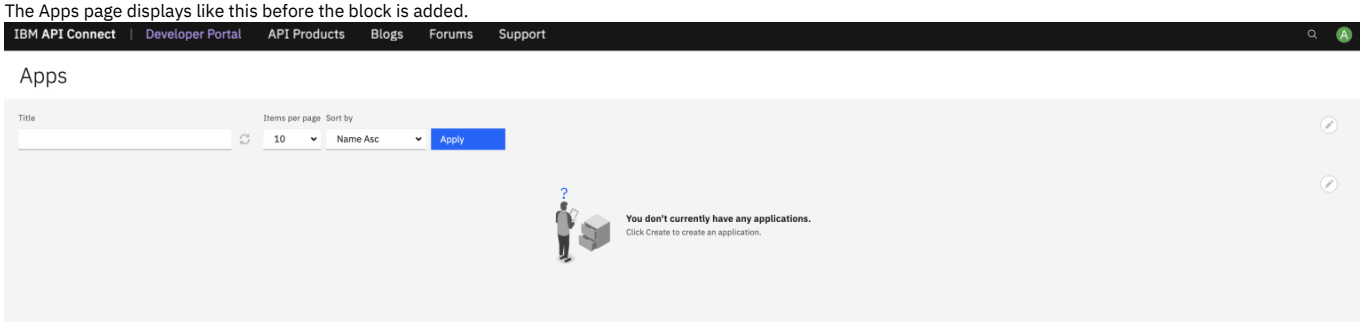
The front page now has the new block with a marketing message.

What to do next

You can add further branding by adding content to your custom blocks such as images, or try using one of the provided custom blocks such as the Featured Content Block. Instead of using inline styling like that provided in the html, adopt best practice by adding class selectors and developing a custom theme. By default this block is English, you might want to consider adding translated versions.

Tutorial: Adding a custom block to a page other than the front page

You can customize the appearance of a page on your Developer Portal by adding a custom block. Blocks are boxes of content that are rendered into an area or region of a web page, such as the Products page or Apps page. Blocks can be displayed in regions, such as footer or sidebar, on your page.

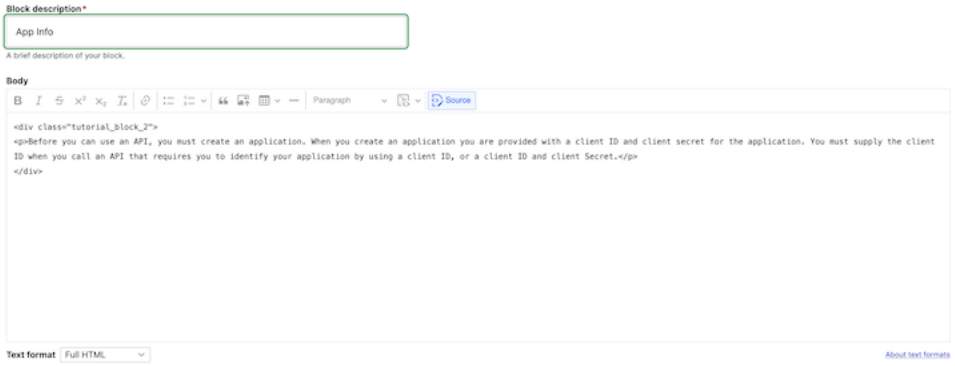


Before you begin

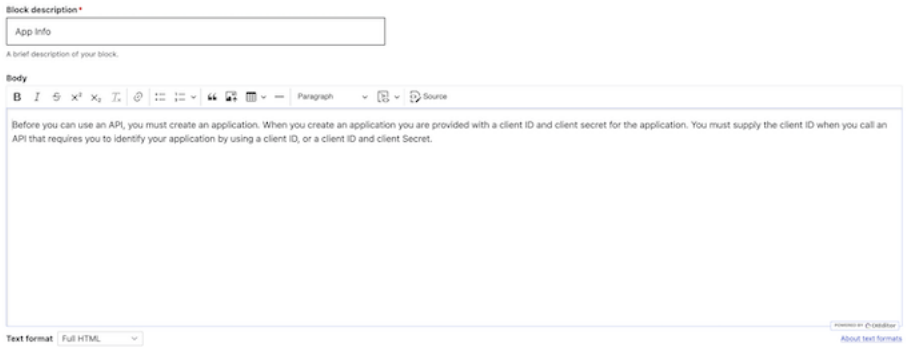
You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so. The tutorial Adding a custom block to the front page explains how to add a custom block to the front page.

About this tutorial

In this tutorial, you create a custom block that contains extra guidance on application creation and registration, and add that custom block to the Apps page of your Developer Portal.

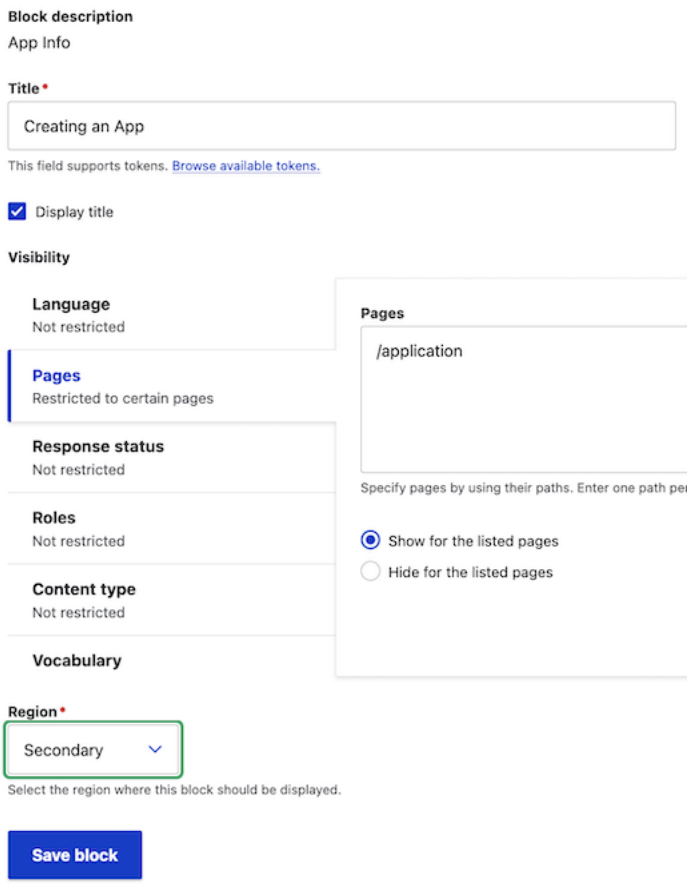


The Apps page displays like this before the block is added.



This tutorial takes you through creating a custom block, and configuring it to show on the Apps page.

1. Log in to your Developer Portal as an administrator.
2. Click Blocks, then click + Add content block.
3. In the **`Block description`**, enter `App Info`.
4. In the body area, click Source, then enter this HTML:



```
<div class="tutorial_block_2">
<p>Before you can use an API, you must create an application. When you create an application you are provided with a
client ID and client secret for the application. You must supply the client ID when you call an API that requires you to
identify your application by using a client ID, or a client ID and client Secret.</p>
</div>
```

5. To see a preview of the block click Source again.

   Note: This block uses almost no inline-styling, instead it allows your theme to decide how it is rendered. The advantage of this set up is that you can easily change the rendering without modifying existing content in the database. Any styling that is required can be added to a custom theme. For more information, see Tutorial: Creating a custom theme for the Developer Portal.
6. Click Save and configure.
7. In the **`Title`** field, enter `Creating an App` and ensure that the Display title checkbox is selected.
8. Under Visibility, click Pages.
9. In the **`Pages`** text area, enter `/application` , ensure that Show for the listed pages is selected.
10. From the Region list, select Secondary.

11. Click Save block.
12. Click Save blocks.

What you did in this tutorial

The Apps page now has an additional block with a guidance message.

What to do next

Instead of using inline styling like that provided in the html, adopt best practice by adding class selectors and developing a custom theme. By default this block is English, so you might want to consider adding translated versions.

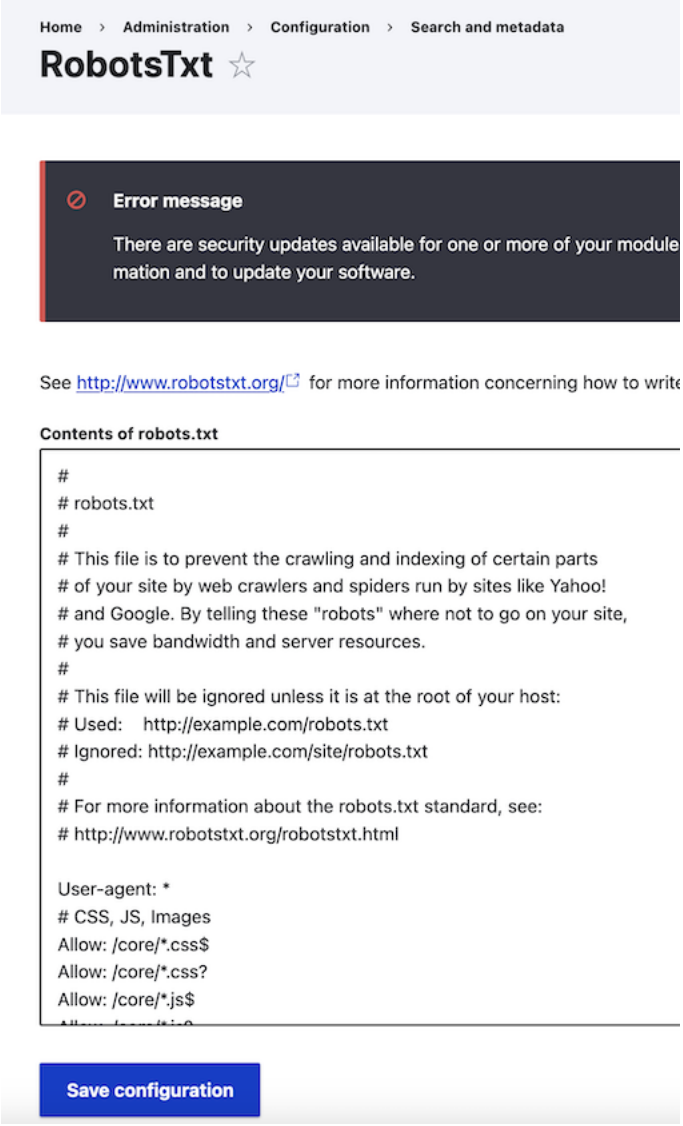
Tutorial: Configuring the RobotsTxt file

You can control the access of a visiting web robot. You can configure the **`robots.txt`** file that exists on your web server, usually at the root level, to control access. Web robots are programs that crawl through the web to obtain web content for all the sites that are visited, and provide indexing for better performance of search engines. You can also specify separate rules for different robots.

Why would you want to edit Drupal's pre-existing robots.txt file?

Malicious robots might choose not to honor the **`robots.txt`** file, and by editing this file that you are broadcasting which sites you do not want others to see. Therefore, do not use this file to hide sensitive data. Instead, you might want to edit your **`robots.txt`** file to:

- Prevent duplicate information from being identified on your site
- Prevent internal pages from appearing in search engines
- Prevent private pages from appearing in search engines
- Prevent particular images, files, and so on, from being crawled
- Specify a **`crawl-delay`** attribute to prevent robots from overloading your server at load time
- Exclude a particular robot



Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

You will edit the pre-existing **`robots.txt`** file and exclude access to a visiting robot called BadBot.

1. Log in to your Developer Portal as an administrator.
2. Navigate to Configuration > Search and Metadata > RobotsTxt.

3. In the **`Contents of robots.txt`** section, enter the policy to exclude access to a robot called BadBot.

```
User-agent: BadBot
Disallow: /
```

4. Click Save Configuration to save your changes.

What you did in this tutorial

Successfully customized the **`robots.txt`** file. Robots now use this updated file to decide where they can crawl on your site. The BadBot robot is excluded access.

You can check whether your **`robots.txt`** file is successfully changed by navigating to your site and appending /robots.txt. You can now view the content you entered into that file.

```
#
# robots.txt
#
# This file is to prevent the crawling and indexing of certain parts
# of your site by web crawlers and spiders run by sites like Yahoo!
# and Google. By telling these "robots" where not to go on your site,
# you save bandwidth and server resources.
#
# This file will be ignored unless it is at the root of your host:
# Used:    http://example.com/robots.txt
# Ignored: http://example.com/site/robots.txt
#
# For more information about the robots.txt standard, see:
# http://www.robotstxt.org/robotstxt.html

User-agent: BadBot
Disallow: /

User-agent: *
# CSS, JS, Images
Allow: /core/*.css$
Allow: /core/*.css?
Allow: /core/*.js$
Allow: /core/*.js?
```

For more information on how to edit your **`robots.txt`** file, see https://www.robotstxt.org/.

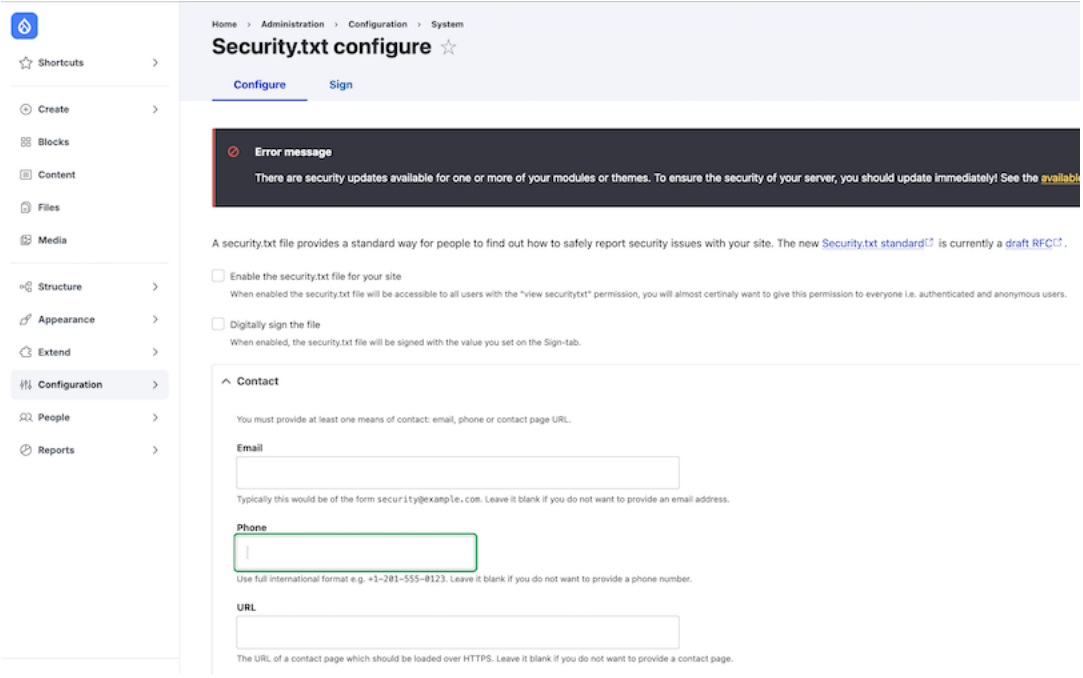
What to do next

You can edit the **`robots.txt`** at any time by navigating back to the page within the configuration settings. You might choose to duplicate this file across all of your sites, or choose different policies for different sites.

Tutorial: Configuring the SecurityTxt file

You can use the **`security.txt`** file to provide your users with a standard way to report security vulnerabilities with your site.

The **`security.txt`** file is a file format that is designed to help your users disclose any security vulnerability. For more information, see securitytxt.org or A File Format to Aid in Security Vulnerability Disclosure.



Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

You edit the **`security.txt`** file and provide information such as a URL of a contact page, for your customers to use if they have a security vulnerability.

1. Log in to your Developer Portal as an administrator.
2. Navigate to Configuration > System > Security.txt.

3. Select the Enable the security.txt file for your site checkbox.
4. Complete the form as per your requirement.
5. Click Save Configuration to save your changes.

What you did in this tutorial

You successfully customized the **`security.txt`** file.

What to do next

You can edit the **`security.txt`** at any time by navigating back to the page within the configuration settings.

Tutorials for using custom modules in the Developer Portal

You can configure custom modules to complete specific actions in the Developer Portal.

Note: You must have administrator access to complete the tutorials.
You can configure rules for the following events that occur in the Developer Portal:

- Change the profile page to display **`firstname`** **`last name`**, instead of **`username`**.
- Add validation to a field on the sign up form.

Tutorial: Changing the profile page to display firstname lastname, instead of username

You might want to change the profile page of your users on your Developer Portal to display their **`firstname`** and **`lastname`** rather than their **`username`**.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

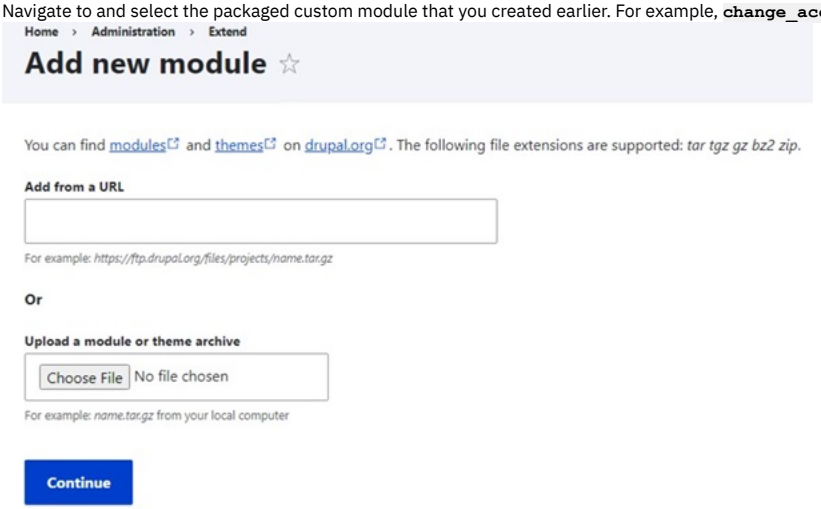
In this tutorial, you change the profile page of your users to display their **`firstname`** and **`lastname`** rather than their **`username`**. The change to the profile page is done by using the custom module **`change account display`** that is already available in IBM APIC Portal - addons. However, for more information, see Custom module development: creating a module skeleton.

This tutorial takes you through the following steps:

1. Cloning and packaging the **`change account display`** module.
2. Installing and enabling the change account display module.

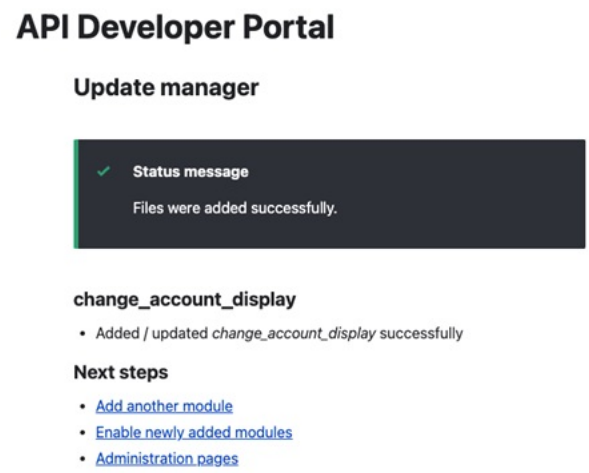
Cloning and packaging the `change account display` module

1. Clone the custom module. Here is an example command if you are using Mac and Linux:



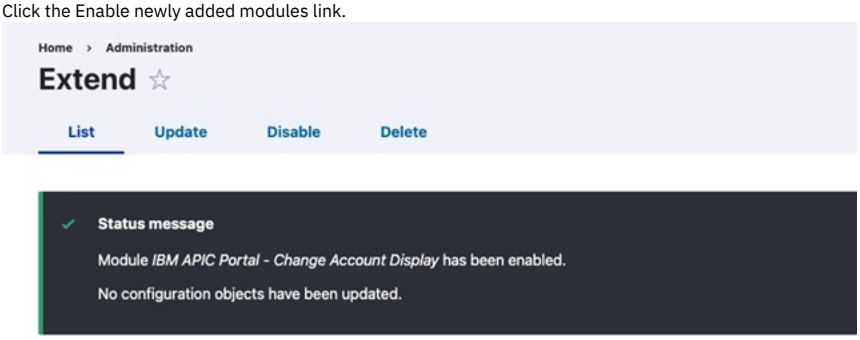
```
git clone https://github.com/ibm-apiconnect/devportal-addons
```

2. Package up the custom module.



```
cd devportal-addons/apic_v10/modules
tar -czf change_account_display.tar.gz change_account_display/
```

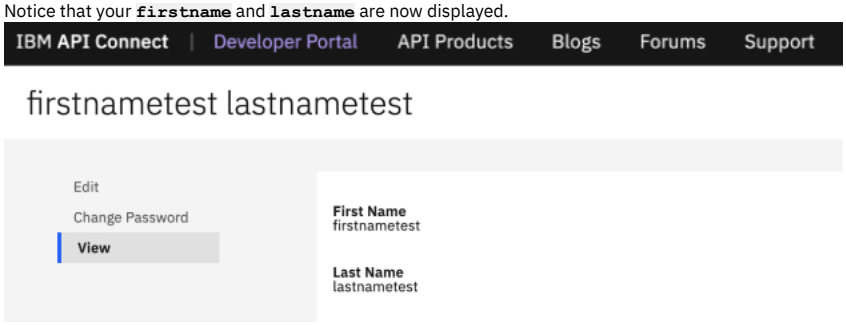
Installing and enabling the `change account display` module



1. Log in to your Developer Portal as an administrator.
2. Click Extend > Extend.
3. Click + Add new module.
4. From the **`Upload a module or theme archive`** section, click Browse file.
5. Navigate to and select the packaged custom module that you created earlier. For example, **`change_account_display.tgz`**, then click Open.

6. Click Continue.

7. Click the Enable newly added modules link.



8. In the filter box, enter `Change Account Display`.
9. Select the Change Account Display checkbox.
10. Click Enable.

The module is now installed and enabled.

Test the profile page change

1. Sign out as the Admin user.
2. Sign in as a user of your Developer Portal.
3. Click the arrow icon next to your **username** and select My account.
4. Notice that your **firstname** and **lastname** are now displayed.

What you did in this tutorial

You used a custom module to change the profile page display for the users of your Developer Portal.

Tutorial: Adding validation to a field on the sign-up form

You might want to add extra validation to a field to help your Developer Portal users. For example, you might want to validate a department name, employee ID, or similar data when a user registers for an account on the portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. You must have completed the tutorial about Adding a field to the sign up form, where you added a Department code field to the Sign-up form.

About this tutorial

In this tutorial, you add some validation to the Department code field on the Sign-up form. This is a required field for all portal users and is a string of the format **DEPnnn**, where **DEP** is the string prefix and **nnn** is a three-digit number, for example, **DEP123**. The validation is done by using a custom module that is already available in IBM APIC Portal - addons. However, for more information, see Custom module development: creating a module skeleton.

This tutorial takes you through the following steps:

1. Cloning and packaging the validation module.
2. Installing and enabling the validation module.
3. Testing the validation in the sign up form.

Look at the files that we will use in this link IBM APIC Portal - addons.

- user_field_example.info.yml - this is the metadata for the module, defining things like the name and version, and containing other important information that is required by Drupal to import and enable the module.

```
name: 'IBM APIC Portal - user field example'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of validating a custom user field'
package: 'Custom'
core_version_requirement: ^8 || ^9 || ^10 || ^11
version: 1.0.0
project: 'user_field_example'
dependencies:
  - ibm_apim
  - auth_apic
```

- user_field_example.module - this contains a validation function and adds this to the Sign-up form by using the **hook_form_alter** function.

```
<?php
use Drupal\Core\Form\FormStateInterface;

/**
 * Implementation of hook_form_alter() to alter the Sign up form
 */
function user_field_example_form_alter(&$form, FormStateInterface $form_state, $form_id) {
  if ($form_id === 'user_register_form' ) {
      $form['#validate'][] = 'user_field_example_validate_department_code';
  }
}

/**
 * Validate the Department code field on the Sign up form.
 *
```

```
 * Valid entry = DEPnnn
 *   where n = single figure digit.
 */
function user_field_example_validate_department_code($form, &$form_state) {
  $dept_code = $form_state->getValue('field_department_code')[0]['value'];
  $valid = preg_match('/^DEP\d{3}$/', $dept_code);
  if (!$valid) {
    $form_state->setErrorByName('field_department_code', t('Invalid department code.'));
  }
}
```

Cloning and packaging the validation module

Validation is added to the **Department code** field on the Sign-up form by using a custom module.

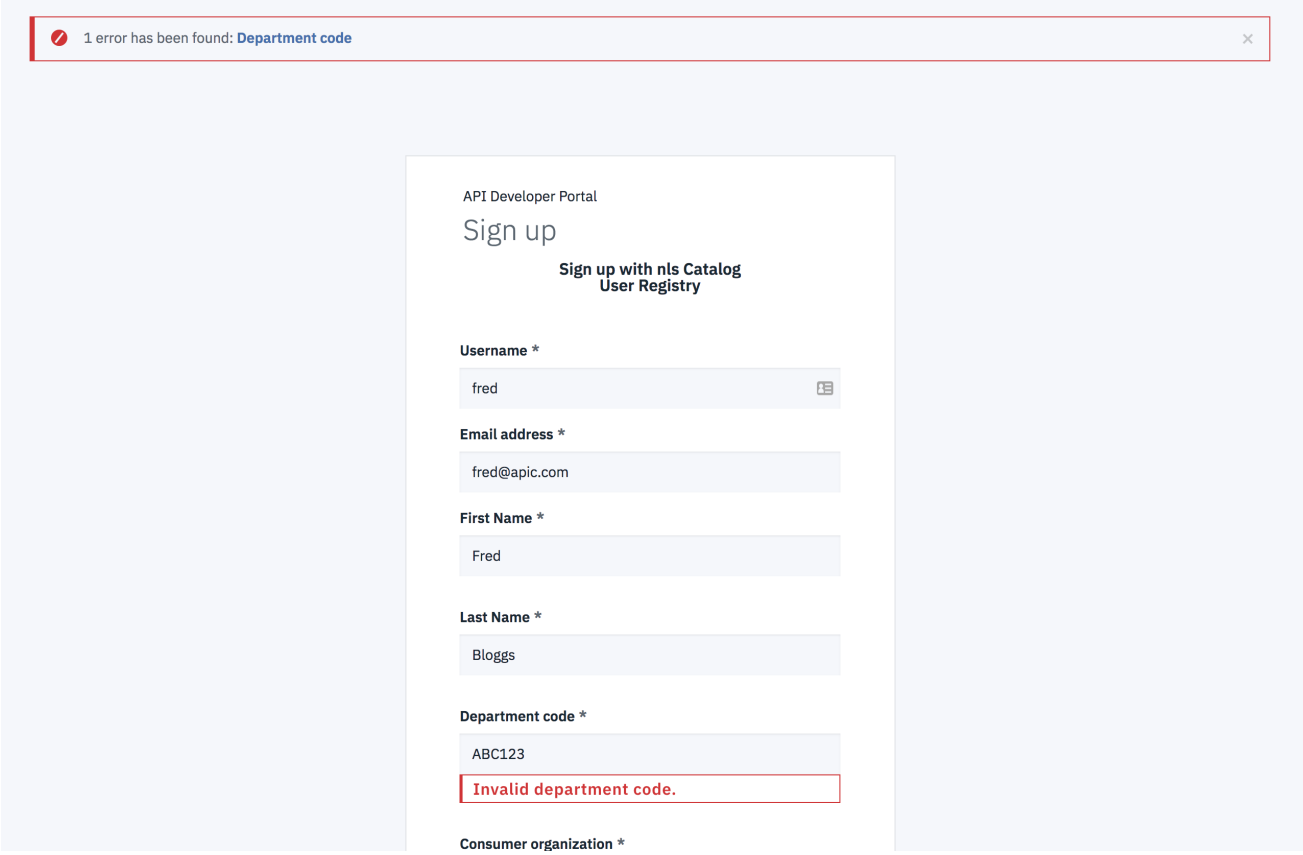
1. Clone the custom module. Here is an example command if you are using Mac and Linux:

   ```
   git clone https://github.com/ibm-apiconnect/devportal-addons
   ```

2. Package up the custom module.

   ```
   cd devportal-addons/apic_v10/modules
   tar -czf user_field_example.tgz user_field_example/
   ```

Installing and enabling the validation module



1. Log in to your Developer Portal as an administrator.
2. Click Extend > Extend.
3. Click + Add new module.
4. Under the Upload a module or theme archive section, click Browse file.
5. Browse to and select **user_field_example.tgz**, the packaged custom module that you created earlier. Click Open.
6. Click Continue.
7. Click the Enable newly added modules link.
8. Enter the `IBM APIC Portal - user field example` in the filter box.
9. Select the **IBM APIC Portal - user field example** checkbox.
10. Click Enable.

The module is now installed and enabled.

Testing the validation in the sign-up form

1. Sign out as the Admin user.
2. Click Create a new account.
3. Enter necessary details in all the fields, set **Department code** to **ABC123**.
4. Click Sign up.

5. Observe the failure message and highlighting on the **`Department code`** field.

6. Change the **`Department code`** field to **`DEP245`**, reenter the password and click **`Sign up`** to see that a valid code is accepted.

What you did in this tutorial

You added some validation to the Department code field on the Sign-up form, then tested the form to ensure that the **`Department code`** field accepts only codes in the format of **`DEPnnn`**.

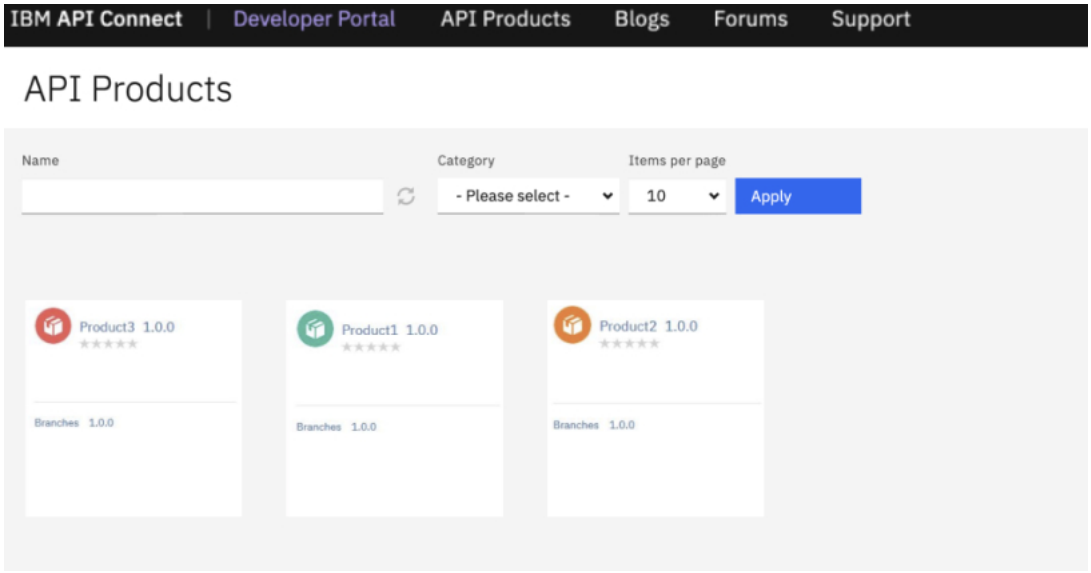
In reality, you would need to add this configuration in such a way that it is available for all sites. To achieve this availability, you would include the configuration in your custom module. For more information, see Drupal custom modules.

Tutorial: Using a custom weighting sort order on the product list page

You can use a custom weighting to sort your products on the API products list page of your Developer Portal.

Before you begin

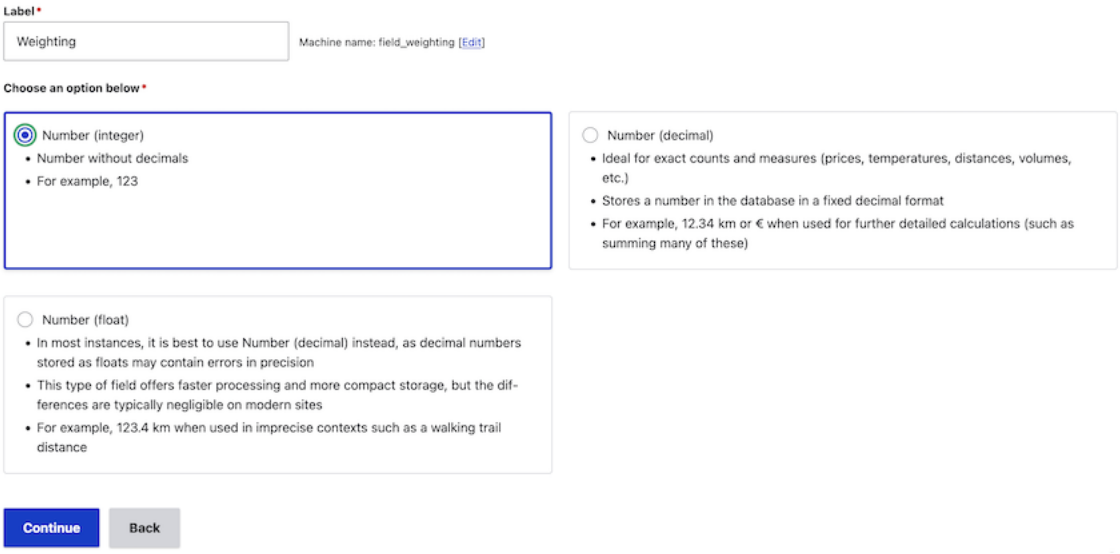
You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.



About this tutorial

In this task, you set up a weighting sort criteria and use it to list your products, on the API Products page, in a particular order. You set up the weightings so the order reads, Product3, Product1, and Product2.

This tutorial takes you through the following steps:

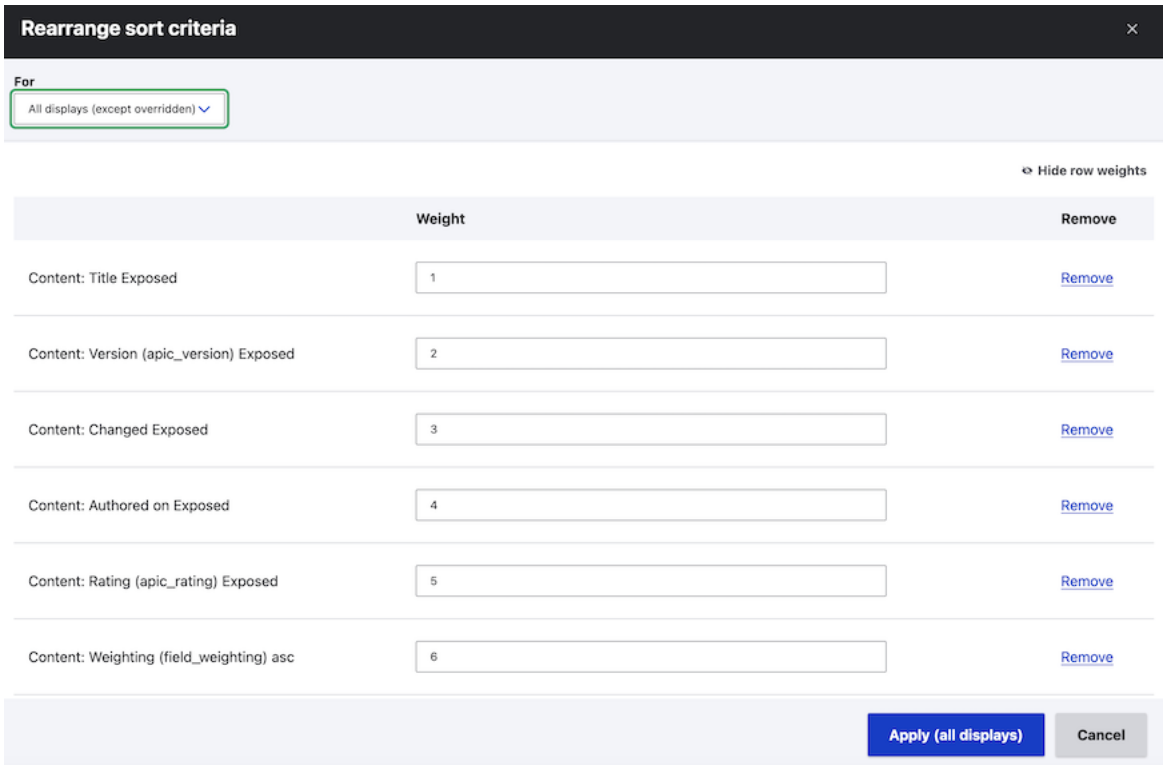


1. Add a custom integer field to the API content type
2. Modify the Products view to change the sort order
3. Add a weighting to each Product

Note: To complete this tutorial, you need to have API products.
For example, the following API Products page displays Product1, Product2, and Product3 in this order before the weightings are added.

Add a custom integer field to the API content type

1. Log in to your Developer Portal as an administrator.
2. Navigate to Structure > Content types.
3. Find **`Product`** and click Manage fields.
4. On the Manage fields page, click + Create a new field.
5. From the Choose a type of field list, select Number, and click Continue.
6. In the **`Label`** field, enter `Weighting` and select Number (integer).



7. Click Continue.
8. Leave the **`Allowed number of values`** as 1.
9. Select the Set default value checkbox and enter `0` as the default value.
10. Click Save settings.

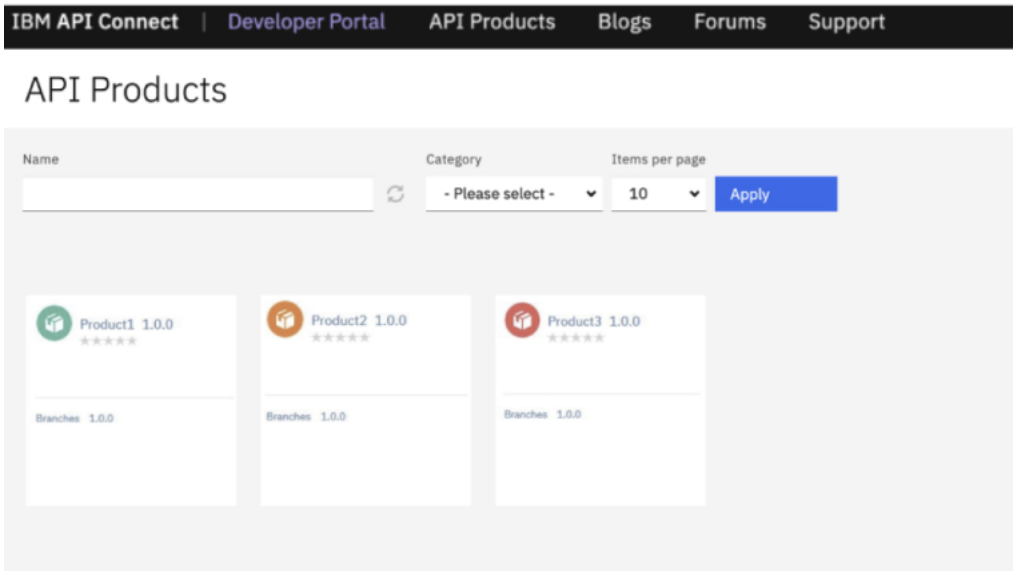
The **`Weighting`** field now shows in the **`Manage fields`** list.

Modify the Products view to change the sort order

1. Navigate to Structure > Views.
2. Find **`Products`** view and click Edit.
3. In the **`Sort criteria`** section, click Add.
4. In the Search field, enter `Weight`. Then, select **`Weighting (field_weighting)`**, and click Apply (all displays).
5. Leave the **`Order`** as **`Sort ascending`**, click Apply (all displays).
6. In the **`Sort Criteria`** section, click the arrow icon next to Add and click Rearrange.

7. For all rows except **`Weighting (field_weighting) asc`**, click Remove.
8. Click Apply (all displays).

You modified the **`Products`** view to sort based on **`Weighting (field_weighting)`**.



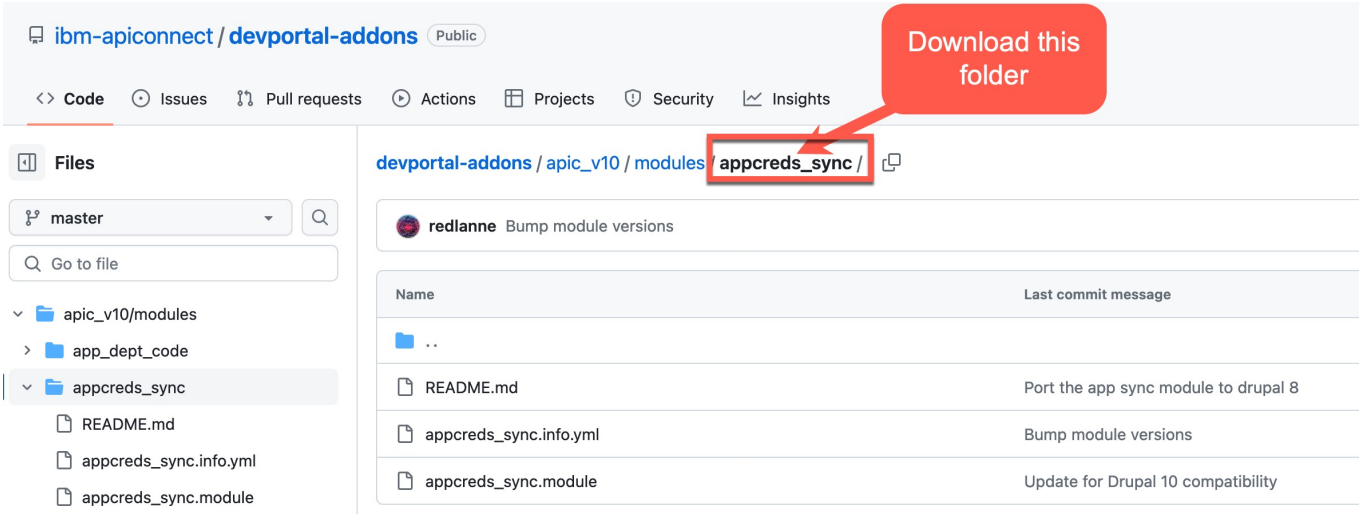
Add a weighting to each Product

1. Click Content, and from the **`Content type`** list, select **`Product`**.
2. Click Filter. A list of available Products on your site is displayed.
3. For Product1, click Edit, in the **`Weighting field`**, select `2` as the value, and click Save.
4. For Product2 click Edit, in the **`Weighting field`**, select `3` as the value, and click Save.
5. For Product3 click Edit, in the **`Weighting field`**, select `1` as the value, and click Save.

The API Products page displays Product3, Product1, and Product2 in this order after the weightings are added.

What you did in this tutorial

You changed the order that the API Products appear on the products page.



Tutorial: Synchronizing application credentials from the Developer Portal with an external server

You can synchronize application credentials from the Developer Portal with an external server.

Before you begin

You must have administrator access to the Developer Portal to complete this task.
Note: This module synchronizes the credentials of applications that are created by consumers in the Developer Portal site UI. It cannot synchronize the credentials for applications that are created by the provider in the API Manager UI.
Download the Application credential synchronization folder.

Perform the following steps:

1. Clone the custom module. Here is an example if you are using Mac or Linux:

   ```
   git clone https://github.com/ibm-apiconnect/devportal-addons
   ```

2. Navigate to the `appcreds_sync` folder:

   ```
   cd devportal-addons/apic_v10/modules/appcreds_sync
   ```

About this task

In this tutorial, you configure a custom module and install it in the Developer Portal to synchronize application credentials between the Developer Portal and an external credentials server.

The `appcreds_sync` folder that you downloaded is a custom module that contains multiple methods that can be configured with your REST endpoints, and any further specifications that you want to define, to synchronize your Developer Portal application credentials with an external credential server.

For more information, see Custom module development: background and prerequisites.

Procedure

To configure the custom module to synchronize application credentials:

1. In the appcreds_sync.module file, replace `example.com` with your REST endpoint for the following method types:
   - `http://example.com/app/create`
   - `http://example.com/app/delete`
   - `http://example.com/app/creds/create`
   - `http://example.com/app/creds/update`
   - `http://example.com/app/creds/delete`
   - `http://example.com/app/clientid/reset`
   - `http://example.com/app/clientsecret/reset`
2. Optional: Replace `username` and `password` with your username and password in the `_appcreds_sync_json_http_request` function:

   ```
   ('username' . ':' . 'password')
   ```

   Note: You can also configure the SSL settings if you need to.
3. Save the file, and package up the custom module:

   ```
   cd..
   tar -czf appcreds_sync.tar.gz appcreds_sync/
   ```

To install the configured custom module in the Developer Portal:

4. Log in to your Developer Portal as an administrator.

5. Click Extend > + Add new module.
6. In the Add from a URL field, enter a path to the module.
   Alternatively, upload the module in the Upload a module or theme archive section.
7. Click Continue.

:

8. To enable the module, complete the following steps.
   a. Click Extend and search for the custom module that is installed.
      For example, Synchronise Application Credentials.
   b. Select the checkbox next to the module name and click Enable.

Results

You have configured a custom module that synchronizes application credentials from the Developer Portal, installed that module in the Developer Portal, and enabled it. No further action or configuration is required.

Using the API Connect Backstage plug-in

The API Connect plug-in consolidates all your API Connect instances into a single location. By using the provider API, the plug-in groups data from each instance and displays it in a centralized dashboard. This grouping of data provides a clear overview of data distribution between different API Connect instances. The plug-in is valid for IBM® API Connect version 10.0.8.0 and later.

Key features

The following main features are available in the API Connect Backstage plug-in:

- The single page view of all APIs in an enterprise estate for quick discovery and easy navigation of API assets within Backstage. This feature minimizes the chance of functionality duplication.
- A simpler and quicker way to build software components in a standardized way and provide a central place to manage all projects and documentation.
- Faster adoption of APIs.
- Internal consumption without moving between different places.

- **Enabling the API Connect plug-in on Backstage**
  Install and configure the API Connect plug-in on Backstage.
- **Enabling the API Connect plug-in on Red Hat Developer Hub**
  Install and configure the API Connect plug-in on Red Hat Developer Hub.

Enabling the API Connect plug-in on Backstage

Install and configure the API Connect plug-in on Backstage.

The API Connect plug-in on Backstage provides a centralized view of all your APIs and products across multiple API Connect clouds, provider organizations, and catalogs. This tool is designed to give API teams a comprehensive overview of their API assets, which provides easier management and monitoring. It serves as a platform for teams to keep track of their infrastructure and microservices. For more information about Backstage, see Official Backstage documentation.

Prerequisites

To configure the API Connect plug-in successfully on Backstage, the following requirements must be met:

- A working Backstage application must be installed and configured.
  Note: Backstage is an external service and needs to be installed on a separate server that is external to API Connect. You do not need to make any changes to the API Connect deployment to set up the Backstage plug-in.
- The API Connect support agreement covers only the API Connect plug-in. The customer is responsible for the deployment and installation of the Backstage server.

Installing the API Connect plug-in for Backstage

1. Open https://github.com/ibm-apiconnect/backstage.
2. Clone the repository or download it as a zip file to get the install files.
3. Unpack the `ibm-apic-backstage-plugin.tar.gz` zip archive into the plugins directory.

   ```
   tar -xvf ibm-apic-backstage-plugin.tar.gz -C <backstage_app_base_path>/plugins
   ```

4. From the Backstage app base path, run the following command:

   ```
   yarn --cwd packages/backend add apic-backstage@^1.0.0
   ```

Configuring Backstage to use the API Connect plug-in

1. For the API Connect instance you want to configure, add the following details for a provider organization at the end of `app-config.yaml` file:
   - Name
   - URL
   - ClientID

- ClientSecret
- Username
- Password
- identityProvider
- apiKey

For example,

```
ibm:
 schedule: '*/10 * * * *'
 apic:
    - name: apic-instance-1
      url: https://api.<instance1>.com/api
      clientId: '<instance1-clientID>'
      clientSecret: '<instance1-clientSecret>'
      username: '<instance1-porg-user>'
      password: '<instance1-porg-pwd>'
      identityProvider: 'default-idp-2' # Default Local User Registry
    - name: apic-instance-2
      url: https://api.<instance2>.com/api
      clientId: '<instance2-clientID>'
      clientSecret: '<instance2-clientSecret>'
      apiKey: my-api-key  # OIDC registry
```

Here,

URL
: The value that corresponds to the `endpoint`.

client_id
: The value that corresponds to the `cliendId`.

client_secret
: The value that corresponds to the `clientSecret`.

identityProvider
: This value can be obtained by running the following API Connect CLI command:

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
```

apikey
: The value that corresponds to the generated `apiKey`.

The `credentials.json` for `apic-instance-1` in this code is:

```
{
  "cloud_id": "<instance1-cloudID>",
  "toolkit": {
    "endpoint": "https://api.<instance1>com/api",
    "client_id": "<instance1-clientID>",
    "client_secret": "<instance1-clientSecret>"
  },
  "consumer_toolkit": {
    ...
  },
  ...
}
```

Note: Download the toolkit credentials to find the values of the **URL**, **ClientId**, and **ClientSecret**. For more information, see https://www.ibm.com/docs/en/api-connect/10.0.x?topic=configuration-installing-toolkit#task_qsv_cgq_nt__download_creds.
You can configure API Connect by using the local user registry or the OIDC user registry.

- **Using a local user registry**
  If the user details are in a local user registry, you must provide the **identityProvider** details, **username**, and **password** as shown in the example for **apic-instance-1**.

- **Using an OIDC registry**
  If the user details are located in an OIDC registry, you must provide the **apiKey** details. Use the following instructions to add the API key:

  - Edit the time period for when the API key expires, and authorize it to be used multiple times. For more information, see Configuring API key settings.
  - Create an API key. For more information, see Managing platform REST API keys.
  - Add the generated API key to the configuration which is shown in the example for **apic-instance-2**.

Note: The **username**, **password**, or the **apiKey** are for a provider organization member. In this example, it is assumed that there is only a single user who is a member of each provider organization. To add the user to the Backstage instance, the user must at least have the Viewer role for each provider organization. The user can also be a member of more than one provider organization.

2. For the Backstage application, edit **packages/backend/src/index.ts** and add the following code at the end of the file:

```
backend.add(import('@internal/apic-backstage'));
```

Enabling the API Connect plug-in on Red Hat Developer Hub

Install and configure the API Connect plug-in on Red Hat Developer Hub.

Red Hat Developer Hub is a developer platform for building Developer Portals and has developed several plug-ins for Backstage to further enhance its capabilities within the Developer Portal. The dynamic plug-in support is based on the backend plug-in manager package, which is a service that scans a designated root directory, **dynamicPlugins.rootDirectory**, for dynamic plug-in packages and loads them as needed. You can use the dynamic plug-ins that are preinstalled with Red Hat Developer Hub or install additional dynamic plug-ins from a public NPM registry.

Prerequisites

To configure the plug-in successfully on Red Hat Developer Hub, the following requirements must be met:

- A working Red Hat application must be installed and configured.
  Note: Red Hat Developer Hub is an external service and needs to be installed on a separate server that is external to API Connect. You do not need to make any changes to the API Connect deployment to set up the plug-in.
- The API Connect support agreement covers only the API Connect plug-in. The customer is responsible for the deployment and installation of the Backstage server.
  Note: If you encounter any issues with Red Hat Developer Hub, contact Red Hat by raising a Red Hat support case to address the issue.

Installing API Connect Backstage Plugin from Redhat Developer Hub marketplace

Note:
Starting with Red Hat Developer Hub version 1.7, you can install the API Connect Backstage plug-in directly from the Red Hat Developer Hub Marketplace.

Before installation, ensure that installing plugins from the Marketplace is enabled in your environment. To find the plug-in, search API Connect Backstage Plugin in the Marketplace.

To complete the setup, provide the plug-in configuration as specified in the plug-in catalog information.

For example,

```
plugins:
   - package: oci://ghcr.io/redhat-developer/rhdh-plugin-export-overlays/apic-backstage:bs_1.39.1__1.0.0!apic-backstage
     disabled: false
     pluginConfig:
      ibm:
        schedule: '* * * * *'
        apic:
          - name: apic-instance-1
            url: APIC_API_URL
            clientId: 'APIC_CLIENT_ID'
            clientSecret: 'APIC_SECRET'
            username: 'PORG_USERNAME'
            password: 'PORG_PASSWORD'
            identityProvider: 'default-idp-2' # Default Local User Registry
          - name: apic-instance-2
            url: APIC_API_URL
            clientId: 'APIC_CLIENT_ID'
            clientSecret: 'APIC_SECRET'
            apiKey: my-api-key # OIDC Registry
```

Here,

URL
: The value that corresponds to the `endpoint`.

client_id
: The value that corresponds to the `cliendId`.

client_secret
: The value that corresponds to the `clientSecret`.

identityProvider
: This value can be obtained by running the following API Connect CLI command:

  ```
  apic identity-providers:list --scope provider --server myserver.com --fields title,realm
  ```

apikey
: The value that corresponds to the generated `apiKey`.

Installing and configuring the API Connect plug-in on Red Hat Developer Hub

To install the plug-in on Red Hat Developer Hub, see Installing dynamic plug-ins.

The following package details are used to configure the plug-in on Red Hat Developer Hub:

```
 - package: 'apic-backstage'
        integrity: 'REPLACE_INTEGRITY'
        disabled: false
        pluginConfig:
          ibm:
            schedule: '* * * * *'
            apic:
              - name: apic-instance-1
                url: APIC_API_URL
                clientId: 'APIC_CLIENT_ID'
                clientSecret: 'APIC_SECRET'
                username: 'PORG_USERNAME'
                password: 'PORG_PASSWORD'
                identityProvider: 'default-idp-2' # Default Local User Registry
              - name: apic-instance-2
                url: APIC_API_URL
                clientId: 'APIC_CLIENT_ID'
                clientSecret: 'APIC_SECRET'
                apiKey: my-api-key # OIDC Registry
```

Here,

URL

The value that corresponds to the **endpoint**.

client_id
: The value that corresponds to the **cliendId**.

client_secret
: The value that corresponds to the **clientSecret**.

identityProvider
: This value can be obtained by running the following API Connect CLI command:

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
```

apikey
: The value that corresponds to the generated **apiKey**.

The **credentials.json** for **apic-instance-1** in this code is:

```
{
  "cloud_id": "<instance1-cloudID>",
  "toolkit": {
    "endpoint": "https://api.<instance1>com/api",
    "client_id": "<instance1-clientID>",
    "client_secret": "<instance1-clientSecret>"
  },
  "consumer_toolkit": {
    ...
  },
  ...
}
```

Note: Download the toolkit credentials to find the values of the **URL**, **ClientId**, and **ClientSecret**. For more information, see https://www.ibm.com/docs/en/api-connect/10.0.x?topic=configuration-installing-toolkit#task_qsv_cgq_nt__download_creds.
You can configure API Connect using the local user registry or the OIDC user registry.

- **Using a local user registry**
  If the user details are located in a local user registry, you must provide the **identityProvider** details, **username**, and **password** as shown in the example for **apic-instance-1**.
- **Using an OIDC registry**
  If the user details are located in an OIDC registry, you must provide the **apiKey** details. Follow the instructions below to add the API key:

  1. Edit the time period for when the API key expires, and authorize it to be used multiple times. For more information, see Configuring API key settings.
  2. Create an API key. For more information, see Managing platform REST API keys.
  3. Add the generated API key to the configuration as shown in the example for **apic-instance-2**.

Monitoring your API usage by using Analytics

Monitor your API usage with API Connect analytics.

API Connect provides the capability to filter, sort, and aggregate your API event data. This data is then presented within correlated charts, tables, and maps, to help you manage service levels, set rate limits, establish controls, set up security policies, manage communities, and analyze trends. API analytics is built on the OpenSearch open source real-time distributed search and analytics engine.

- **Key concepts of API Connect analytics**
  An overview of how API Connect analytics works.
- **Preinstallation planning**
  Review the analytics subsystem requirements and decide how you want to configure analytics for your environment.
- **Managing your analytics subsystem**
  Understand the architecture of the analytics subsystem and how to configure it.
- **Installing the analytics subsystem**

- **Troubleshooting analytics**
  How to diagnose and resolve common issues with the analytics subsystem.

Key concepts of API Connect analytics

An overview of how API Connect analytics works.

How the gateway and analytics services work together

When a user calls one of your published APIs, the gateway that processes the API call creates an API event record that contains details of the API call such as the application ID, current time, result code, etc. For a full list of all the data stored in an API event record, see API event record field reference. The gateway buffers API event records for each API call until a threshold of either number of events, or elapsed time is reached. When this threshold is reached, the API events are sent in bulk to the analytics subsystem. API events are sent by the gateway to the management subsystem with TCP, and if a network failure occurs the gateway does retry. However, the gateway does not retain unsent API event records and retry indefinitely, and so delivery of every API event record is not guaranteed.
Tip: If the analytics dashboards in your UIs are not showing the API events that you expect, the most common cause is a communication failure between your gateway and analytics subsystems. Check both the gateway and analytics subsystem logs.

You can deploy multiple gateway and analytics services in all API Connect deployment types except for OpenShift® top-level CR. After you register a gateway service in the Cloud Manager UI, you associate an analytics service with that gateway service. All API event data that the gateway generates is sent to its associated analytics service. Multiple gateways can be associated with the same analytics service. You cannot associate multiple analytics services with the same gateway.

Each analytics service in your API Connect deployment stores API event data only from the gateways it is associated with. When you view analytics data, you must select which analytics service you want to view the data from. API Connect provides no aggregated view of all analytics data from all analytics services. If you have multiple analytics services and want to combine the data from all of them, you can export or offload the data and manually create your own reports.

If you use the top-level CR on OpenShift or Cloud Pak for Integration, then your API Connect deployment consists of one gateway service and one analytics service. All API calls in your API Connect deployment are handled by the one gateway service, and all API event records that are generated, are stored by the one analytics service.

Customizing the analytics data that is stored for your APIs

Note: What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings. For more information, see Configuring analytics in the developer portal.
When you configure an API in the API Manager UI, you choose what data is stored in the API event records for calls to that API with the **`activity log`** property. The **`activity log`** property has separate settings for successful API calls, and for failed API calls. The activity log options are:

- none - API events are not logged.
- activity - Logs the API resource URI. **`activity`** is the default log setting for successful API calls.
- header - Logs the API resource URI and HTTP headers.
- payload - Logs API resource URI, HTTP headers, and request and response payloads. **`payload`** is the default log setting for failed API calls, since the response payload might have useful information on the cause of the failure.

The more detailed the **`activity log`** setting, the larger the API event records, and the greater the persistent storage requirements for the analytics subsystem. For more information about configuring activity logging, see Activity log policy.

If you want to make specific customizations to your API event data, two methods are available:

- Customize API event records as they arrive from the gateway, by using ingestion filters. Ingestion filters can be applied conditionally based on the data in the API event.
- Customize API event records as they are created on the gateway. Use a gateway script or the **`set-variable`** operation in the definitions of each API that you want to customize. See Customizing data with a gateway script or set-variable operation.

Retention and rollover of analytics data

API event data takes up persistent storage space on your analytics subsystem. To ensure that you do not run out of persistent storage space, API event data is summarized, and the oldest API event records are deleted. Analytics API event records are retained for a maximum number of days, which is defined by your deployment profile. Summary analytics data that is created from the API event records is retained for 1 year. You can change how long the analytics data is stored with the Retention and rollover settings.

Accessing your analytics data

You can view your analytics data in the Cloud Manager, API Manager, and Developer Portal UIs.

- The cloud admin user can see total API call volumes and call volumes per gateway in the Cloud Manager UI. Provider organization owners can enable the cloud admin user to also see analytics data and individual API event data for their provider organization.
- In the API Manager UI, the provider organization owner can see analytics data for APIs that are published in their catalogs.
- In the Developer Portal UI, the API consumer can see analytics data for APIs published in their consumer organization.
  Note: If two gateway services are configured for a catalog that has a portal site, those two gateway services must be associated with the same analytics service. If they are associated with different analytics services, then no analytics data is displayed in the portal UI.
  This limitation means that analytics data is not available in the developer portal sites of a two data center disaster recovery deployment, where two analytics subsystems are deployed.

The maximum number of API events that can be accessed from the UIs is 10,000. The maximum number of event records that can be displayed per page in the UIs is 200.

Your analytics data can also be accessed by using the toolkit CLI or REST API.

You can manage user access to analytics data with User roles and permissions. For more information about user-based analytics data visibility, see Catalogs, spaces, and analytics

You can export analytics data from your UIs, however, UI export is not a practical method if you want to export more than 200 API event records. Use the toolkit CLI or REST API to export more than 200 API event records at a time. If you think that you might want to regularly export all your analytics data, then consider Offloading your analytics data to a third-party system.

Offloading your analytics data to a third-party system

The API event data that is received from your gateways can be directed to a third-party system, instead of or in addition to being stored by the analytics subsystem.

For more information about offloading, see Offload to third-party systems.

Preinstallation planning

Review the analytics subsystem requirements and decide how you want to configure analytics for your environment.

- **Estimating storage requirements**
  Estimate the persistent storage requirements for your analytics subsystem.
- **Kubernetes and Red Hat OpenShift preinstallation planning**
  Review deployment profiles, storage, and analytics settings that must be decided before installation.

Estimating storage requirements

Estimate the persistent storage requirements for your analytics subsystem.

This information applies only to data that is stored in your API Connect analytics subsystem, and not to data that is offloaded to a third-party system. If you plan to disable local storage, you can skip this topic. The formula and guidelines are based on how the API Connect analytics subsystem stores data, and cannot be directly applied to any other storage system.

Warning: Increasing the analytics storage space after installation is not a simple operation, and it can require reinstallation of the analytics subsystem. Decreasing storage space always requires reinstallation. If you do not have the information that is needed to make an estimate, then set your storage to at least 500Gi and monitor your usage closely. For an installation where you expect to store little or no analytics data, you can set the storage to 50Gi.
After installation, if you find you do not have enough space, then reduce the data retention period to keep less analytics data and stay within your persistent storage limit. See Running out of storage space for other steps that you can take if you run out of space.

To understand the concepts that are required for estimating your storage requirements, first review the following pages:

- OpenSearch nodes, indices, shards, and replicas.
- Activity log policy.
- Retention and rollover.

Use the following guidelines to provide an estimate of the amount of persistent storage you need for your API Connect analytics subsystem.

Factors that determine persistent storage requirement

Number of copies of the analytics data
: The number of copies of the analytics data you store depends on your deployment profile:

  - Three replica profiles store 3 copies of your analytics data (one OpenSearch shard replica per analytics replica).
  - One replica profiles store 1 copy of your analytics data.

Number of days that API data is retained
: The default number of days your API event data is retained depends on your deployment profile. For example, the **`n1xc4.m32`** profile retains data for 30 days. To see the retention period for each analytics deployment profile, see retention and rollover.

  API summary data is retained for 366 days by default on all deployment profiles.

  If you customized your retention and rollover settings, then use the updated retention periods in your calculations.

API event logging policy and customization
: The logging policy that you set for each API determines the size of the event records for that API. Typical sizes of API event records for each activity log policy are:

  - Activity logging: 1.5 Kb. This is the default log policy for successful API calls.
  - Header logging: 4 Kb.
  - Payload logging: 4 Kb plus size of expected request and response payloads. This is the default log policy for failed API calls.

  You can also Customize your analytics data to add, redact, or remove fields. If you add fields to your API events, calculate the average size of the new fields and add that number to your event size. If you remove fields, subtract this size only if you are also removing headers or payloads.

Percentage of each type of data
: Estimate the percentage of each type of log policy (activity, header, payload) for your published APIs. Use these percentages and your estimates of API event size to calculate you average API event size.
  Remember: API logging policy can be set differently for success and failure responses of the same API. The default is activity logging for successful API calls, and payload logging for failed calls. Consider the percentages of successful and failed calls that you expect in your calculations.

API calls per day
: Estimate the total number of API calls that you expect per day.

Backup configuration
: If you enable backups and configure **`type=all`**, then double your calculated storage requirement.

  If you enable backups and configure **`type=default`** (which only backs up summary data and shared queries), then increase your calculated storage requirement by 25%.

  For more information about analytics backups, see Backup, restore, and disaster recovery.

Calculating your persistent storage requirements

Calculate the expected size of your API event data with the following formula:

```
Storage required for API events = (average bytes per API event) * (API events per day) * (API event retention period) * (copies of data)
```

Calculate the expected size of your API summary data with the following formula:

```
Storage required for API summary data = (expected size of all API events with header logging) * (API events per day) * (summary data retention period) * (copies of data) * 0.1
```

Note: Ignore the percentages of different logging types you calculated for your APIs and assume that all your APIs are set to header logging. API summary data uses approximately 10% of the space of header-logged API event data per day. Remember that header logging includes everything that is logged by activity logging plus the API call headers.
Your analytics data must not use more than 70% of your persistent storage space. Add some buffer space in case your analytics data is larger than you expect. It is recommended that the persistent storage space you provide for your analytics subsystem is double the space that you calculated your data requires.

Example calculation, based on the following information:

```
Copies of data = 3
API event data retention = 45 days
API summary data retention = 366 days
Activity log bytes per call = 1500 bytes
Header log bytes per call = 15000 bytes
Payload log bytes per call = 30500 bytes
% of Activity log = 70%
% of Header log = 20%
% of Payload log = 10%
Calls per day = 100000
```

1. Calculate the average API event size:

   ```
   ( (70*1500) + (20*15000) + (10*30500) ) / 100 = 7100 bytes
   ```

2. Calculate the space needed for your API event data:

   ```
   7100 * 100000 * 45 * 3 = 89.3 Gi (95.6 Gb)
   ```

3. Calculate the space needed for your summary data:

   ```
   15000 * 100000 * 366 * 3 * 0.1 = 153 Gi (165 Gb)
   ```

4. Add API event data and summary data totals:

   ```
   153 Gi + 89.3 Gi = 242.3 Gi
   ```

5. Double the storage calculated in step 4 to get the storage size to allocate to your analytics subsystem:

   ```
   242.3 Gi * 2 = 484.6 Gi
   ```

6. If you plan to enable backups, then add extra space as follows:
   - If you plan to set backups `type=all`, then add the total that you calculated in step 4.

     ```
     242.3 Gi + 484.6 Gi = 726.9 Gi
     ```

   - If you plan to set backups `type=default`, then multiply the total that you calculated in step 4 by 0.25 and add this to your total storage requirement:

     ```
     484.6 Gi + (242.3 Gi * 0.25) = 545.2 Gi
     ```

Kubernetes and Red Hat OpenShift preinstallation planning

Review deployment profiles, storage, and analytics settings that must be decided before installation.

Deployment profile

Decide which deployment `profile` you want to use, the available profiles are:

- For Kubernetes and OpenShift® (individual subsystem) installations: Analytics deployment profiles.
- For Cloud Pak for Integration and Red Hat OpenShift top-level CR installations: API Connect deployment profiles.

For a scalable analytics deployment, choose a three replica profile. If you do not expect a high API transaction rate and plan to keep a limited amount of analytics data, then a one replica profile is sufficient.

Storage class

Before you install analytics, you must choose a storage class. `Ceph`, `Block`, and `Local Volume` are all supported; however, `Local Volume` is the most suitable for analytics. The analytics subsystem provides internal data replication and HA support, so the additional HA capabilities that `Ceph` or `Block` storage might give you are not needed. In addition, analytics require a high throughput of disk I/O operations to successfully handle the analytics data load from the gateway. `Local Volume` is the best-performing storage class for disk I/O.

Note: GlusterFS, NFS, Rook-CephFS, or any shared file system storage class is not supported for analytics. If you use these storage classes, you might encounter severe performance degradation, pod crashloops, and possibly loss of data.

Storage type

Note: Storage type selection is available on three replica deployments only.
To make an informed choice on which storage type is best for you, first read and understand the OpenSearch concepts that are described in OpenSearch nodes, indices, shards, and replicas.
API Connect provides two OpenSearch storage types:

- **Shared storage**
  A single pod provides data storage and OpenSearch cluster management. Shared storage is the only option on a one replica deployment.
- **Dedicated storage**
  OpenSearch data storage and cluster management functions are split, and run in separate pods on each worker node:
  - The `storage-os-master` pod runs an OpenSearch "manager eligible" node that manages the OpenSearch cluster, but does not store any API event data.
  - The `storage` pod runs an OpenSearch "data" node that stores API event data.

  Dedicated storage is the default storage type for three replica deployments.

Dedicated storage facilitates horizontal scaling to support greater analytics data storage and throughput. Add worker nodes and increase the number of `storage` pod replicas to scale horizontally (you do not need to increase the number of `storage-os-master` replicas). Dedicated storage also provides greater stability and allows some OpenSearch configuration changes to be made without downtime.
You can change storage type after installation, see Dedicated storage and scaling up.

Disabling internal storage

The analytics subsystem provides a complete solution for routing, storing, and viewing the analytics data. However, you might not need the internal storage and viewing solution if you are using a third-party system for data offloading. In this scenario, you can greatly reduce your CPU and memory costs by disabling the internal storage and viewing components.

When you disable internal storage for analytics data, the following microservices are disabled:

- `osinit`
- `storage`

Important:
If you disable local storage, the analytics views in your API Connect UIs remain accessible, but are empty.

Configure local storage disablement before installation. It is not possible to disable or re-enable internal storage after installation.

You can enable offload of analytics data to third-party systems after installation.

For the steps to disable internal storage, see Disable local storage.

Persistent storage space

Based on your expected API transaction rate, you can estimate how much storage space your analytics subsystem requires. See Estimating storage requirements.

Inter-subsystem communication security

By default the network communication from the management and gateway subsystems, to the analytics subsystem uses Kubernetes ingresses or Red Hat OpenShift routes, and is secured with mTLS. You can configure alternative network communication options if your environment requires. For more information, see Network requirements for inter-subsystem communication.

Kubernetes operating map counts

When the analytics service is configured to store data, it uses OpenSearch, which requires map counts higher than the operating system defaults. The minimum recommended value is `262144`. Unless you plan to disable local storage, increase the default map count on every Kubernetes worker node:

1. To change the map counts on the live system, run the following command on every Kubernetes node:

   ```
   sudo sysctl -w vm.max_map_count=262144
   ```

2. To persist this change when node restarts occur, add the following setting to the /etc/sysctl.conf file:

   ```
   vm.max_map_count = 262144
   ```

For more information, see Important settings in the OpenSearch documentation.

PV requirements

The number of PVs needed depends on if you disable local storage, and if you have backups that are configured .

Table 1. Analytics PV requirements

Deployment profile	Local storage disabled (ingestion only)	Local storage enabled	Local storage and backups enabled
Single node (n1)	1	2	3
Three node (n3)	3	6	9

To understand how much storage capacity your analytics subsystem needs, see Estimating storage requirements.

Firewall requirements

The analytics firewall requirements are documented here: Firewall requirements

Managing your analytics subsystem

Understand the architecture of the analytics subsystem and how to configure it.

- **API Connect on Kubernetes, Red Hat OpenShift, and Cloud Pak for Integration**
  Understand the Kubernetes artifacts that make up the analytics subsystem, and how to configure your AnalyticsCluster CR.
- **OpenSearch nodes, indices, shards, and replicas**
  Understand the main concepts of the OpenSearch database: nodes, indices, shards, and replicas.

API Connect on Kubernetes, Red Hat OpenShift, and Cloud Pak for Integration

Understand the Kubernetes artifacts that make up the analytics subsystem, and how to configure your AnalyticsCluster CR.

The AnalyticsCluster Custom Resource (CR)

Your analytics subsystem is defined by a Custom Resource (CR) called `AnalyticsCluster`. Throughout this documentation, the `AnalyticsCluster` CR is also referred to as the "analytics CR".

Certain analytics features are configured in the `AnalyticsCluster` CR. How you edit the CR depends on your platform:

- **Kubernetes and OpenShift® individual subsystem CRs:** Edit the `AnalyticsCluster` directly.
- **Cloud Pak for Integration and Red Hat OpenShift top-level CR:** Edit the analytics section of the top-level CR. When saved, the changes to the top-level CR are applied to `AnalyticsCluster` CR. If you change the `AnalyticsCluster` CR directly, changes can be overwritten by the top-level CR.

Note: For convenience, the alias `a7s` can be used instead of `AnalyticsCluster` when you edit the CR. For example:

```
kubectl edit a7s
```

instead of:

```
kubectl edit AnalyticsCluster
```

The properties that you can configure in the `AnalyticsCluster` CR are listed in Analytics CR properties reference.

Ingresses

The analytics subsystem has one ingress, called the "ingestion endpoint". The ingestion endpoint serves requests coming from both the management subsystem and the gateway. The management subsystem communicates with the ingestion endpoint to query API event data stored by the analytics subsystem, and also to manage the analytics subsystem. The gateway sends API event data to the ingestion endpoint.

The ingestion endpoint is listed as `ai-endpoint` or `<instance name>-ai-endpoint` in the output of `kubectl get ingress`.

Note: In Red Hat OpenShift, "routes" are used instead of ingresses. The functions of the ingestion endpoint are the same for both the Kubernetes `ai-endpoint` ingress and the Red Hat OpenShift `ai-endpoint` route.

Pods

The following table shows the Kubernetes pods that make up an analytics subsystem:

Table 1. Analytics pods

Name	Description
`osinit`	OpenSearch initialization job. This pod is in `completed` state after installation.
`oscron`	Manages the jobs that transform API event data into summary data. Runs every 15 minutes.
`director`	Manages the analytics subsystem. The director pod serves all requests that come from the management subsystem, such as: initial subsystem registration, queries for analytics data, management of saved queries, and changes to retention settings.
`ingestion`	Logstash based data pipeline that receives the API event data from the gateway, applies any ingestion filters that the user configures, and forwards the events to the storage pods or to third-party offload targets.
`mtls-gw`	Secures all communication that arrives on the analytics ingestion endpoint, forwarding communication from the management subsystem to the `director` pod, and communication from the gateway to the `ingestion` pod.
`storage`	The `storage` pods contain the OpenSearch database that stores all the analytics data. By default the storage pods also run the OpenSearch cluster management tasks. If dedicated storage is enabled the OpenSearch cluster management tasks are done by the `storage-os-master` pods, and the `storage` pods contain just the analytics data.
`storage-os-master`	The `storage-os-master` pod exists only on deployments where dedicated storage is enabled. The `storage-os-master` pods manage the OpenSearch cluster, while the `storage` pods are dedicated to the storage of the analytics data.
`warehouse`	The `warehouse` pod stores your local backups and stages them for transmission to your remote SFTP server or object-store.

PersistentVolumeClaims (PVCs)

The following table describes the PVCs that are created for the analytics subsystem:

Table 2. Analytics PVCs

Name	Description

Name	Description
`data-analytics-storage-<integer>`	The PVC that stores your analytics data. A `data-analytics-storage-<integer>` PVC is created for each analytics `storage` pod. The `<integer>` is the replica number, starting from 0.
`data-analytics-storage-os-master-<integer>`	If dedicated storage is enabled, then the `storage-os-master` PVCs are created. Each `storage-os-master` PVC corresponds to a `storage-os-master` pod. The `<integer>` corresponds to the pod replica number, starting from 0. The PVC stores data that is related to the management of your OpenSearch cluster.
`data-analytics-ingestion-<integer>`	If the persistent queue feature is enabled, a `data-analytics-ingestion-<integer>` PVC is created for each `ingestion` pod. The `data-analytics-ingestion-<integer>` PVC stores API event data temporarily when the `ingestion` pod is unable to forward the data to the `storage` pods. The `<integer>` corresponds to the pod replica number, starting from 0.
`data-a7s-warehouse`	If backups are enabled, then local backups are stored on this PVC.

Certificates

The following table describes the certificates that are used by the analytics subsystem:

Table 3. Analytics certificates

Certificate name	Issuer	Description
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint in the `mtls-gw` pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the `analytics-ai-endpoint` certificate. If this certificate is updated, restart the `mtls-gw` pod for the update to take effect.
`analytics-ca or a7s-ca`	`selfsigning-issuer`	The issuer for the `analytics-client` and `analytics-server` certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If you update this certificate, you must then update the `analytics-client` and `analytics-server` server certificates, and then ensure that the following pods are restarted: • `storage`- Restarts automatically. • `warehouse`- Restarts automatically. • `ingestion`- Restarts automatically. • `director`- Restart manually.
`analytics-client or a7s-client`	`analytics-ca`	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, then the `storage`, `warehouse` and the `ingestion` pods restart automatically. You must manually restart the `director` pod.

`analytics-server or a7s-server`	`analytics-ca`	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`<instance name>-storage`
		`<instance name>-director`
		`<instance name>-ingestion`
		`<instance name>-mtls-gw`
		`<instance name>-storage-os-master`
		`<instance name>-warehouse`
		
		If this certificate is updated, then the `storage`, `warehouse` and `ingestion` pods restart automatically. Manually restart the `director` pod.

For more information about certificates in API Connect, see API Connect certificates.

Analytics CR properties reference

List of all the properties that can be configured in the analytics CR.

The following properties must be defined in your analytics CR:

- `ingestion.endpoint`
- `ingestion.clientSubjectDN`

All other properties are optional.
Note: If you are using Cloud Pak for Integration or the top-level CR on OpenShift®, then configure your analytics properties in the `analytics` section of the top-level CR. Do not edit the analytics CR directly. If the properties you want to set are missing from the top-level CR, then copy them from the analytics CR to the top-level CR.

Table 1. Analytics subsystem CR properties.

Property	Type	Default value	Description	Comments
`allowUpgrade`	Boolean	false	Legacy property for upgrade to v10.0 5 from previous releases.	The `allowUpgrade` property is not used in v10.0.6 and can be deleted from the analytics CR.
`databaseBackup:` `  host`	String		The URL to your S3 object store.	See Backup, restore, and disaster recovery.

Property	Type	Default value	Description	Comments
`databaseBackup: path`	String		The path to your S3 object store at the URL specified by `databaseBackup.host`.	See Backup, restore, and disaster recovery.
`databaseBackup: schedule`	String		Specifies the frequency of automatic backups. Use any valid `cron` string.	See Backup, restore, and disaster recovery.
`databaseBackup: enableCompression`	Boolean	`true`	Specifies whether to compress the backups.	See Backup, restore, and disaster recovery.
`databaseBackup: credentials`	String		The name of your S3 object store authentication secret.	See Backup, restore, and disaster recovery.
`databaseBackup: backupCerts`	String		The name of the secret that contains your S3 server certificate.	See Backup, restore, and disaster recovery.
`databaseBackup: chunkSize`	String	`1gb`	Specifies the size of large file chunks. The format is lowercase and no spaces, for example: `1gb`, `50mb`, `800kb`.	See Backup, restore, and disaster recovery.
`databaseBackup: enableServerSideEncryption`	Boolean	`true`	Specifies whether metadata files are stored in compressed format.	See Backup, restore, and disaster recovery.
`external: offload: filter`	String		Filter configuration for external offload.	See Offload to third-party systems.
`external: offload: enabled`	Boolean	`false`	Enables analytics offload feature.	See Offload to third-party systems.
`external: offload: output`	String		Output configuration for external offload.	See Offload to third-party systems.
`external: offload: passwordSecretName`	String		The name of the secret that has the password to access the certificate keystore.	See Offload to third-party systems.
`external: offload: secretName`	String		The name of the secret that contains the certificate that is used for connecting to the offload target.	See Offload to third-party systems.
`ingestion: endpoint`	Object		FQDN and TLS Secrets for client endpoint.	The external endpoint of the analytics subsystem. Both the gateway and management subsystems use the ingestion endpoint to communicate with your analytics subsystem. The gateway sends API event data to the ingestion endpoint.
`ingestion: clientSubjectDN`	String		Subject DN (distinguished name) for authenticating with ingestion endpoint (RFC 2253).	
`ingestion: filter`	String		Filter to modify API event data before it is sent for local storage (not offloaded).	See Customizing data with ingestion filters.
`ingestion: geoIPEnabled`	Boolean	`true`	Include the `client_geoip` and `gateway_geoip` fields in your API event records.	Applies to both locally stored and offloaded data.
`ingestion: queue`	Object		Persistent queue settings.	See Logstash persistent queue.
`ingestion: queue: type`	String		Persistent queue settings. Default is `persisted`.	Set to `memory` if you want to disable the persistent queue. See Logstash persistent queue.
`ingestion: queue: volumeClaimTemplate: volumeSize`	String		Storage size for your persistent queue. Default is 50Gi.	Do not change this value. See Logstash persistent queue.
`ingestion: queue: volumeClaimTemplate: storageClassName`	String		Storage class name for your persistent storage.	See Logstash persistent queue.
`ingestion: pipelineWorkers`	4 <= integer <= 128	24	Number of pipeline workers.	See Performance tuning with ingestion pipeline properties.

Property	Type	Default value	Description	Comments
`ingestion: pipelineBatchSize`	10 <= integer <= 10000	250	Batch size of a pipeline worker.	See Performance tuning with ingestion pipeline properties.
`ingestion: pipelineBatchDelay`	10 <= integer <= 5000	50	Batch delay of a pipeline worker.	See Performance tuning with ingestion pipeline properties.
`ingestion: configReloadAutomatic`	Boolean	true	Whether to automatically reload the pipeline on configuration changes.	See Performance tuning with ingestion pipeline properties.
`ingestion: pipelineUnsafeShutdown`	Boolean	false	Whether to allow unsafe shutdown of the pipeline.	See Performance tuning with ingestion pipeline properties.
`longTermDataEnabled`	Boolean	true	Enables the collection of long-term summary data that is required for reports and leaderboards.	If you set `longTermDataEnabled` to false, no long-term summary data is generated, however the `oscron` job still runs. Long-term summary data is only generated when local storage is not disabled.
`standaloneCluster`	Boolean	false	Legacy property related to Zen endpoints.	The `standaloneCluster` property is not used in v10.0.6 and can be deleted from the analytics CR.
`storage: type`	String	`shared`	Type of storage deployment.	Shared or dedicated. See Storage type.
`storage: shared: volumeClaimTemplate: storageClassName`	String	cluster default	Storage class name.	Name of the storage class for your analytics data. See Storage class.
`storage: shared: volumeClaimTemplate: volumeSize`	String	`50Gi`	Volume size.	Size of the volume used for data storage. See Estimating storage requirements.

OpenSearch nodes, indices, shards, and replicas

Understand the main concepts of the OpenSearch database: nodes, indices, shards, and replicas.

OpenSearch do not use the term "database", but "search and analytics suite". For simplicity, in API Connect the terms "analytics database" or "OpenSearch database" are used instead of "search and analytics suite".

The term OpenSearch "cluster" is used when referring to the analytics subsystem of a multi-replica API Connect deployment.

Nodes

An OpenSearch cluster is made up of separate OpenSearch nodes. On Kubernetes, an analytics storage pod replica runs a single OpenSearch node.
You control the number of OpenSearch nodes that you have when you select your API Connect deployment profile: A one replica deployment has one OpenSearch node. A three replica deployment has three OpenSearch nodes.

If you installed a three replica deployment on Kubernetes or OpenShift®, you can enable the dedicated storage feature to increase your number of OpenSearch nodes above three.

Indices

Your analytics API event data is stored in OpenSearch indices. The creation and management of your analytics indices is time-based. By default, your OpenSearch database creates a new index each day to be used for storing the API events that arrive that day; so on the day of installation your analytics subsystem has 1 index for API event data, and after 10 days your subsystem has 10 API event data indices. The maximum number of days that API event data is stored depends on your deployment profile, see Retention and rollover.
API Connect also creates indices for shared queries and for API summary data. By default API summary indices are kept for 1 year.

You can configure the retention and rollover periods for API event and summary data to suit your requirements and available storage space.

Shards

To efficiently distribute the data in OpenSearch indices across a cluster, the indices are subdivided into what are called "shards", which can be stored in different nodes of the cluster.

Replicas

In a three node OpenSearch deployment, each shard (known as the "primary shard") has 2 replica shards that contain a copy of the data that is in the primary shard. OpenSearch stores the primary shard and each replica on different nodes to ensure that all data is available on all nodes, and to provide high-availability if one node fails.

A single node OpenSearch deployment has no replica shards, since no other nodes are available to store them.

Installing the analytics subsystem

Links to the installation steps for each platform.

For all features and settings that must be decided and configured before installation, see Preinstallation planning.

It is recommended configure your backup settings after installation. See backup and disaster recovery.

Follow the installation steps for your platform:

- Kubernetes
- OpenShift and Cloud Pak for Integration

Backup, restore, and disaster recovery

How to back up your analytics subsystem and restore after a disaster.

An analytics subsystem backup consists of:

Analytics infrastructure configuration backup
: Your infrastructure configuration backup contains information such as endpoints, offload configuration, remote backup site credentials.
The infrastructure configuration backup is also referred to as the "config backup".

  On Kubernetes and OpenShift®, the config backup consists of YAML file backups of your analytics CR and certificates.

  Your config backup is needed for disaster recovery, where you must redeploy your analytics subsystem.

Analytics database backup
: Your database backup contains all your analytics summary data and shared queries. If you have storage capacity, you can configure your analytics database backups to include all your API event data. When you enable database backups, local backups are created at 55 minutes past each hour. You can configure your database backups to be periodically copied to a remote SFTP server or S3 compatible object-store. The configuration of your database backups, such as object-store credentials, are defined in your analytics infrastructure configuration. Therefore, to restore an analytics database backup after a disaster, you must first restore your config backup.
Your analytics database backups are intended for use in two scenarios:

  - Disaster recovery: Your entire analytics subsystem fails. You redeploy the subsystem (use your config backup to ensure that the same config settings and certificates are defined) and then restore your most recent database backup.
  - Corrupted index recovery: One or more analytics indices are corrupted, so you restore just those indices from a backup that contains them.

  Analytics database backups are not intended for long-term storage of your analytics data. If you require long-term storage, use the offload or export features.

Review the backup, restore, and disaster recovery documentation for your platform:

- **Kubernetes, OpenShift, and Cloud Pak for Integration**
  How to configure analytics backups and recover from a disaster in Kubernetes, OpenShift, and Cloud Pak for Integration environments.

Kubernetes, OpenShift, and Cloud Pak for Integration

How to configure analytics backups and recover from a disaster in Kubernetes, OpenShift®, and Cloud Pak for Integration environments.

The analytics subsystem backup consists of:

- Analytics infrastructure configuration backup.
  - Backup of your analytics CR YAML file.
  - Backup of any custom certificates you configured. For example, the certificates that secure your communication with your remote object-store, and any certificates used for connecting to third-party systems for analytics offload.

  The infrastructure configuration backup is also referred to as the "config backup".

  If you have a disaster, your config backup is essential for restoring your analytics subsystem.

- Analytics database backup. Analytics database backups are stored locally on a dedicated PVC called **`data-a7s-warehouse`**, and can also be configured for periodic transfer to a remote STFP server or S3 compatible object-store (for example, IBM Cloud® Object Storage).
  Note: If you are using a self-managed S3 backup server, check that you have a DNS hostname entry and matching TLS certificate for your S3 backup endpoint.

Analytics subsystem backups are intended for restoration in the same environment where they were taken, or a different environment that has the same network configuration, endpoints, and deployment profile.

Taking an analytics infrastructure configuration backup

How to backup your analytics subsystem deployment configuration.

About this task

The analytics infrastructure configuration backup consists of:

- Backup of your analytics CR YAML file.
- Backup of any custom certificates you configured. For example, the certificates that secure your communication with your remote S3 object-store, and any certificates used for connecting to third-party systems for analytics offload.

Note: Every time that you update the analytics subsystem CR or any custom analytics certificates, take a new analytics infrastructure configuration backup.
The infrastructure configuration backup is also referred to as the "config backup".

If you have a disaster, your config backup is essential for restoring your analytics subsystem.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Backup your analytics CR to a file called analytics-subsystem-cr-backup.yaml:

   ```
   kubectl get a7s -o yaml > analytics-subsystem-cr-backup.yaml
   ```

2. Backup your analytics database backup secret to a file called analytics-backup-secret_backup.yaml:

   ```
   kubectl get secret analytics-backup-secret -o yaml > analytics-backup-secret_backup.yaml
   ```

   The backup secret is created when you configure analytics database backups: Configuring analytics database backups. If database backups are not yet configured, ensure that this secret is backed up when it is configured.

3. If you are using the analytics offload feature, then backup any custom offload certificates that are used:

   ```
   kubectl get secret <offload secret name> -o yaml > analytics-offload-secret_backup.yaml
   ```

   For more information about offload certificates, see Offload to third-party systems.

4. If your object-store has a self-signed CA certificate, then backup the secret that contains this certificate:

   ```
   kubectl get secret <object-store CA secret name> -o yaml > analytics-objstore-CA-secret_backup.yaml
   ```

   For more information about object-store CA certificates, see Creating the object-store CA certificates.

5. If you manually created or customized any other analytics subsystem certificates, then take a backup of them:
   To identify all the secrets in your analytics namespace, run:

   ```
   kubectl get secrets
   ```

   For each secret that you want to backup, use the following command:

   ```
   kubectl get secret <secret name> -o yaml > <backup filename>
   ```

   You do not need to backup any secrets that cert-manager created and maintains. For more information about analytics TLS certificates, see API Connect TLS certificates.

6. Copy all the backup files that were created in the previous steps to a safe location.

Configuring analytics database backups

Configure scheduled database backups of your analytics subsystem.

Before you begin

You must have a PV available for backups to be stored. If you did not configure a PV during installation, then configure it now by completing the following steps.

1. Open the analytics CR for editing.
   - On Kubernetes and OpenShift® individual subsystem installations, edit your analytics CR directly:

     ```
     kubectl edit a7s
     ```

   - On Cloud Pak for Integration and OpenShift top-level CR installations, edit the `APIConnectCluster` CR:

     ```
     kubectl edit APIConnectCluster
     ```

2. Add a `backup.volumeClaimTemplate` section to define your local backups PVC, in the `spec.storage` section. For example:

   ```
   spec:
     storage:
       backup:
         volumeClaimTemplate:
   ```

```
      storageClassName: <storage class>
      volumeSize: <backups size>
```

where,

- *<storage class>* - The storage class for this PVC, see Storage class.
- *<backups size>* - The size you calculated for your backups in Estimating storage requirements.

On Cloud Pak for Integration and OpenShift top-level CR installations, add **backup.volumeClaimTemplate** to **spec.analytics.storage**.

Procedure

1. Create the analytics backup secret for your object-store or remote SFTP server.
   If you want to store your backups in an object-store and use an access key and secret, then follow the documentation of your object-store provider to obtain an access key and secret. Documentation links for some common object-store providers are as follows:

   - IBM Cloud® Object Storage
   - AWS

   Create a Kubernetes secret called **analytics-backup-secret** that contains your remote SFTP or object-store credentials in the same namespace as your analytics subsystem:

   - Object-store

     ```
     kubectl -n <namespace> create secret generic analytics-backup-secret --from-literal=access_key='<your access key>' --from-literal=secret_key='<your access secret>'
     ```

     or

     ```
     kubectl -n <namespace> create secret generic analytics-backup-secret --from-literal=username='<username>' --from-literal=password='<password>'
     ```

   - SFTP server

     ```
     kubectl -n <namespace> create secret generic analytics-backup-secret --from-literal=username='<username>' --from-literal=password='<password>'
     ```

   If your object-store or remote SFTP server credentials change, then update the **analytics-backup-secret** by deleting and then re-creating as follows:

   a. Delete the **analytics-backup-secret**:

      ```
      kubectl -n <namespace> delete secret analytics-backup-secret
      ```

   b. Re-create **analytics-backup-secret** with your new credentials.

2. Open the analytics CR for editing.
   On Kubernetes and OpenShift individual subsystem installations, edit your analytics CR directly:

   ```
   kubectl edit a7s
   ```

   On Cloud Pak for Integration and OpenShift top-level CR installations, edit the **APIConnectCluster** CR:

   ```
   kubectl edit APIConnectCluster
   ```

3. Add the **databaseBackup** configuration.
   On Kubernetes and OpenShift individual subsystem installations, add **databaseBackup** to the **spec** section of the analytics CR. On Cloud Pak for Integration and OpenShift top-level CR installations, add **databaseBackup** to the **spec.analytics** section of the **APIConnectCluster** CR.

   ```
   databaseBackup:
     enabled: [true|false]
     protocol: [local|sftp|objstore]
     scope: [default|all]
     credentials: analytics-backup-secret
     host: <remote backup site hostname>
     port: <remote backup site port>
     path: <remote backup site path>
     backups3URIStyle: [host|path]
     backupCerts: <object-store server CA secret>
     schedule: <cron formatted schedule> # "0 2 * * *"
   ```

   where,

   - **enabled** - Set to **true** to enable backups. Set to **false** to disable.
   - **protocol** - Type of remote backup site, **objstore** or **sftp**.
     If you do not have a remote backup site then, set to **local**.
   - **scope** - Set to **all** to include all your analytics data, or set to **default** to backup only the summary data and shared queries.
     To estimate the size of your analytics data, see Estimating storage requirements.
   - **host** - is the hostname of your remote SFTP server or object-store endpoint.
     If you are using an object-store, then this property must include the corresponding region. Examples:
     - Region provided in the FQDN -

       s3.*s3region.s3domain*

     - Region provided in the path:

       s3.*s3domain/s3region*

     - If the endpoint has no region:

       s3.*s3domain*

   - **path**-

    - If object-store is used, this property is a combination of the object-store bucket and the base path within the bucket. Use the format: `bucket_name/path`.
    - If a remote SFTP server is used, this property is the directory where your backups are stored.
  - `backups3URIStyle` - If object-store is used, this property defines the path style, set to `host` or `path`.
  - `backupCerts` - If object-store is used, this property is the name of a secret that contains your object-store server certificate.
    This property is only required if your object-store has a self-signed root certificate, see Creating the object-store CA certificates. If your object-store server does not have a self-signed root certificate, then you can omit this line.

  - `schedule` - The cron schedule for when backups are copied to your remote SFTP server or object-store.
    This property does not control when backups are taken. Local backups are taken at 55 minutes past the hour, and this property defines the schedule for transferring the most recent local backup to your remote SFTP server or object store. The format for the schedule is any valid `cron` string. The time zone for backups is that of the `kube-controller-manager`.

    Do not set the schedule to more frequently than once every hour.

What to do next

After your backup settings are configured in your analytics CR, take a new config backup to capture the updated CR settings and backup secrets.

- **Creating the object-store CA certificates**
  Configure your analytics subsystem to trust your object-store.

Creating the object-store CA certificates

Configure your analytics subsystem to trust your object-store.

If your object-store presents a self-signed public server certificate, create a Kubernetes secret that contains the certificate, and specify the secret in your analytics CR.

1. Create a file called `ca.crt` that contains your object-store public server certificate.
   Note: If the certificate includes intermediate certificates, then provide the entire chain in the `ca.crt` file, for example:

   ```
   intermediate-certificate-1
   intermediate-certificate-2
   . . .
   intermediate-certificate-n
   root-certificate
   ```

   where, the first certificate in the `ca.crt` (intermediate-certificate-1) is the issuer of the object-store server certificate, and each subsequent certificate is the issuer of the preceding certificate.
2. Run the following command to create a Kubernetes secret from the certificate file:

   ```
   kubectl create secret generic analytics-custom-objstore-server-ca --from-file=ca.crt=/path/to/cert.crt
   ```

3. Specify your new secret in your analytics CR:

   ```
   databaseBackup:
     ...
     backupCerts: analytics-custom-objstore-server-ca
     ...
   ```

4. Take a backup of the `analytics-custom-objstore-server-ca` secret object:

   ```
   kubectl get secret analytics-custom-objstore-server-ca -o yaml > analytics-custom-objstore-server-ca.yaml
   ```

   Keep the generated analytics-custom-objstore-server-ca.yaml with your infrastructure backup.

Running an on-demand analytics database backup

Deploy the `AnalyticsBackup` CR to initiate a backup of the analytics database.

Before you begin

Configure your backup settings in your analytics CR: Configuring analytics database backups.

About this task

An on-demand backup is triggered by creating an `AnalyticsBackup` CR. The API Connect operator detects the presence of the backup CR and runs the backup job.

When you trigger an on-demand backup, a local backup is taken and then copied to your remote backup location (SFTP of object-store). If a remote backup location is not configured, then the backup is stored locally.

Local backups are taken automatically every 55 minutes past each hour. If you trigger an on-demand backup while a scheduled local backup is running, then the on-demand backup waits until the scheduled backup is complete, and then creates a new local backup.

Note: You can run only one backup or restore process at a time.

Procedure

1. Create a file called analyticsbackup_cr.yaml and paste in the following contents:

```
apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsBackup
metadata:
  generateName: <backup prefix>
spec:
  name: <backup name>
  analyticsCluster: <cluster name>
  crType: create
  comment: <comment>
```

   where:
   - *<backup prefix>* is prefix for the name of your backup. The remainder of the name is automatically generated. Keep the prefix short, 8 characters or less.
   - Optional: *<backup name>*. If you don't want an autogenerated backup name with a prefix, you can specify the complete backup name here and remove the **metadata.generateName** property.
   - *<cluster name>* is the name or your analytics CR. To get the name of your analytics cluster, run:

     ```
     kubectl get AnalyticsCluster
     ```

   - *<comment>* is an optional comment that you can give your backup, for example "load test backup".
2. Deploy your CR by running the following command to create it in the namespace of your analytics subsystem:

   ```
   kubectl -n <namespace> create -f analyticsbackup_cr.yaml
   ```

3. To see the progress of your backup, run the following command:

   ```
   kubectl  -n <namespace> get analyticsbackup
   ```

   ```
   NAME                  STATUS    ID                                      CR TYPE       CLUSTER     AGE    COMMENT
   <backup name>         Running                                         analytics      create       12s    <comment>
   ```

   When the backup is complete the status changes from **Running** to **Ready**.
4. Display the details for your backup by running the following command:

   ```
   kubectl  -n <namespace> get analyticsbackup <backup name> -o yaml
   ```

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsBackup
   metadata:
     creationTimestamp: "2020-05-20T16:18:05Z"
     generateName: a7s-bup-
     generation: 1
     name: a7s-bup-gb6s5
     namespace: my-namespace
     resourceVersion: "867329"
     uid: f43b8400-733d-411a-9e9a-de2166bbfb0a
   spec:

     id: my-backup-id
   ```

Restoring the analytics database

Deploy the **AnalyticsRestore** CR to initiate restoration of an analytics database backup.

About this task

Analytics database backups are restored by creating an **AnalyticsRestore** CR. The API Connect operator detects the presence of the restore CR, and triggers a restore of the backup that is specified in the CR.

Two types of restore are available:

- Repair. The repair restore is for recovering corrupted or accidentally deleted indexes. The repair restore compares the contents of your backup and your current analytics database. Any corrupted indexes in your current database are replaced by the corresponding indexes in your backup. Any indexes that are in your backup but are missing from your current database (and are still within your retention period) are restored from the backup.
  Note: The current write index is an exception. The current write index is where incoming API events are recorded, and contains the API event data for the current day (if you left your rollover period as the default). If your current write index is corrupted, then open a support case. The repair restore does not recover the current write index.
- Replace. The replace restore deletes all indexes in your current database and then restores all the indexes (including the current write index) from the backup that is within your retention period.

A replace restore is used in a disaster recovery situation, where your analytics subsystem is redeployed.

Note: You can run only one backup or restore process at a time.
Note: Analytics database backups that were taken on an earlier release cannot be restored on V10.0.8.0.

Procedure

1. Get a list of available backups by running the following command:

   ```
   kubectl -n namespace get analyticsbackup | grep record
   ```

   ```
   NAME                   STATUS   ID                                        CR TYPE   CLUSTER      AGE   COMMENT
   analytics-bup-kxwq5    Ready    analytics-all-2020-09-07t03:49:15utc   record    analytics    34h
   analytics-bup-p29z8    Ready    analytics-all-2020-09-07t18:04:03utc   record    analytics    20h
   ```

   Note the ID of the backup that you want to restore.
   Note: You cannot restore backups that have `CR TYPE` of `create`.
2. Create a file called analyticsrestore_cr.yaml and paste in the following text:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsRestore
   metadata:
     generateName: a7s-restore-
   spec:
     analyticsCluster: <cluster name>
     backupID: <backup ID>
     type: [repair|replace]
   ```

   - **analyticsCluster** is the name or your analytics CR. To get the name of your analytics cluster, run:

     ```
     kubectl get AnalyticsCluster
     ```

   - **backupID** is the ID of the backup that you want to restore, identified in step 1. If you do not specify this property, then the most recent backup is restored.
   - **type** is the type of restore. Set `type` to `repair` to recover corrupted or missing indices. Set `type` to `replace` to delete all indices and replace with the indices from the backup.
3. Deploy your CR by running the following command to create it in the namespace of your analytics subsystem:

   ```
   kubectl -n <namespace> create -f analyticsrestore_cr.yaml
   ```

4. To monitor your restore, run the following command:

   ```
   kubectl -n <namespace> get analyticsrestore
   ```

   ```
   NAME              STATUS     ID                                        AGE
   a7s-restore-9z4fr Ready      analytics-all-2022-07-01t04:49:15utc              1h
   ```

   When the restore is successfully started, `STATUS` shows `Running`. When the restore is successfully completed, `STATUS` shows `complete`.
5. Display the details for a particular restore by running the following command:

   ```
   kubectl -n <namespace> get analyticsrestore <restore name> -o yaml
   ```

   where *<restore name>* is the name of your restore, that you identified in step 4.
   Example output for a one replica deployment where the repair restore is complete:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsRestore
   metadata:
     creationTimestamp: "2024-06-14T21:42:02Z"
     generateName: analytics-restore-
     generation: 2
     name: analytics-restore-82p6f
     namespace: apic
     ownerReferences:
     - apiVersion: analytics.apiconnect.ibm.com/v1beta1
       blockOwnerDeletion: true
       controller: true
       kind: AnalyticsCluster
       name: analytics
       uid: f71b0c9c-1c00-4c1b-b4a4-36643cb92c41
     resourceVersion: "20708170"
     uid: 858796d1-b4b0-42aa-a86e-5060bae9c405
   spec:
     analyticsCluster: analytics-2
     backupID: analytics-2-all-2024-06-14t21:14:18.628z
     enableIgnoreUnavailable: false
     enableOverride: false
     type: repair
   status:
     backupID: analytics-2-all-2024-06-14t21:14:18.628z
     commentLeft: ""
     conditions:
     - lastTransitionTime: "2024-06-14T21:42:02Z"
       message: ""
       reason: StatusUnknown
       status: "False"
       type: Warning
     - lastTransitionTime: "2024-06-14T21:42:02Z"
       message: SUCCESS
       reason: Finished
       status: "True"
       type: Ready
   ```

```
    ...
details: summary-api-2024.06.14-000001
id: "2"
phase: Ready
state: ""
```

The `status.details` property shows the analytics index that was restored.

6. When restore is complete, delete the `AnalyticsRestore` CR:

```
kubectl -n <namespace> delete analyticsrestore <restore name>
```

Note: If your restore failed, and you want to investigate why, do not delete the `AnalyticsRestore` CR, it is needed for problem analysis.

Recovering from a disaster

Reinstall your analytics subsystem, restore your analytics CR, secrets, and your database backup.

About this task

Analytics subsystem backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore an analytics subsystem backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.

Procedure

1. Install the replacement analytics subsystem, configuring the same `ai-endpoint` as your original installation.
   Follow the installation procedures for your platform:
   - Kubernetes
   - OpenShift® and Cloud Pak for Integration

   Refer to your infrastructure configuration backup to check the `ai-endpoint`. Also, if you disabled local storage, you must configure this in your analytics CR before installation.

2. Update the analytics CR on your replacement installation with the analytics backup settings and any other analytics features you configured in your previous installation.
   Your previous analytics settings are in your infrastructure configuration backup. If you are installed on Cloud Pak for Integration or OpenShift with the top-level CR, then add these settings to the `spec.analytics` section of your `APIConnectCluster` CR.
3. Re-create the analytics secrets that you backed up in your infrastructure configuration backup:
   a. Create the backup credential secret from your backup file: analytics-backup-secret_backup.yaml.

   ```
   kubectl -n <analytics namespace> apply -f analytics-backup-secret_backup.yaml
   ```

   b. If you are using the analytics offload feature, then create the offload secret from your backup file: analytics-offload-secret_backup.yaml.

   ```
   kubectl -n <analytics namespace> apply -f analytics-offload-secret_backup.yaml
   ```

   c. If your object-store has a self-signed CA certificate, then create the secret that contains the certificate from your backup file.

   ```
   kubectl -n <analytics namespace> apply -f analytics-objstore-CA-secret_backup.yaml
   ```

   d. If you manually created or customized any other analytics subsystem certificates, then restore those secrets from their backup files.

   ```
   kubectl -n <analytics namespace> apply -f <backup filename>
   ```

4. Restore the analytics database: Restoring the analytics database.

Deleting old backups

Manage the retention of your analytics backups.

To delete old backups, you can delete the backup files directly on your remote SFTP server or object-store.
Warning: For V10.0.7 and earlier, do not delete backup files directly from your remote server. In previous releases, the analytics database backups are incremental, and deleting any files can corrupt all the backups. Refer to the API Connect documentation for your API Connect version.

Troubleshooting backup and restore

Troubleshooting steps for problems with backup and restore of the analytics database on Kubernetes and OpenShift®.

Check the CR status

List the analytics backup jobs:

```
kubectl -n <namespace> get analyticsbackup -n <namespace>
```

```
NAME                STATUS   ID                                      CR TYPE                 AGE   COMMENT
<backup name>       Ready                                            create                  <age>   <comment>
```

check the status of the backup that you are interested in:

```
kubectl -n <namespace> get analyticsbackup <backup name> -o yaml
```

List the analytics restore jobs:

```
kubectl get analyticsrestore -n <namespace>
```

```
NAME              STATUS     ID                                          AGE
<restore name>    Ready      analytics-all-2022-07-01t04:49:15utc              1h
```

check the status of the restore job you are interested in:

```
kubectl -n <namespace> get analyticsrestore <restore name> -o yaml
```

Check the logs

Check for backup or restore related errors in the logs of the API Connect operator pod and analytics warehouse:

1. Identify the API Connect operator pod `ibm-apiconnect` by running the following command:

   ```
   kubectl -n <namespace> get pods
   ```

   Note: *<namespace>* might not be the same namespace as your analytics subsystem. On a default Red Hat OpenShift deployment, the API Connect operator runs in a global namespace called `openshift-operators`.
2. View the API Connect operator pod logs with:

   ```
   kubectl -n <namespace> logs <ibm-apiconnect pod name>
   ```

   Check for messages with the "error" label that contain the words "analytics", "backup", or "restore".

3. Identify the name of your warehouse pod:

   ```
   kubectl get pods | grep warehouse
   ```

4. View warehouse pods log with:

   ```
   kubectl logs <warehouse pod name>
   ```

Common problems with backup and restore

These are some frequent issues that can cause backup or restore to fail:

- Invalid login credentials for your remote backup server. Check that the username and password that you configured in your subsystem database backup settings is correct.
- The user does not have write permissions on the backup server. Check that the username you configured in your subsystem database backup settings has write permission to the specified backup path.
- Remote backup server storage full. Check your remote backup server and if the storage is full either extend the storage space or delete older backups.
- No network access to the remote backup server. Check that you can communicate with your remote backup server from your API Connect environment.
- TLS handshaking failure with the remote backup server. If your remote backup server has a self-signed CA certificate, check that this certificate is trusted by your API Connect deployment, see the database backup configuration steps for your subsystem for more information.

Increasing storage space for your local backup PVC

Local database backups are stored on the warehouse PVC. The warehouse PVC has either `data-a7s-warehouse` or `data-analytics-warehouse` in its name. By default the warehouse PVC has 150 Gi of storage space.

If you find you do not have enough space in your warehouse PVC, then follow these steps:

1. Disable analytics database backups.
   Edit your analytics CR:

   ```
   kubectl edit a7s
   ```

   set `spec.databaseBackup.enabled = false`.
2. Delete the warehouse PVC:
   a. Identify the name of your warehouse PVC:

      ```
      kubectl get pvc | grep warehouse
      ```

   b. Delete the identified PVC:

      ```
      kubectl delete pvc <warehouse PVC name>
      ```

3. Edit your analytics CR and increase the size of your warehouse PVC.
   Set the new size in `spec.storage.backup.volumeClaimTemplate.volumeSize`.

4. Re-enable analytics database backups.
   Edit your analytics CR and set `spec.databaseBackup.enabled = true`.

Backup failure due to warehouse node failure

The analytics warehouse service is responsible for staging and exporting analytics database backups to your remote SFTP or S3 object-store. The warehouse service runs as a single Kubernetes pod on all deployment profiles. In a three replica deployment, if the worker node where the warehouse pod is running fails, then take the manual steps that are documented here to recover the service.

When the warehouse pod is not running, the analytics CR reports that status of **Pending**, and all backup related features are unavailable.

To recover the warehouse service on a different worker node, complete the following steps:

1. Disable analytics database backups.
   Edit your analytics CR:

   ```
   kubectl edit a7s
   ```

   set **spec.databaseBackup.enabled = false**.

2. Identify the name of the warehouse PVC:

   ```
   kubectl get pvc | grep warehouse
   ```

   Look for the warehouse PVC in the output:

   ```
   NAME                                     STATUS   VOLUME                                     CAPACITY   ACCESS MODES
   STORAGECLASS   AGE
   warehouse-data-analytics-warehouse-0     Bound    pvc-4cbbb8a0-10ad-45de-b7da-ae6c26bde1de   150Gi      RWO
   standard       24h
   ```

3. Delete the warehouse PVC:

   ```
   kubectl delete pvc <name of warehouse pvc>
   ```

4. Re-enable analytics database backups.
   Edit your analytics CR and set **spec.databaseBackup.enabled = true**.

   The PVC is then re-created on one of the two available nodes, and the warehouse pod starts on this same node.

API event record field reference

Reference table and examples of the data that is stored in an API event record.

When a user calls one of your published APIs, the gateway that processes the API call creates an API event record. Each API event record contains details of the API call such as the application ID, current time, result code, etc. Table 1 shows all the data that can be contained in an API event record.

Activity log settings

The contents of API event records depends on the activity log setting for each API, and any custom gateway scripts and ingestion filters that are configured. To find out more about activity logging and customizing API event contents, see Customize your analytics data.

Important: The maximum API event record size is 19 Mb. The analytics subsystem rejects any API event records that are larger than 19 Mb.

API event record fields

Table 1. API event record fields

Field name	Type	Description
@timestamp	Date	A timestamp that records when the Logstash data collection engine (which feeds data into OpenSearch) wrote the record.
ai_cache_hit	Boolean	Boolean indicating whether the response was served from the AI Gateway cache
ai_model	String	The name of the AI model used in this AI Gateway call
ai_request_tokens	Integer	The number of request tokens in this AI Gateway call
ai_response_tokens	Integer	The number of response tokens in this AI Gateway call
ai_total_tokens	Integer	The total (sum or request and response) tokens in this AI Gateway call
api_ref	String	The API reference (api_name:api_version)
api_type	String	The API type: rest, soap, graphql, asyncapi
api_id	String	The API identifier.
api_name	String	The name of the API.
api_resource_id	String	Field format is: **api_name:api_version:method:path**. Only available on API Gateway v10.5.3 or higher.
api_version	String	The version number of the API.
app_id	String	The identifier for the registered application.
app_name	String	The name of the registered application. Note: The property is set to **undefined** when a client ID is not used or is invalid on the API. The gateway needs a client ID to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app was invoked, because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
app_type	String	The application type, with a value of **Production** or **Development**.
backend_method	String	The HTTP method used in the backend call
backend_request_body	String	The request body sent to the backend

Field name	Type	Description
backend_request_headers	Object	The HTTP headers of the backend request
backend_response_body	String	The response body from the backend
backend_response_headers	Object	The HTTP headers of the backend response
backend_status_code	string	The HTTP status code of the backend response
backend_time_to_serve_request	integer	Time taken to serve the backend request
backend_url	String	The full URL of the backend call
billing	Object	Object containing billing information for events using monetization
bytes_received	Number	The number of bytes received from the consumer in the request.
bytes_sent	Number	The number of bytes sent to the consumer in the response.
cached_response	Boolean	Boolean indicating whether this API call was served from the gateway cache
client_geoip.area_code	Number	The public switched telephone network (PSTN) area code of the client, as identified from its IP address.
client_geoip.asn	Number	Autonomous system number of client IP address.
client_geoip.as_org	String	
client_geoip.city_name	String	The city name of the client, as identified from its IP address.
client_geoip.continent_name	String	The continent name of the client, as identified from its IP address.
client_geoip.continent_code	String	The two-letter continent code of the client, as identified from its IP address.
client_geoip.country_code2	String	The two-letter country code of the client, as identified from its IP address.
client_geoip.country_code3	String	The three-letter country code of the client, as identified from its IP address.
client_geoip.country_name	String	The country name of the client, as identified from its IP address.
client_geoip.dma_code	Number	The Designated Market Area (DMA) code of the client, as identified from its IP address.
client_geoip.domain	String	The domain of the client IP address.
client_geoip.ip	String	The IP address of the client.
client_geoip.isp	String	The internet service provider of the client.
client_geoip.latitude	Number	The latitude of the client location, as identified from its IP address.
client_geoip.location	String	The longitude and latitude of the client location (separated by a comma), as identified from its IP address.
client_geoip.location.lat	Number	The latitude of the client location, as identified from its IP address.
client_geoip.location.long	Number	The longitude of the client location, as identified from its IP address.
client_geoip.longitude	Number	The longitude of the client location, as identified from its IP address.
client_geoip.organization	String	The client's organization, as identified from its IP address.
client_geoip.postal_code	String	The postal code of the client, as identified from its IP address.
client_geoip.region_iso_code	String	The ISO code of the client's region, as identified from its IP address.
client_geoip.region_name	String	The abbreviated form of the region that corresponds to the IP address of the client.
client_geoip.timezone	String	The time zone of the client, as identified from its IP address.
client_id	String	The unique ID of the client that is attached to the API request.
client_ip	String	The consumer's IP address
custom_data	Array map	Custom data can be added to this field.
datetime	Date	A timestamp that records when the API was invoked. The timestamp is always shown in Coordinated Universal Time.
developer_org_id	String	The identifier for the consumer organization that owns the application.
developer_org_name	String	The name of the consumer organization that owns the application.
endpoint_url	String	When the request failed, **`endpoint_url`** identifies the proxy or invoke target URL on which the request failed. It is not included with a successful request. On V5 compatible gateway, this field is only populated when the backend server URL that was invoked returns an HTTP 404 code.
env_id	String	The catalog identifier.

Field name	Type	Description
env_name	String	The name of the catalog.
event_id	String	Unique ID assigned to the event by the gateway. Generated based on a hashed version of the **`datetime`**, **`transaction_id`**, and **`client_id`** fields combined by using the SHA1 algorithm.
gateway_geoip.area_code	Number	The public switched telephone network (PSTN) area code of the gateway, as identified from its IP address.
gateway_geoip.asn	Number	Autonomous system number of client IP address.
gateway_geoip.as_org	String	
gateway_geoip.city_name	String	The city name of the gateway, as identified from its IP address.
gateway_geoip.continent_code	String	The two-letter continent code of the gateway, as identified from its IP address.
gateway_geoip.continent_name	String	The continent name of the gateway, as identified from its IP address.
gateway_geoip.country_code2	String	The two-letter country code of the gateway, as identified from its IP address.
gateway_geoip.country_code3	String	The three-letter country code of the gateway, as identified from its IP address.
gateway_geoip.country_name	String	The country name of the gateway, as identified from its IP address.
gateway_geoip.dma_code	Number	The Designated Market Area (DMA) code of the gateway, as identified from its IP address.
gateway_geoip.domain	String	The domain of the gateway IP address.
gateway_geoip.ip	String	The IP address of the gateway.
gateway_geoip.isp	String	The internet service provider of the gateway.
gateway_geoip.latitude	Number	The latitude of the gateway location, as identified from its IP address.
gateway_geoip.location	String	The longitude and latitude of the gateway location (separated by a comma), as identified from its IP address.
gateway_geoip.location.lat	Number	The latitude of the gateway location, as identified from its IP address.
gateway_geoip.location.long	Number	The longitude of the gateway location, as identified from its IP address.
gateway_geoip.longitude	Number	The longitude of the gateway location, as identified from its IP address.
gateway_geoip.organization	String	The gateway's organization, as identified from its IP address.
gateway_geoip.postal_code	String	The postal code of the gateway, as identified from its IP address.
gateway_geoip.region_name	String	The abbreviated form of the region that corresponds to the IP address of the gateway.
gateway_geoip.region_iso_code	String	The ISO code of the gateway's region, as identified from its IP address.
gateway_geoip.timezone	String	The time zone of the gateway, as identified from its IP address.
gateway_host	String	Gateway hostname (not set for all gateway types
gateway_ip	String	The IP address of the gateway.
gateway_port	Integer	Gateway port number (not set for all gateway types)
gateway_service_name	String	The name of the DataPower® API gateway service. Configured by the cloud admin user when registering the gateway service. Only available on DataPower API Gateway v10.5.3 or higher.
gateway_time_to_serve_request	Float	The time taken to process this API request (total time to serve request - backend time to serve request) in the gateway
gateway_type	String	The type and version of the gateway that processed the call, in format: **`type`**/**`version`**. Set by all gateway types except for v5c, and only available on v10.0.8.0 or higher.
global_transaction_id	String	The DataPower global transaction ID. See https://www.ibm.com/docs/en/datapower-gateway/latest?topic=variables-varserviceglobal-transaction-id-servicevarsglobaltransactionid.
graphql_request_field_cost	Number	GraphQL APIs only. The maximum cost of all fields accessed in the query. The cost of each field access is configured in the schema.
graphql_request_max_nesting	Number	GraphQL APIs only. The maximum nesting depth found in the query by the assembly validate action. The schema configuration is used to determine which types are nested, so this value might be less than the nesting depth found by the assembly parse action.
graphql_request_top_field_counts	Object	GraphQL APIs only. The maximum number of times that a query can retrieve each field. This number is equal to the number of times that the resolver is required to run. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.

Field name	Type	Description
graphql_request_top_type_counts	Object	GraphQL APIs only. The maximum number of times that a query can retrieve an object of each type. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_request_type_cost	Number	GraphQL APIs only. The maximum cost of all types retrieved in the query. The cost of each type is configured in the schema.
graphql_response_field_cost	Number	GraphQL APIs only. The cost of all fields accessed in the query. The cost of each field access is configured in the schema.
graphql_response_max_nesting	Number	GraphQL APIs only. The nesting depth found in the query by the assembly validate action. The schema configuration is used to determine which types are considered nested, so this value might be less than the nesting depth found by the assembly parse action.
graphql_response_top_field_counts	Object	GraphQL APIs only. The number of times that each field was retrieved by the query. This number is equal to the number of times that the resolver is required to run. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_response_top_type_counts	Object	GraphQL APIs only. The number of times that an object of each type was retrieved by the query. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_response_type_cost	Number	GraphQL APIs only. The cost of all types that were retrieved in the query. The cost of each type is configured in the schema.
host	String	The hostname or IP address of the ingestion node that received the API event.
http_user_agent	String	The value of the User Agent header on the inbound request.
immediate_client_ip	String	The client IP address that is directly in front of the gateway. Usually **`immediate_client_ip`** is the IP of a load balancer.
latency_info.started	Number	The time delay (in milliseconds) between when the request was received and when the gateway started the corresponding task. Starting a task comprises multiple steps to prepare for executing an API; for example, completing the TCP/TLS handshake, verifying an app's client ID and secret, and matching the request URI to a catalog, API, and Plan. When the gateway receives a request, the "Start" duration is set to 0. The duration of each step within the Start task is then added up, and the total represents the duration of the Start task.
latency_info.task	String	The API transaction that was processed.
log_policy	String	The defined logging policy. Values include none, event, headers, and payload.
org_id	String	The identifier for the provider organization that owns the API and associated Products.
org_name	String	The name of the provider organization that owns the API and associated Products.
opentracing_info	Object	Opentracing information used in AI test generation calls in cp4i
operation_path	String	The path of the API request as would match the path in the open API documen
path_id	String	The path identifier
plan_id	String	The Plan identifier.
plan_name	String	The name of the Plan. Note: The property is set to **`undefined`** when a client ID is not used or is invalid on the API. The gateway needs a client id to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app was invoked because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
plan_version	String	The version number of the Plan.
product_id	String	The product identifier
product_name	String	The Product name. Note: The property is set to **`undefined`** when a client ID is not used or is invalid on the API. The gateway needs a client ID to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app wasinvoked because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
product_ref	String	The product reference (product_name:product_version)
product_title	String	The title of the Product.
product_version	String	The version number of the Product.
query_string	String	The URL query string value on the inbound request.
rate_limit.count	Number	The number of API calls remaining in the specified rate limit time window.
rate_limit.interval	Number	The total time window during which a certain number of API calls are allowed.
rate_limit.limit	Number	The maximum number of requests an application is allowed to make to the API during a specified time window.
rate_limit.period	Number	The time window that is used to set a rate limit for API calls.
rate_limit.reject	String	An indication of whether calls that exceed the specified rate limit are rejected. If true, the API call is rejected with a 429 status code. If false, a record is created in the Activity log.
rate_limit.shared	String	An indication of whether the rate limit is shared at a Plan level by all operations, or whether a rate limit is specified on indivIDual operations.
rate_limit.unit	Number	The time unit used for calculating the rate limit. Note: Allowed values are second, minute, hour, day, and week
request_body	String	The body of the inbound request.

Field name	Type	Description
request_http_headers.*field_name*	String	A component of the HTTP header section of the inbound request; for example, the acceptable encodings, the identification string for the user agent, or the proxies through which the request was sent. Note: The following types of headers are considered sensitive and do not show in analytics data for security reasons: • Any secret key configured in the API security • Any header that contains **`secret`** • Any header that contains **`Authorization`**
request_method	String	The method of the inbound request.
request_protocol	String	The protocol of the inbound request.
resource	String	The name of the operation.
resource_id	String	The operation identifier.
resource_path	String	The operation path.
response_body	String	The body of the outbound response.
response_http_headers.*field_name*	String	A component of the HTTP header section of the outbound response; for example, the MIME type of the content or the data and time when the message was sent.
scope	String	Not used for DataPower API Gateway or DataPower Gateway.
space_id	String	The space identifier for products published to a space
space_name	String	The space name for products published to a space
status_code	String	The status code set on the outbound response.
time_to_serve_request	Number	The time elapsed (in milliseconds) from when the gateway received the request to when it sent a response.
transaction_id	String	The identifier for the API transaction. See https://www.ibm.com/docs/en/datapower-gateway/latest?topic=variables-varservicetransaction-id-servicevarstransactionid.
uri_path	String	The URI path on the inbound request.
user_agent	Object	The parsed contents of the **`http_user_agent`** field, which contains information about the user that made the API call.
user_agent.device	String	Device name.
user_agent.major	String	User agent major version number.
user_agent.minor	String	User agent minor version number.
user_agent.name	String	User agent name.
user_agent.os_full	String	Detected operating system full name.
user_agent.os_major	String	Detected operating system major version number.
user_agent.os_minor	String	Detected operating system minor version number.
user_agent.os_name	String	Detected operating system name.
user_agent.os_patch	String	Detected operating system patch version.
user_agent.os_version	String	Detected operating system version.
user_agent.patch	String	User agent patch version.
user_agent.version	String	Detected user agent version.
api_type	String	Specifies the type of API that the event is associated with. Supported values are **`rest`**, **`soap`** and **`graphql`**. Note: The **`v5c gateway`** does not send this field, but the **`API Gateway`** and **`Converged Gateway`** support it.

Note:

- To ensure the value in the **`client_geoip`** field is accurate, the gateway must receive the **`X-Forwarded-For`** header in all API calls. Check with the administrator of your deployment environment to ensure that the **`X-Forwarded-For`** header is passed to your gateways. For example, in a Kubernetes environment where NINGX ingresses are used, configure the NGINX ingress that is used by your gateway to use the **`X-Forwarded-For`** header: NGINX Configuration "use-forwarded-headers".

  The geoIP feature is useful with internet routable IP addresses only. For instance, 192.168.x.x and 10.x.x.x IP addresses, being internal private IP addresses, cannot be resolved to a geographical location.

- Not all fields are present on all events. Some fields are specific to certain types of APIs, while others are sent only by specific gateway types or versions.

Example API event record with payload logging set

Summary API event record field reference

Summary API event records are retained for longer durations than individual event records.

Summary API event record fields

Table 1 shows examples of the fields that are stored in a Summary API event record.

Table 1. API event record fields

Field name	Type	Description
api_ref	String	The API reference (api_name:api_version)
app_name	String	The name of the registered application. Note: The property is set to `undefined` when a client ID is not used or is invalid on the API. The gateway needs a client ID to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is cannot determine which plan, product, or app was invoked. This is because a single API can belong to multiple products, each of which have multiple plans and apps that are subscribed to those plans with client IDs.
bytes_received	Number	The number of bytes received from the consumer in the request.
bytes_sent	Number	The number of bytes sent to the consumer in the response.
catalog_name	String	The name of the catalog
datetime	Date	A timestamp that records when the API was invoked. The timestamp is always shown in Coordinated Universal Time.
developer_org_name	String	The name of the consumer organization that owns the application.
gateway_service_name	String	The name of the DataPower® API gateway service. Configured by the cloud admin during gateway service registration. Only available on DataPower API Gateway v10.5.3 or higher.
org_name	String	The name of the provider organization that owns the API and associated Products.
plan_id	String	The Plan identifier.
product_ref	String	The product reference (product_name:product_version)
space_name	String	The space name for products that are published to a space
status_code	String	The status code set on the outbound response.
summary_event_id	String	Unique ID assigned to the event
time_to_serve_request	Number	The time elapsed (in milliseconds) from when the gateway received the request to when it sent a response

Example Summary Event Record

```
{
            "api_ref": "switch-api:1.0.0",
            "app_name": "api-connect-app-4",
            "bytes_received": 888,
            "bytes_sent": 9177,
            "catalog_name": "api-connect-catalog-1",
            "datetime": "2025-06-11T04:00:00.000Z",
            "developer_org_name": "api-connect-emard-greenholt-awesome-fantastic-soft-sausages-consumer-organization",
            "gateway_service_name": "v6gw",
            "org_name": "ibm",
            "plan_id": "api-connect-crooks-group-luxurious-tasty-rubber-chair-product:1.0.0:default-plan",
            "product_ref": "api-connect-crooks-group-luxurious-tasty-rubber-chair-product:1.0.0",
            "space_name": null,
            "status_code": "201 Created",
            "summary_event_id": "A11ybP3Dnla5jttwIQuGjA",
            "time_to_serve_request": 571
        }
```

Use the following operations to retrieve analytics summary event data with the API Connect Analytics REST API:

Table 2. Operations to retrieve analytics summary event data

Operation	Description
GET /summary	This operation returns a list of summary event records.
GET /summary/:id	This operation returns a specific summary event record by its unique ID.
GET /summary/count	This operation returns the total number of summary event records.

Note: These operations are also present within the Analytics CLI in Toolkit.

Advanced configuration options

Configure advanced features and settings such as offload, retention period, and dedicated storage.

- **Dedicated storage and scaling up**
  Use dedicated storage for improved performance, stability, and scalability. Available on Kubernetes and OpenShift®.
- **Retention and rollover**
  Manage how long your analytics subsystem stores data.
- **Logstash persistent queue**
  Configuring the Logstash persistent queue feature.

- **Offload to third-party systems**
  Offload your API event data for storage on a third-party system.
- **Replicating analytics data to a 2DCDR warm-standby data center**
  If you have a two data center warm-standby deployment, you can configure the analytics subsystem in your active data center to offload incoming API event records to the analytics subsystem in your warm-standby data center.
- **Disable local storage**
  If you are offloading you API event data to a third-party system, you can disable local storage to reduce subsystem resource requirements.
- **Shutting down the analytics subsystem**
  Disable the analytics service and shutdown the analytics subsystem.
- **Restarting analytics pods**
  How to restart the analytics pods in your API Connect deployment.
- **Enable Amazon SNS for Engagement**
  To enable Amazon SNS for Engagement, you must create the AWS client secret and reference the secret in the analytics custom resource YAML file.
- **Changing deployment profile**
  Change your deployment profile to switch between one replica and three replica deployments, or to change the computing resources available for your subsystem.
- **Performance tuning with ingestion pipeline properties**
  Fine-tune your ingestion pipeline settings for optimal performance.

Dedicated storage and scaling up

Use dedicated storage for improved performance, stability, and scalability. Available on Kubernetes and OpenShift®.

Note: Storage type selection is available on three replica deployments only.
To make an informed choice on which storage type is best for you, first read and understand the OpenSearch concepts that are described in OpenSearch nodes, indices, shards, and replicas.
API Connect provides two OpenSearch storage types:

- **Shared storage**
  A single pod provides data storage and OpenSearch cluster management. Shared storage is the only option on a one replica deployment.

- **Dedicated storage**
  OpenSearch data storage and cluster management functions are split, and run in separate pods on each worker node:
  - The `storage-os-master` pod runs an OpenSearch "manager eligible" node that manages the OpenSearch cluster, but does not store any API event data.
  - The `storage` pod runs an OpenSearch "data" node that stores API event data.

  Dedicated storage is the default storage type for three replica deployments.

Dedicated storage facilitates horizontal scaling to support greater analytics data storage and throughput. Add worker nodes and increase the number of `storage` pod replicas to scale horizontally (you do not need to increase the number of `storage-os-master` replicas). Dedicated storage also provides greater stability and allows some OpenSearch configuration changes to be made without downtime.
Note: For OpenShift users - The example steps in this document use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR (`APIConnectCluster`), make sure that the `spec.gateway` section is included. If it is not included already, you must add the `spec.gateway` section before adding the required property within it.
The storage type is defined in the analytics CR, in the `spec.storage.type` section as follows:

- Shared storage:

```
  storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
```

- Dedicated storage:

```
  storage:
    type: dedicated
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    master:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
```

Changing from shared to dedicated storage

1. Edit your analytics CR:

   ```
   kubectl -n <namespace> edit a7s
   ```

2. Change storage type to dedicated:

   ```
     storage:
       type: dedicated
   ```

3. If your environment does not have a default storage class, or want to use a different storage class for your `storage-os-master` pods, then also add the `spec.storage.master` section to specify the storage class, for example:

   ```
     storage:
       type: dedicated
   ...
       master:
   ```

```
    volumeClaimTemplate:
      storageClassName: local_storage
```

Changing from dedicated to shared storage

1. Edit your analytics CR:

   ```
   kubectl -n <namespace> edit a7s
   ```

2. Change storage type to shared:

   ```
   storage:
     type: shared
   ```

3. Wait until all of your **storage** pods restart and are in the **Ready** state.
4. Edit your analytics CR and remove the **spec.storage.master** section.
5. Delete the **data-analytics-storage-os-master** PVCs:

   ```
   kubectl -n <namespace> delete pvc data-analytics-storage-os-master-<integer>
   ```

Horizontal scaling with dedicated storage

To take advantage of the horizontal scaling options with dedicated storage, see Horizontal scaling of storage pods.

Horizontal scaling of storage pods

Scale your storage pod replicas for increased API event data storage and throughput.

To take advantage of storage pod scaling, you must have a three replica deployment, and be using dedicated storage, see Dedicated storage and scaling up.

Note:

- The term "replica" when used with "data storage pod" refers to the Kubernetes storage pod, not OpenSearch replicas. OpenSearch replica settings are not configurable in API Connect.
- The OpenSearch term "node" refers to OpenSearch data storage nodes. OpenSearch nodes have a one-to-one relationship with the API Connect storage pod replicas, and have the same name.

This operation requires the use of the Analytics CLI.

Increase the number of storage pod replicas

1. Edit your analytics CR:

   ```
   kubectl -n <namespace> edit a7s
   ```

2. Add the following to the **spec:** section:

   ```
   template:
   - name: storage
     replicaCount: <new replica count>
   ```

   where *<new replica count>* must be less than or equal to the number of worker nodes you have available.
3. Wait for the new storage pod replicas to start on your new worker nodes, and for the analytics cluster to rebalance your API event data to use your new replicas. The time the rebalancing takes depends on the size of your API event data and the network transmission speed between worker nodes. You can check the rebalancing status with the CLI health command:

   ```
   apic --mode analytics clustermgmt:getHealth  --server <platform api endpoint> --analytics-service <analytics service name>
   --format json
   ```

   where:
   - ***<platform api endpoint>*** is the platform API endpoint.
   - ***<analytics service name>*** is the name of the analytics service as configured in the Cloud Manager UI.

   When rebalancing is complete, the **number_of_data_nodes** matches your updated **replicaCount**, and the highlighted **_shards** properties are all zero, as shown:

   ```
   {
     "cluster_name":"apic-analytics-cluster",
     "status":"green",
     "timed_out":false,
     "number_of_nodes":8,
     "number_of_data_nodes":5,
     "discovered_master":true,
     "discovered_cluster_manager":true,
     "active_primary_shards":8,
     "active_shards":24,
     "relocating_shards":0,
     "initializing_shards":0,
     "unassigned_shards":0,
     "delayed_unassigned_shards":0,
     "number_of_pending_tasks":0,
     "number_of_in_flight_fetch":0,
     "task_max_waiting_in_queue_millis":0,
     "active_shards_percent_as_number":100
   }
   ```

Note: If in the past you increased and then reduced the number of data storage replicas in your deployment, you might have an OpenSearch exclude list that contains the names of the previous replicas you removed. New storage pod replicas cannot be created if their name is in the OpenSearch exclude list. To empty the OpenSearch exclude list, follow the same steps that you used to create it: Create exclude list, but set `persistent.cluster.routing.allocation.exclude._name` to an empty string.

Reduce the number of storage pod replicas

1. Verify that your analytics cluster health is green. Use the analytics CLI health command:

   ```
   apic --mode analytics clustermgmt:getHealth  --server <platform api endpoint> --analytics-service <analytics service name>
   --format json
   ```

   where:
   - *<platform api endpoint>* is the platform API endpoint.
   - *<analytics service name>* is the name of the analytics service as configured in the Cloud Manager UI.

   Check that the status property is green:

   ```
   {
      "cluster_name":"apic-analytics-cluster",
      "status":"green",
      "timed_out":false,
      "number_of_nodes":8,
      "number_of_data_nodes":5,
      "discovered_master":true,
      "discovered_cluster_manager":true,
      "active_primary_shards":8,
      "active_shards":24,
      "relocating_shards":0,
      "initializing_shards":0,
      "unassigned_shards":0,
      "delayed_unassigned_shards":0,
      "number_of_pending_tasks":0,
      "number_of_in_flight_fetch":0,
      "task_max_waiting_in_queue_millis":0,
      "active_shards_percent_as_number":100
   }
   ```

   Do not proceed if the status is not green.
2. Replicas are removed by reducing the Kubernetes `replicaCount` in the analytics CR. When `replicaCount` is reduced, the replicas that are deleted are always the highest numbered replicas. For example:

   ```
   kubectl get pods | grep storage
   ```

   ```
   NAME                                  READY   STATUS      RESTARTS   AGE
   analytics-storage-0                   1/1     Running     0          140d
   analytics-storage-1                   1/1     Running     0          140d
   analytics-storage-2                   1/1     Running     0          140d
   analytics-storage-3                   1/1     Running     0          140d
   analytics-storage-4                   1/1     Running     0          140d
   ```

   If you reduce `replicaCount` from 5 to 3, the two replicas that are deleted are `analytics-storage-3` and `analytics-storage-4`.
   Before you reduce the `replicaCount`, you must ensure that replicas to be deleted contain no API event data. To make OpenSearch relocate all API event data to the replicas you are keeping, add the replicas that you want to delete to the OpenSearch exclude list:

   a. Export the current analytics cluster settings to a JSON file:

      ```
      apic -m analytics clustermgmt:getSettings --server <platform api endpoint> --analytics-service <analytics service
      name> --format json > a7s_cluster_settings.json
      ```

      This command creates a file called a7s_cluster_settings.json in your current directory.

   b. Edit the a7s_cluster_settings.json file, and set the `persistent.cluster.routing.allocation.exclude._name` property to a comma-separated list of replicas you plan to remove. For example:

      ```
      {
          "persistent": {
              "cluster": {
                  "routing": {
                      "allocation": {
                          "exclude": {
                              "_name": "analytics-storage-3,analytics-storage-4"
                          }
                      }
                  }
              },
              "plugins": {
                  "index_state_management": {
                      "metadata_migration": {
                          "status": "1"
                      },
                      "template_migration": {
                          "control": "-1"
                      },
                      "history": {
                          "enabled": "false"
                      }
                  }
              }
          },
          "transient": {}
      }
      ```

You might need to add the **cluster.routing.allocation.exclude** structure if this property has not been set before.

c. Apply the updated a7s_cluster_settings.json file:

```
apic -m analytics clustermgmt:putSettings --server <platform api endpoint> --analytics-service <analytics service name> a7s_cluster_settings.json --format json
```

3. Wait for your analytics cluster to remove all data from the replicas you want to delete, which you specified in step 2. You can check that the data rebalancing is complete with the **clustermgmt:catAllocation** CLI command:

```
apic -m analytics clustermgmt:catAllocation --server <platform api endpoint> --analytics-service <analytics service name> --format json --return_format json
```

Replicas that don't have data appear as entries with a **shards** value of zero in the output (you can ignore the **disk.*** properties):

```
[
  {
    "shards": "5",
    "disk.indices": "113.3kb",
    "disk.used": "27.3gb",
    "disk.avail": "222.5gb",
    "disk.total": "249.8gb",
    "disk.percent": "10",
    "host": "192.168.87.226",
    "ip": "192.168.87.226",
    "node": "analytics-storage-0"
  },
  {
    "shards": "0",
    "disk.indices": "0",
    "disk.used": "36.9kb",
    "disk.avail": "212.9kb",
    "disk.total": "249.8kb",
    "disk.percent": "1",
    "host": "192.168.64.225",
    "ip": "192.168.64.225",
    "node": "analytics-storage-3"
  },
  {
    "shards": "5",
    "disk.indices": "16.8kb",
    "disk.used": "28.2gb",
    "disk.avail": "221.6gb",
    "disk.total": "249.8gb",
    "disk.percent": "11",
    "host": "192.168.112.227",
    "ip": "192.168.112.227",
    "node": "analytics-storage-1"
  },
  {
    "shards": "5",
    "disk.indices": "23.3kb",
    "disk.used": "29.3gb",
    "disk.avail": "220.4gb",
    "disk.total": "249.8gb",
    "disk.percent": "11",
    "host": "192.168.24.102",
    "ip": "192.168.24.102",
    "node": "analytics-storage-2"
  },
  {
    "shards": "0",
    "disk.indices": "0",
    "disk.used": "35.4kb",
    "disk.avail": "214.4kb",
    "disk.total": "249.8kb",
    "disk.percent": "1",
    "host": "192.168.91.149",
    "ip": "192.168.91.149",
    "node": "analytics-storage-4"
  }
]
```

The time rebalancing takes depends on the size of your API event data and the network transmission speed between pod replicas.
Note: The value in the **node** property of the **clustermgmt:catAllocation** output is the same as the names of the Kubernetes storage pod replicas.

4. Verify that your analytics cluster health is green. Use the analytics CLI health command:

```
apic --mode analytics clustermgmt:getHealth  --server <platform api endpoint> --analytics-service <analytics service name> --format json
```

where:

- *<platform api endpoint>* is the platform API endpoint.
- *<analytics service name>* is the name of the analytics service as configured in the Cloud Manager UI.

Check that the status property is green:

```
{
   "cluster_name":"apic-analytics-cluster",
   "status":"green",
   "timed_out":false,
   "number_of_nodes":8,
   "number_of_data_nodes":5,
   "discovered_master":true,
   "discovered_cluster_manager":true,
   "active_primary_shards":8,
```

```
   "active_shards":24,
   "relocating_shards":0,
   "initializing_shards":0,
   "unassigned_shards":0,
   "delayed_unassigned_shards":0,
   "number_of_pending_tasks":0,
   "number_of_in_flight_fetch":0,
   "task_max_waiting_in_queue_millis":0,
   "active_shards_percent_as_number":100
}
```

Do not proceed if the status is not green.

5. Edit your analytics CR:

```
kubectl -n <namespace> edit a7s
```

6. Update the `replicaCount`:

```
  template:
  - name: storage
    replicaCount: <new replica count>
```

where *<new replica count>* is the reduced number of replicas that you want.
Note: If the `replicaCount` property does not exist in the analytics CR, check that you are not attempting to reduce `replicaCount` to 2. Reducing `replicaCount` to less than 3 is not a supported operation.

7. Monitor the health status of your analytics cluster with the CLI health command:

```
apic --mode analytics clustermgmt:getHealth  --server <platform api endpoint> --analytics-service <analytics service name>
--format json
```

where:

- `<platform api endpoint>` is the platform API endpoint.
- `<analytics service name>` is the name of the analytics service as configured in the Cloud Manager UI.

Confirm that the `status` is `green`, the `number_of_data_nodes` matches your updated `replicaCount`, and that the highlighted shard properties are all zero:

```
{
   "cluster_name":"apic-analytics-cluster",
   "status":"green",
   "timed_out":false,
   "number_of_nodes":6,
   "number_of_data_nodes":3,
   "discovered_master":true,
   "discovered_cluster_manager":true,
   "active_primary_shards":8,
   "active_shards":24,
   "relocating_shards":0,
   "initializing_shards":0,
   "unassigned_shards":0,
   "delayed_unassigned_shards":0,
   "number_of_pending_tasks":0,
   "number_of_in_flight_fetch":0,
   "task_max_waiting_in_queue_millis":0,
   "active_shards_percent_as_number":100
}
```

Retention and rollover

Manage how long your analytics subsystem stores data.

Each API event is recorded as a document in an OpenSearch index. When this index reaches a maximum size or age it is archived, and a new index is created for recording new API events. This is known as index rollover. When an archived index reaches a maximum age, which is known as the data retention maximum, it is deleted. You can specify the index rollover size and the data retention period in the Cloud Manager UI.

For more information about OpenSearch indices, see OpenSearch nodes, indices, shards, and replicas.
Note: If a rollover is in the *failed* state for more than 36 hours, an automated forced rollover is attempted. If this attempt is unsuccessful, the following error message is displayed in the analytics director pod logs:

```
Error triggering forced rollover
```

To learn more about OpenSearch indices, see OpenSearch nodes, indices, shards, and replicas.

The index rollover settings determine how long an index accumulates data before it "rolls over" and a new index is created. You can control the duration of an index two ways: by setting a maximum age for the index (default is 1 day), or by setting a maximum number of documents that can be recorded in the index (default is 25 million documents). When the rollover occurs, a new index is created for new API events to be stored in, while the previous index is archived and kept until its age exceeds the data retention setting. If you change the rollover settings, consider both the amount of data to be stored within each index and the total number of indices. Allowing indices to grow too large, or storing too many indices, can cause performance problems.

The data retention setting determines how long the stored indices are retained. When an index's creation date exceeds the retention period, that index and all its data is deleted.
Note: It is the creation date of the index that is used to determine retention, not the age of the newest record in the index.
The default retention period depends on the deployment profile, as shown in the following table:

Table 1. Default analytics retention periods

Profile	Retention (days)
n1xc2.m16	3

Profile	Retention (days)
n1xc4.m32	30
n1xc6.m48	45
n3xc4.m16 - DEPRECATED	2
n3xc4.m32	30
n3xc6.m48	45
n3xc8.m64	45

Reasons for changing this setting might include storage constraints, and the data retention requirements for your organization. You might want to set this value to be less than the default if you have a high transaction load and limited persistent storage space, especially if payload logging is enabled on many of your APIs. Increasing the retention period above the default is not recommended, if you want to store your analytics data for longer, then Offload to third-party systems.
The most recently created index (the index that is currently being written to) is not deleted, even if you set the retention period as small as 1 hour. If you regularly need to delete data quickly, adjust the index rollover so that a new index is rolled over to sooner, and the old index can be deleted.

Before an index is deleted, the API event data in the index is summarized and stored in a separate summary index to provide long-term data. The summary index has a separate retention setting, which is set to one year by default.

Note: The rollover and retention settings have a significant impact on the memory that is required by the analytics subsystem. If rollover is set to higher than one day, then more analytics data can be stored before a performance deterioration is observed. However, a higher rollover setting has the disadvantage that more data is deleted when an index reaches the retention age. For example, if you set your rollover period to seven days and you have the default 90-day retention period, then when your oldest index reaches the 90 days since it was created, it is deleted and you are left with 83 days of API event data.
To view and update the rollover and retention settings, use the Cloud Manager UI.

1. From the Cloud Manager UI, click Topology.
2. Select the Analytics Service you want to view or edit.
3. Click Advanced settings.

Alternative method using the Analytics CLI.

1. View the current retention and rollover settings by using the `clustermgmt:getStorageSettings` analytics CLI command:

   ```
   apic -m analytics clustermgmt:getStorageSettings --server <platform api endpoint> --analytics-service <analytics service name> --format json
   ```

   - `<platform api endpoint>` is the platform API endpoint.
   - `<analytics service name>` is the name of analytics service as configured in the Cloud Manager UI.
2. To update the retention and rollover settings create a JSON file that is called `retention_and_rollover_settings.json`, paste in the output from step 1 and set the retention and rollover setting as required. Apply these new settings with: `clustermgmt:putStorageSettings`

   ```
   apic -m analytics clustermgmt:putStorageSettings --server <platform api endpoint> --analytics-service <analytics service name> retention_and_rollover_settings.json
   ```

   - `<platform api endpoint>` is the platform API endpoint.
   - `<analytics service name>` is the name of analytics service as configured in the Cloud Manager UI.

Note:
If the retention or rollover process fails, the Cloud Manager and API Manager UIs show the following error message:

Error: Analytics internal storage rollover might be experiencing problems. Contact your system administrator to investigate further. Rollover failure means that data retention is not correctly enforced and storage usage continues to grow which can eventually lead to service shutdown.

If you see this error, then open a support case.

Logstash persistent queue

Configuring the Logstash persistent queue feature.

The Logstash persistent queue provides enhanced reliability in the data pipeline. The ingestion pod buffers incoming API event data to persistent storage so that no events are lost if the downstream local storage pods or offload targets are temporarily not available.

For example, when you restart the analytics storage pods they take a few seconds to be able to receive API event data. While the storage pods are restarting, incoming API events are held in the persistent queue until the storage pods are available again. If the storage pods are not available and the persistent queue is not enabled, then new API event data is lost during the storage pod outage.

If you find you are missing API event records, it is possible that the default persistent queue size is insufficient. This document provides the steps to increase your persistent queue size.

Note: For OpenShift® users - The example steps in this document use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR (`APIConnectCluster`), make sure that the `spec.gateway` section is included. If it is not included already, you must add the `spec.gateway` section before adding the required property within it.

Customizing the persistent queue size

By default the size of the persistent queue is 8 Gi. If you want to change this size, then follow these steps according to your platform.
Note: The configuration of the size of the persistent queues is supported only on API Connect 10.0.8.1 and later.

1. Calculate the storage space required based on the queue size you want to set.
   - Local storage enabled and no offload is configured - `2 x queue size + 5 Gi`.
   - Local storage enabled and one offload target is configured - `3 x queue size + 5 Gi`.
   - Local storage enabled and two offload targets configured - `4 x queue size + 5 Gi`.
   - Local storage disabled and one offload target is configured - `2 x queue size + 5 Gi`.

- Local storage disabled and two offload targets configured - `3 x queue size + 5 Gi`.

Note: Disabling local storage and no offload configured require `1 * queue size + 5 Gi`. However, this configuration is not required as it means that analytics data is not recorded anywhere.

2. Check whether the required storage exceeds the current value of `ingestion.queue.volumeClaimTemplate.volumeSize`. By default this is 50 Gi, so if you are increasing the queue size over 11 Gi, then you must increase storage.
   On Kubernetes and Red Hat OpenShift you can check the storage by looking at the analytics CR.

   ```
   kubectl -n <namespace> edit a7s
   ```

3. If you need more storage than you have defined in `ingestion.queue.volumeClaimTemplate.volumeSize`, then complete the following steps.
   Note: Increasing the ingestion storage size causes analytics ingestion downtime. No incoming API event data is stored or offloaded while you complete these steps.
   a. Scale down the ingestion pods to 0 replicas.
      Identify the name of the ingestion `StatefulSet`:

      ```
      kubectl get sts | grep ingestion
      ```

      Set ingestion replicas to zero:

      ```
      kubectl scale sts <ingestion statefulset> --replicas=0
      ```

   b. Delete the ingestion pod PVCs.
      Identify the ingestion pod PVCs:

      ```
      kubectl get pvc | grep ingestion
      ```

      Delete all ingestion PVCs:

      ```
      kubectl delete pvc <name>-analytics-ingestion-<integer>
      ```

   c. Update the analytics CR with the new `defaultQueueSize` and `volumeSize`:

      ```
      queue:
        type: persisted
        defaultQueueSize: <queue size>Gi
        volumeClaimTemplate:
          ...
          volumeSize: <volumeSize>Gi
      ```

   d. Scale the ingestion pods back up:

      ```
      kubectl scale sts <ingestion statefulset> --replicas=<original number of replicas>
      ```

   e. Verify that ingestion pod and PVC are re-created:

      ```
      kubectl get pods | grep ingestion
      ```

      ```
      kubectl get pvc | grep ingestion
      ```

4. Make sure that you have sufficient storage that is defined in `ingestion.queue.volumeClaimTemplate.volumeSize`, then complete the following steps.
   - **Kubernetes, Openshift, and Cloud Pak for Integration** - Edit your analytics CR by using the following command.

     ```
     kubectl -n <namespace> edit a7s
     ```

     Add the `spec.ingestion.queue.defaultQueueSize` property to your analytics CR, and set the `volumeClaimTemplate.volumeSize`. For example,

     ```
     queue:
       type: persisted
       defaultQueueSize: <queue size>Gi
       volumeClaimTemplate:
         ...
         volumeSize: <volumeSize>Gi
     ```

Important points are as follows.

1. `defaultQueueSize` is optional. If not specified it defaults to 8 Gi.
2. `defaultQueueSize` must be specified in Gi, and must be an integer.
3. The minimum value for `defaultQueueSize` 8 Gi.
4. The maximum value for `defaultQueueSize` 100 Gi.
5. The `ingestion.queue.volumeClaimTemplate.volumeSize` must be at least 30 Gi, the recommended and default value is 50 Gi.

Offload to third-party systems

Offload your API event data for storage on a third-party system.

The analytics event data that is sent from the gateway to analytics can be offloaded to a third-party system in real time. The third-party system can provide enhanced monitoring, alerting, storage, and analysis, in addition to what the built-in analytics subsystem provides. Multiple target systems are supported, and the data can be modified before offloading.

APIC supports offloading analytics data to the following third-party systems:

- HTTP endpoints
- OpenSearch
- Elasticsearch
- Apache Kafka
- Syslog servers

You can configure two offload targets that run in parallel. If you want to offload to more than two targets, you can append additional targets to your second offload target configuration.

If you do not need internal storage and want to use only the third-party system for working with your analytics data, consider disabling internal storage entirely as explained in Disable local storage.

  Checks to help determine the cause of offload failure.

Configuring offload on Kubernetes and Red Hat OpenShift

Configure your analytics subsystem to offload API event data to a third-party system.

Procedure

1. Edit your analytics CR:

   ```
   kubectl edit a7s
   ```

   Note: If you are using the OpenShift® top-level CR deployment, edit your `APIConnectCluster` CR instead. Update the `spec.analytics` section.
2. Set `spec.external.offload` to true, and add the offload plug-in configuration:
   The following example shows an HTTP output plug-in:

   ```
   spec:
     external:
       offload:
         enabled: true
         output: |
           http {
             url => "https://example.com"
             http_method => "post"
             ssl_verification_mode => "none"
             id => "API Connect analytics event data"
           }
   ```

   In this example, the URL points to an HTTPS endpoint, but verification of the endpoint's server certificate is disabled by setting `ssl_verification_mode` to "none". If you want your analytics subsystem to verify the endpoint server certificate, then see Configuring offload server certificates on Kubernetes and Red Hat OpenShift.

   The `id` property is not mandatory, but it is recommended.

   For more information about the HTTP output plug-in configuration, see the Logstash HTTP plugin documentation.

3. Optional: Add a `filter` after the output plug-in configuration to modify data before it is sent to the offload target.
   The following example filter removes the `query_string` field:

   ```
   spec:
     external:
       offload:
         enabled: true
         output: |
           http {
             ...
           }
         filter: |
           ruby {
             remove_field => ["query_string"]
           }
   ```

   For information about modifying offloaded data, see Customizing data with ingestion filters.
4. Optional: To configure a second offload target, create a new `spec.external.offload2` section and add the configuration for this second target to this section.
   If you have three or more offload targets, then you can put multiple configurations in `spec.external.offload2`. For example:

   ```
   spec:
     external:
      offload:
         enabled: true
         output: |
           http {
             url => "https://target1.com"
             ...
           }
       offload2:
         enabled: true
         output: |
           http {
             url => "https://target2.com"
             ...
           }
         output: |
   ```

```
      http {
        url => "https://target3.com"
        ...
    }
```

Note: Multiple offload targets that are defined in `spec.external.offload2` are run in series. If offload to the first target in `offload2` fails, then subsequent offloads are not run. Define your most important offload target first.

5. If you want to offload API events or audit events selectively, use the offload filters as follows:
   Note: If API Connect is configured to send audit events to a registered analytics service and if offload filters are not used, the default offload includes both API events and audit events. When filter is used to offload a specific event, the offload includes only that event and all other events are discarded.
   a. To offload only API events, add a `filter` after the output plug-in configuration as in the following example:

```
filter: |
  if "apicapievent" not in [tags] {
    drop {}
  }
```

   b. To offload only audit events, add a `filter` after the output plug-in configuration as in the following example:

```
filter: |
  if "audit" not in [tags] {
    drop {}
  }
```

6. Save the changes to your analytics CR. The ingestion pods restart automatically.
7. Update your analytics subsystem infrastructure backup with your updated analytics CR. See Backup, restore, and disaster recovery.

- **Configuring offload server certificates on Kubernetes and Red Hat OpenShift**
  Configure your analytics subsystem to trust your offload endpoint.
- **Configuring offload client certificates on Kubernetes and Red Hat OpenShift**
  Configuring client keys for analytics offload.

Configuring offload server certificates on Kubernetes and Red Hat OpenShift

Configure your analytics subsystem to trust your offload endpoint.

Before you begin

You must have the offload target's server certificate in either of these formats:

- Base64 encoded `pem` file.
- JKS file. If you are using a JKS file, encode the contents in Base64:

```
cat <JKS certificate filename> | base64
```

  Note: IBM® API Connect does not support .p12 format certificates for analytics. It supports only `PEM` and `JKS` certificate formats.

About this task

The ingestion pod of your analytics subsystem sends your API event data to your offload target. If your offload target uses TLS, then your ingestion pod must be configured to trust the offload target. The steps in this procedure insert the server certificate in the ingestion pod's offload certificates directory, so that the ingestion pod can validate the certificate that it receives from the offload endpoint.

Procedure

1. Create a file called analytics_offload_certificates.yaml, and paste in the following contents:
   - If you are using a JKS file, then in the `data` section of the secret, paste the encoded JKS string as shown:

```
apiVersion: v1
kind: Secret
metadata:
  name: offload-certificates
data:
  keystore.jks: "<base64 encoded JKS string>"
```

   - If you are using a PEM file, then in the `stringData.cacert` section paste the contents of the PEM file.

```
apiVersion: v1
kind: Secret
metadata:
  name: offload-certificates
stringData:
  cacert: |-
    -----BEGIN CERTIFICATE-----
    MIIDIDCCAomgAwIBAgIENd70zzANBgkqhkiG9w0BAQUFADBOMQswCQYDVQQGEwJVUzEQMA4GA1UE
    ChMHRXF1aWZheDEtMCsGA1UECxMkRXF1aWZheCBTZWN1cmUgQ2VydGlmaWNhdGUgQXV0aG9yaXR5

    BIZCe/zuf6IWUrVnZ9NA2zsmWLIodz2uFHdh1voqZiegDfqnc1zqcPGUIWVEX/r87yloqaKHee95
    70+sB3c4
    -----END CERTIFICATE-----
```

Note: If you have multiple offload targets, then add the certificates for each target with a unique name. For example,

```
stringData:
  certname_target1: |-
    -----BEGIN CERTIFICATE-----
    ...
  certname_target2: |-
    -----BEGIN CERTIFICATE-----
    ...
```

2. Create the `offload-secret` in your analytics namespace from the analytics_offload_certificates.yaml file.

   ```
   kubectl -n <namespace> apply -f analytics_offload_certificates.yaml
   ```

   Verify that the `offload-secret` was created:

   ```
   kubectl -n <namespace> get secrets
   ```

3. If the output plug-in you are configuring supports the use of an offload-secret and you plan to use a password-protected keystore to store the CA certificate for the target offload server, create a Kubernetes secret to securely store the keystore's password:

   ```
   kubectl -n <namespace> create secret generic offload-credentials --from-literal=keystore_password='<KeystorePassword>'
   ```

4. Edit your analytics CR:

   ```
   kubectl edit a7s
   ```

   Note: If you are using the OpenShift® top-level CR deployment, edit your `APIConnectCluster` CR instead. Update the `spec.analytics` section.
5. Add the new property `spec.external.offload.secretName`, and set it to `offload-secret` (the secret you created in step 2).

   ```
   offload:
     enabled: true
     secretName: offload-secret
     output: |
       ...
   ```

   When your ingestion pod restarts, it copies the contents of the offload-secret into its /etc/velox/external_certs/offload directory.

   If you want to use a password-protected keystore, also include the property `spec.offload.passwordSecretName` and set it to offload-credentials (the secret you created in step 3):

   ```
   offload:
     enabled: true
     secretName: offload-secret
     passwordSecretName: offload-credentials
     output: |
       ...
   ```

6. Update your plug-in properties to include the path to the server certificate. The property name for the endpoint server certificate depends on your output target. For HTTP the property name is `ssl_certificate_authorities`. Consult the Logstash documentation to confirm the property name that is used by other plug-in types such as Syslog and Elasticsearch.
   Example HTTP output plug-in:

   ```
   ...
         output: |
           http {
             url => "https://example.com"
             http_method => "post"
             id => "API Connect analytics event data"
             ssl_certificate_authorities => "/etc/velox/external_certs/offload/<certname>"
           }
   ```

   where *<certname>* is the name that you specified in the analytics_offload_certificates.yaml file in step 1, either `cacert` or `keystore.jks` depending on the format of certificate used.
   If you want to use a password-protected keystore, configure the relevant properties of your wanted plug-in type to point to the keystore location and password.
   Example HTTP output plug-in:

   ```
   ...
         output: |
           http {
             url => "https://example.com"
             http_method => "post"
             id => "API Connect analytics event data"
             ssl_truststore_password => "${keystore_password}"
             ssl_truststore_path => "/etc/velox/external_certs/offload/keystore.jks"
           }
   ```

7. Save the updated analytics CR.
   When you save the updated CR, your ingestion pod restarts itself automatically and detects the new `secretName` in the CR. On startup, the ingestion pod copies the certificate from the specified `secretName` to its /etc/velox/external_certs/offload directory. You can verify that the certificate was successfully imported with:

   ```
   kubectl exec -ti <ingestion pod> -- bash -ic "ls /etc/velox/external_certs/offload"
   ```

   This command should return the certificate name that you specified in the analytics_offload_certificates.yaml file, either `cacert` or `keystore.jks` depending on the format of certificate used.

When your ingestion pod communicates with your HTTPS endpoint, it verifies the server certificate that the endpoint returns against the certificate that is stored in /etc/velox/external_certs/offload.

8. Make sure that you take a backup of your offload secret and your updated analytics CR. For more information about backups, see Backup, restore, and disaster recovery

Configuring offload client certificates on Kubernetes and OpenShift®

Configuring client keys for analytics offload.

The topic Configuring offload server certificates on Kubernetes and Red Hat OpenShift covers how to configure your ingestion pod to trust your offload endpoint server certificate. This documentS covers how to configure mTLS client certificates to be used when your ingestion pod communicates with the offload endpoint.

To configure client certificates, follow the same steps as Configuring offload server certificates on Kubernetes and Red Hat OpenShift, but add your client certificate and key to the analytics_offload_certificates.yaml file.

For example:

```
apiVersion: v1
kind: Secret
metadata:
  name: offload-certificates
stringData:
  cacert: |-
    -----BEGIN CERTIFICATE-----
    ...
  clientcert: |-
    -----BEGIN CERTIFICATE-----
    ...
  clientkey: |-
    -----BEGIN CERTIFICATE-----
    ...
```

All certificates added to the `offload-certificates` secret are created as individual files in the ingestion pod's /etc/velox/external_certs/offload directory. You can confirm that the certificate files were created with this command:

```
kubectl exec -ti <ingestion pod> -- bash -ic "ls /etc/velox/external_certs/offload"
```

In this example, the command output that is returned shows the three certificate files corresponding to the ones specified in analytics_offload_certificates.yaml:

```
cacert  clientcert  client
```

Note: If you have multiple offload targets, then add the certificates for each target with a unique name. For example,
Update the offload plug-in configuration in your analytics CR to reference the certificates in /etc/velox/external_certs/offload as required.

Example HTTP plug-in that specifies client certificates:

```
  external:
    offload:
      enabled: true
      output: |
        http {
          url => "https://example.com"
          http_method => "post"
          ssl_certificate_authorities => "/etc/velox/external_certs/offload/cacert"
          ssl_certificate => "/etc/velox/external_certs/offload/clientcert"
          ssl_key => "/etc/velox/external_certs/offload/clientkey"
          id => "API Connect analytics event data"
        }
```

For other plug-in types the TLS property names might differ, check the Logstash documentation.
Important: After updating your offload configuration, take a new analytics infrastructure configuration backup to ensure that you have backups of your analytics_offload_certificates.yaml file, your offload secret, and your analytics CR. See Backup, restore, and disaster recovery.

Sample output plug-ins for offloading data

Review sample output plug-ins to see how to code your own plug-ins for offloading data from API Connect analytics.

For complete details of output plug-in syntax, see the Logstash output plugins documentation.

HTTP

Example HTTP output plug-in:

```
http {
   url => "example.com"
   http_method => "post"
   format => "json"
   content_type => "application/json"
   headers => {
      "x-acme-index" => "8"
      "x-acme-key" => "0d5d259f-b8c5-4398-9e58-77b05be67037"
   }
```

```
   id => "offload_http"
}
```

Example HTTP output plug-in that references a custom certificate for accessing the third-party endpoint:

```
http {
   url => "https://example.com:443"
   http_method => "post"
   format => "json"
   content_type => "application/json"
   headers => {
      "x-acme-index" => "8"
      "x-acme-key" => "0d5d259f-b8c5-4398-9e58-77b05be67037"
   }
   id => "offload_http"
   ssl_certificate_authorities => "/etc/velox/external_certs/offload/cacert"
}
```

Note: Ensure that the endpoint, which receives the offload data, is able to handle the raw JSON data.
For more information about offloading to HTTP, refer to the HTTP output plugin documentation.

Elasticsearch

To configure data offload to an Elasticsearch cluster, you must specify the following properties:

- One or more server Elasticsearch server URLs.
- A dynamically configured name to define how indexes are created.
- The number of primary shards for storing the indexed documents.
- The number of replica shards for redundancy.
- Server authentication credentials (if requried).

The naming syntax that you specify for your indices determines how many indexes are created and how they are characterized. For example, you can define indices that are created based on a date pattern, or indices that are created to store data by provider organization or by API name.

Example Elasticsearch output plug-in:

```
elasticsearch {
      hosts => "https://example.com:443"
      index => "apiconnect"
      ssl  => true
      cacert => "/etc/velox/external_certs/offload/cacert"
}
```

For more information about offloading to Elasticsearch, refer to the Elasticsearch output plugin documentation.

Apache Kafka

To configure data offload to a Kafka cluster, provide host and port connection details for one or more servers, and the name of the Kafka topic. To be able to identify API Connect data, include the string identifier **id**.

Example Kafka output plug-in:

```
kafka {
      topic_id => "api_events"
      bootstrap_servers => "example.com:9093"
      codec => "json"
      id => "apic_kafka_offload"
      ssl_truststore_location => "/usr/share/logstash/jdk/lib/security/cacerts"
      ssl_truststore_password => "changeit"
      ssl_truststore_type => "JKS"
      security_protocol => SSL
}
```

You can configure Kafka with an external certificate and a keytab file. The following example shows how to set up Kafka offload with Kerberos authentication to secure data transmission to the Kafka topic.

```
    kafka {
    topic_id => "api_events"
    bootstrap_servers => "example.com:9093"
    id => "kafka_offload"
    kerberos_config => {
    keytab => "<keytab_file>"
    principal => "<kerberos_principal>"
    service_name => "kafka"
      }
    }
```

Each field label represents the following:

- kerberos_config: Contains the Kerberos authentication settings
- keytab: Path to the Kerberos keytab file
- principal: The Kerberos principal name used for authentication
- service_name: Service name for Kerberos

For more information on offloading to Apache Kafka, refer to the Kafka output plugin documentation.

Syslog

To configure data offload to Syslog, you must provide host and port connection details for the server.

Restriction: Syslog does not support the use of chained client certificates for TLS profiles.
Example Syslog output plug-in:

```
syslog {
  host => "example.com"
  port => 601
  protocol => "ssl-tcp"
  id => "offload_syslog"
  appname => "apiconnect"
  msgid => "%{org_id}"
  facility => "user-level"
  severity => "informational"
  codec => "json"
  ssl_cacert => "/etc/velox/external_certs/offload/cacert"
}
```

Attention: Due to a third-party issue with Logstash, most of the facility values are not set correctly on the offload server. As a temporary workaround, set the facility to "user-level" to ensure that the corresponding value is correctly sent to the offload server. When Logstash corrects this problem, you must update the offload configuration to change the value to a more appropriate setting.
For more information about offloading to Syslog, refer to the Syslog output plugin documentation.

OpenSearch

To configure data offload to OpenSearch, see the Ship to OpenSearch documentation.

Noname

To configure data offload to Noname, see the Noname documentation.

Example Noname offload plug-in:

```
http {
  url => "https://<ENGINE_URL>/engine?structure=ibm-apiconnect"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  headers => ["x-nn-source-index", "<INDEX>", "x-nn-source-key", "<KEY>"]
  id => "noname-offload"
  ssl_certificate_authorities => "/etc/velox/external_certs/offload/cacert"
}
```

Combining offload configuration with filters

The following examples show how to use filters to control what data is offloaded.

Offload events from `catalog1` only:

```
   offload:
     enabled: true
     if  [catalog_name] == "catalog1" {
          http {
            url => "http://offloadhost.example.com/offload"
            http_method => "post"
            codec => "json"
            content_type => "application/json"
            id => "offload_http"
           }
        }
```

Offload to different locations based on catalog name:

```
offload:
  enabled: true
  output: |
    if  [catalog_name] == "catalog1" {
      http {
        url => "http://offloadhost.example.com /offload1"
        http_method => "post"
        codec => "json"
        content_type => "application/json"
        id => "offload1_http"
      }
    }
    else if  [catalog_name] == "catalog2" {
      http {
        url => "http://offloadhost2.example.com /offload2"
        http_method => "post"
        codec => "json"
        content_type => "application/json"
        id => "offload2_http"
      }
    }
```

Use the catalog name as a variable in the offload location:

```
 offload:
   enabled: true
   http {
```

```
    url => "http://offloadhost.example.com /%{[catalog_name]}"
    http_method => "post"
    codec => "json"
    content_type => "application/json"
    id => "offload_http"
  }
```

Do not offload events from `apic` and `sandbox` catalogs:

```
offload:
  enabled: true
  if  [catalog_name] !~ /sandbox|apic/ {
    http {
      url => "http://offloadhost.example.com /%{[catalog_name]}"
      http_method => "post"
      codec => "json"
      content_type => "application/json"
      id => "offload_http"
    }
  }
```

Using offloaded analytics data to train AI models

How to use API Connect analytics data to train AI models.

API Connect analytics holds full information on all of your API events. This information can prove invaluable in training AI models by using machine learning. Possible use cases include training data for automated tests or for security anomaly detection.

IBM Cloud Pak® for Data (CP4D) includes the means to train AI models with data from various data sources. It is not possible for CP4D to pull data directly from API Connect's internal analytics database because the database is secured with no external access. However, you can offload your analytics data to an external database, and then configure CP4D to load data from that external database. You can use any external database that both API Connect analytics offload and CP4D support. The simplest option might be an external ELK stack (Elasticsearch Logstash Kibana). A list of supported data sources for CP4D can be found here: https://www.ibm.com/docs/en/cloud-paks/cp-data/latest?topic=data-supported-sources.

Documentation on how to configure Cloud Pak for Data to access Elasticsearch can be found here: https://www.ibm.com/docs/en/cloud-paks/cp-data/latest?topic=catalogs-elasticsearch-connection.

When your analytics data is offloaded to an external database, you can use it to train your AI model. Here is an example of how to create and train an AI model in CP4D using IBM Watson® Machine Learning: https://www.ibm.com/docs/en/cloud-paks/cp-data/latest?topic=deploying-managing-ai-assets.

Troubleshooting offload

Checks to help determine the cause of offload failure.

- Check the ingestion pod logs for error messages that are related to offload.
  - Kubernetes, Red Hat® OpenShift®, and Cloud Pak for Integration:

    ```
    kubectl -n <namespace> logs <analytics ingestion pod name>
    ```

  A common problem is TLS handshaking errors, such as untrusted or expired certificates.
- Check logs on your third-party system.
- Verify that the specified URL or the host and port values for the target system are accurate.
- Verify that the server or cluster of servers in the target system are running and reachable. If applicable, also verify that firewall settings are not causing connection problems.
- If offloading data to an Elasticsearch or Kafka target, verify that your configuration settings are valid; for example, the user credentials for authenticating to Elasticsearch or the Kafka topic name.

Replicating analytics data to a 2DCDR warm-standby data center

If you have a two data center warm-standby deployment, you can configure the analytics subsystem in your active data center to offload incoming API event records to the analytics subsystem in your warm-standby data center.

About this task

If you have a two data center disaster recovery deployment, with an analytics subsystem that is deployed in each data center, then you can replicate the API event data between the data centers.

The offload feature is used for the API event data replication. In 2DCDR deployments, since both data centers have the same contents in their management subsystem databases, the analytics data from all data centers can be seen from the management UIs in either data center.

Analytics two data center replication key points:

- Only API event data that is generated by API Gateways can be replicated. Data from V5 compatible gateways cannot be replicated.
- The feature requires additional CPU, RAM, and storage space. Use dedicated storage and horizontal scaling to meet the resource requirements.
- The limitation of no analytics data available in the portal sites still exists with this configuration.

The steps in this task refer to your two data centers as DC1 (the active data center) and DC2 (the standby data center).

Note: For OpenShift users - The example steps in this document use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR (`APIConnectCluster`), make sure that the `spec.gateway` section is included. If it is not included already, you must add the `spec.gateway` section before adding the required property within it.

Procedure

1. In DC1, identify the analytics ingestion client secret, by running this command in the management subsystem namespace:

   ```
   kubectl -n <management namespace> get secrets | grep "\-client"
   ```

   The secret name is either `analytics-ingestion-client` or `a7s-ing-client`, possibly prefixed with other text.

2. In DC1, view the contents of the analytics ingestion client secret:

   ```
   kubectl -n <management namespace> get secret -o yaml <analytics ingestion secret>
   ```

   The output should look like this:

   ```
   apiVersion: v1
   data:
     ca.crt: <ca.crt encoded certificate string>
     tls.crt: <tls.crt ncoded certificate string>
     tls.key: <tls.key encoded certificate string>
   ...
   ```

3. In DC1, convert the `tls.key` value to PKCS #8 format.
   a. Base64 decode `tls.key`, and copy to a file called tls.key:

      ```
      echo <tls.key encoded certificate string> | base64 --decode > tls.key
      ```

   b. Convert the tls.key file contents to PKCS #8, and Base64 encode it to a file called converted_tls.key:

      ```
      openssl pkcs8 -topk8 -in tls.key -nocrypt | base64 -w 0 > converted_tls.key
      ```

4. In DC2, create or update your analytics_offload_certificates.yaml file, using the DC1 certificate strings and TLS key that you obtained in steps 2 and 3.
   If you did not previously configure analytics offload targets, then create a new file that is called analytics_offload_certificates.yaml and paste in the following contents:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     name: offload-certificates
   data:
     replication_ca.crt: <ca.crt string from ingestion secret>
     replication_tls.crt: <tls.crt string from ingestion secret>
     replication_tls.key: <converted_tls.key file contents>
   ```

   If you already have other offload targets configured, then edit your existing analytics_offload_certificates.yaml file and add the certificate strings from the previous step under the data section:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     name: offload-certificates
   data:
     replication_ca.crt: <ca.crt string from ingestion secret>
     replication_tls.crt: <tls.crt string from ingestion secret>
     replication_tls.key: <converted_tls.key file contents>
     existing_offload_target1_ca.crt: hGywkdWE...
     existing_offload_target1_tls.crt: kY7fW..
     ...
   ...
   ```

5. In DC2, apply the analytics_offload_certificates.yaml file to create the `offload-certificates` secret:

   ```
   kubectl -n <analytics namespace> apply -f analytics_offload_certificates.yaml
   ```

   A new secret that is called `offload-certificates` is created. Verify that this secret exists by running:

   ```
   kubectl -n <analytics namespace> get secrets
   ```

   If you previously created offload targets, then this secret is updated.

6. In DC2, identify the analytics ingestion client secret, by running this command in the management subsystem namespace:

   ```
   kubectl -n <management namespace> get secrets | grep "\-client"
   ```

   The secret name is either `analytics-ingestion-client` or `a7s-ing-client`, possibly prefixed with other text.

7. In DC2, view the contents of the analytics ingestion client secret:

   ```
   kubectl -n <management namespace> get secret -o yaml <analytics ingestion secret>
   ```

   The output should look like this:

   ```
   apiVersion: v1
   data:
     ca.crt: <ca.crt encoded certificate string>
     tls.crt: <tls.crt ncoded certificate string>
   ```

```
  tls.key: <tls.key encoded certificate string>
...
```

8. In DC2, convert the `tls.key` value to PKCS #8 format.
   a. Base64 decode `tls.key`, and copy to a file called tls.key:

   ```
   echo <tls.key encoded certificate string> | base64 --decode > tls.key
   ```

   b. Convert the tls.key file contents to PKCS #8, and Base64 encode it to a file called converted_tls.key:

   ```
   openssl pkcs8 -topk8 -in tls.key -nocrypt | base64 -w 0 > converted_tls.key
   ```

9. In DC1, create or update your analytics_offload_certificates.yaml file, by using the DC2 certificate strings and TLS key that you obtained in steps 7 and 8.
   If you did not previously configure analytics offload targets, then create a new file that is called analytics_offload_certificates.yaml and paste in the following contents:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     name: offload-certificates
   data:
     replication_ca.crt: <ca.crt string from ingestion secret>
     replication_tls.crt: <tls.crt string from ingestion secret>
     replication_tls.key: <converted_tls.key file contents>
   ```

   If you already have other offload targets configured, then edit your existing analytics_offload_certificates.yaml file and add the certificate strings from the previous step under the data section:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     name: offload-certificates
   data:
     replication_ca.crt: <ca.crt string from ingestion secret>
     replication_tls.crt: <tls.crt string from ingestion secret>
     replication_tls.key: <converted_tls.key file contents>
     existing_offload_target1_ca.crt: hGywkdWE...
     existing_offload_target1_tls.crt: kY7fW..
     ...
   ...
   ```

10. In DC1, apply the analytics_offload_certificates.yaml file to create the `offload-certificates` secret:

    ```
    kubectl -n <analytics namespace> apply -f analytics_offload_certificates.yaml
    ```

    A new secret that is called `offload-certificates` is created. Verify that this secret exists by running:

    ```
    kubectl -n <analytics namespace> get secrets
    ```

    If you previously created offload targets, then this secret is updated.

11. In DC1, edit the analytics CR, and set the `spec.external.offload` section as shown:

    ```
    kubectl edit a7s
    ```

    ```
    external:
        offload:
          enabled: true
          output: |
            if  [gateway_service_name] == "<DC1 gateway service name>" {
              http {
                url => "https://<DC2 analytics ingestion endpoint>/ingestion"
                http_method => "post"
                codec => "json"
                content_type => "application/json"
                id => "offload1_http"
                ssl_certificate_authorities => "/etc/velox/external_certs/offload/replication_ca.crt"
                ssl_certificate => "/etc/velox/external_certs/offload/replication_tls.crt"
                ssl_key => "/etc/velox/external_certs/offload/replication_tls.key"
              }
            }
          secretName: offload-certificates
    ```

    Where,
    - *<DC1 gateway service name>* is the name of the gateway service in DC1.
    - *<DC2 analytics ingestion endpoint>* is the analytics ingestion endpoint of the analytics service in DC2.

    If you have multiple offload targets, then see Multiple offload targets.

    After you save the updated the CR, the analytics ingestion pod restarts, and new API events are sent to DC2.
    Note: If you later return to edit properties in the `external.offload.output` section, you might need to restart the ingestion pod manually:

    ```
    kubectl delete pod <analytics ingestion pod>
    ```

12. In DC2, edit the analytics CR, and set the `spec.external.offload` section as shown:

    ```
    kubectl edit a7s
    ```

    ```
    external:
        offload:
          enabled: true
          output: |
            if  [gateway_service_name] == "<DC2 gateway service name>" {
              http {
                url => "https://<DC1 analytics ingestion endpoint>/ingestion"
    ```

```
            http_method => "post"
            codec => "json"
            content_type => "application/json"
            id => "offload1_http"
            ssl_certificate_authorities => "/etc/velox/external_certs/offload/replication_ca.crt"
            ssl_certificate => "/etc/velox/external_certs/offload/replication_tls.crt"
            ssl_key => "/etc/velox/external_certs/offload/replication_tls.key"
          }
        }
      secretName: offload-certificates
```

Where,

- *<DC2 gateway service name>* is the name of the gateway service in DC2.
- *<DC1 analytics ingestion endpoint>* is the analytics ingestion endpoint of the analytics service in DC1.

After saving the updated the CR, the analytics ingestion pod restarts, and new API events are sent to DC1.

13. Confirm that replication is working by making a test API call to your DC2 gateway service and confirming that you see the event in the Discover view of the API Manager UI in DC1.

    To verify replication from DC1 to DC2, you must complete a failover of the management subsystem so that you can access the API Manager UI in DC2 and see data from the analytics subsystem in DC2.

If API events are not replicating between your data centers, then check the ingestion pod logs for error messages when API calls are made:

```
kubectl logs <analytics ingestion pod>
```

Disable local storage

If you are offloading you API event data to a third-party system, you can disable local storage to reduce subsystem resource requirements.

The analytics subsystem provides a complete solution for routing, storing, and viewing the analytics data. However, you might not need the internal storage and viewing solution if you are using a third-party system for data offloading. In this scenario, you can greatly reduce your CPU and memory costs by disabling the internal storage and viewing components.

Important:
If you disable local storage, the analytics views in your API Connect UIs remain accessible, but are empty.

Configure local storage disablement before installation. It is not possible to disable or re-enable internal storage after installation.

You can enable offload of analytics data to third-party systems after installation.

Disabling local storage on Kubernetes, Red Hat OpenShift and Cloud Pak for Integration

When you disable internal storage for analytics data, the following microservices are disabled:

- `osinit`
- `storage`

During the API Connect installation process, set `storage.enabled` to false in the CR:

```
storage:
  enabled: false
```

The relevant installation pages for each platform are:

- Kubernetes analytics install
- OpenShift® analytics subsystem install
- OpenShift top-level CR install.
- Cloud Pak for Integration: Use the YAML tab to edit the CR before installation, see *API management deployment* in https://www.ibm.com/docs/en/cloud-paks/cp-integration.

Shutting down the analytics subsystem

Disable the analytics service and shutdown the analytics subsystem.

About this task

This operation requires the use of the analytics CLI.

Disabling the analytics subsystem stops the collection and storage of data and makes the subsystem inaccessible.

Procedure

1. Backup your analytics data as explained in Backup, restore, and disaster recovery.
2. Setup the toolkit CLI so you can run analytics CLI operations: Analytics CLI.
3. Optional: Disable shard allocation.
   Disable shard allocation to prevent new shards from being created for replication when a node is not available. For more information about shards, see OpenSearch nodes, indices, shards, and replicas.

a. Create a JSON file called **analytics_persistent_settings.json** and insert the contents:

```
{"persistent":{"cluster.routing.allocation.enable":"none"}}
```

b. Run the following analytics CLI command:

```
apic --mode analytics clustermgmt:putSettings --server <platform api endpoint> --analytics-service <analytics service name> --format json analytics_persistent_settings.json
```

where:

- ***<platform api endpoint>*** is the platform API endpoint.
- ***<analytics service name>*** is the name of analytics service as configured in the Cloud Manager UI.

Expected output:

```
{"acknowledged":true,"persistent":{"cluster":{"routing":{"allocation":{"enable":"none"}}}},"transient":{}}
```

4. Optional: Run a synced flush of storage.
The synced flush operation flushes all current index operations synchronously and writes all in-flight transactions to disk.

```
apic --mode analytics clustermgmt:postFlush --server <platform api endpoint> --analytics-service <analytics service name> --format json
```

where,

- ***<platform api endpoint>*** is the platform API endpoint.
- ***<analytics service name>*** is the name of analytics service as configured in the Cloud Manager UI.

When you flush storage, the response looks like the following example, with the *failed* count set to zero:

```
{
    "_shards": {
        "total": 16,
        "successful": 6,
        "failed": 0
    }
}
```

This operation occasionally fails, but it is safe to rerun it multiple times until it passes and the "failed" count is zero.

5. Unassociate the analytics service from all gateway services.
   a. In Cloud Manager, click Topology.
   b. In the section for the Availability Zone that contains the analytics service, locate the Gateway service that the analytics service is associated with.
   c. Click ⋮ and select Unassociate.

For more information, see Associating an analytics service with a gateway service.

6. Unregister the analytics service from Cloud Manager:
   a. In Cloud Manager, click Topology.
   b. In the section for the Availability Zone that contains the analytics service, locate the analytics service and click Delete.

For more information, see Registering an analytics service.

7. **Kubernetes, OpenShift®, and Cloud Pak for Integration only** - Set replicas to zero for the analytics pods by editing the Deployments and StatefulSets that manage them: **director**, **mtls-gw**, **ingestion**, and **storage**.

```
kubectl -n <namespace> edit deploy analytics-director
kubectl -n <namespace> edit deploy analytics-mtls-gw
kubectl -n <namespace> edit sts analytics-ingestion
kubectl -n <namespace> edit sts analytics-storage
```

Note: The Deployments and StatefulSets on Cloud Pak for Integration and Red Hat OpenShift with the top-level CR have the name format *<instance name>-a7s-...*
Set *replicas* to zero.

```
spec:
  ...
  replicas: 0
  ...
```

The analytics **director**, **mtls-gw**, **ingestion**, and **storage** pods all discontinued.

Reenabling the analytics subsystem

8. **Kubernetes, Red Hat OpenShift, and Cloud Pak for Integration only** - Repeat the step 7 in reverse and set the *replicas* value back to what it was before.
The pods all start:

```
kubectl get deploy -n <namespace>
analytics-director                      1/1     1            1           7h10m
analytics-mtls-gw                       1/1     1            1           7h6m

kubectl get sts -n <namespace>
analytics-ingestion   1/1     7h10m
analytics-storage     1/1     7h12m
```

9. Reregister the analytics service: Registering an analytics service.
10. Reassociate your analytics service with your gateways Associate new analytics service(s) with gateway(s).
11. Enable shard allocation by following these steps:
Note: If you did not disable shard allocation in step 3, skip this step.
    a. Create a JSON file called **analytics_persistent_settings.json** and insert the contents:

```
{"persistent":{"cluster.routing.allocation.enable":"all"}}
```

    b. Run the following analytics CLI command:

```
apic --mode analytics clustermgmt:putSettings --server <platform api endpoint> --analytics-service <analytics service name> --format json analytics_persistent_settings.json
```

where:

- *<platform api endpoint>* is the platform API endpoint.
- *<analytics service name>* is the name of analytics service as configured in the Cloud Manager UI.

When you enable shard allocation, the response looks like the following example:

```
{"acknowledged":true,"persistent":{"cluster":{"routing":{"allocation":{"enable":"all"}}}},"transient":{}}
```

Restarting analytics pods

How to restart the analytics pods in your API Connect deployment.

About this task

Certain scenarios might require you to restart your analytics subsystem pods. To restart your analytics pods, follow the steps in this document.

Procedure

1. Restart the analytics pods.
   - Kubernetes and Red Hat® OpenShift® - Run the following command.

     ```
     kubectl -n <namespace> delete pod -l app.kubernetes.io/instance=<analytics CR>
     ```

2. Verify that all analytics pods restart successfully.

   ```
   kubectl -n <namespace> get pods
   ```

   where, *<namespace>* is the namespace where the analytics subsystem is installed.

Enable Amazon SNS for Engagement

To enable Amazon SNS for Engagement, you must create the AWS client secret and reference the secret in the analytics custom resource YAML file.

About this task

To enable Amazon SNS for Engagement, complete the following steps.

Procedure

1. Create the AWS credentials secret.
   Run the following command to create a Kubernetes/OpenShift secret containing your AWS credentials:

   ```
   kubectl create secret generic <aws-creds-secret> \

     --from-literal=access_key_id=<aws_access_key_id> \

     --from-literal=secret_access_key=<aws_secret_access_key> \

     -n <namespace>
   ```

   Here,

   aws-creds-secret
   : The name for the secret

   aws_access_key_id
   : Your actual AWS IAM Access Key ID

   aws_secret_access_key
   : Your actual AWS IAM Secret Access Key

   namespace
   : The namespace where your Analytics CR is deployed

   Important: The keys must be named exactly as follows:
   - access_key_id
   - secret_access_key

   If you rename these keys, the integration will fail.
2. Reference the Secret in the Analytics CR.
   In your Analytics Custom Resource YAML, add the following entry under the `spec` header:

   ```
   spec:
             awsCredentialsSecret:
                secretName: <aws-creds-secret>
   ```

Replace *aws-creds-secret* with the exact name of the secret that you created in Step 1. The analytics service can now use the AWS credentials for accessing Amazon SNS.

Changing deployment profile

Change your deployment profile to switch between one replica and three replica deployments, or to change the computing resources available for your subsystem.

- **Changing deployment profile on Kubernetes and Red Hat OpenShift**
  Update your analytics CR to change your deployment profile.

Changing deployment profile on Kubernetes and Red Hat® OpenShift

Update your analytics CR to change your deployment profile.

Note: This document covers Kubernetes and OpenShift® individual subsystem installations. For other platforms, see the following documents.

- Changing deployment profile on Cloud Pak for Integration
- Changing deployment profile on OpenShift, top-level CR

Note: If you have a three replica profile, and want to change to one replica, you must first change your analytics configuration to shared storage. Dedicated storage is not supported on the one replica profile.

1. Verify that the subsystem is in `Running` state.

   ```
   kubectl -n <namespace> get a7s
   ```

2. Edit the analytics CR:

   ```
   kubectl -n <namespace> edit a7s
   ```

   Change `spec.profile` value to the new profile that you want to use: Analytics deployment profiles.

3. Monitor you analytics pods to confirm the expected number of replicas are running:

   ```
   kubectl -n <namespace> get pods
   ```

4. Verify that the subsystem is in `Running` state.

   ```
   kubectl -n <namespace> get a7s
   ```

Performance tuning with ingestion pipeline properties

Fine-tune your ingestion pipeline settings for optimal performance.

Table 1.

Field	Type	Default value	Description	Comments
`ingestion: pipelineWorkers`	4 <= integer <= 128	24	Number of pipeline workers.	More workers mean more CPU and memory requirements, but gives you the benefit of extra threads to pull data off the ingestion HTTP interface and process it for storage. Increasing the number of pipeline workers excessively results in diminishing returns. `pipelineWorkers` should usually be a multiple of the number of cores of your hardware. Adjust with caution.
`ingestion: pipelineBatchSize`	10 <= integer <= 10000	250	The batch size of a pipeline worker.	Pulling more or less data off the HTTP interface per worker can have benefits. Recommended values are `125`, `250`, and `500`. Increasing the value requires more memory.
`ingestion: pipelineBatchDelay`	10 <= integer <= 5000	50	The batch delay of a pipeline worker.	How long to wait for the batch size to fill before leaving the HTTP interface to process for storage. Having threads wait too long causes idle threads in your system; however, setting this value too low decreases performance. Adjust with caution.
`ingestion: configReloadAutomatic`	Boolean	True	Whether to automatically reload the pipeline on configuration changes.	Typically, when the underlying files for the pipeline are modified, the pipeline process automatically reloads and picks up the changes. However, in Kubernetes environments where the pipeline is mapped to ConfigMaps, this is unreliable. Ingestion pod restarts are required.
`ingestion: pipelineUnsafeShutdown`	Boolean	False	Whether to allow unsafe shutdown of the pipeline.	Typically, the pipeline attempts to empty all workers' batches before shutdown to prevent data loss. You might need to enable this setting if the pipeline is badly configured and refuses to respond to shut down requests (uncommon). Adjust with caution.

Customize your analytics data

How to customize the data stored in your API event records.

- **Activity log policy**
  Configure the activity log policy to manage the level of detail of the data stored in API events.
- **Customizing data with a gateway script or set-variable operation**
  Customize your API event records on the gateway before they are sent to your analytics subsystem.
- **Customizing data with ingestion filters**
  Customize you API event records as they are received from the gateway.

Activity log policy

Configure the activity log policy to manage the level of detail of the data stored in API events.

When you configure an API in the API Manager UI, you choose what data is stored in the API event records for calls to that API with the `activity log` property. The `activity log` property has separate settings for successful API calls, and for failed API calls. The activity log options are:

- none - API events are not logged.
- activity - Logs the API resource URI. `activity` is the default log setting for successful API calls.
- header - Logs the API resource URI and HTTP headers.
- payload - Logs API resource URI, HTTP headers, and request and response payloads. `payload` is the default log setting for failed API calls, since the response payload might have useful information on the cause of the failure.

Note:
If your gateway is configured to authenticate all API calls with an OAuth provider, the data that is related to the OAuth call is only included in the API event data when the OAuth call fails. Successful OAuth authentication is not recorded in the API event data.

Important: The maximum API event record size is 19 Mb. The analytics subsystem rejects any API event records that are larger than 19 Mb.

Defining log setting in the API Manager UI

1. In the API Manager UI Develop view, select the API that you want to work with. If you are not familiar with the API Manager UI Develop view, see Working with API definitions.
2. Select the Gateway tab, expand Gateway and portal settings, then select Activity Log.
3. Select Enabled, then select the preferred log setting for Success Content and Error Content:
   - none - API events are not logged.
   - activity - Logs the API resource URI. `activity` is the default log setting for successful API calls.
   - header - Logs the API resource URI and HTTP headers.
   - payload - Logs API resource URI, HTTP headers, and request and response payloads. `payload` is the default log setting for failed API calls, since the response payload might have useful information on the cause of the failure.
4. Click Save to save your changes.

Defining log setting in source for DataPower® API Gateway

Use the `activity-log` extension to configure your logging preferences.

```
activity-log:
  success-content: <success log setting: none, activity, header, payload>
  error-content: <failure log setting: none, activity, header, payload>
  enabled: <if activity logging is enabled: true or false>
```

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: <success log setting: none, activity, header, payload>
  error-content: <failure log setting: none, activity, header, payload>
  enabled: <if activity logging is enabled: true or false>
buffering: true
```

Example

No logging of successful calls, header logging for failed calls

```
activity-log:
    success-content: none
    error-content: header
    enabled: true
```

Disable activity logging

```
activity-log:
    enabled: false
```

Defining log setting in source for DataPower Gateway (v5 compatible)

The activity-log policy has the following format:

```
- activity-log:
  version: <version>
  title: <title>
  description: <description>
  content: <success log setting: none, activity, header, payload>
  error-content: <failure log setting: none, activity, header, payload>
```

where,

- *<version>* is the policy version number. Set version to 1.0.0.
- *<title>* is a title for the policy.
- *<description>* is a description for the policy.

You can apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
buffering: true
```

Examples:

Maintain default log behavior

Do not specify `content` or `error-content`:

```
- activity-log:
  version: 1.0.0
  title: default activity logging
```

No logging of successful calls, activity logging for failed calls

```
- activity-log:
  version: 1.0.0
  title: no logging for successful calls
  content: none
  error-content: activity
```

Customizing data with a gateway script or set-variable operation

Customize your API event records on the gateway before they are sent to your analytics subsystem.

Before you begin

Ensure that you are familiar with the API Manager UI, and working with API definitions.
Note: This feature is not available with DataPower® Gateway (v5 compatible).

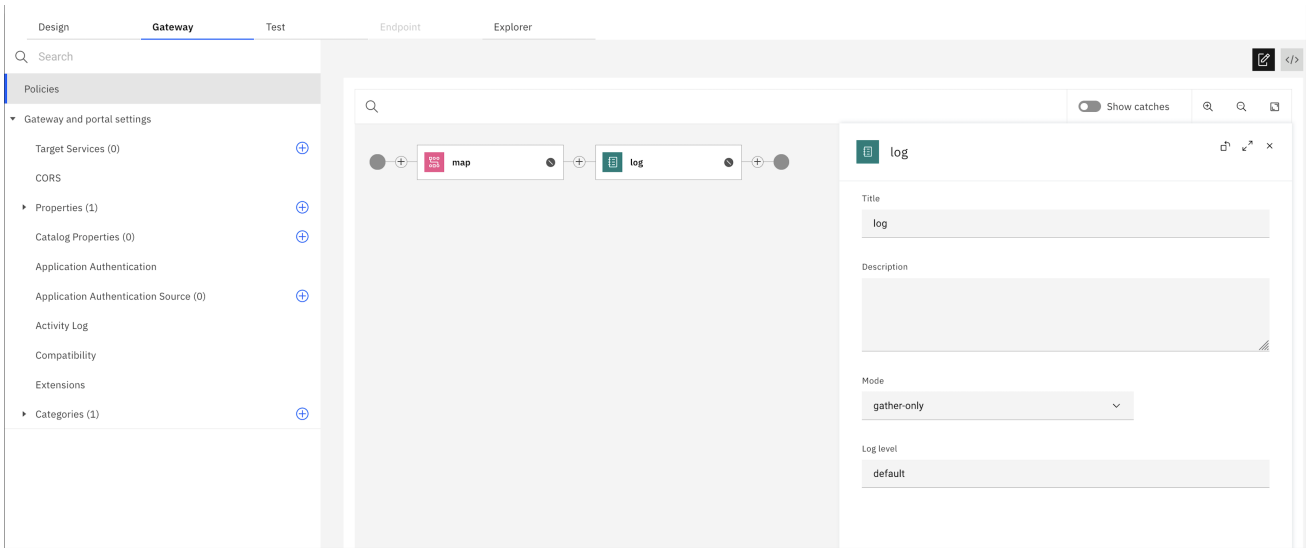
About this task

During API execution, the activity data is stored in the `log` context variable, which populates the API event record on completion of the API execution. For more information about `log` context variables, see API activity logging context variables.

The analytics subsystem stores analytics data as individual API event records. The API event record fields are documented here: API event record field reference. It is possible to customize the API event records for specific APIs. You can modify the contents of existing API event fields, and add new custom fields by using a gateway script or the `set-variable` operation.
Note: If you want to make updates to all incoming API event data, rather than specific APIs, you can use ingestion filters instead.

Procedure

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select New OpenAPI .
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the `info.version` property of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the `X-IBM-Client-Id` parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower API Gateway.
     - When CORS is enabled, the API Gateway runs the `cors` preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The `cors` preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.



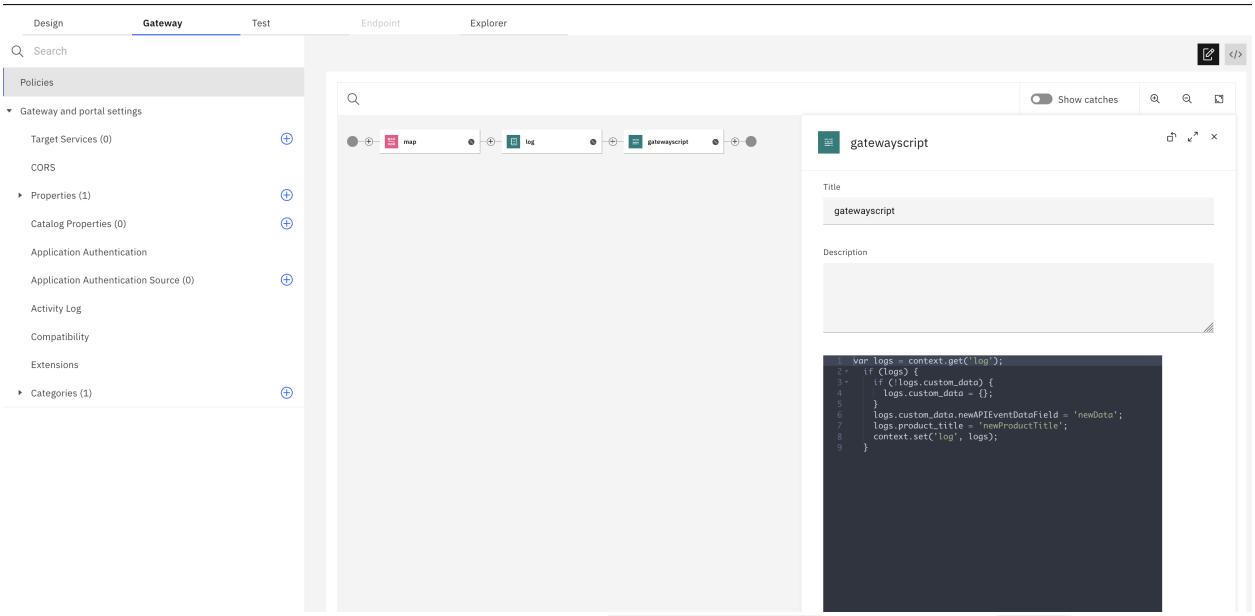
- For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.

6. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
7. To further configure your API, click Edit API. For details, see Editing an API definition.
8. Select the YAML source view </>. Replace the generated YAML with the following YAML and click Save:

```
swagger: '2.0'
info:
  title: Hello World
  x-ibm-name: hello-world-rest
  version: 1.0.0
schemes:
  - https
basePath: /hello-world
securityDefinitions:
  clientID:
    type: apiKey
    in: header
    name: X-IBM-Client-Id

x-ibm-configuration:
  phase: realized
  testable: true
  enforced: true
  properties:
    target-url:
      value: http://example.com/operation-name
      description: The URL of the target service
      encoded: false
  cors:
    enabled: true
  activity-log:
    enabled: true
    error-content: header
    success-content: activity
  application-authentication:
    certificate: false
  assembly:
    execute:
      - map:
          version: 2.0.0
          title: map
          inputs:
            name:
              schema:
                type: string
              variable: request.parameters.name
          outputs:
            response:
              schema:
                $ref: '#/definitions/Result'
              variable: message.body
          actions:
            - set: response.hello
              from: name
              value: '''Hello '' +$(name)'
    catch: []
    finally: []
  gateway: datapower-api-gateway
  categories:
    - /tests
  type: rest
definitions:
  Result:
    type: object
    additionalProperties: false
    properties:
      hello:
        type: string
paths:
  /hello:
    get:
      parameters:
        - name: name
          in: query
          required: false
          type: string
      responses:
        '200':
          description: OK Response
          schema:
            $ref: '#/definitions/Result'
    parameters: []
```

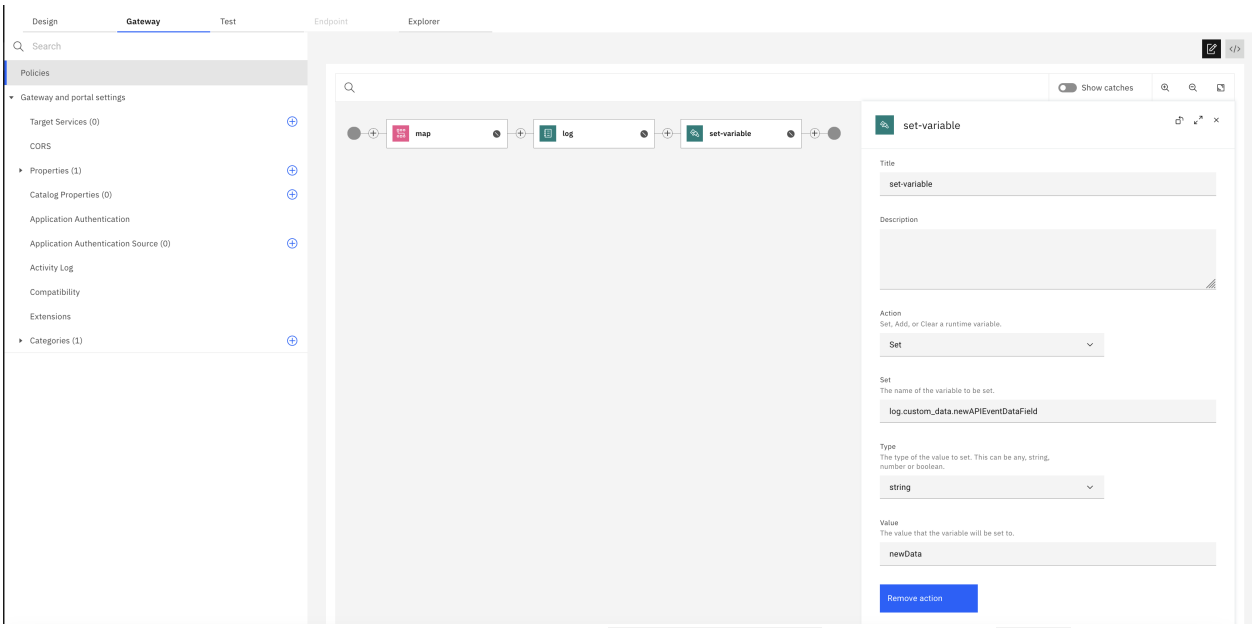
9. Click the Form icon to switch to the Form view and select the Gateway tab.
10. Ensure that Policies is selected.
11. On the canvas, click the plus icon ⊕ at the last position in the flow. The palette listing the available elements to build the assembly flow appears.
12. From the palette, add the Log policy element onto the canvas by clicking it. Set the log policy Mode drop-down to Gather-only. This step is so that the "log" context variable is populated, for use in the next step.



13. Modify API event data or add custom data either with a gateway script or by using the set-variable operation.

Gateway script method

Add a gateway script policy to the assembly flow and paste in the following script code:



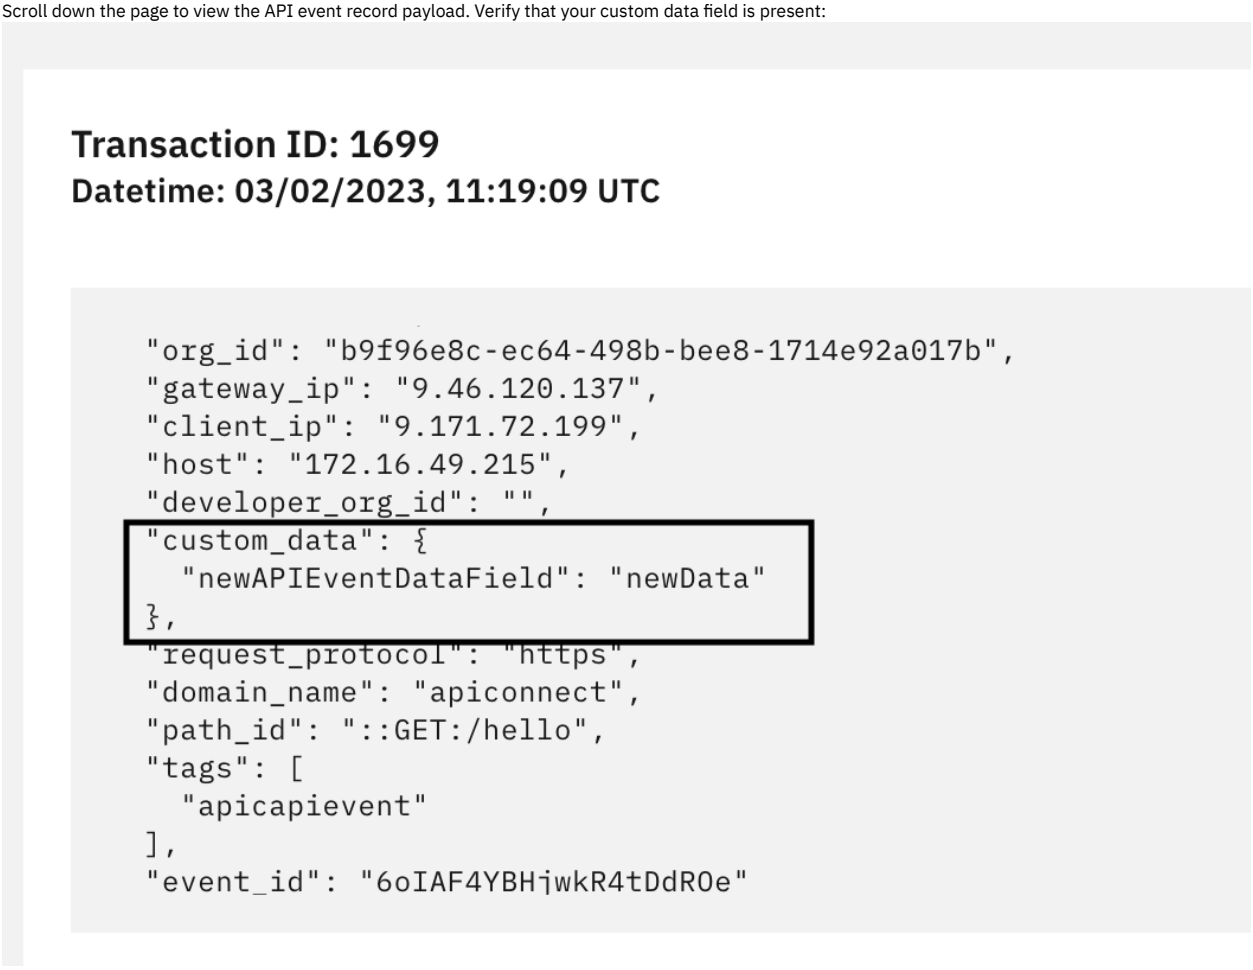
```
var logs = context.get('log');
  if (logs) {
    if (!logs.custom_data) {
      logs.custom_data = {};
    }
    logs.custom_data.newAPIEventDataField = 'newData';
    logs.product_title = 'newProductTitle';
    context.set('log', logs);
  }
```

In this example, the new field that is added to the API event record is called **`newAPIEventDataField`** and its value is set to **`newData`**. The value of the existing field **`product_title`** is changed to **`newProductTitle`**.

Set-variable method

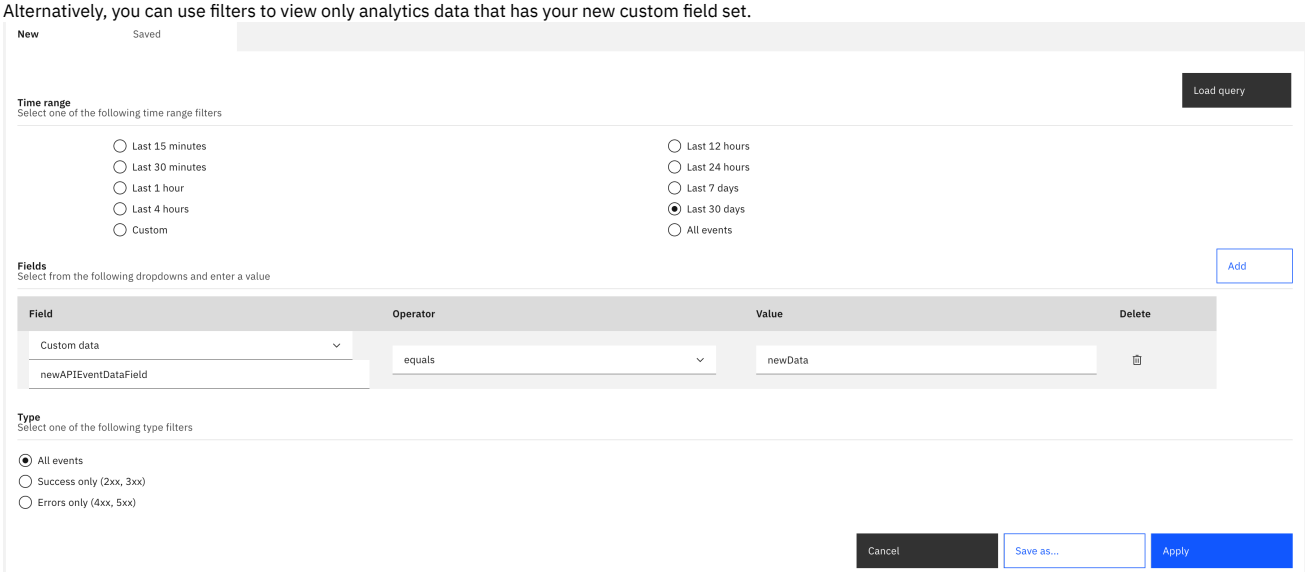
If you cannot or do not want to use a gateway script, then you can use a set-variable policy instead. Add a set-variable policy to the assembly flow, and set it as follows:

In this example, the new field that is added to the API event record is called **`newAPIEventDataField`** and its value is set to **`newData`**
The YAML code for set-variable is:



```
      - set-variable:
          version: 2.0.0
          title: set-variable
          actions:
            - set: log.custom_data.newAPIEventDataField
              value: newData
              type: string
            - set: log.product_title
              value: newProductTitle
              type: string
```

Warning: **`context.log.custom_data`** supports the addition of primitive typed values such as strings and integers, no limit is enforced on how many you can add, but adding too many does impact performance. Add data only to the **`context.log.custom_data`** object. Do not add data to **`context.log`**.



The field types cannot be changed. If you attempt to assign a value of the wrong type to a field, then the event record is lost. For example, if you define a custom field as an integer, and a particular API call results in a string being assigned to this variable, then the analytics database does not store the event record for that API call. If your APIs might return different types, then define the new **`custom_data`** type as a string and ensure that everything you assign to it is converted to a string before it is assigned.

14. Publish your new API to a catalog.
15. Make a test call to the API and verify that the new custom data is set. For more information see, Using the Test tab to debug your API.
    a. From the Analytics view, select Discover and click the API event record corresponding to your test call:

b. Scroll down the page to view the API event record payload. Verify that your custom data field is present:

16. Alternatively, you can use filters to view only analytics data that has your new custom field set.

17. To use new data with REST API calls, use the custom_data query parameter:

```
/cloud/events?custom_data[newAPIEventDataField]=newData
```

Customizing data with ingestion filters

Customize you API event records as they are received from the gateway.

Create ingestion filters to customize the analytics API event records as they are received from the gateway and before they are sent on to internal storage or offloaded to a third-party system. Filters enable you to add new fields, modify existing fields, or remove fields from the API event record. Filters are applied to all incoming API events, but you can include a conditional check in your filter syntax if you want a filter to apply to specific APIs only.

Ingestion filters use Logstash plug-ins. For more information about Logstash plug-ins, see the Logstash documentation.

All fields in the API event record are modifiable with ingestion filters, but to avoid problems you must adhere to the following restrictions:

- Do not modify the following fields:
  - org_id
  - catalog_id
  - space_id
  - developer_org_id
  - datetime
  - @timestamp
- Do not change the data type of existing fields. Create a new field that has the type you want and copy the contents to this field.
- If you want to sanitize data, it is more efficient to delete fields entirely than delete their contents.

To review all the fields in the API event record, see API event record field reference.

For examples of ingestion filters, see Example ingestion filters.

The steps for configuring ingestion filters depend on your platform:

- **Kubernetes and Red Hat OpenShift individual subsystem installations**
  Define ingestion filters to customize API event data before it is stored or offloaded.
- **Cloud Pak for Integration and OpenShift top-level CR**
  Define ingestion filters to customize API event data before it is stored or offloaded.

Kubernetes and OpenShift® individual subsystem installations

Define ingestion filters to customize API event data before it is stored or offloaded.

Procedure

1. Edit your `AnalyticsCluster` CR:

   ```
   kubectl -n <namespace> edit a7s
   ```

2. Filters for API events that are offloaded to a third-party system are defined in the `external.offload` section. Filters for API events that are stored in the API Connect OpenSearch database are defined in the `ingestion` section.

   Ingestion filters - for API event data stored by API Connect
   Add the filter definition to the `ingestion` section:

   ```
   ingestion:
     ...
     filter: |
       if [api_name] == "test-api" {
         mutate {
           remove_field => ["query_string"]
         }
       }
   ```

   In this example, a conditional filter is used to apply the change to API event records where the API name is `test-api`.

   Offload filters - for API event data that is sent to a third-party system.
   Add the filter definition to the `external.offload` section:

   ```
   external:
     offload:
       filter: |
         mutate {
           remove_field => ["query_string"]
         }
   ```

   In this example, no conditional filter is used; the change is applied to all APIs.

   For more examples, see Example ingestion filters.

3. Save the changes. Updates to filters take effect after approximately 30 seconds.

Cloud Pak for Integration and OpenShift® top-level CR

Define ingestion filters to customize API event data before it is stored or offloaded.

Procedure

1. Edit your `APIConnectCluster` CR:

   ```
   oc -n <namespace> edit APIConnectCluster
   ```

2. In the `analytics.spec` section, add your ingestion filter.
   Filters for API events that are offloaded to a third-party system are defined in the `external.offload` section. Filters for API events that are stored in the API Connect OpenSearch database are defined in the `ingestion` section.

   Ingestion filters - for API event data stored by API Connect

Add the filter definition to the **ingestion** section:

```
ingestion:
  ...
  filter: |
    if [api_name] == "test-api" {
      mutate {
        remove_field => ["query_string"]
      }
    }
```

In this example, a conditional filter is used to apply the change to API event records where the API name is **test-api**.

Offload filters - for API event data that is sent to a third-party system.

Add the filter definition to the **external.offload** section:

```
external:
  offload:
    filter: |
      mutate {
        remove_field => ["query_string"]
      }
```

In this example, no conditional filter is used; the change is applied to all APIs.

For more examples, see Example ingestion filters.

3. Save the changes. Updates to filters take effect after approximately 30 seconds.

Example ingestion filters

Review example ingestion filters to see how to add, modify, and delete fields from API event records.

You can use these example filters in the **ingestion.filter** and the **external.offload.filter** configurations. For more information about the filter syntax, see the Logstash documentation: https://www.elastic.co/guide/en/logstash/current/filter-plugins.html.

Add a field

You can add custom data to API event data by adding a field.

To avoid naming conflicts with future or current analytics fields, include a prefix that ensures your new field name is unique. For example, instead of naming the field **employee_num** you might name it **x_mycompany_employee_num**.

The following example copies the contents of the **X-Employee-Num** field from the request header and adds it to the **x_mycompany_employee_num** field.

```
if [request_http_headers] {
  ruby {
    code => "event.get('[request_http_headers]').collect {|i| event.set('[x_mycompany_employee_Num]', i['X-Employee-Num']) if i.has_key?('X-Employee-Num')}"
  }
}
```

Modifying an existing field

Sometimes you don't want to remove a field entirely from your data, but you want to redact sensitive information such as IDs. You can modify the contents of a field and replace information with symbols or a message.

Remember: The following fields must not be modified if the data is being written to internal analytics storage: **org_id**, **catalog_id**, **space_id**, **developer_org_id**, **datetime**, and **@timestamp**.

The following example replaces sensitive information in the **X-Employee-Name** and **X-Employee-ID** request headers with the string: **********sanitized**********.

```
if [request_http_headers] {
  ruby {
    code => "headers=['X-Employee-Name','X-Employee-ID']; newHeaders = event.get('[request_http_headers]').collect {|i| headers.each {|header| i[header] = '**********sanitized**********' if i.has_key?(header)}; i}; event.set('[request_http_headers]', newHeaders)"
  }
}
```

Removing an existing field

Use the mutate **remove_field** operation to delete a field. To remove multiple fields, delimit the field names with commas.

The following example removes multiple fields (**request_http_headers**, **response_http_headers**, **request_body**, **response_body**, and **query_string**) from the API event record:

```
mutate {
  remove_field => ["request_http_headers", "response_http_headers", "request_body", "response_body", "query_string"]
}
```

Drop API event records

If you want certain API events to not be stored at all, use the **drop** syntax.

Do not store events from the **apic** and **sandbox** catalogs:

```
if  [catalog_name] =~ /sandbox|apic/ {
  drop { }
}
```

Access your analytics data

How to view, analyze, and export your analytics data.

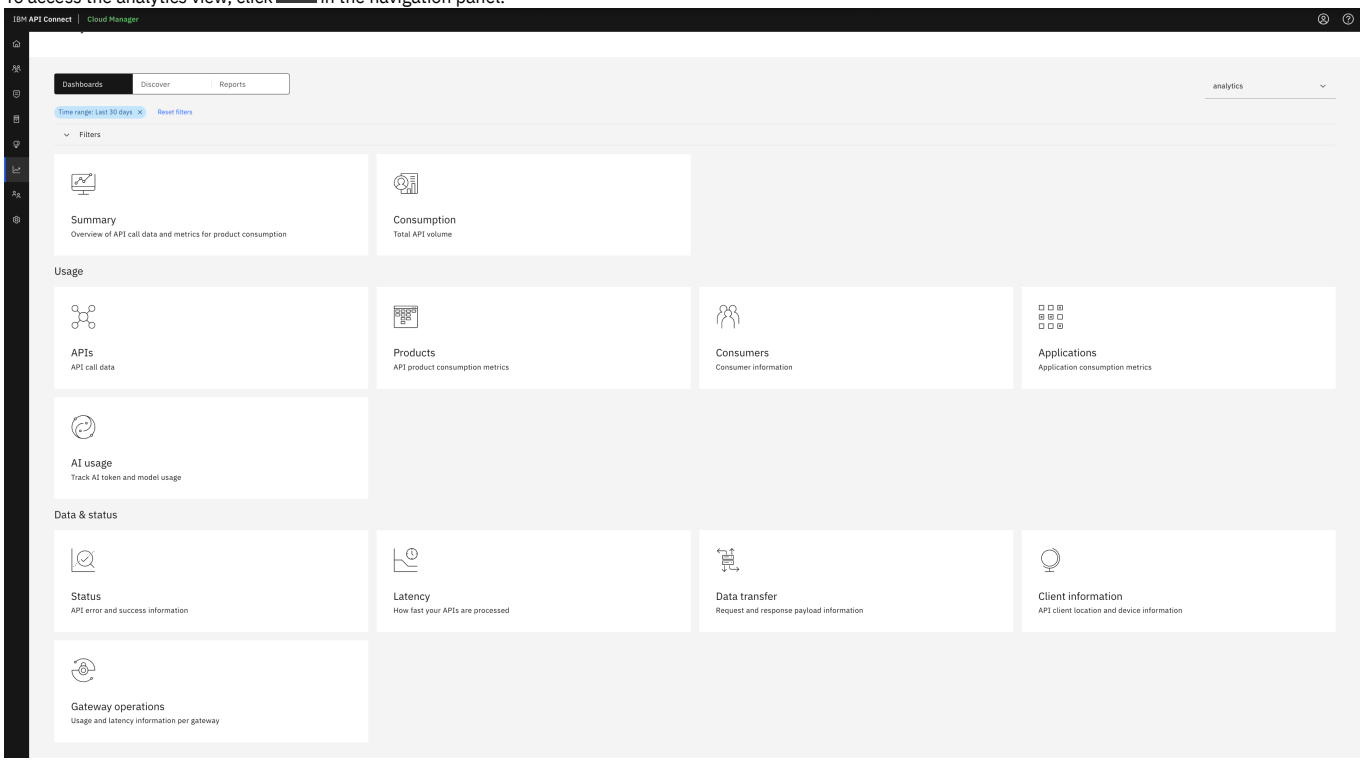
- **API Connect UIs**
  View, query, and export your analytics data from the API Connect Analytics UIs.
- **Counting total API calls for your analytics service**
  Count the API calls for the analytics subsystem and see the total that is categorized by response status.
- **Export your analytics data**
  Export your analytics data with either the toolkit CLI or the REST API.
- **Allowing API Connect cloud admin users to view provider organization analytics data**
  The owner of a provider organization can enable or disable the sharing of analytics data with API Connect cloud administrators.
- **Sharing analytics data for API discovery**
  Share your provider organization's analytics data to enable API discovery.
- **Analytics CLI**
  How to access your analytics data with the toolkit CLI.
- **Analytics REST API**
  How to access your analytics data with the REST API.

API Connect UIs

View, query, and export your analytics data from the API Connect Analytics UIs.

- **Accessing analytics in the Cloud Manager UI**
  How to view, analyze, and export your analytics data from the Cloud Manager UI.
- **Accessing analytics in the API Manager UI**
  How to view, analyze, and export your analytics data from the API Manager UI.
- **Accessing analytics in the Developer Portal**
  How to view your analytics data from the Developer Portal.

Accessing analytics in the Cloud Manager UI

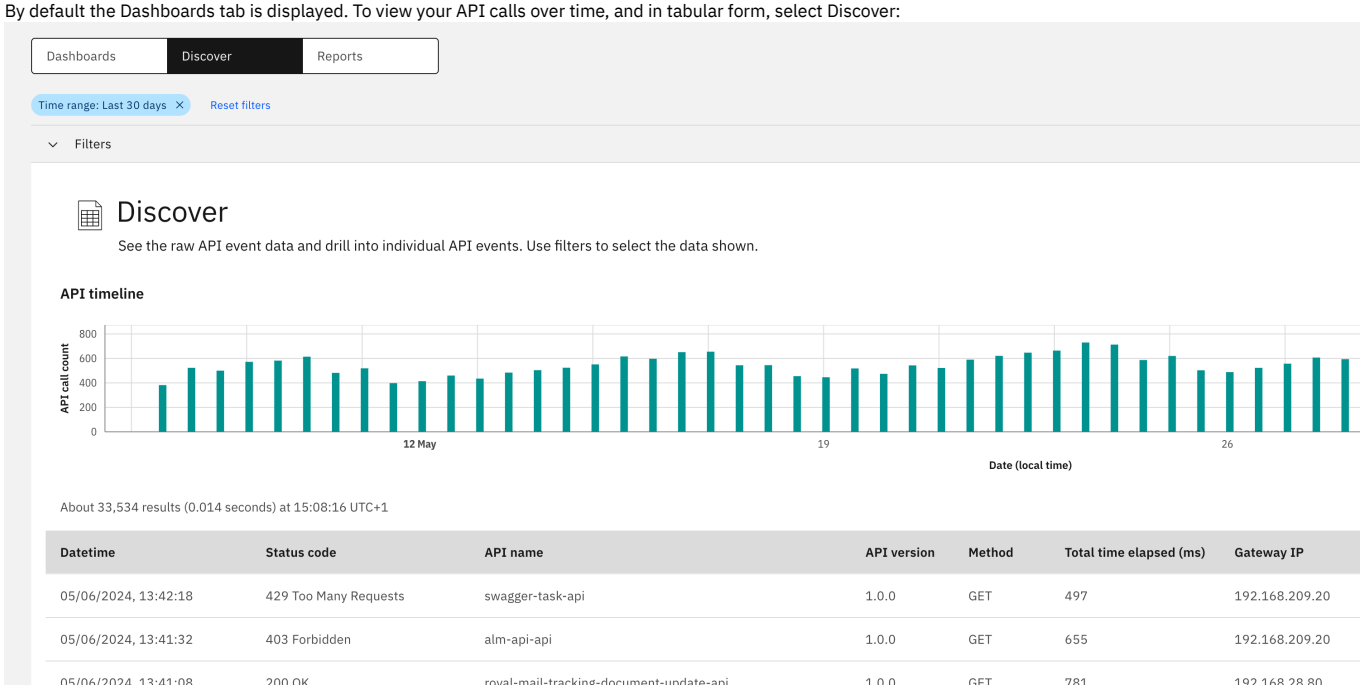


How to view, analyze, and export your analytics data from the Cloud Manager UI.

The Cloud Manager UI analytics view shows total API call volume data, and total call volumes per gateway.

The Cloud Manager UI analytics view also shows analytics data for provider organizations where the organization owner allows sharing of this data. For more information about analytics data sharing, see Allowing API Connect cloud admin users to view provider organization analytics data.
Note: If no provider organization owners enable data sharing with the cloud admin user, then the only analytics data you can see are on the following dashboards:

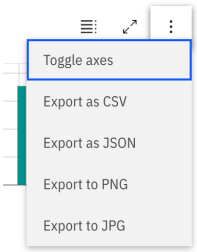
- Consumption: Total API calls in your cloud. Required for consumption-based licensing.
- Gateway Operations: Call volume and latency information for each gateway in each gateway service. This information can be used to determine whether load is being spread evenly or if a gateway is under-performing.



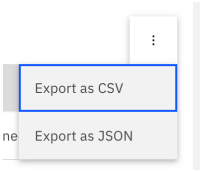
To access the analytics view, click  in the navigation panel:

If you have multiple analytics services, use the list at the upper-right to select the analytics service whose API event data you want to view.

Discover view



By default the Dashboards tab is displayed. To view your API calls over time, and in tabular form, select Discover:

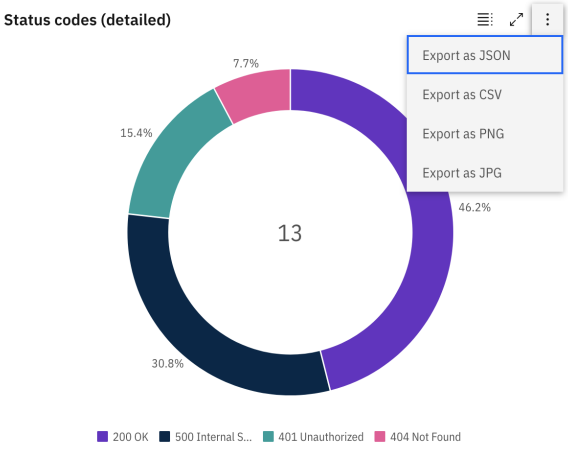


The maximum number of API events that can be accessed from the UI is 10,000. The maximum number of event records that can be displayed per page on the Discover view is 200.

You can customize the columns that are displayed in the Filters section.

You can switch the timeline chart to a logarithmic y axis, and export the data for the chart by clicking Actions at the upper right of the chart:

You can export the API event data from the table by clicking Actions at the upper right of the table:

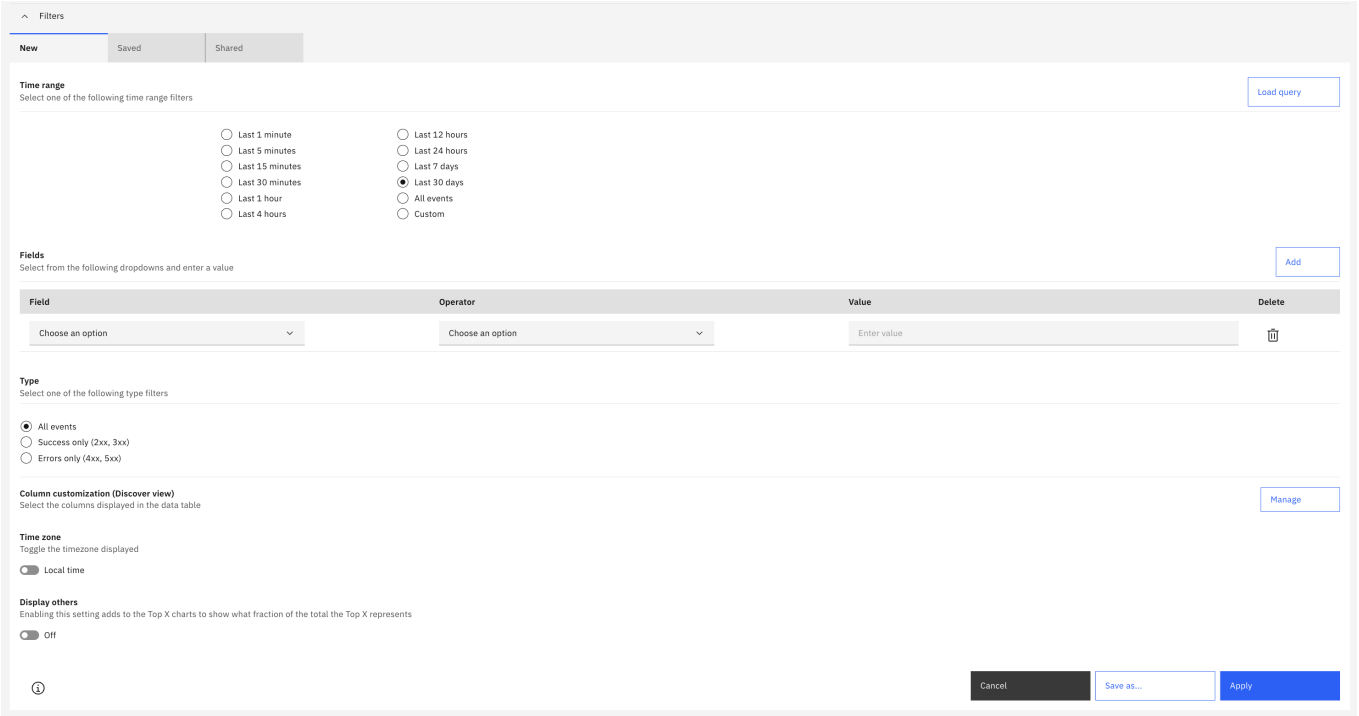


Note: When you export from the Discover view, only the data that is displayed on the current page of results is exported. If you want to export the data from all pages, you must export separately from each page. To export all your analytics data, do not use the UI, see Export your analytics data.
If you see unexpected HTTP OPTIONS events in the Discover view, these events are due to CORS requests from browser-based API test tools. For more information about test tools and the OPTIONS call, see Testing an API.

Dashboards view

The following dashboards are available:

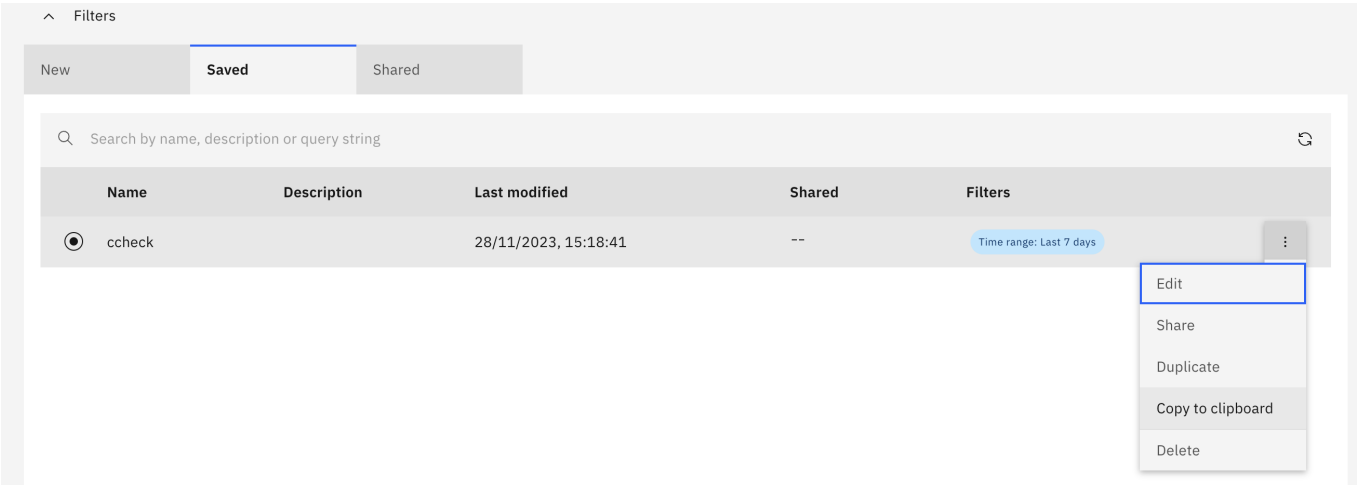
- Summary: At a glance information on call volumes, latencies and when those calls are happening.
- Consumption: Total API calls in your cloud. Required for consumption-based licensing.
- APIs: Everything that you need to know about which APIs are being called and which ones aren't.
- Products : Which products are the most popular both in total and over time.
- Consumers: Determine which consumer organizations are making the most API calls in total and over time.
- Applications: Which applications are responsible for the most API calls both in total and over time.
- AI usage: Track AI token counts and model usage to see how AI services are being used.
- Status: Critical information on API call successes and failures, showing both success and failure rates over time along with an HTTP response code breakdown.
- Latency: How long APIs take to return a response, and the change in latency over time.
- Data transfer: All about request and response payloads. Which APIs, consumers and applications are responsible for the largest request and response payloads.
- Client information: Who is calling your APIs and from what devices.
  Note: Only internet-accessible IP addresses can be resolved to a geographical location. Internal IP addresses are ignored.
- Gateway Operations: Call volume and latency information for each gateway in each gateway service. This information can be used to determine whether load is being spread evenly or if a gateway is under-performing.



Each chart in a dashboard can be exported as a PNG or JPG image. The source data for each chart can be exported as a JSON or CSV file. To export a chart, click Actions at the upper right:

It is also possible to enlarge the chart to full-screen by clicking . To see the source data in tabular form click .

Filtering displayed data



You can filter the data that is displayed in the Dashboards and Discover view by defining filters (also called "queries"). Expand the Filters section to view, define, and apply queries to your displayed data:

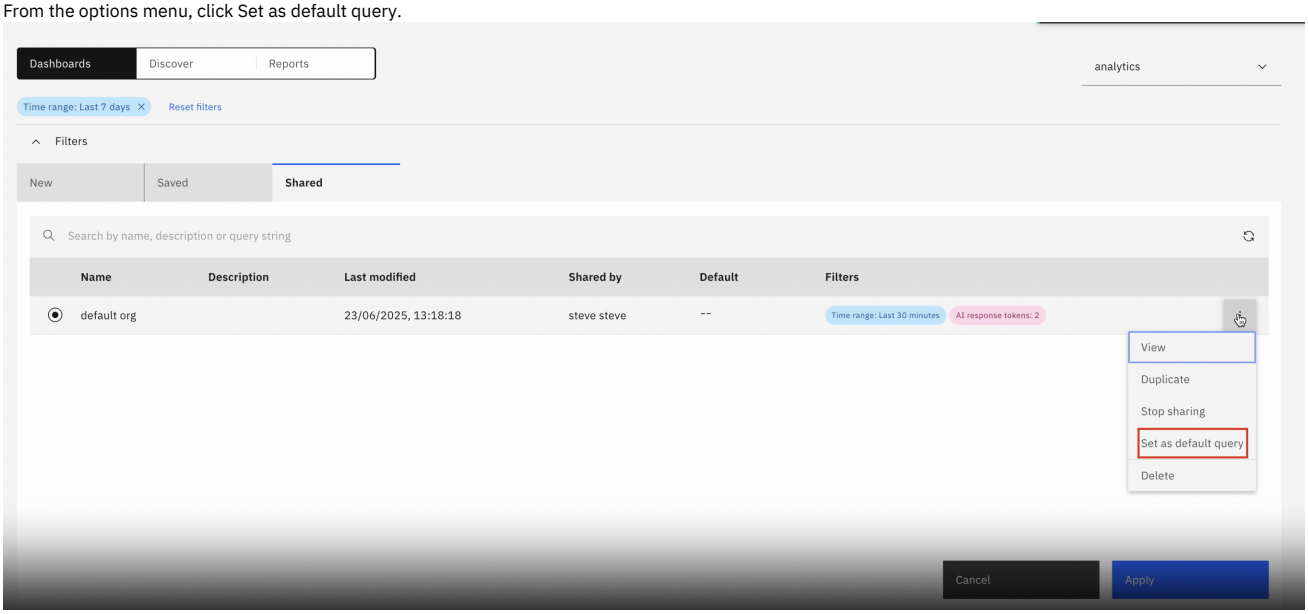
You can save and share the queries that you define:

- Shared queries are visible to all users at the same scope. They are not visible to users in a different scope. For example, a query that Cloud Manager UI users shares is not visible to an API Manager UI user. Within the API Manager UI, a query that is created at catalog scope is not visible to users who are viewing analytics data at provider organization scope.
- Other users cannot edit or delete queries that you share, but they can create a duplicate query, which they can edit and share.
- All queries have a name and an optional description. The name does not need to be unique.

Saved queries can be exported as strings for use in REST API and toolkit CLI queries, for example:

copies the following string to the clipboard:

```
timeframe=last7days
```

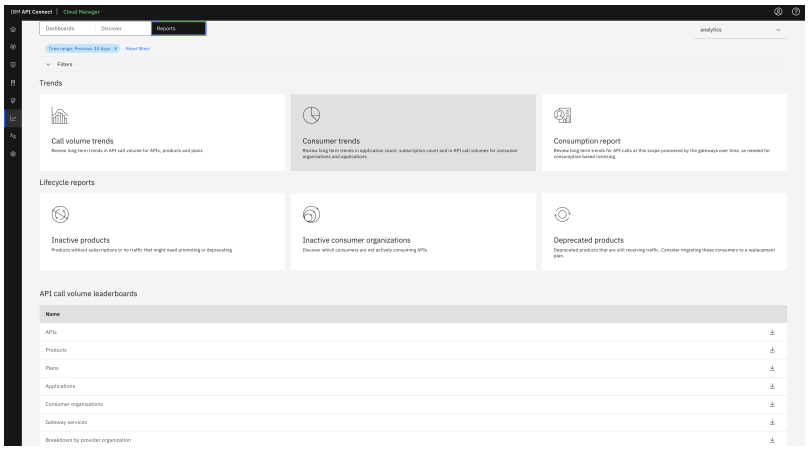


Set a default query in analytics

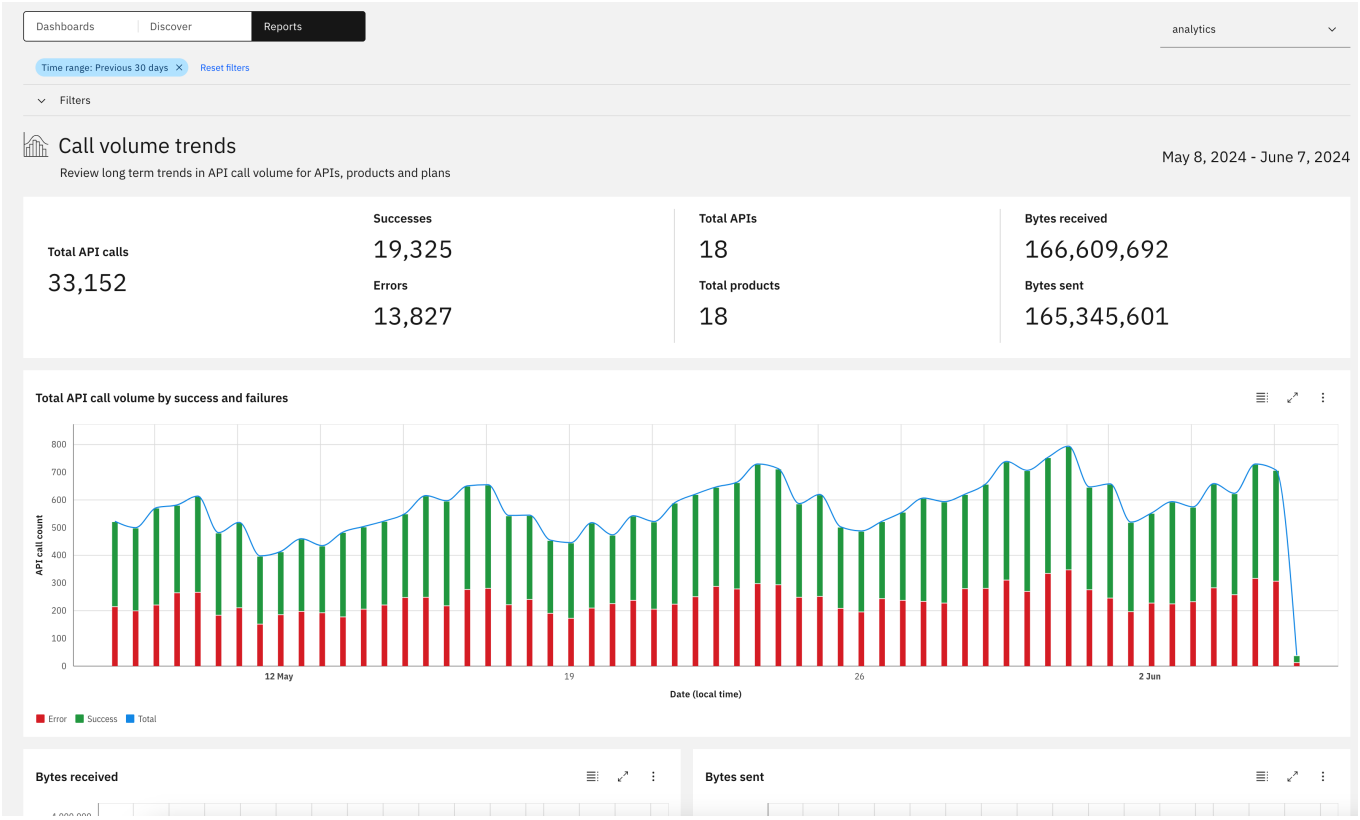
You can now set a default query that is automatically applied when you visit the Dashboard or Discover pages in Analytics. The default query is configured per user and per scope (organization, catalog, or space).
Note:

- Only shared queries can be set as default queries.
- Each scope can have one default query per user. A different default query can be set for each catalog and space.

1. Ensure that the query you want to set as default is saved.
2. To share the saved query, complete the following steps.
   - Click Saved tab.
   - From the options menu, click Share.
   - In Share query window, click Share.
3. Click Shared tab.

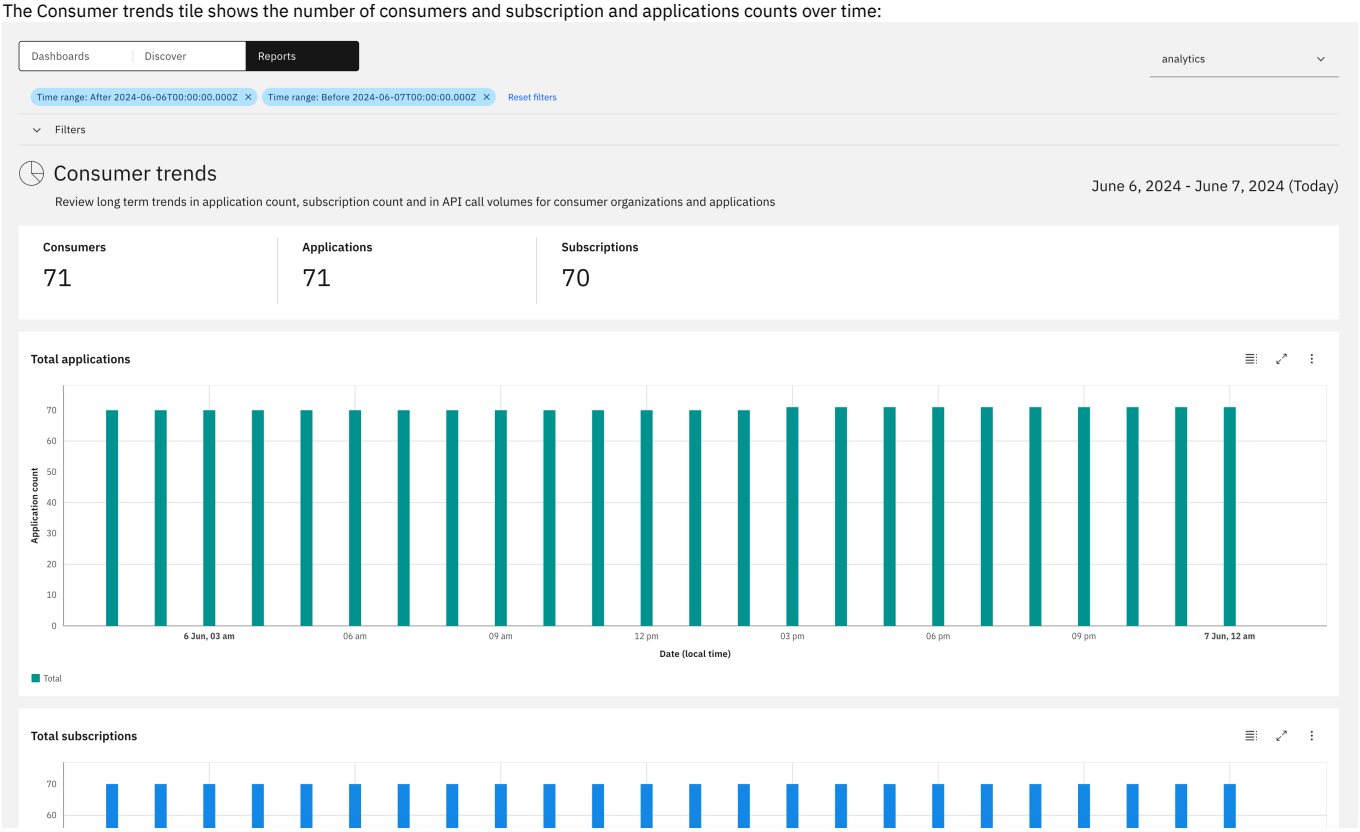


4. From the options menu, click Set as default query.

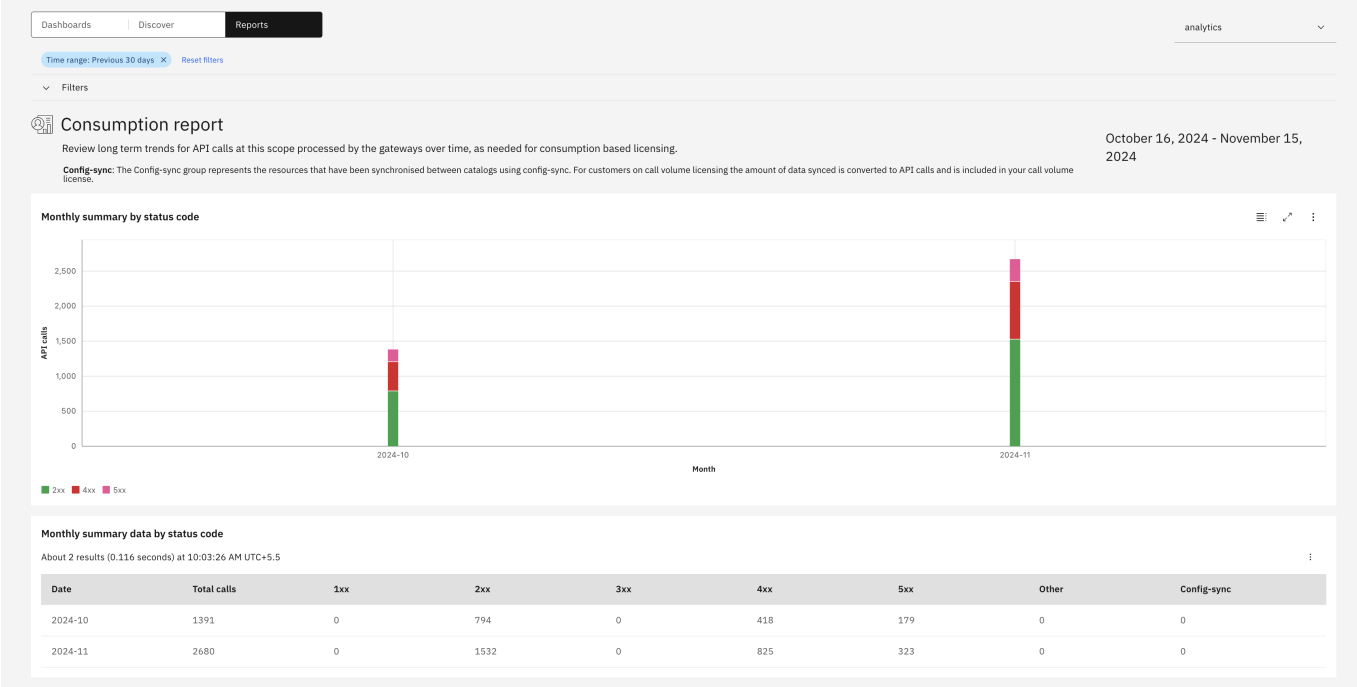


5. In Default query window, click Default.
6. To apply the default query immediately. Click Apply. The default query is applied immediately for all users in that scope. If you do not click Apply after setting the default query, it is automatically applied the next time you visit the Dashboard or Discover tabs.

Reports view

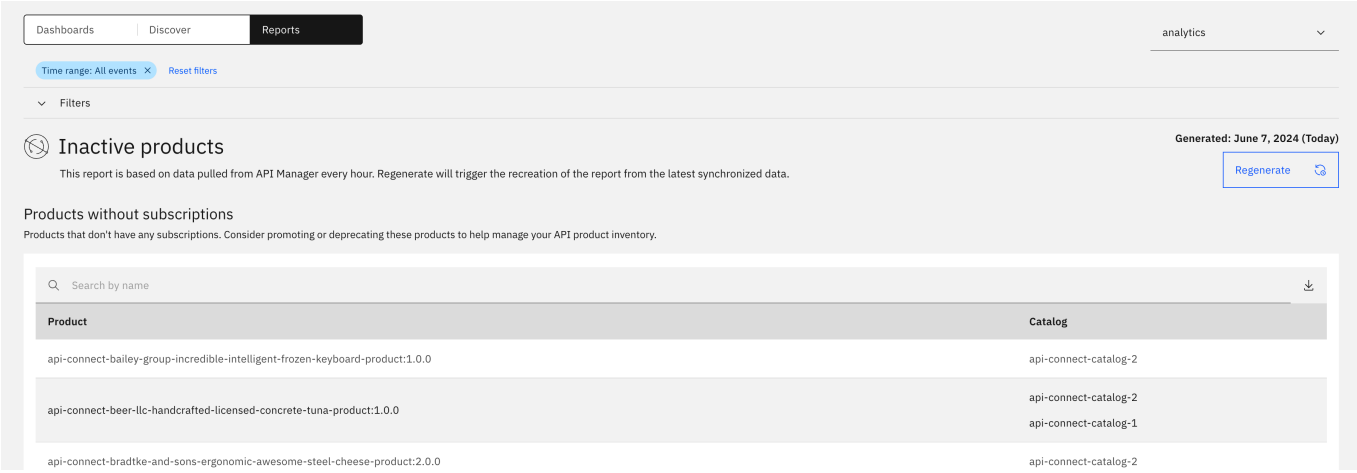


The reports view displays long-term summary data rather than individual API events.
Note: The reports view was introduced in v10.0.6, and does not include data that was generated before upgrade to v10.0.6.
The reports view contains 6 tiles and an API call volume leaderboard.

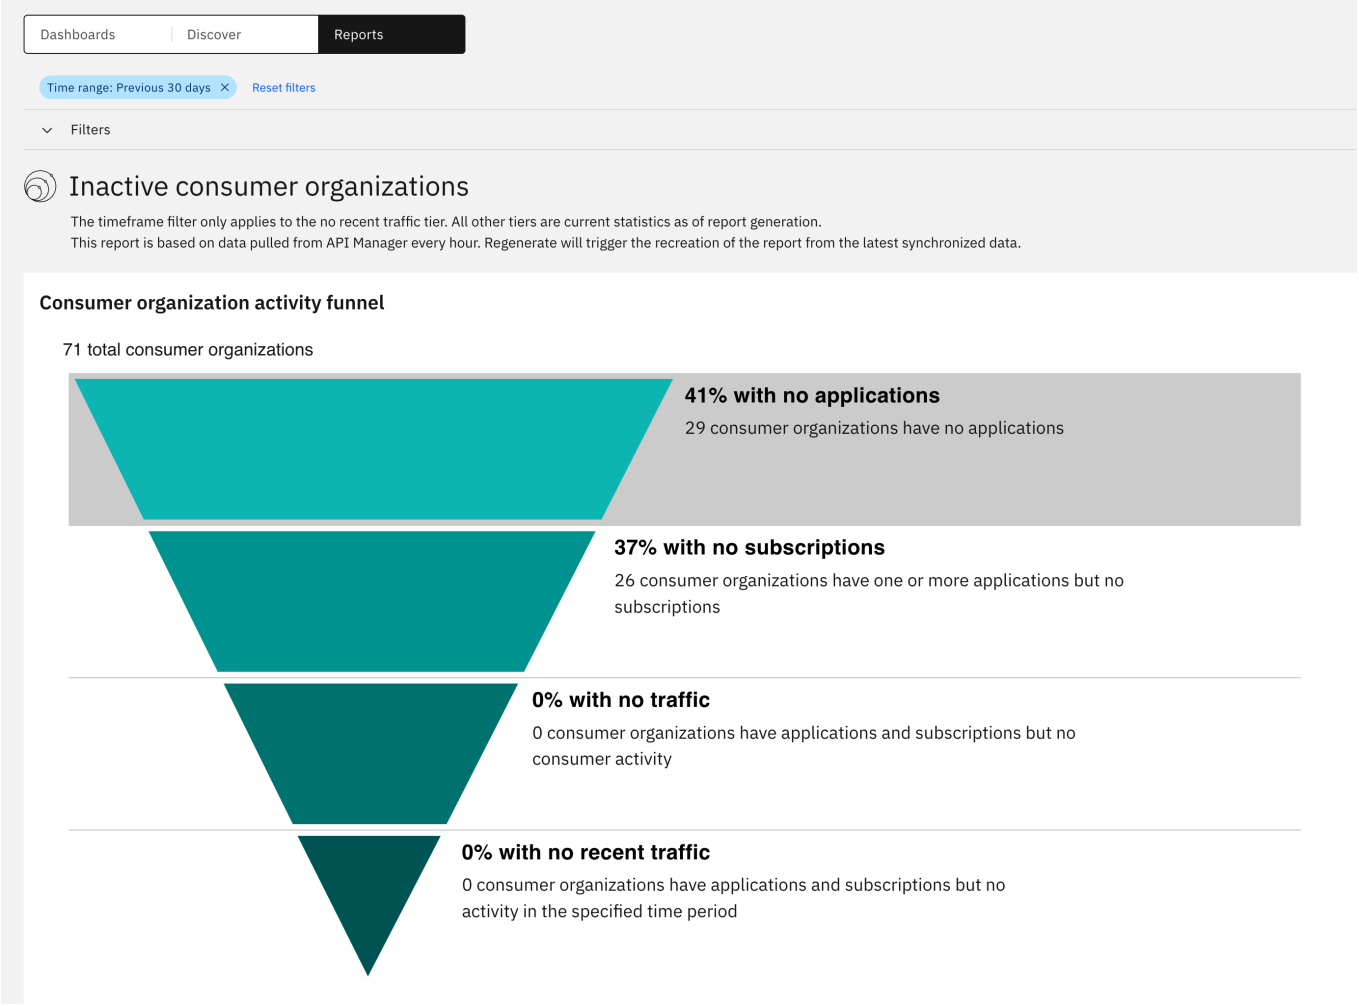


Call volume trends shows your most and least active APIs, total successful and failed API calls, total bytes sent and received, and totals based on scope.

The Consumer trends tile shows the number of consumers and subscription and applications counts over time:

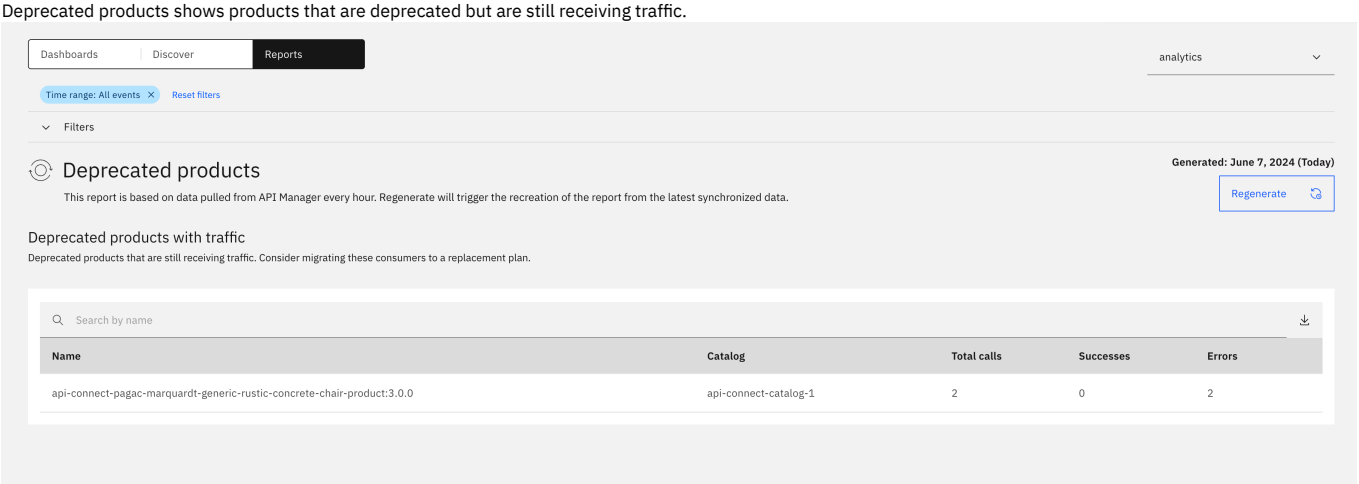


Consumption report shows long-term trends for API calls processed by gateways, which are essential for consumption-based licensing insights.



Date	Total calls	1xx	2xx	3xx	4xx	5xx	Other	Config-sync
2024-10	1391	0	794	0	418	179	0	0
2024-11	2680	0	1532	0	825	323	0	0

Inactive products shows products that have no subscriptions, and products that have no traffic.



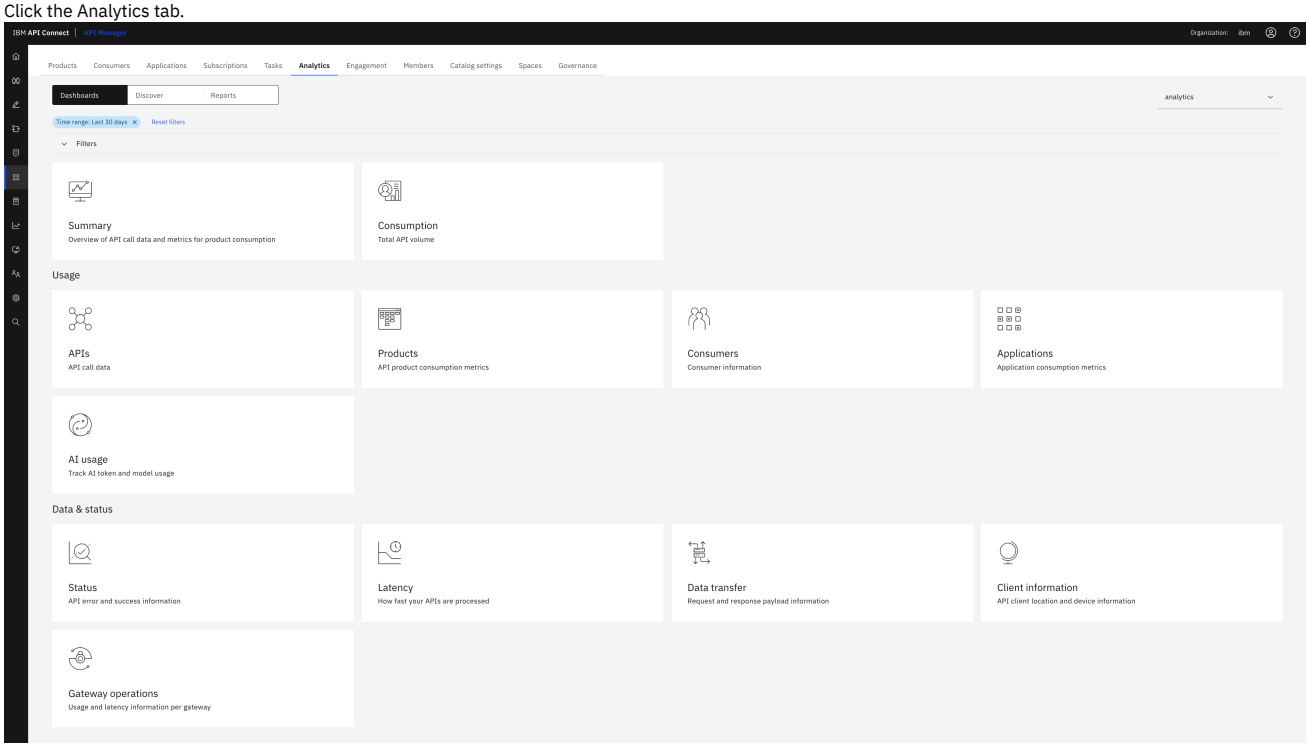
Product	Catalog
api-connect-bailey-group-incredible-intelligent-frozen-keyboard-product:1.0.0	api-connect-catalog-2
api-connect-beer-llc-handcrafted-licensed-concrete-tuna-product:1.0.0	api-connect-catalog-2 api-connect-catalog-1
api-connect-bradtke-and-sons-ergonomic-awesome-steel-cheese-product:2.0.0	api-connect-catalog-2

Inactive consumer organizations shows consumer organizations that have no applications, subscriptions, recent traffic, or no traffic at all.

Deprecated products shows products that are deprecated but are still receiving traffic.

API call volume leaderboards shows leaderboards for APIs, Products, Plans, Applications, Consumer organizations , Gateway service and Breakdown by catalog. Click in the name column to see the data for each item.

Accessing analytics in the API Manager UI

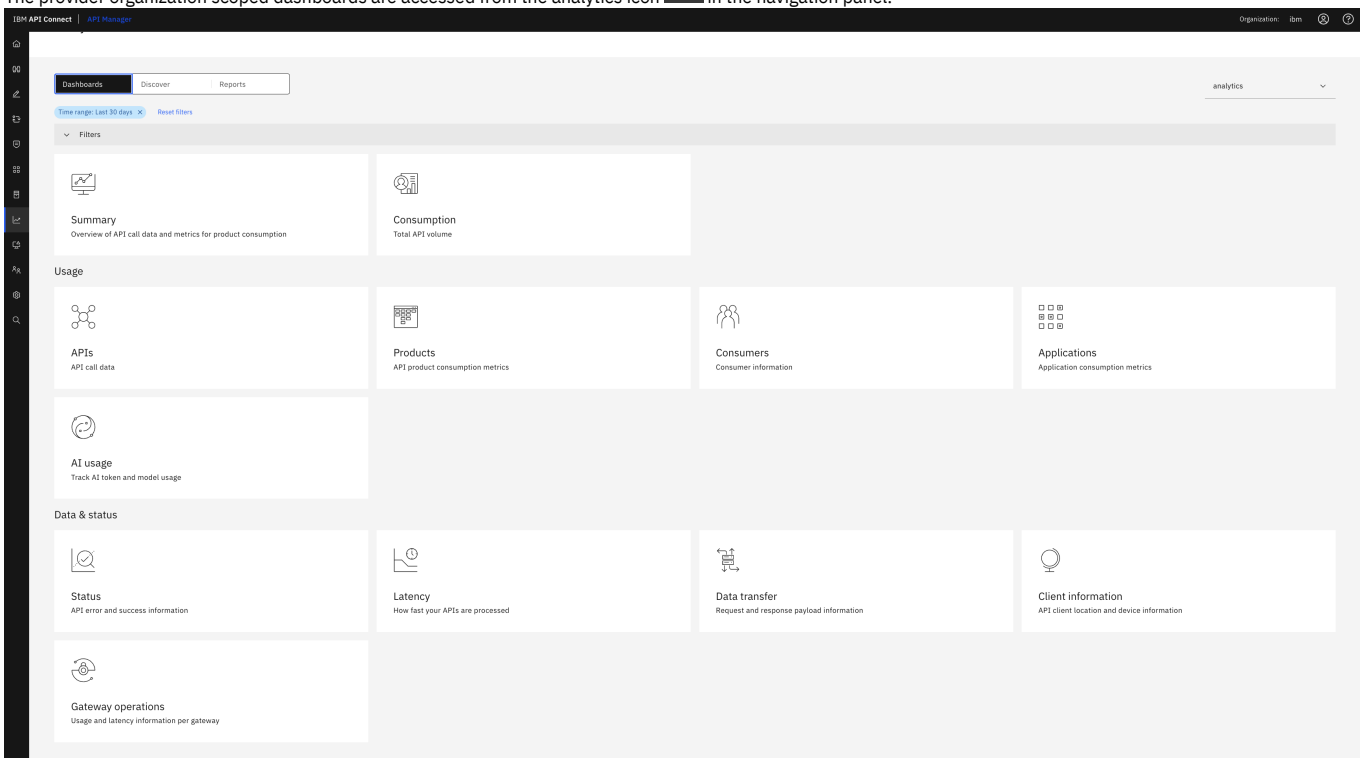


How to view, analyze, and export your analytics data from the API Manager UI.

Analytics data is displayed in dashboards in the API Manager UI. Dashboards are scoped at the provider organization, catalog, and space level.

The ability to access analytics data at a catalog or space level depends on your assigned roles and permissions. For more information about catalogs and spaces, see Working with catalogs and Using syndication in API Connect.

To access the Catalog scoped analytics dashboard, complete the following steps:

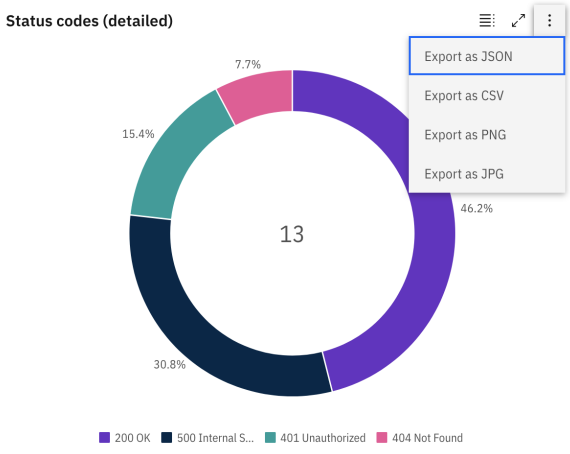


1. In the API Manager UI, select Manage in the navigation panel.
2. From the list of available catalogs in the API Manager Dashboard, select the required catalog.
3. **Optional:** If spaces are enabled and want to see analytics at the scope of a space, then:
   a. Click the Spaces tab.
   b. Select the space that you want to view.
4. Click the Analytics tab.

Analytics dashboards

The analytics dashboards in the API Manager UI show the API event data at the scopes of provider organization, catalog, and space.

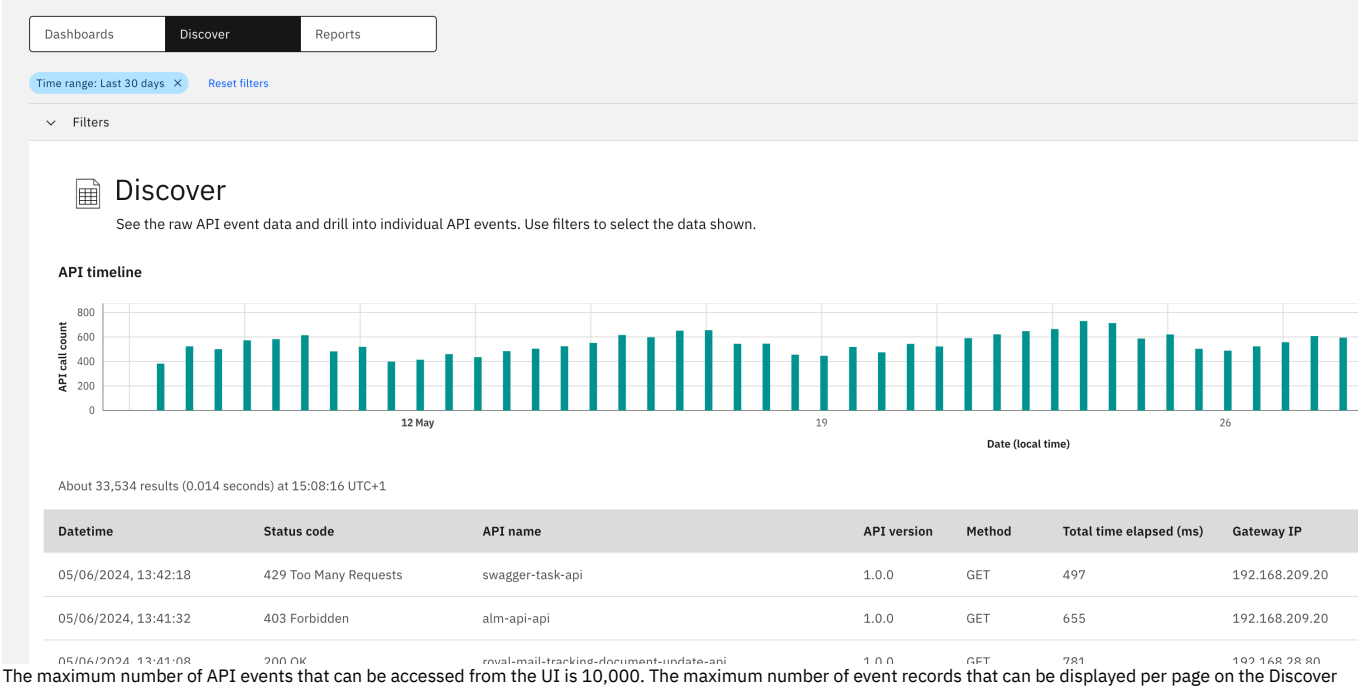
The provider organization scoped dashboards are accessed from the analytics icon in the navigation panel.



The space scoped dashboards are accessed from the Analytics tab when viewing the space.

The following dashboards are available:

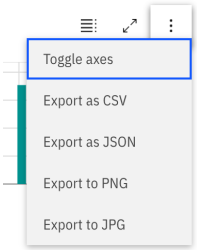
- Summary: At a glance information on call volumes, latencies and when those calls are happening.
- Consumption: Total API calls in your cloud. Required for consumption-based licensing.
- APIs: Everything that you need to know about which APIs are being called and which ones aren't.
- Products : Which products are the most popular both in total and over time.
- Consumers: Determine which consumer organizations are making the most API calls in total and over time.
- Applications: Which applications are responsible for the most API calls both in total and over time.
- AI usage: Track AI token counts and model usage to see how AI services are being used.
- Status: Critical information on API call successes and failures, showing both success and failure rates over time along with an HTTP response code breakdown.
- Latency: How long APIs take to return a response, and the change in latency over time.
- Data transfer: All about request and response payloads. Which APIs, consumers and applications are responsible for the largest request and response payloads.
- Client information: Who is calling your APIs and from what devices.
  Note: Only internet-accessible IP addresses can be resolved to a geographical location. Internal IP addresses are ignored.
- Gateway Operations: Call volume and latency information for each gateway in each gateway service. This information can be used to determine whether load is being spread evenly or if a gateway is underperforming.



Each chart in a dashboard can be exported as a PNG or JPG image. The source data for each chart can be exported as a JSON or CSV file. To export a chart, click Actions at the upper right:

It is also possible to enlarge the chart to full-screen by clicking . To see the source data in tabular form click .

Discover view

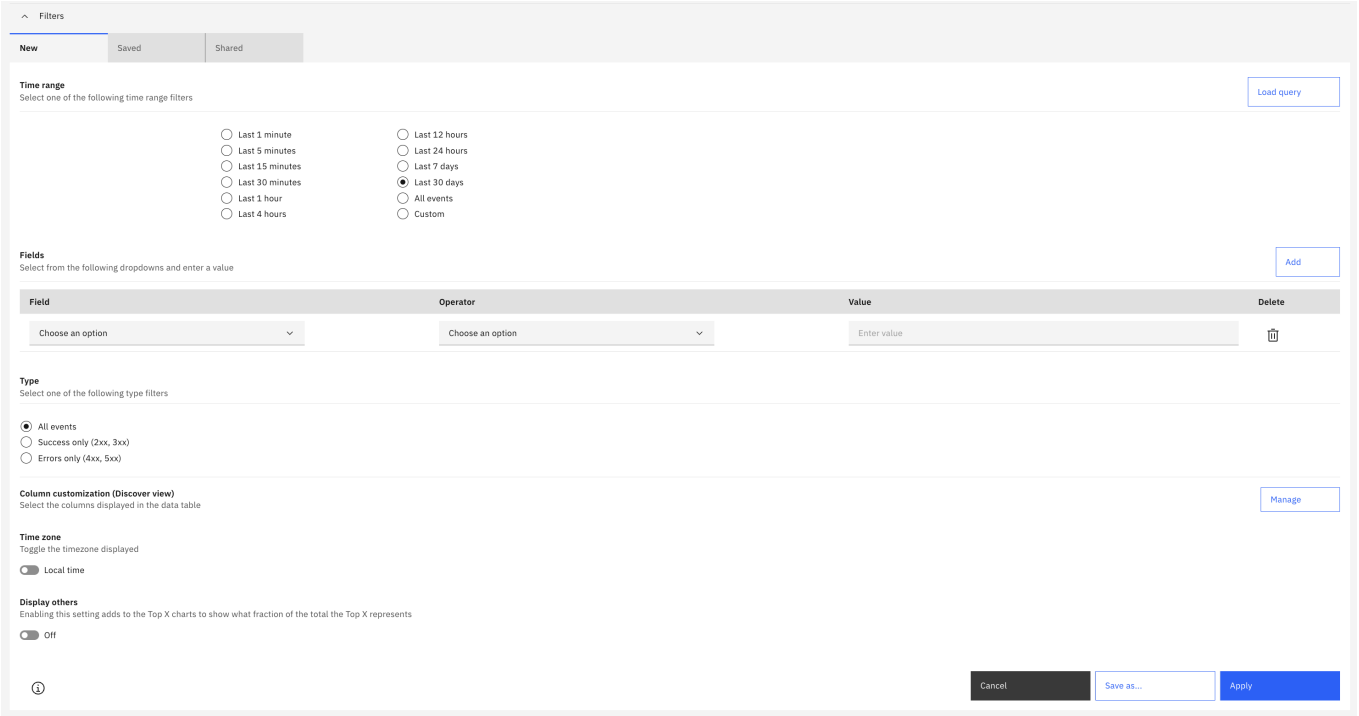


By default the Dashboards tab is displayed. To view your API event data in tabular form, select Discover:

The maximum number of API events that can be accessed from the UI is 10,000. The maximum number of event records that can be displayed per page on the Discover view is 200.

You can customize the columns displayed in the Filters section. You can sort the table in ascending or descending order by clicking on the column headers.

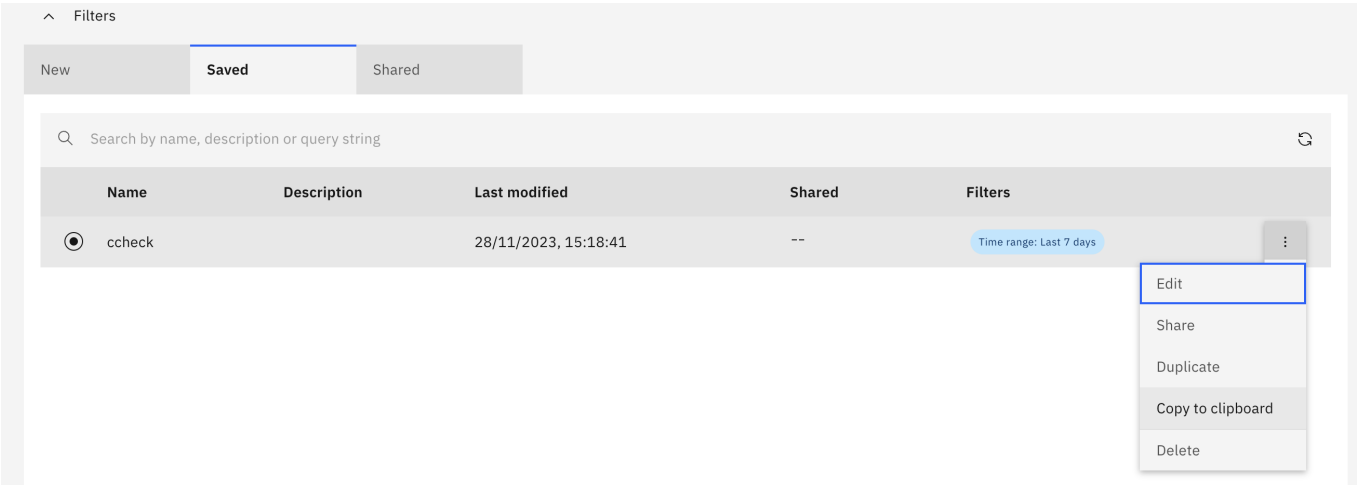
You can switch the timeline chart to a logarithmic y axis, and export the data for the chart by clicking Actions at the upper right of the chart:



You can export the API event data from the table by clicking Actions at the upper right of the table:

Note: When you select Export as CSV or Export as JSON to export from the Discover view, only the data that is displayed on the current page of results is exported. To export data from all pages, select Full data as CSV or Full data as JSON. You can also export all your analytics data using the toolkit CLI. For more information, see Export your analytics data.
If you see unexpected HTTP OPTIONS events in the Discover view, these events are due to CORS requests from browser-based API test tools. For more information about test tools and the OPTIONS call, see Testing an API.

Filtering displayed data



You can filter the data that is displayed in the Dashboards and Discover view by defining filters (also called "queries"). Expand the Filters section to view, define, and apply queries to your displayed data:

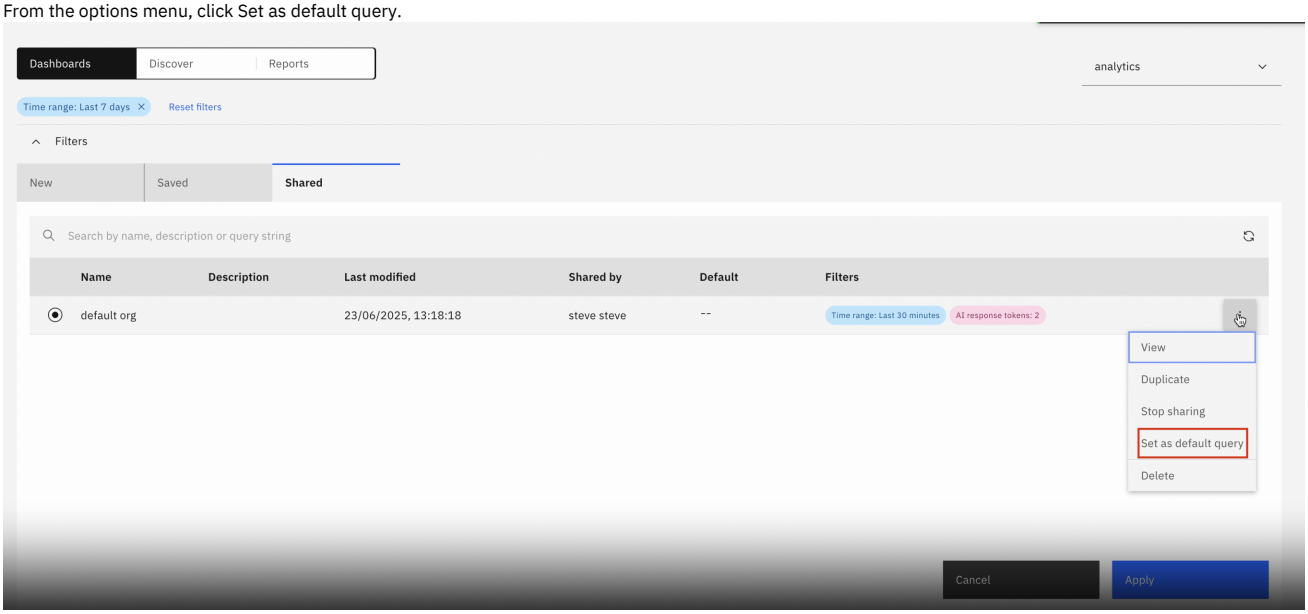
You can save and share the queries that you define:

- Shared queries are visible to all users at the same scope. They are not visible to users in a different scope. For example, a query that Cloud Manager UI users shares is not visible to an API Manager UI user. Within the API Manager UI, a query that is created at catalog scope is not visible to users who are viewing analytics data at provider organization scope.
- Other users cannot edit or delete queries that you share, but they can create a duplicate query, which they can edit and share.
- All queries have a name and an optional description. The name does not need to be unique.

Saved queries can be exported as strings for use in REST API and toolkit CLI queries, for example:

copies the following string to the clipboard:

```
timeframe=last7days
```

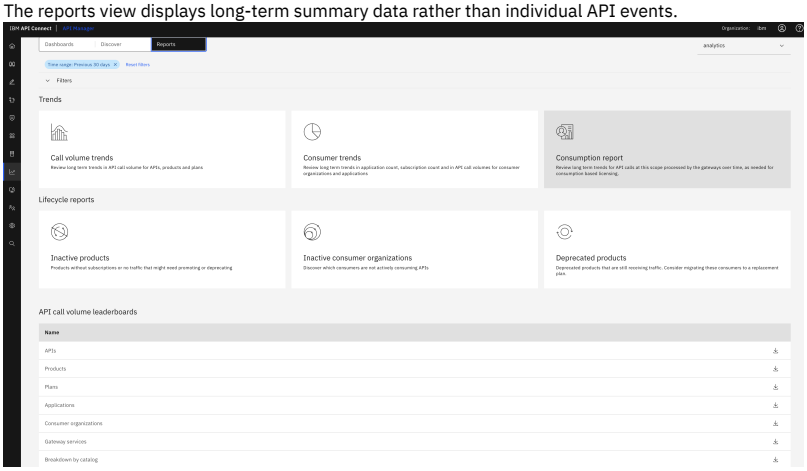


Set a default query in analytics

You can now set a default query that is automatically applied when you visit the Dashboard or Discover pages in Analytics. The default query is configured per user and per scope (organization, catalog, or space).
Note:

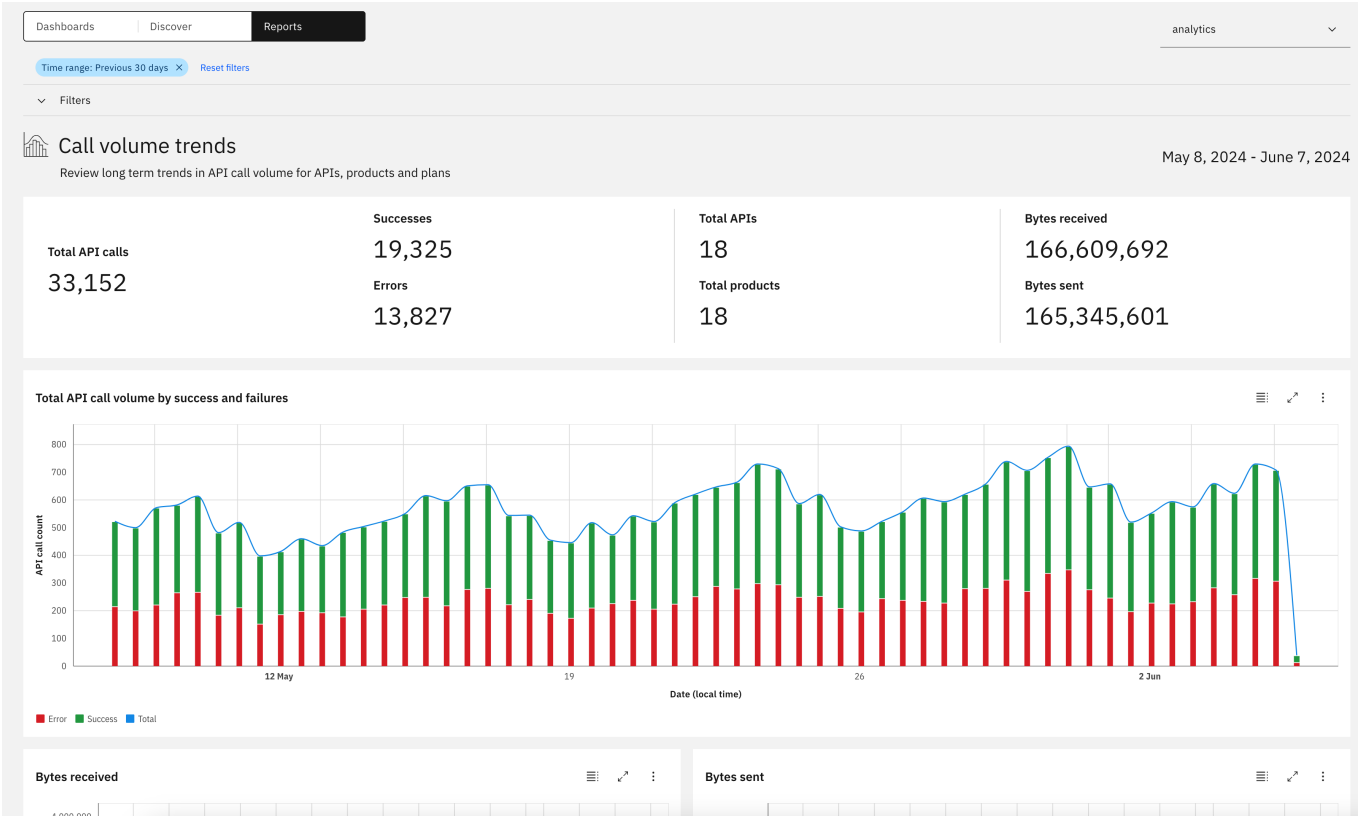
- Only shared queries can be set as default queries.
- Each scope can have one default query per user. A different default query can be set for each catalog and space.

1. Ensure that the query you want to set as default is saved.
2. To share the saved query, complete the following steps.
   - Click Saved tab.
   - From the options menu, click Share.
   - In Share query window, click Share.
3. Click Shared tab.



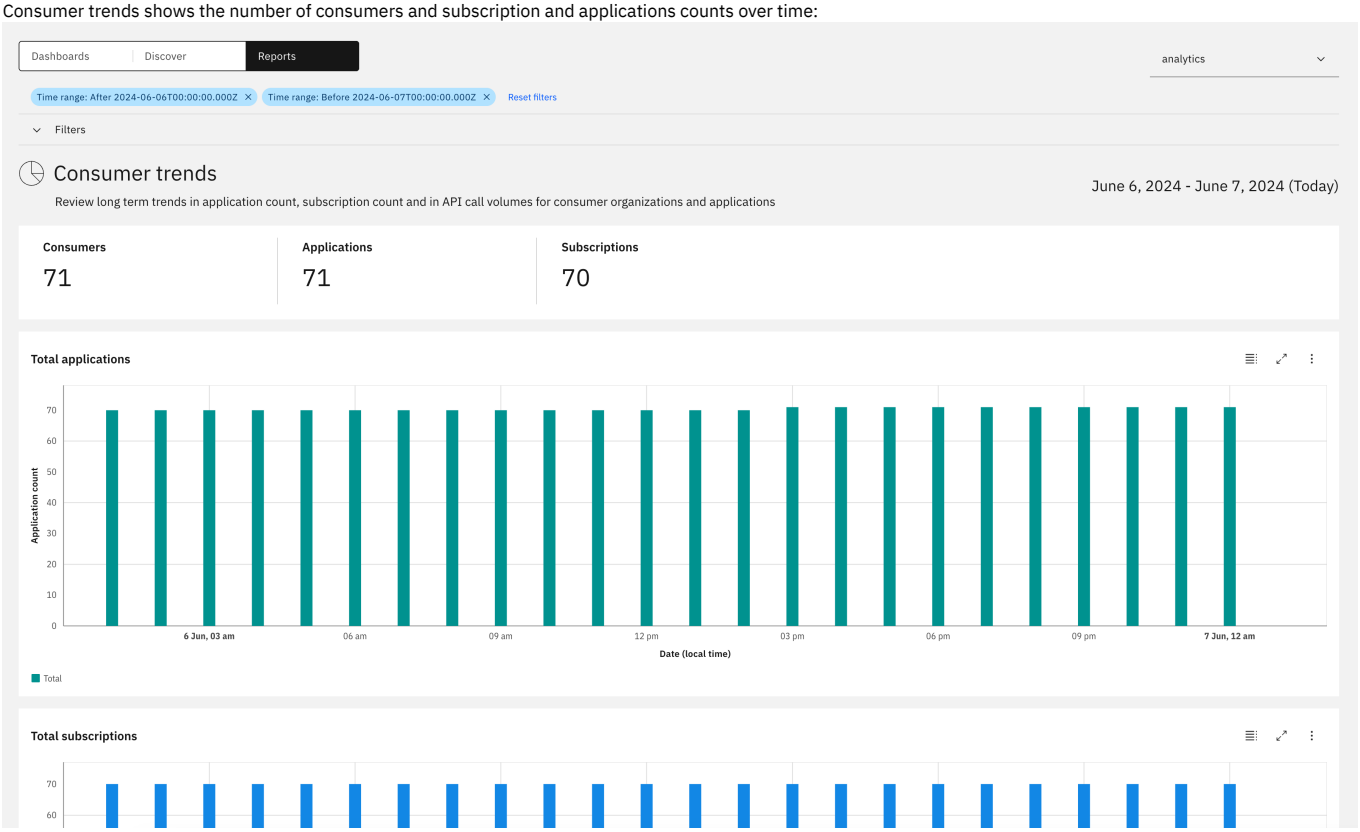
4. From the options menu, click Set as default query.

5. In Default query window, click Default.
6. To apply the default query immediately. Click Apply. The default query is applied immediately for all users in that scope. If you do not click Apply after setting the default query, it is automatically applied the next time you visit the Dashboard or Discover tabs.

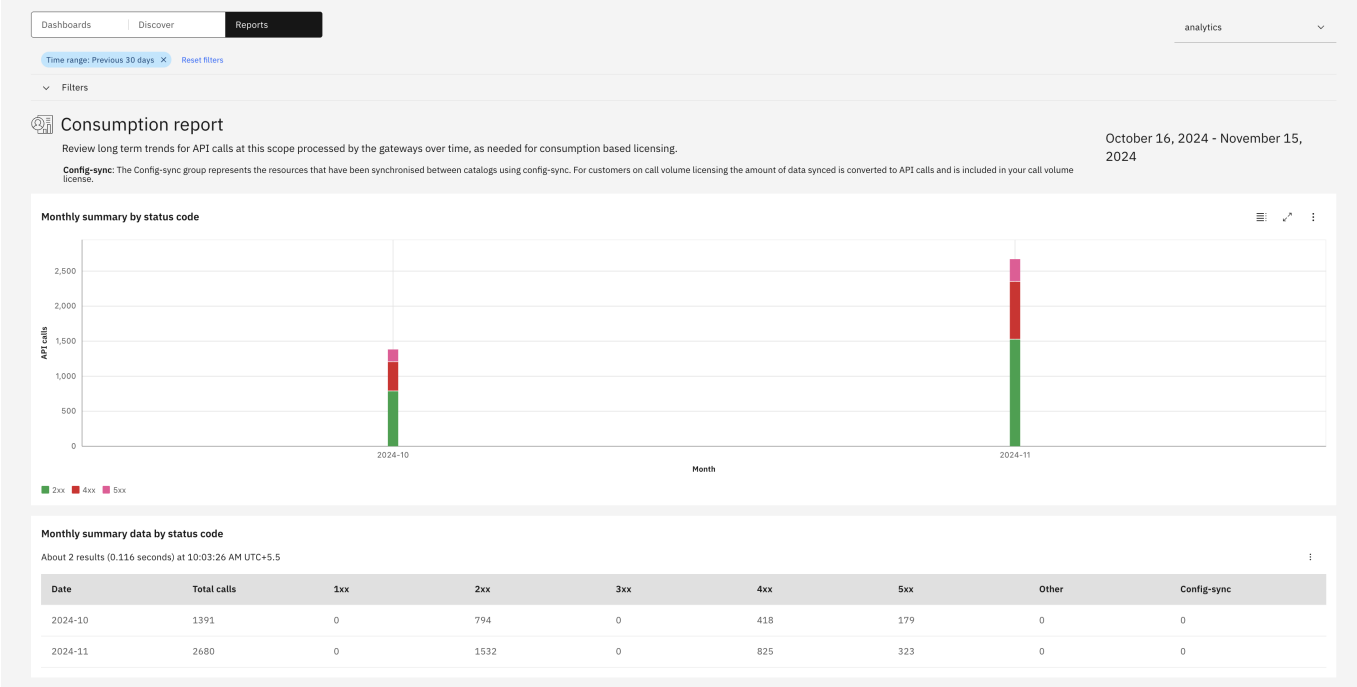


Reports view

The reports view displays long-term summary data rather than individual API events.

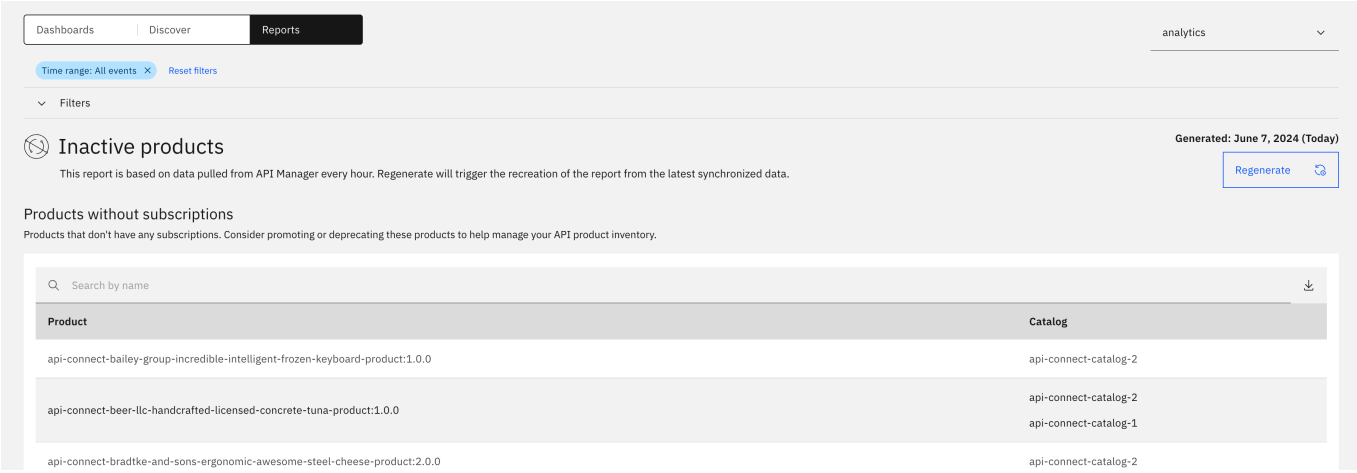


Note: The reports view was introduced in v10.0.6, and does not include data that was generated before upgrade to v10.0.6.

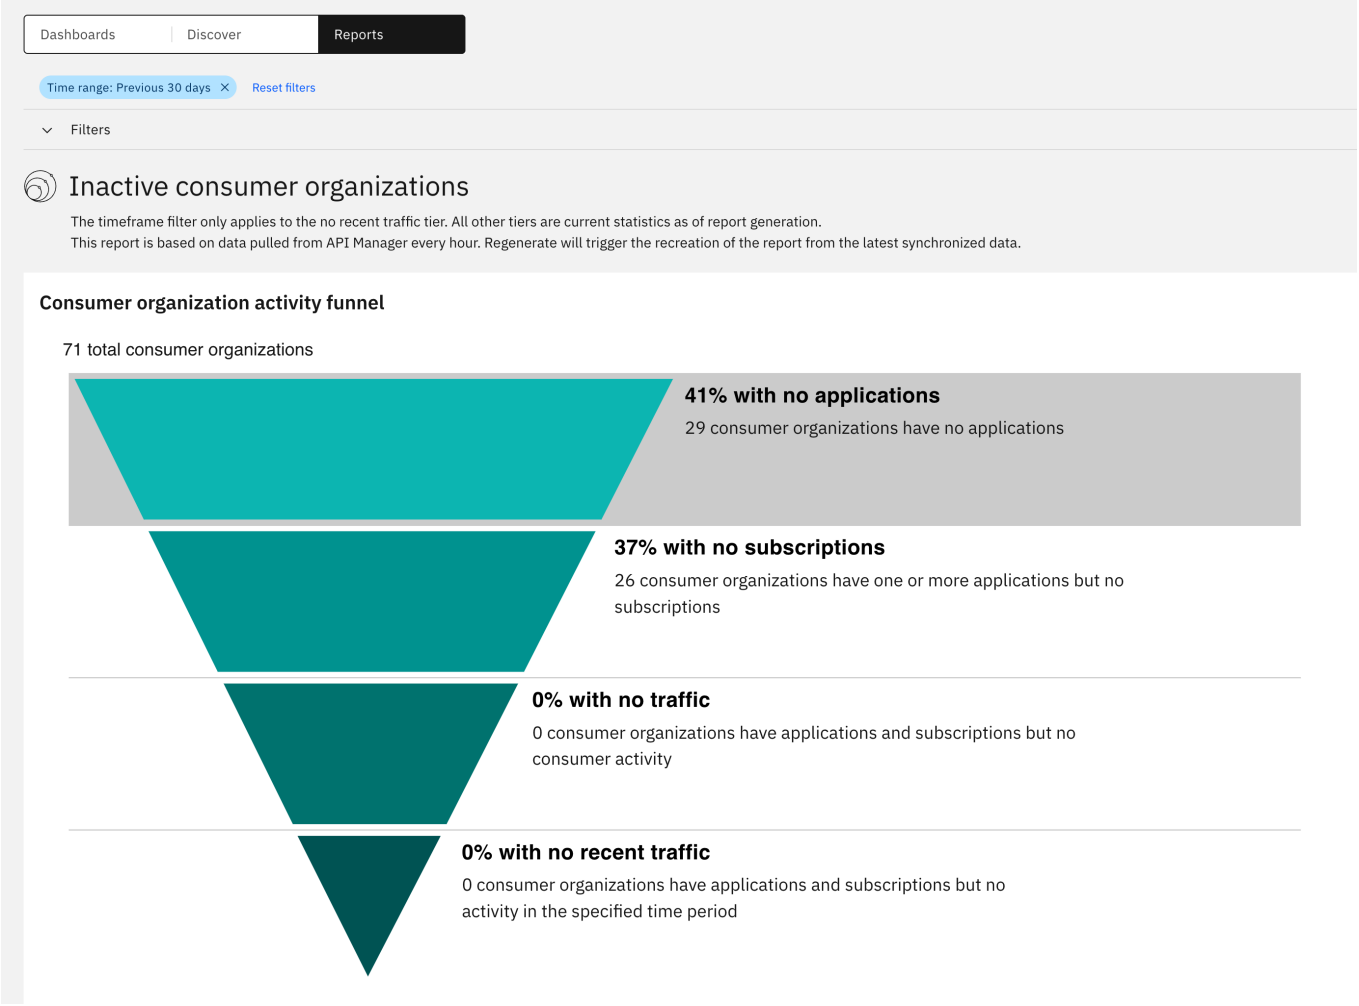


Call volume trends shows your most and least active APIs, total successful and failed API calls, total bytes sent and received, and totals based on scope.

Consumer trends shows the number of consumers and subscription and applications counts over time:

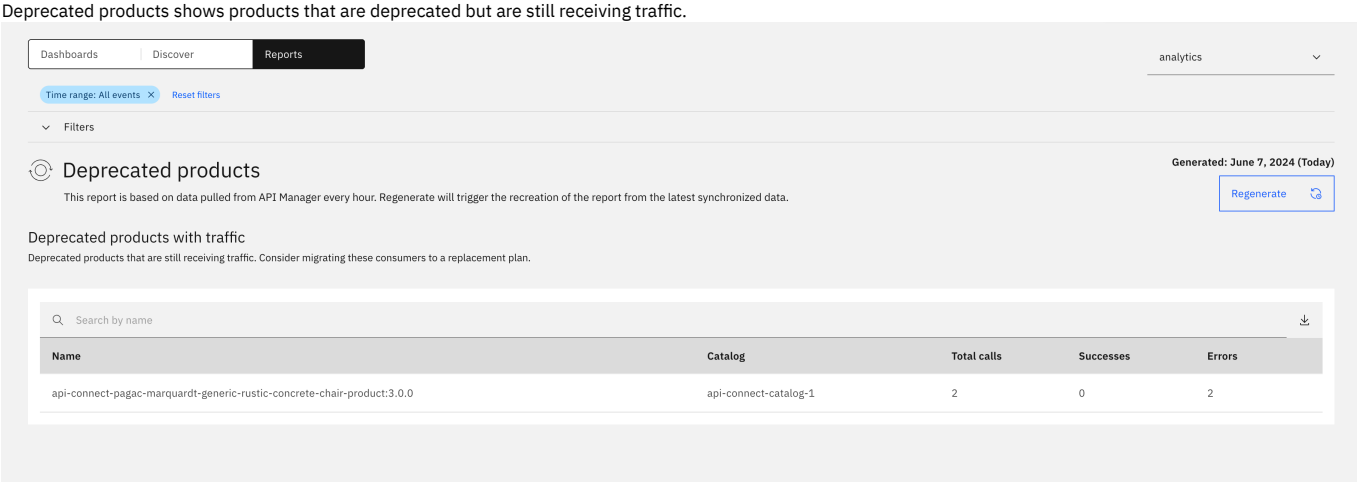


Consumption report shows long-term trends for API calls processed by gateways, which are essential for consumption-based licensing insights.



Date	Total calls	1xx	2xx	3xx	4xx	5xx	Other	Config-sync
2024-10	1391	0	794	0	418	179	0	0
2024-11	2680	0	1532	0	825	323	0	0

Inactive products shows products that have no subscriptions, and products that have no traffic.



Product	Catalog
api-connect-bailey-group-incredible-intelligent-frozen-keyboard-product:1.0.0	api-connect-catalog-2
api-connect-beer-llc-handcrafted-licensed-concrete-tuna-product:1.0.0	api-connect-catalog-2 api-connect-catalog-1
api-connect-bradtke-and-sons-ergonomic-awesome-steel-cheese-product:2.0.0	api-connect-catalog-2

Inactive consumer organizations shows consumer organizations that have no applications, subscriptions, recent traffic, or no traffic at all.

Deprecated products shows products that are deprecated but are still receiving traffic.

The API call volume leaderboards section shows leaderboards for APIs, Products, Plans, Applications, Consumer organizations, Gateway services and Breakdown by catalog. Click in the name column to see the data for each item.

Accessing analytics in the Developer Portal

How to view your analytics data from the Developer Portal.

Restriction: The Developer Portal sites show analytics data from the analytics service that is associated with the gateways that are used by the catalog. If a Developer Portal site's catalog uses more than one gateway service, then those gateway services must be associated with the **same** analytics service. If multiple analytics services are used by a catalog's gateways, then no analytics data is shown in the portal site corresponding to that catalog. Analytics services are associated with gateway services in the Cloud Manager UI, see Associating an analytics service with a gateway service.

Viewing organization scoped analytics data

1. Click the arrow next to your consumer organization name on the Developer Portal home page, and click My organization.
2. Click the Analytics tab.

From the Analytics tab, you can see your organization analytics, which include: API statistics, total calls, and total errors.

Viewing application scoped analytics data

1. Click Apps from the Developer Portal dashboard.
2. Click the name of the application for which you want to view analytics data.

From the Dashboard tab, you can see your application analytics, which include: API statistics, total calls, and total errors.

Counting total API calls for your analytics service

Count the API calls for the analytics subsystem and see the total that is categorized by response status.

Note: If your API Connect bases costs on usage, you can use the following methods to track this information so that you can accurately report it. If your organization did not deploy the analytics subsystem, then this feature is not available. If you deployed analytics but offload your data and disabled local storage, then you must capture usage information from the third-party system where you offload data.
You can see the total API calls over time for each analytics service in the consumption dashboard or report in the Cloud Manager UI.

Alternatively, the Analytics CLI can be used to get your API count:

1. Login as the cloud admin user:

   ```
   apic login --server <platform api endpoint> --username admin --realm admin/default-idp-1
   ```

2. Use the following CLI command to retrieve a count of all analytics events recorded by the analytics service:

   ```
   apic -m analytics events:cloudCount --server <platform api endpoint> --analytics-service <analytics service name> --format
   json
   ```

   where *<analytics service name>* is the name of analytics service as configured in the Cloud Manager UI.
3. If required, more filters can be applied to the results. For example, `--timeframe last12hours`. See the `help` output from: `apic -m analytics events:cloudCount -h` for more details.

Export your analytics data

Export your analytics data with either the toolkit CLI or the REST API.

The analytics export function in the UIs export just the data that is displayed in the UI, and is limited to 200 API events per page.

To export up to 10,000 API event records, use the toolkit CLI.

To export all your analytics data, use the REST API.
Note: If you plan to export you API event data regularly, use the offload feature instead. See Offload to third-party systems.

Exporting with the toolkit CLI

1. Follow the steps to install and configure the toolkit CLI.
2. Login with the correct user for the scope of analytics data you want to export. For example, to export all API event from a provider organization called `prod`, login as a member of that organization:

   ```
   apic login --server <platform api endpoint> --username <provider org member> --realm provider/default-idp-2
   ```

3. Use the `events` command to export your analytics data. For example, to export the events for a provider organization:

   ```
   apic -m analytics events:orgList --server <platform api endpoint> --analytics-service <analytics service name> --org <org
   name> --format=json
   {
       "total": 200,
       "search_time": 7,
       "events": [
           {
   ```

```
            "log_policy": "activity",
...
```

Note: Data is returned as a JSON array, each element is a single API event record.

Exporting with the REST API

1. Follow the steps to get started with the Analytics REST API.
2. Use the `events` API to export your data. For example, to get all analytics API event records from a provider organization, specify the organization's API path:

```
curl -v -k -H 'Accept: application/json' -H 'Authorization: Bearer <bearer_token>' -X GET --url
'https://<management_server_api_endpoint>/analytics/<analytics_service>/orgs/<provider_organization>/events'

{
    "total": 45543,
    "search_time": 36,
    "events": [...]
```

To get just the events for a catalog, specify the catalog in the API path; for example:

`/analytics/<analytics_service>/catalogs/<provider_organization>/<catalog>/events`

Allowing API Connect cloud admin users to view provider organization analytics data

The owner of a provider organization can enable or disable the sharing of analytics data with API Connect cloud administrators.

About this task

Beginning with API Connect version 10.0.7.0, analytics data is not shared with cloud admins by default; the owner of a provider organization must enable the sharing of analytics data with cloud admins.

This setting does not apply to total API call volume data. Cloud admins can always see the total volume of API calls across all provider organizations and for specific gateways. The setting applies only to analytics data that identifies the provider organization.

Procedure

To enable sharing of analytics data with cloud administrators, complete the following steps.

1. In API Manager, click Settings > Analytics > Share analytics data.
2. Click the slider to set it to On.

Sharing analytics data for API discovery

Share your provider organization's analytics data to enable API discovery.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. For more information about the API discovery feature, see Configuring a DataPower API Gateway proxy collector for API discovery.

Procedure

To enable API discovery, complete the following steps.

1. In API Manager, click Settings > Analytics > Share analytics data.
2. Click the slider to set it to On.

Analytics CLI

How to access your analytics data with the toolkit CLI.

About this task

The toolkit CLI provides commands for viewing your analytics data, and also for configuring analytics storage settings. To view organization scoped event data, login to the toolkit CLI with provider organization's user credentials. To view cloud scoped event data and analytics storage settings, login to the toolkit CLI as the cloud admin user.

Procedure

1. Install the toolkit: Setting up the API Connect toolkit
2. Log in with the CLI.
   For example,

```
apic login --server <platform api endpoint> --username <username> --realm <realm>
```

Where,

- *<platform api endpoint>* is the FQDN or base URL of your platform API endpoint, for example: `platform.example.com` or `https://platform.example.com`
- *<username>* is the provider org owner. To access cloud scoped data, login as the admin user.
- *<realm>* is the user registry realm for the specified *<username>*. By default the realm for provider organization owners is `provider/default-idp-2`. The realm for cloud admin users is `admin/default-idp-1`.

For more information, see Toolkit CLI Login.

3. View the available toolkit analytics commands by using `-m analytics -h`.
   Example

```
apic -m analytics -h

...
Available Commands:

  Creating applications and artifacts
     config                                  Manage configuration variables

  Publishing to the cloud
     clustermgmt                             Clustermgmt operations
     dashboards                              Dashboards operations
     events                                  Events operations
     filterparams                            Filterparams operations

  Other commands
     licenses                                Review the license for API Connect
     validate                                Validate an API or product definition
     version                                 Get the API Connect toolkit version
...
```

4. View your analytics events by using the `events` commands.

```
apic -m analytics events -h
Type "apic [command] --help" for help on the following related commands:
      events:catalogCount  Count events at catalog scope.
      events:catalogGet    Get specific event at catalog scope.
      events:catalogList   List events at catalog scope.
      events:cloudCount    Count events at cloud scope.
      events:cloudGet      Get specific event at cloud scope.
      events:cloudList     List events at cloud scope.
      events:orgCount      Count events at organization scope.
      events:orgGet        Get specific event at organization scope.
      events:orgList       List events at organization scope.
      events:spaceCount    Count events at space scope.
      events:spaceGet      Get specific event at space scope.
      events:spaceList     List events at space scope.

# To get a count of all API events at cloud level:
apic -m analytics events:cloudCount --analytics-service <analytics service name> --server <management server api endpoint>
--format=json
{
    "total": 200
}

# To get all the cloud level events:
apic -m analytics events:cloudList --analytics-service <analytics service name> --server <management server api endpoint>
--format=json
{
    "total": 200,
    "search_time": 7,
    "events": [
        {
            "log_policy": "activity",
...
```

Analytics REST API

How to access your analytics data with the REST API.

Before you begin

API Connect REST API calls are authenticated by using a bearer token in the authorization header. Use the toolkit credentials to request a bearer token. Toolkit credentials can be found in the API Manager UI:

1. Log in to the API Manager UI.
2. From the home page, click the Download toolkit tile.
3. Download the Toolkit credentials.
4. Open the downloaded `credentials.json` file:

```
...
  "toolkit": {
    "endpoint": "https://mgmt.api.example.com/api",
    "client_id": "7409693f-f726-48b4-8909-7c0d26f13e81",
    "client_secret": "5feeb0be-17f8-41a4-96d6-d40f33d69ef6"
```

```
  },
...
```

Take note of the `toolkit.client_id`, `toolkit.client_secret`, and `toolkit.endpoint` from this file. You use these values to get your bearer token.

Procedure

1. Create an API key. For more information about how to create an API key, see Managing platform REST API keys.
2. Use your API key to request a bearer token:

```
curl -v -k -X POST -d '{"api_key": "<api_key>", "client_id": "<client_id>", "client_secret": "<client_secret>",
"grant_type": "api_key"}' -H 'Content-Type: application/json' -H 'Accept: application/json'
https://<management_server_platform_api_endpoint>/api/token
```

Where,

- `<api-key>` is the API key that you have generated.
- `<client_id>` is the client ID from the "toolkit" section of the `credentials.json` file, or as provided by your API Connect cloud administrator.
- `<client_secret>` is the client secret from the "toolkit" section of the `credentials.json` file, or as provided by your API Connect cloud administrator.

The bearer token is returned in the access_token property:

```
{
    "access_token": "<bearer_token>",
    "token_type": "Bearer",
    "expires_in": 28800
}
```

Note the `expires_in` value, which is the number of seconds before the token expires. After expiry, you must request a new bearer token.

3. Use the returned bearer token to call the analytics REST API.

```
# This call to /orgs/<provider_organization>/events requires a bearer token that was requested with provider org
credentials:
curl -k -H 'Authorization: Bearer <bearer_token>' -X GET --url 'https://<platform api
endpoint>/analytics/<analytics_service>/orgs/<provider_organization>/events'

{
    "total": 300,
    "search_time": 3,
    "events": [...]
}

# This call to the consumer API: orgs/<consumer org>/dashboard, requires a bearer token that was requested with consumer
org credentials.
curl -k -H 'X-IBM-Consumer-Context: <provider org>.<catalog>' -H 'Authorization: Bearer <bearer_token>' -X GET --url
'https://<consumer api endpoint>/consumer-analytics/orgs/<consumer org>/dashboard'
{
    "search_time": 16,
    "status_codes": {
        "total": 300,
        "data": [...]
    },
    "min_response_time": {
        "data": ...
    ...

# This call to /cloud/events requires a bearer token that was requested with admin credentials:
curl -k -H 'Authorization: Bearer <bearer_token>' -X GET --url 'https://<platform api
endpoint>/analytics/<analytics_service>/cloud/events'

{
    "total": 45543,
    "search_time": 36,
    "events": [...]
```

Where,

- `<platform api endpoint>` is the `toolkit.endpoint`, but with the `/api` at the end that is replaced with `/analytics` to access the analytics APIs.
- `<analytics_service>` is the name of the analytics service.
- *<bearer_token>* is the token from step 2. Do not wrap the token with quotation marks.

4. Use query parameters to filter your results and display only certain fields.
If you want to search for specific analytics event records, then append the query parameters to the API call. For example, to get only event data for calls to a specific API and product:

```
/events?api_name=<api name>&product_name=<product name>
```

To get only certain API event record fields in the output, then append the `fields` query parameter. For example, to get only the API name and the time of the call:

```
/events?fields=api_name,datetime
```

To request only events before or after a certain time, use the `start` and `end` parameters. For example:

```
/events?start=2024-07-11T10:01:00.000Z&end=2024-07-11T10:02:00.000Z
```

What to do next

Complete documentation of the analytics REST API is here: Analytics REST API.

- **Using the events scroll operation to export analytics data**
Use the `/events/scroll` operation to export 10,000 or more analytics event records with the REST API.

Using the events scroll operation to export analytics data

Use the **/events/scroll** operation to export 10,000 or more analytics event records with the REST API.

The standard method to retrieve analytics event data with the API Connect Analytics REST API is using the **/events** API call. The **/events** API call is optimized for fast retrieval of the most recent event data, and is limited to returning a maximum of 10,000 API event records. If you want to retrieve more than 10,000 event records, then use the **/events/scroll** API, which is optimized for retrieval of large sets of analytics event data.

When you query your analytics data with **/events/scroll**, OpenSearch finds all the event records that match your query and creates a pointer that is called the scroll context. You then use the scroll context to retrieve the event data in batches.

Important: The creation of the results set and scroll context uses a lot of OpenSearch resources. It is recommended to not run multiple different **/events/scroll** queries simultaneously, and to delete the scroll context after your event data is retrieved.

Exporting analytics events with /events/scroll

The **/events/scroll** operation returns event data in batches. You define the batch size in the first call to **/events/scroll**, and then retrieve each batch in subsequent calls. You must make each subsequent call to **/events/scroll** within a certain time, called the scroll context keep-alive time. The procedure is as follows:

1. Make the first **/events/scroll** call. Specify the batch size and the keep-alive time for the scroll operation. For example, to return event data in batches of 1000, and to keep the scroll context alive for 10 minutes, then POST the following JSON to **/events/scroll**:

   ```
   {
     "size": 1000, # Return the first 1000 event records.
     "scroll": 10m # Keep the scroll context alive for 10 minutes.
   }
   ```

   - **size** defines the batch size.
   - **scroll** defines the keep-alive time and uses the format *<number><units>*, for example: 30s, 5m, 3h, 1d. The maximum value for **scroll** is 1d.

   Example response:

   ```
   {
       "total": 5926, # The total events found that match the query.
       "scroll_id": "FGl....", # Scroll context id to be used to get the next batch.
       "events": [...] # First batch of event data.
   }
   ```

2. Make the next **/events/scroll** call, specifying the **scroll_id** from the previous response:

   ```
   {
     "size": 1000,
     "scroll_id": "<as returned from previous call>",
     "scroll": 10m
   }
   ```

   The API returns the next batch of 1000 event records, and a new **scroll_id** for the next call.
   Note: If your **scroll_id** is expired, the following response is returned:

   ```
   {
     "status": 404,
     "message": [
       {
         "trace": "7c7b3b11ee0e95b61452e8a78086d8e2",
         "errors": [
           {
             "code": "search_context_missing_exception",
             "message": "No search context found for id [48420]",
             "more_info": ""
           }
         ]
       }
     ]
   }
   ```

   If your **scroll_id** expires, then you must start again. Set a higher keep-alive time for the scroll context to allow more time for event record batches to be returned and the next **/events/scroll** call to be made.

3. Continue making **/events/scroll** calls, updating the **scroll_id** each time with the response from the previous call.
4. After the last call to retrieve your event data, delete the scroll context with a POST to **/events/scroll/delete**:

   ```
   {"scroll_id": "<as returned from previous call>"}
   ```

   Example response:

   ```
   {
       "succeeded": true,
       "num_freed": 15
   }
   ```

   Note: The scroll context is automatically deleted when it expires, but if you have a long keep-alive time, then it is recommended to delete it explicitly to release resources.

Worked example

The following example shows how you can use the **curl** command to manually retrieve your API event data by using the **/events/scroll** API.

Note: For large amounts of analytics data, manual retrieval with **curl** is slow and prone to human error. A better approach is to write a script to make the `/events/scroll` calls and update the `scroll_id` each call. See https://ibm.biz/apic-analytics-events-scroll for an example Python script.

1. Get a count of total event records to decide the optimal batch size and number of calls to make:

   ```
   curl -k -X GET --url 'https://example.api.connect.com/analytics/analytics/cloud/events/count' -H 'Authorization: Bearer <bearer_token>'

   {
       "total": 12453
   }
   ```

   For 12453 events, a batch size of 1250, and a total of 10 calls might be a good balance between size of output and number of calls.

2. Make the first request, specifying the batch size of 1250, and a scroll context keep-alive time of 5 minutes:

   ```
   curl -k -X POST -d '{"size": "1250", "scroll": "5m"}' --url
   'https://example.api.connect.com/analytics/analytics/cloud/events/scroll' -H 'Content-Type: application/json' -H
   'Authorization: Bearer <bearer_token>'
   ```

   Returns:

   ```
   {
       "total": 12453, # The total events found that match the query.
       "scroll_id": "<scroll_id>",
       "events": [...] # First batch of 1250 events.
   }
   ```

3. Make the second request, specifying the `scroll_id` returned from the previous request:

   ```
   curl -k -X POST -d '{"size": "1250", "scroll": "5m", "scroll_id": "<scroll_id from previous response>"}' --url
   'https://example.api.connect.com/analytics/analytics/cloud/events/scroll' -H 'Content-Type: application/json' -H
   'Authorization: Bearer <bearer_token>'
   ```

4. Repeat the request 8 more times, updating the `scroll_id` with the output from the previous request each time.
   Because total events are 12453 and batch size is 1250, the last request returns just 1203 events.

   Any subsequent requests that you make with the `scroll_id` return an empty events array.

5. Delete the scroll context:

   ```
   curl -k -X POST -d '{"scroll_id": "<scroll_id from previous response>"}' --url
   'https://example.api.connect.com/analytics/analytics/cloud/events/scroll/delete' -H 'Content-Type: application/json' -H
   'Authorization: Bearer <bearer_token>'
   ```

Performance comparison of `/events/scroll` and `/events`

The following tables show performance comparisons for querying analytics event data by using scripted calls. Times are the total time to retrieve all event records in seconds. The `/events` API cannot retrieve more than 10000 events (nor batches of 1000 or more), so these fields are marked as n/a.
Note: Response times on your analytics subsystem might vary according to the size of your API event records, total number of records, and your available hardware resources.

Table 1. Fetching 1000 event records (5.3 Mb)

Batch size	Number of calls	`/events` time	`/events/scroll` time
100	10	7	9
500	2	3	4
1000	1	n/a	3
2000	1	n/a	5

Table 2. Fetching 10,000 event records (26 Mb)

Batch size	Number of calls	`/events` time	`/events/scroll` time
100	100	67	75
500	20	27	32
1000	10	n/a	24
2000	5	n/a	20

Table 3. Fetching 100,000 event records (265 Mb)

Batch size	Number of calls	`/events` time	`/events/scroll` time
100	1000	n/a	732
500	200	n/a	299
1000	100	n/a	258
2000	50	n/a	196

Table 4. Fetching 760,265 event records (2 GB)

Batch size	Number of calls	`/events` time	`/events/scroll` time
100	7603	n/a	5647
500	1521	n/a	2423
1000	761	n/a	2158
2000	381	n/a	1919

Troubleshooting analytics

How to diagnose and resolve common issues with the analytics subsystem.

- **No analytics data in UIs**
  How to check that your analytics subsystem is receiving API event data from the gateways.
- **Running out of storage space**
  Actions that you can take if your analytics data is using more persistent storage space than you expected.
- **Offload failure**
  What to check if offload to a third-party system is failing.
- **Gathering postmortem logs**
  The logs are gathered for upload to a support case.
- **Analytics subsystem CR is in an error state**

No analytics data in UIs

How to check that your analytics subsystem is receiving API event data from the gateways.

1. The **mtls-gw** is the pod that receives the API events from the gateway. Identify the name of your **mtls-gw** pod or pods with:

   ```
   kubectl get pods -n <namespace>
   ```

   Expected output:

   ```
   NAME                                                    READY   STATUS      RESTARTS   AGE
   ...
   analyt-mtls-gw-7665f5d445-4cx4n                           1/1     Running     0          3d19h
   ```

2. For each **mtls-gw** pod, run the following command to see the logs of that pod:

   ```
   kubectl logs <mtls-gw pod name> -n <namespace>
   ```

3. The gateway sends API event data to the **mtls-gw** pod as an HTTP POST call to the path **/x2020/v1/apievent/_bulk**.
   Every time that the **mtls-gw** pod receives API event data from the gateway, it logs the following message, known as a **_bulk** message:

   ```
   10.254.6.1 - - [22/Sep/2021:18:05:54 +0000] "POST /x2020/v1/apievent/_bulk HTTP/1.1" 200 2 "-""-" 2841 0.072 0.070
   ```

   Check the **mtls-gw** pod logs for recent **_bulk** messages.

   If you find no **_bulk** messages in the **mtls-gw** logs, then the analytics subsystem is not receiving API event data from the gateway. Check the network connection between your gateway and analytics subsystems, and review *Analytics endpoints* in the gateway documentation.

   The HTTP return code is shown in the **mtls-gw** log messages. In the example, this code is 200, which means the API event data was received successfully by the analytics subsystem. Whatever the return code is, if your **mtls-gw** pod logs contain recent "_bulk" messages and you do not see any analytics data for this time period in the UI, then gather postmortem logs and open an IBM® support case.

Running out of storage space

Actions that you can take if your analytics data is using more persistent storage space than you expected.

Reduce retention period

The simplest remedy to running out of storage space is to reduce the data retention period.

By default, API event records are retained for a maximum number of days. This maximum depends on your deployment profile. To see the default retention settings for each profile, refer to Retention and rollover.

If your analytics subsystem was deployed more recently than your retention period and you are running out of storage space, then there is a risk that your persistent storage fills up before the retention period is reached. For example, if you deployed the **n1xc4.m32** profile 15 days ago, and you are already low on storage space, then it is likely you all your storage is used before the 30-day retention period for this profile is reached. Check in the Cloud Manager UI how many days back your API event data goes, and set the retention period to a lower number. For example, if you see API event records from 15 days ago, reduce your storage requirement by one-third by setting your retention period to 10 days.

Kubernetes and Red Hat OpenShift users: Reinstall with larger PVCs

It is not possible to increase the PVC size after installation. If you require more space for your analytics data, the analytics subsystem must be reinstalled. Follow these steps:

1. Take a backup of your analytics subsystem: Kubernetes, OpenShift, and Cloud Pak for Integration.
2. Reinstall your analytics subsystem with a larger PVC size:
   - Kubernetes
   - OpenShift and Cloud Pak for Integration
3. Restore your analytics data from your backup: Recovering from a disaster.

Note: If you use a storage class that supports volume expansion, then instead of reinstalling you can attempt to increase the PVC size and then increase the storage **volumeSize** in the analytics CR. If this is successful, then you do not need to reinstall the analytics subsystem.
If you want to try increasing your PVC size, then consult your Kubernetes or Red Hat® OpenShift administrator for the steps.

Reduce space used by new API event data

To reduce the storage required for new analytics data, update the activity log settings of your APIs: Activity log policy.
Tip: If you're not able to update the activity log configuration for your APIs, you can disable response payload logging for all APIs with ingestion filters. For example,

```
filter {
  if "apicapievent" in [tags] {
     mutate {
            remove_field => ["response_body"]
        }
  }
}
```

What to do if your storage is 100% full

If your storage space is 100% full, your analytics subsystem might be unresponsive, so reducing the retention period is not possible. In this scenario, follow the disaster recovery steps: Recovering from a disaster.

Offload failure

What to check if offload to a third-party system is failing.

- Check the ingestion pod logs for error messages that are related to offload.
  - Kubernetes, Red Hat® OpenShift®, and Cloud Pak for Integration:

    ```
    kubectl -n <namespace> logs <analytics ingestion pod name>
    ```

  A common problem is TLS handshaking errors, such as untrusted or expired certificates.
- Check logs on your third-party system.
- Verify that the specified URL or the host and port values for the target system are accurate.
- Verify that the server or cluster of servers in the target system are running and reachable. If applicable, also verify that firewall settings are not causing connection problems.
- If offloading data to an Elasticsearch or Kafka target, verify that your configuration settings are valid; for example, the user credentials for authenticating to Elasticsearch or the Kafka topic name.

Gathering postmortem logs

The logs are gathered for upload to a support case.

The `mustgather` script

For more information, See the following documents.

- Gathering logs on Kubernetes and OpenShift®.

Gathering the pod logs

If the **`mustgather`** script fails, the pod logs can be gathered manually:

- **Kubernetes and Red Hat® OpenShift** Get the logs from all analytics pods in your environment. Use the command:

  ```
  kubectl -n <namespace> logs <analytics pod name> > <analytics pod name>.log
  ```

  where:
  - *<namespace>* is the namespace of your analytics subsystem.
  - *<analytics pod name>* is the name of the analytics pod. See the list of analytics pods.

  The logs for each pod are written to the file *<analytics pod name>*.log. Upload all the generated logs to the support case.

Getting the OpenSearch cluster status

If the **`mustgather`** script fails you can use the toolkit CLI to get the status of your OpenSearch cluster, and a list of the indices.

1. Follow the steps to install and configure the toolkit CLI.
2. Login to the CLI as the cloud admin user:

   ```
   apic login --server <platform api endpoint> --username admin --realm provider/default-idp-1
   ```

3. Get the OpenSearch cluster status with:

   ```
   apic --mode analytics clustermgmt:catIndices --server <platform api endpoint> --analytics-service <analytics service name>
   --format json
   ```

4. Get the details of the OpenSearch indices with:

   ```
   apic --mode analytics clustermgmt:catIndices --server <platform api endpoint> --analytics-service <analytics service name>
   --format json
   ```

Upload the cluster status and indices output to the support case.

Analytics subsystem CR is in an error state

If the analytics subsystem CR is in error state and contains the following message that is related to the analytics client endpoint, remove the client endpoint definition from the analytics CR as it is no longer used.

```
"APIC_APICOPS_0089E - The provided issuer did not sign the certificate. Expected Issuer: "CN=<NAME>",
          Signed Issuer: "CN=<NAME>", see status.SystemCheck for more details."
```

For example, if you encounter an issue as stated earlier, remove the following block from the CR specification.

```
client:
         clientAuthEnabled: true
         clientSubjectDN: CN=analytics-client-client,O=cert-manager
         enabled: true    endpoint:
         annotations:
         cert-manager.io/issuer: production-ingress-issuer
         hosts:
        - name: ac.apps.2dcdr.awsciondemand.com
        secretName: analytics-endpoint-secret
```

Note: If you are using a top level **`APIConnectCluster CR`**, then remove the block from the **`spec.analytics`** section.

Reference

Reference information for IBM® API Connect, including summary reference material for the developer toolkit command-line tool (CLI), a link to the API Connect Version 10.x White Paper, and information about the API Connect platform REST APIs.

Reference item	Description
The API Connect REST APIs	The platform REST APIs that can be used to manage the API Connect cloud configuration, access the API provider capability, and use the consumer API microservice.
API Connect TLS certificates	Table of all TLS certificates created and used by an API Connect installation.

The API Connect REST APIs

How to get started with the API Connect REST APIs

The API Connect REST APIs can be used for the following actions:

- Automate the administration of API Connect.
- Implement scripts and tools to support a continuous integration environment for API development and publishing.
- Manage catalogs of APIs, and their subscribers.
- View analytics data.

Complete reference documentation for the API Connect REST APIs is available here: API Connect REST API documentation.

Prerequisites

To use the API Connect REST APIs, you must meet the following prerequisites:

- Have an API Connect user that is a member of a provider or consumer organization. To call APIs that are cloud scoped, your user must be a member of the admin organization, see Adding members to the admin organization.
- App credentials: A client_id and client_secret. These credentials can be obtained from the API Manager or Cloud Manager UI, or provided to you by your API Connect administrator.

To get the API endpoint URLs and the app credentials, follow these steps:

1. In the API Manager UI home page, click the Download toolkit tile.
2. Download the Toolkit credentials (you do not need to download the CLI or API Designer).
3. Open the downloaded **`credentials.json`** file to see the platform and consumer endpoints, and the credentials to call APIs on these endpoints:

```
{
  "cloud_id": "e8fcdec3-bfb9-44bd-bf90-03d8639c4916",
  "toolkit": {
    "endpoint": "https://example-platform-api.ibm.com/api",
    "client_id": "7ad7b6c5-fa07-4222-808d-8de7266dcd1a",
    "client_secret": "b7127e44-4811-48be-be9d-6591302de04a"
  },
  "consumer_toolkit": {
    "endpoint": "https://example-consumser-api.ibm.com/consumer-api",
    "client_id": "3b10e0db-1cd4-4aa8-af02-51a83e334f1c",
```

```
    "client_secret": "a5a672b7-e3b2-4d2b-984b-4059ea82ae65"
  },
  "governance": {
    "endpoint": "https://example-governance.ibm.com/governance",
    "client_id": "ba48537c-7a6e-4232-92b6-ae67ad764933",
    "client_secret": "790d8a6d-e323-46bd-a05c-3d212e93d794"
  },
  "discovery": {
    "endpoint": "https://example-discovery.ibm.com/discovery",
    "client_id": "d872a2f4-bc6e-4e91-b187-bbb5b99d4605",
    "client_secret": "c0b5ddf9-58e6-4246-88de-243ce217731a"
  }
}
```

The endpoints and credentials that are contained in the **credentials.json** file are

a. **toolkit**: The platform API endpoint. Use this for provider organization scoped and cloud scoped API calls.
b. **consumer_toolkit**: The consumer API endpoint. Use this for consumer organization scoped API calls, such as creating an app in a consumer organization.
c. **governance**: See the API Governance feature.
d. **discovery**: See the API Discovery feature.

Note: Your API Connect cloud administrator might provide you with different app credentials to use. In this case, do not use the credentials that are in the **credentials.json** file.

Generating app credentials

If you are the cloud administrator, you can create separate app credentials for each user with the toolkit CLI. Follow these steps:

1. Create a JSON file that contains the new credentials:

```
{
  "name": "User1App",
  "client_id": "User1ID",
  "client_secret": "User1Secret",
  "client_type": "<toolkit or consumer_toolkit>"
}
```

Where **client_type** is set to **toolkit** for creating credentials for provider organization members, and set to **consumer_toolkit** for consumer organization members.

2. Use the toolkit CLI to register the credentials:
   a. Log in as a cloud admin user:

```
apic login --server <platform api endpoint> --username <username> --realm <realm>
```

   b. Register the new credentials:

```
apic registrations:create --format json --server <platform API endpoint>  <JSON credentials file>
```

If you do not have the toolkit CLI installed, then refer to Setting up the API Connect toolkit.

Obtaining a bearer token

Each call to the REST APIs must be authenticated with a bearer token in the HTTP **Authorization** header. Create an API key. For more information about how to create an API key, see Managing platform REST API keys.

Use your app credentials to obtain a bearer token:

```
curl -v -k -X POST -d '{"api_key": "<api_key>", "client_id": "<client_id>", "client_secret": "<client_secret>", "grant_type":
"api_key"}' -H 'Content-Type: application/json' -H 'Accept: application/json'
https://<management_server_platform_api_endpoint>/api/token
```

Where:

- **<api-key>** is the API key you have generated.
- **<client_id>** is the client ID from the "toolkit" section of the **credentials.json** file, or as provided by your API Connect cloud administrator.
- **<client_secret>** is the client secret from the "toolkit" section of the **credentials.json** file, or as provided by your API Connect cloud administrator.
- **provider/default-idp-2** for provider organization members.
- consumer: **<provider org>:<catalog>/<catalog>-idp** for consumer organization members.

The bearer token is returned in the **access_token** property:

```
{
    "access_token": "<bearer_token>",
    "token_type": "Bearer",
    "expires_in": 28800
}
```

Note: The **expires_in** value is the number of seconds before the token expires. After expiry, you must request a new bearer token.

Making REST API calls

Use your bearer token when you make calls to the REST API:

```
curl -k -X <HTTP Method> --url 'https://<rest api endpoint>/<api path> -H 'Authorization: Bearer <bearer_token>'
```

If you make calls to the consumer API, then you must include an extra header that specifies the provider organization and catalog:

```
-H 'X-IBM-Consumer-Context: <provider org>.<catalog>'
```

Example REST API calls

Get a list of the provider organizations

User a bearer token that was created with provider organization member credentials, and specify the platform API endpoint:

```
curl -k -X GET --url 'https://<platform api endpoint>/api/orgs' -H 'Authorization: Bearer <bearer_token>'
```

Get a list of the apps in a catalog

Use a bearer token that was created with consumer organization member credentials, specify the consumer API endpoint, and include the **X-IBM-Consumer-Context** header:

```
curl -k -X GET --url 'https://<consumer api endpoint>/consumer-api/orgs/<consumer org>/apps' -H 'X-IBM-Consumer-Context: <provider org>.<catalog>' -H 'Authorization: Bearer <bearer_token>'
```

Get analytics API event data for a catalog:

```
curl -k -X GET --url 'https://<platform api endpoint>/analytics/<analytics service>/orgs/<provider org>/events' -H 'Authorization: Bearer <bearer_token>'
```

For provider organization scoped analytics data, use *<platform api endpoint>*.

For consumer organization scoped analytics data, use *<consumer api endpoint>*, and **/consumer-analytics** instead of **/analytics**. Also include the **X-IBM-Consumer-Context** header. For example:

```
curl -k -X GET --url 'https://<consumer api endpoint>/consumer-analytics/orgs/<consumer org>/dashboard' -H 'X-IBM-Consumer-Context: <provider org>.<catalog>' -H 'Authorization: Bearer <bearer_token>'
```

For more information about querying analytics data with the REST API, see Using the analytics REST API.

Get a list of the availability zones in your API Connect deployment

Use a bearer token that was created with cloud admin user credentials, and specify the platform API endpoint:

```
curl -k -X GET --url 'https://<platform api endpoint>/api/orgs/admin/availability-zones' -H 'Authorization: Bearer <bearer_token>'
```

Reference documentation for the API Connect REST APIs: API Connect REST API documentation.

Troubleshooting failed REST API calls

The HTTP return code and error message provide information on the possible causes of the failure:

- HTTP 403: "Forbidden". Check that your bearer token was created with the correct credentials for the API call.
- HTTP 404: "Not Found". Verify that your API endpoint URL and path are correct. Are you making a consumer API call on the platform API endpoint?
- HTTP 401: "Unauthorized". Check that your bearer token is correct and is not expired. If this is returned when you request a bearer token, verify that the **username**, **password**, **realm**, **client_id**, and **client_secret** are correct.

Example: Using the platform REST APIs to publish a product containing a SOAP API

Review this sample scenario to see how you can use the API Connect platform REST APIs to publish a product that contains a SOAP API.

This example demonstrates how to format a request to publish the product, and includes sample files that illustrate the product definition, the API definition, and the SOAP API's WSDL description.

Using the `Catalogs` API

Publish the product using the API Connect platform **Catalogs** API:

- To publish a product to a catalog, use the following syntax:

  ```
  POST catalogs/{org}/{catalog}/publish
  ```

- To publish a product to a space within a catalog, additionally specify the space with the following syntax:

  ```
  POST catalogs/{org}/{catalog}/{space}/publish
  ```

The payload in both cases is a multipart, form-encoded body containing three required parts and one optional part:

- (Required) A part named **product** with media type **application/yaml** or **application/json**, containing the yaml or JSON source for the product to be published.
- (Required) One or more occurrences of a part named **openapi** with media type **application/yaml** or **application/json**, containing the YAML or JSON source for each API in the product.
- (Required for SOAP APIs) One or more occurrences of a part named **wsdl** with media type **application/wsdl**, **application/wsdl+xml**, **text/xml**, or **application/zip** containing the WSDL definitions (and referenced XSD files if applicable) associated with the API content.
- (Optional) A part named **gateway_service_urls** with media type **application/yaml** or **application/json** which is a YAML or JSON array of URLs to specify a subset of the configured gateway services within the catalog or space as publish targets. These URLs can be obtained using the following calls:
  - For a catalog:

    ```
    GET /api/catalogs/{org}/{catalog}/configured-gateway-services
    ```

  - For a space:

    ```
    GET /spaces/{org}/{catalog}/{space}/configured-gateway-services
    ```

Within the **product** content, the form of the references to APIs in the **apis** section is significant. Each API reference must use the **name** property instead of the **$ref** form that may appear in other situations. Here is an example showing a product that refers to the API **globalweather** version **1.0.0** in the correct form:

```
info:
  version: 1.0.0
  title: GlobalWeatherProduct
  name: globalweatherproduct
plans:
  ...
apis:
  globalweather1.0.0:
    name: globalweather:1.0.0
...
```

Example publish operation using cURL

This example publishes a product containing a SOAP API to the *Sandbox* catalog of the *onlinebanking* provider organization, using the **curl -F** option to create a set of form-encoded payload parts and the **@** prefix to read the content for each part from a file. Note the part name (**product**, **openapi**, **wsdl**) and the content type of each part given by the **type=** value.

In this example, the access token has been retrieved earlier and placed in an environment variable named **TOKEN**. The command is split onto multiple lines for ease of reading but must be entered as a single line.

Request:

```
curl -v -k
  -F "product=@globalweatherproduct_1.0.0.yaml;type=application/yaml"
  -F "openapi=@globalweather_1.0.0.yaml;type=application/yaml"
  -F "wsdl=@globalweather.wsdl;type=application/wsdl"
  -H "Authorization: Bearer $TOKEN"
  -H 'Content-Type: multipart/form-data'
  -H 'Accept: */*' https://dev.apic.example.com/api/catalogs/onlinebanking/sandbox/publish
```

Response:

```

96a8ca9667fd/products/d03129a4-9a99-4c88-85e6-d51bbf312164"
```

The request specifies three files, which are included with this example for reference:

- Product definition `-F "product=@globalweatherproduct_1.0.0.yaml;type=application/yaml"`
- API definition `-F "openapi=@globalweather_1.0.0.yaml;type=application/yaml"`
- WSDL description `-F "wsdl=@globalweather.wsdl;type=application/wsdl"`

Example Product file: globalweatherproduct_1.0.0.yaml

The following code sample contains a Product definition.

The Product definition file globalweatherproduct_1.0.0.yaml is referenced by the example scenario in Example: Using the platform REST APIs to publish a product containing a SOAP API.

```
info:
  version: 1.0.0
  title: GlobalWeatherProduct
  name: globalweatherproduct
gateways:
  - datapower-api-gateway
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    rate-limits:

```

API Connect TLS certificates

Details of all Kubernetes TLS certificate objects that are created and used in a default installation of API Connect.

Overview

TLS is used to secure communications between API Connect pods, subsystems, external services, and users. The TLS certificates that are used by API Connect are created automatically during the installation of API Connect. The certificates are managed by an open source product called cert-manager.

The certificates that are described in this topic all exist as Kubernetes certificate objects in the API Connect namespace where the subsystem that uses the certificate is installed. Run **`kubectl get certs -n <namespace>`** to see the certificates in your environment. Some of the API Connect Kubernetes certificates are also stored in the management subsystem database. These certificates can be seen in the Cloud Manager UI, in the truststores and keystores of the subsystem default TLS profiles. When the management subsystem **`apim`** pod is restarted, the certificates in the management database are reloaded from the Kubernetes certificates.

Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.

The certificates that are created and used by API Connect are categorized as follows:

- CA certificates - API Connect creates self-signed CA certificates to sign all the API Connect end-entity certificates. The CA certificates are:
  - **`ingress-ca`** - used by the ingress-issuer. The ingress-ca signs all user-facing and inter-subsystem certificates.
  - **`management-ca`** - signs all the management intra-subsystem certificates.
  - **`portal-ca`** - signs all the portal intra-subsystem certificates.
  - **`analytics-ca`** - signs all the analytics intra-subsystem certificates.

  CA certificates have a default duration of 10 years. All the end-entity certificates have a default duration of 2 years.
- Ingress certificates - API Connect creates a self-signed issuer that is called the ingress-issuer. Ingress certificates are the API Connect certificates that are issued by the ingress-issuer. Ingress certificates are divided into two types:
  - Inter-subsystem certificates - certificates that are used for communication between API Connect subsystems, for example between the management subsystem and gateway. By default, communication between most subsystems uses mTLS. From v10.0.5.3, it is possible to use JWT instead of mTLS: Using JWT instead of mTLS on Kubernetes and OpenShift®, .
  - User-facing certificates - certificates that API Connect users see when they interact with the API Connect UIs and REST API.
- Intra-subsystem certificates - certificates that are used between pods in the same subsystem. Intra-subsystem certificates are signed by a subsystem specific CA certificate: **`management-ca`**, **`portal-ca`**, **`analytics-ca`**. The gateway subsystem is a single pod, and has no intra-subsystem certificates.

Note: On Cloud Pak for Integration, and Red Hat OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the **`APIConnectCluster`** instance name. For example, the certificate **`managment-ca`** is called ***`<apic instance name>`*`-mgmt-ca`**.

Customizing certificates

It is possible to customize certificates with ones from your own organization. However, it is recommended to customize only the user-facing certificates, which are the certificates that your users see when they access the API Connect UIs, CLI, and the REST API.

Important: If you do customize certificates, then you are responsible for maintaining those certificates. Ensure that your custom certificates meet the requirements that are defined in the Reference tables (which are subject to change in future fix packs), and that you renew them before they expire.
All other certificates are used internally between API Connect microservices.
Note: The inter and intra-subsystem certificates use of a self-signed root CA presents no security risk. For internal communications with a limited number of predefined endpoints, use of locally generated self-signed CA certificates can be more secure than external CA certificates, as certificates are only ever issued for the known components and the domain of trust is kept as small as possible.

Renewing certificates

Cert-manager handles the renewal of expired certificates so that the user does not need to monitor or manually renew any of the certificates. However, there are scenarios where the renewal of certificates must be triggered manually. Every API Connect certificate has a corresponding Kubernetes secret object of the same name, deleting this secret triggers cert-manager to re-create the secret with a new TLS certificate. For more information about certificate renewal, see Renewing TLS certificates.
Remember: The Kubernetes certificate objects do not contain the TLS certificates themselves, they are pointers to Kubernetes secrets that contain the TLS certificate. See Key Concepts: Cert-manager, Issuers, and Secrets.
For most of the certificates, when they are renewed, the pods that use those certificates are automatically restarted so that they pick up the updated certificate. The minority of certificates that require manual pod restarts after renewal are identified in the reference tables.

If you renew a CA certificate, any end-entity certificates that use this CA certificate must also be renewed. The following command identifies and renews all certificates that are signed by **`ingress-ca`** in the specified namespace:

```
kubectl get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <namespace>
```

Warning: Cert-manager automatically renews the **`ingress-ca`** 30 days before it expires. The automatic renewal of **`ingress-ca`** does not trigger the renewal of the end-entity certificates that are signed by **`ingress-ca`**. When **`ingress-ca`** is automatically renewed, you must manually renew all end-entity certificates.

Reference tables

The tables show all the API Connect certificates that are created in all possible deployment configurations.

Each table corresponds to a subsystem, and shows the certificates that are used by that subsystem.
Note: On Cloud Pak for Integration or top-level CR deployments, some of the certificates have a shortened name. Where two names for a certificate are shown in the tables, the second name is the name that is used on Cloud Pak for Integration or top-level CR deployments. For example, **`management-ca or mgmt-ca`**.

Table 1. Management certificates

Certificate name	Issuer	Description
`-ingress-ca`	**`selfsigning-issuer`**	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with **kubectl**. When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem **`apim`** pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the **`portal-www`** pods for the update to take effect.

Certificate name	Issuer	Description
`management-ca or mgmt-ca`	`selfsigning-issuer`	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using **`in-cluster`** communication. See In-cluster service communication between subsystems
`management-client or mgmt-client`	`management-ca`	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.

`management-server or mgmt-server`	`management-ca`	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`

`analytics-client-client or a7s-cl-client`	`ingress-issuer`	Legacy certificate from pre-v10.0.5 releases. Not used for anything and safe to delete. In v10.0.5, communication with the analytics subsystem uses the **`analytics-ingestion-client`** certificate.

`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have:
		• The same CA as the server certificate **`analytics-ai-endpoint`** on the analytics subsystem.
		• The common name must match the **`spec.clientSubjectDN`** in the analytics CR:
		`kubectl describe cert analytics-admin-client`
		`Spec:`
		`Common Name: a7s-ing-client`
		`kubectl get a7s -o yaml`
		`spec:`
		`clientSubjectDN: CN=a7s-ing-client`
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be **`CN=a7s-ingestion-client`**, or they could both be **`CN=a7s-ingestion-client, O=cert-manager`**, but they must be identical.
		To update this certificate, use kubectl. Restart the **`apim`**, **`taskmanager`**, and **`analytics-proxy`** pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
		This certificate is loaded by the management subsystem into the **`Analytics ingestion TLS client profile`** that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service.

`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the **`portalAdminEndpoint`**. This certificate must have:
		• The same CA as the server certificate **`portal-admin or ptl-director`** on the portal subsystem.
		• The common name must match the **`spec.adminClientSubjectDN`** in the portal CR:
		`kubectl describe cert portal-admin-client`
		`Spec:`
		`Common Name: ptl-adm-client`
		`kubectl get ptl -o yaml`
		`spec:`
		`adminClientSubjectDN: CN=ptl-adm-client`
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be **`CN=portal-admin-client`**, or they could both be **`CN=ptl-adm-client, O=cert-manager`**, but they must be identical.
		This certificate is loaded by the management subsystem into the **`Portal Director TLS client profile`** that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service.

`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the **`apim`** and **`taskmanager`** pods after update. This certificate must have the same CA as the **`gwv6-manager-endpoint or gw-gateway-manager`** certificate on the gateway. This certificate is loaded by the management subsystem into the **`Gateway management client TLS client profile`** that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the gateway, then create a new profile and specify it when you register the gateway service.
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
`consumer-catalog-endpoint`	`ingress-issuer`	Consumer catalog endpoint server certificate.

Certificate name	Issuer	Description
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`db-client-apicuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`management-s3proxy-all`	`ingress-issuer`	Inter-subsystem certificate for communication between management subsystem and s3proxy pods. Used for management database local and SFTP backups.
`natscluster-mgmt`	`management-ca`	Intra-subsystem certificate for the `nats` pods.
`mgmt-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate used in the warm-standby data center's `<remote-sitename>-postgres` pod to connect to the active data center.
`mgmt-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<management_CR>-tunnel` pod. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the management CR.
`hub-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the `hub-endpoint`. If there is a problem with this certificate, then the user's browser shows a warning or error message.

Table 2. Analytics certificates

Certificate name	Issuer	Description
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint in the `mtls-gw` pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the `analytics-ai-endpoint` certificate. If this certificate is updated, restart the `mtls-gw` pod for the update to take effect.
`analytics-ca or a7s-ca`	`selfsigning-issuer`	The issuer for the `analytics-client` and `analytics-server` certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If you update this certificate, you must then update the `analytics-client` and `analytics-server` server certificates, and then ensure that the following pods are restarted: • `storage`- Restarts automatically. • `warehouse`- Restarts automatically. • `ingestion`- Restarts automatically. • `director`- Restart manually.
`analytics-client or a7s-client`	`analytics-ca`	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, then the `storage`, `warehouse` and the `ingestion` pods restart automatically. You must manually restart the `director` pod.

`analytics-server or a7s-server`	`analytics-ca`	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`<instance name>-storage`
		`<instance name>-director`
		`<instance name>-ingestion`
		`<instance name>-mtls-gw`
		`<instance name>-storage-os-master`
		`<instance name>-warehouse`
		
		If this certificate is updated, then the `storage`, `warehouse` and `ingestion` pods restart automatically. Manually restart the `director` pod.

Table 3. Portal certificates

Certificate name	Issuer	Description
`portal-ca or ptl-ca`	`selfsigning-issuer`	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.
`portal-client or ptl-client`	`portal-ca`	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.

Certificate name	Issuer	Description

`portal-server or ptl-server`	`portal-ca`	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate.
		
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`*.<instance name>-<site name>-db-all.<namespace>.svc`
		`*.<instance name>-<site name>-www-all.<namespace>.svc`
		`*.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local`
		`*.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local`
		`*.<namespace>.svc.cluster.local`
		`<instance name>-db`
		`#<remote portal CR name>-db # For 2DCDR only.`
		
		<instance name> and *<remote portal CR name>* are truncated if more than 15 characters.
		This certificate is used by all portal pods.

`portal-admin or ptl-director or portal-director`	`ingress-issuer`	Server certificate used on the `portalAdminEndpoint`. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the `portal-admin-client` certificate. This certificate must have the same CA as the `portal-admin-client` certificate on the management subsystem. This certificate is used by the `portal-nginx` pod.
`portal-web`	`ingress-issuer`	The server certificate used on the `portalUIEndpoint`. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default `portal-web` certificate is issued by the `ingress-issuer`, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the `portal-web` ingress (`portal-web` route on Red Hat OpenShift).
`ptl-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate that is used in the warm-standby data center's `<remote-sitename>-www` and `<remote-sitename>-db` pods to connect to the active data center. This certificate is used by all the portal pods that are related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.
`ptl-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<portal_CR>-tunnel` pod, the counterpart to the `ptl-replication-client` certificate. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the portal CR. This certificate is used by all the portal pods that are related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.

Table 4. Gateway certificates

Certificate name	Issuer	Description
`gateway-peering or gw-peer`	`ingress-issuer`	This certificate secures the communication between gateways in your gateway cluster. If you update this certificate, then restart your gateway pods. See Changing the secret for gateway peering.
`gateway-service or gw-svc`	`ingress-issuer`	Legacy certificate that is not used.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on the management subsystem If you update this certificate, then all gateway pods are restarted automatically.

Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.

Table 5. Event gateway certificates -Cloud Pak for Integration only

Certificate name	Issuer	Description
`event-gateway-management-client`	`ingress-issuer`	The `event-gateway-management-client` certificate exists only on Cloud Pak for Integration deployments.

TLS certificates organized by usage

Certificates tables organized by where they are used.

Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.

Table 1. Management to gateway communication

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with **kubectl**. When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the `portal-www` pods for the update to take effect.
`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the `apim` and `taskmanager` pods after update. This certificate must have the same CA as the `gwv6-manager-endpoint or gw-gateway-manager` certificate on the gateway. This certificate is loaded by the management subsystem into the `Gateway management client TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the gateway, then create a new profile and specify it when you register the gateway service.
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on the management subsystem If you update this certificate, then all gateway pods are restarted automatically.

Table 2. Management to portal communication

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with **kubectl**. When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the `portal-www` pods for the update to take effect.

`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have:
		
		• The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem.
		• The common name must match the `spec.adminClientSubjectDN` in the portal CR:
		
		`kubectl describe cert portal-admin-client`
		
		`Spec:`
		`  Common Name:  ptl-adm-client`
		
		`kubectl get ptl -o yaml`
		
		`  spec:`
		`    adminClientSubjectDN: CN=ptl-adm-client`
		
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
		
		This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service.

`portal-admin or ptl-director or portal-director`	`ingress-issuer`	Server certificate used on the `portalAdminEndpoint`. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the `portal-admin-client` certificate. This certificate must have the same CA as the `portal-admin-client` certificate on the management subsystem. This certificate is used by the `portal-nginx` pod.

Table 3. Management and gateway to analytics communication

Certificate name	Issuer	Description

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with **kubectl**. When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the `portal-www` pods for the update to take effect.

`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have:
		
		• The same CA as the server certificate `analytics-ai-endpoint` on the analytics subsystem.
		• The common name must match the `spec.clientSubjectDN` in the analytics CR:
		
		`kubectl describe cert analytics-admin-client`
		
		`Spec:`
		`  Common Name:  a7s-ing-client`
		
		`kubectl get a7s -o yaml`
		
		`  spec:`
		`    clientSubjectDN: CN=a7s-ing-client`
		
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical.
		
		To update this certificate, use kubectl. Restart the `apim`, `taskmanager`, and `analytics-proxy` pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
		
		This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service.

`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint in the `mtls-gw` pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the `analytics-ai-endpoint` certificate. If this certificate is updated, restart the `mtls-gw` pod for the update to take effect.

Table 4. User-facing certificates

Certificate name	Issuer	Description
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
`consumer-catalog-endpoint`	`ingress-issuer`	Consumer catalog endpoint server certificate.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`portal-web`	`ingress-issuer`	The server certificate used on the `portalUIEndpoint`. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default `portal-web` certificate is issued by the `ingress-issuer`, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the `portal-web` ingress (`portal-web` route on OpenShift®).
`hub-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the `hub-endpoint`. If there is a problem with this certificate, then the user's browser shows a warning or error message.

Table 5. Inter-subsystem certificates

Certificate name	Issuer	Description

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with **kubectl**. When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the `portal-www` pods for the update to take effect.

`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have:
		
		• The same CA as the server certificate `analytics-ai-endpoint` on the analytics subsystem.
		• The common name must match the `spec.clientSubjectDN` in the analytics CR:
		
		`kubectl describe cert analytics-admin-client`
		
		`Spec:`
		`  Common Name:  a7s-ing-client`
		
		`kubectl get a7s -o yaml`
		
		`  spec:`
		`    clientSubjectDN: CN=a7s-ing-client`
		
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical.
		
		To update this certificate, use kubectl. Restart the `apim`, `taskmanager`, and `analytics-proxy` pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
		
		This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service.

`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have:
		
		• The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem.
		• The common name must match the `spec.adminClientSubjectDN` in the portal CR:
		
		`kubectl describe cert portal-admin-client`
		
		`Spec:`
		`  Common Name:  ptl-adm-client`
		
		`kubectl get ptl -o yaml`
		
		`  spec:`
		`    adminClientSubjectDN: CN=ptl-adm-client`
		
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
		
		This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service.

`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the `apim` and `taskmanager` pods after update. This certificate must have the same CA as the `gwv6-manager-endpoint or gw-gateway-manager` certificate on the gateway. This certificate is loaded by the management subsystem into the `Gateway management client TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the gateway, then create a new profile and specify it when you register the gateway service.
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`mgmt-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate used in the warm-standby data center's `<remote-sitename>-postgres` pod to connect to the active data center.

Certificate name	Issuer	Description
`mgmt-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<management_CR>-tunnel` pod. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the management CR.
`hub-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the `hub-endpoint`. If there is a problem with this certificate, then the user's browser shows a warning or error message.
`management-s3proxy-all`	`ingress-issuer`	Inter-subsystem certificate for communication between management subsystem and s3proxy pods. Used for management database local and SFTP backups.
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint in the `mtls-gw` pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the `analytics-ai-endpoint` certificate. If this certificate is updated, restart the `mtls-gw` pod for the update to take effect.
`portal-admin or ptl-director or portal-director`	`ingress-issuer`	Server certificate used on the `portalAdminEndpoint`. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the `portal-admin-client` certificate. This certificate must have the same CA as the `portal-admin-client` certificate on the management subsystem. This certificate is used by the `portal-nginx` pod.
`portal-web`	`ingress-issuer`	The server certificate used on the `portalUIEndpoint`. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default `portal-web` certificate is issued by the `ingress-issuer`, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the `portal-web` ingress (`portal-web` route on Red Hat OpenShift).
`ptl-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate that is used in the warm-standby data center's `<remote-sitename>-www` and `<remote-sitename>-db` pods to connect to the active data center. This certificate is used by all the portal pods that are related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.
`ptl-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<portal_CR>-tunnel` pod, the counterpart to the `ptl-replication-client` certificate. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the portal CR. This certificate is used by all the portal pods that are related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.
`gateway-peering or gw-peer`	`ingress-issuer`	This certificate secures the communication between gateways in your gateway cluster. If you update this certificate, then restart your gateway pods. See Changing the secret for gateway peering.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.
`gateway-service or gw-svc`	`ingress-issuer`	Legacy certificate that is not used.
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on the management subsystem If you update this certificate, then all gateway pods are restarted automatically.
`event-gateway-management-client`	`ingress-issuer`	The `event-gateway-management-client` certificate exists only on Cloud Pak for Integration deployments.

Table 6. Intra-subsystem certificates

Certificate name	Issuer	Description
`management-ca or mgmt-ca`	`selfsigning-issuer`	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using `in-cluster` communication. See In-cluster service communication between subsystems
`management-client or mgmt-client`	`management-ca`	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.

`management-server or mgmt-server`	`management-ca`	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`

`db-client-apicuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.

Certificate name	Issuer	Description
`natscluster-mgmt`	`management-ca`	Intra-subsystem certificate for the `nats` pods.
`analytics-ca or a7s-ca`	`selfsigning-issuer`	The issuer for the `analytics-client` and `analytics-server` certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If you update this certificate, you must then update the `analytics-client` and `analytics-server` server certificates, and then ensure that the following pods are restarted: • `storage`- Restarts automatically. • `warehouse`- Restarts automatically. • `ingestion`- Restarts automatically. • `director`- Restart manually.
`analytics-client or a7s-client`	`analytics-ca`	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, then the `storage`, `warehouse` and the `ingestion` pods restart automatically. You must manually restart the `director` pod.

`analytics-server or a7s-server`	`analytics-ca`	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`<instance name>-storage`
		`<instance name>-director`
		`<instance name>-ingestion`
		`<instance name>-mtls-gw`
		`<instance name>-storage-os-master`
		`<instance name>-warehouse`
		If this certificate is updated, then the `storage`, `warehouse` and `ingestion` pods restart automatically. Manually restart the `director` pod.

`portal-ca or ptl-ca`	`selfsigning-issuer`	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.
`portal-client or ptl-client`	`portal-ca`	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.

`portal-server or ptl-server`	`portal-ca`	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`*.<instance name>-<site name>-db-all.<namespace>.svc`
		`*.<instance name>-<site name>-www-all.<namespace>.svc`
		`*.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local`
		`*.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local`
		`*.<namespace>.svc.cluster.local`
		`<instance name>-db`
		`#<remote portal CR name>-db # For 2DCDR only.`
		<instance name> and *<remote portal CR name>* are truncated if more than 15 characters.
		This certificate is used by all portal pods.

Troubleshooting API Connect

This section provides some general troubleshooting steps for use when encountering common problems with API Connect.

About

The following sections provide advice on diagnosing some common problems. This information can help you to identify whether a specific API Connect component is failing, whether it's an environmental problem, and whether you should raise a support request. Some advice includes reviewing specific log files so you can narrow down the source of the problem.

- Unable to access Management UIs
- Unable to access the portal sites
- Login failure on Management UIs
- Login failure on Portal sites
- Management operations not reflected on Gateway or Portal
- UI error after management database key rotation in Cloud Manager

Related information

- IBM Support Service Requests and PMRs
- Gathering logs on Kubernetes and OpenShift

Unable to access Management UIs

If you are unable to access the UI login page, getting a blank page, an HTTP 404, or some other error.

When this happens it means that either the Management subsystem is down, or the access attempt is not reaching the Management subsystem due to a problem in the environment.

Check the following:

- Is the access attempt actually reaching the Management subsystem? To confirm this, check what is in the logs of the `juhu` pods which run on the Management subsystem. The `juhu` pods are the entry point for all UI, REST, and CLI requests to the Management subsystem. For every access request there should be line logged by the `juhu`pod, for example: When the user attempts to access the admin UI login page, the following is logged by the juhu pod:

  ```
  kubectl logs abc-management-juhu-fc8f6bb5d-jnw2q --since=5m
  ...
  9.20.85.205 - - [27/May/2022:10:35:49 +0000] [675fa59030a1a68028712ad2fdb2fdb1] "GET /api/cloud/admin/identity-providers
  HTTP/1.1" 200 301 "https://apimsvc20.hursley.ibm.com/auth/admin/sign-in/" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)
  AppleWebKit/537.36 (KHTML, like Gecko) Chrome/101.0.4951.64 Safari/537.36" "9.145.13.216" [127.0.0.1:2000]
  request_time=0.222 upstream_response_time=0.224
  ...
  ```

  Note that the timestamp of these log records are not the time when the request arrived, but the time when the response to the request was sent back. To work out the arrival time you can subtract the `request_time=0.222` that appears later in the log message. If there is nothing logged in the `juhu` pods at the time the UI access is attempted, then check if you have any network problems between your browser and the Management subsystem.
- Are the Management subsystem pods all up and running? Check this with `kubectl get ManagementCluster -n <namespace>`. If this does not show all pods running, then check which pods are failing: `kubectl get pods -n <namespace>`. Otherwise it's worth checking the reasons why the pods are failing to start with `kubectl describe` as it might be something in your kubernetes environment that you can fix. Note that on the Management subsystem the `postgres` pods will need to be running first, so if these are not running then most other Management pods will not start.
- Check the logs of the `apim` pods while attempting to access the UI. The `juhu` pods receive the requests from the UI, and send them on to the `apim` pods for processing. The logs of the `apim` pods may reveal some clues as to the cause of the problem. If nothing is logged in the `apim` pods at the time of the access attempt then it suggests a problem in the environment, the `juhu` pods unable to forward requests to `apim`.

Related information

- IBM Support Service Requests and PMRs
- Gathering logs on Kubernetes and OpenShift

Unable to access the portal sites

If you are unable to access the login page of a portal site, getting a blank page, an HTTP 404, or some other error.

A portal site outage can occur for one of the following reasons:

- The portal site is down.
- The portal subsystem is down (and so all sites are down).
- The access attempt is not reaching the portal due to a problem in the network or Kubernetes environment.

Check for the following problems:

- Does the access attempt reach the portal subsystem?
  To confirm that your browser is able to reach the portal site, check the `admin` container logs of the portal's `www` pods. The `nginx` process that runs in the `admin` container is the entry point for site access. For every attempt to access a portal site, the `admin` container logs the HTTP call, for example:

  ```
  # kubectl logs abc-portal-site1-www-0 -c admin | grep nginx
  ...
  [     nginx stdout]   584 ce6ce0:adad58:00580c 2022-05-27 12:57:38: "9.145.11.161, 9.20.85.206" portal.site1.example.com
  "GET /providerorg1/sandbox/ HTTP/1.1" 200 5026 5315 5992 "-" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)
  AppleWebKit/537.36 (KHTML, like Gecko) Chrome/101.0.4951.64 Safari/537.36" 0.330 "-"
  ...
  ```

  Note: On v10.0.6, v10.0.5.4 and previous releases, the `nginx` logs are in the `web` container. Use the same command, but replace "`-c admin`" with "`-c web`".
  If the `admin` container logs nothing at the time the site access is attempted, then check for:
  - Network problems between your browser and the portal subsystem.
  - Problems with Kubernetes ingresses or OpenShift routes to the portal web endpoint.
- Are the portal subsystem pods all up and running?
  Run `kubectl get ptl` to check that your portal pods are running. If this does not show that all pods are running, then check which pods are failing: `kubectl get pods`. If you are on Kubernetes or OpenShift, then check why the pods are failing to start with `kubectl describe <pod name>`. On the portal subsystem, the `-db-` pods must be running first; the other pods do not start until the `-db-` pods are running.

- If the `admin` container logs show that the access attempt is received, then check the `web` container logs to see whether there are any errors at the PHP level.

Login failure on Management UIs

If you are able to access the Management UIs login page, but the login attempt is failing.

Check the logs of the `juhu` and `apim` pods at the time of the login attempt to confirm that the login attempt did reach the Management subsystem. For more information on the `juhu` logs see Unable to access Management UIs. If the login attempt reached the Management subsystem, more details of the login failure for Local User Registry users can be found in the `lur` pod logs, and for LDAP users in the `ldap` pods. Example:

```
# kubectl logs abc-management-lur-8bbc47b54-9vl8q --since=1m -f
...
2022-05-27T13:41:13.511Z audit [4d55be1800dcef18c64e0470484e6eac] START: >>>>>>>> [POST]: /user-login
2022-05-27T13:41:13.704Z lur:error [4d55be1800dcef18c64e0470484e6eac] Requested login, but user, notauser not found in user
registry,
2022-05-27T13:41:13.706Z bhendi:error [4d55be1800dcef18c64e0470484e6eac] Error in POST post:/user-login (user.js:login)
  - status : 401
...
```

Login failure on Portal sites

If you are able to access the Portal sites login page, but the login attempt is failing.

All Portal users except for the site Admin user are ultimately authenticated by the Management subsystem, however Portal adds additional security controls such as IP banning and Flood control which should be first place to check for portal login issues: Managing Developer Portal security.

If the login problem is with the Admin user, then check the logs of the `web` container in the `www` pod at the time of the attempt, for example:

```
# kubectl logs abc-portal-site1-www-0 -c web --since=1m
...
[   php-fpm stderr]   585 ce6ce0:adad58:c3852e 2022-05-27 14:16:49: WARNING: [pool www] child 1023 said into stderr: "WATCHDOG:
[NOTICE] [user] Login attempt failed for admin. | user: anonymous | uri:
https://provorg1.sandbox.portal.apimsvc21.hursley.ibm.com/provorg1/sandbox/user/login | referer:
https://portal.site1.example.com/provorg1/sandbox/user/login
...
```

If the Portal site itself is not rejecting the user login, then check the Management server logs during the login attempt: Login failure on Management UIs. It may also be worth checking the logs of the `admin` container in the `www` pod, which manages the Portal end of the communications with the Management subsystem.

Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.

Management operations not reflected on Gateway or Portal

Where publishes or deletes executed on the Management subsystem are not reflected on the gateway or portal within a few minutes. These problems are often caused by a network failure between Management and the other subsystems, or due to TLS handshaking failures.

For Gateway, the first place to check is the processing status page: Reviewing processing status and downloading gateway logs

For Portal and Gateway check the logs of the `taskmanager` pods at the time of the publish attempt. These pods send the publish operations to the gateway and portals via webhooks. If there is a network problem you may see socket timeout errors in the logs of these pods, or TLS errors if there is problem with your certificates. A common problem are load-balancers doing TLS termination instead of passthrough (where JWT security is not used, see Using JWT instead of mTLS on Kubernetes and OpenShift®,). If the logs suggest that the webhook was sent successfully then check the gateway director (gwd) logs on the Gateway, and the `www` pod `admin` container logs on the portal, for example:

```
kubectl logs abc-portal-site1-www-0 -c admin
```

Taskmanager pods execute "send" tasks to publish operations to the gateways and portals. The taskmanager pods log messages about the progress of tasks, so there should be messages in a taskmanager pod for a send task soon after applying a change on the Management subsystem. A "send running in pod" message like the following example means the send task is running:

```
2023-05-05 14:02:37.270 management-taskmanager-f5d6fd77-dmnnt taskmanager apim:taskmanager:info:taskProcessor [0d30189c-db39-
4260-bb1f-a75a3ac5f1ba] task id: b3933261-5799-473d-9b83-9e29c245fde8 / kind: send running in pod: management-taskmanager-
f5d6fd77-dmnnt / containerId: cri-o://d5afe6d3960e333c1ea5d8f95b79564e769bc2ed5de9d8baebebd84b3f3ad4be 269ms after claimed
```

If the taskmanager logs an error containing "dispatching task failed for task"(logged when attempting to start a task) or an error containing "Stale claimed task" (logged 15 minutes later), API Connect might have a problem running tasks. A small number of these errors might be reported from time to time, and the system recovers automatically. But if the errors continue being reported, restart the natscluster pods (all together) and then restart the taskmanager pods to recover by running the following commands:

```
kubectl -n <namespace> delete po -l app.kubernetes.io/name=natscluster
kubectl -n <namespace> delete po -l app.kubernetes.io/name=taskmanager
```

When raising a support case, be sure to include logs from both the Management subsystem and the affected subsystems gateway/portal, stating when the publish attempt was made.

UI error after management database key rotation in Cloud Manager

After a management database key rotation, the Cloud Manager UI occasionally display a 500 API error, which indicates a server issue. In the **management-apim** pods, sometimes you encounter the missing reload message, "`detected database encryption secret update, clearing cache`".

To resolve the management database key rotation error, delete the affected **management-apim** pods, which restarts these pods.

Externally linked support topics

Topics that are linked to externally, covering maintenance operations, known issues, and error handling.

- **Management database changes from V10.0.7**
  Management database operator changes from V10.0.7 that impact upgrade from earlier releases.
- **Restore blocked on 2DCDR deployments**
  V10.0.7.0 and later. Management database restore is blocked on two data center disaster recovery deployments.

Management database changes from V10.0.7

Management database operator changes from V10.0.7 that impact upgrade from earlier releases.

Note: If you are upgrading to V10.0.8, then SFTP and local backups are supported, and your V10.0.5 management database backup configuration is automatically migrated. You do not need to take any other actions. The rest of this topic applies to upgrades to V10.0.7 only.
In V10.0.7.0, the Crunchy Postgres operator is replaced with a different operator called EDB. The Postgres database itself remains the same, but the Kubernetes pods and jobs that manage the Postgres database are new.

The change in Postgres operator results in new CR status outputs, and new backup requirements and settings, which are explained in this topic.

Management upgrade warning

When you upgrade the API Connect operator to V10.0.7.0, the management CR reports a **Warning** state until the management subsystem is also upgraded to V10.0.7.0. The reason for the warning is that due to the database operator change in V10.0.7.0 the management subsystem must not be left on V10.0.6.0 while the operator is on V10.0.7.0.

S3 backup settings automatically updated

If your management subsystem is already configured for S3 backups, then no extra pre-upgrade steps are required. The upgrade process converts the existing S3 backup settings for the new management database in V10.0.7.0.

When you upgrade to V10.0.7.0 with S3 backups configured, an extra backup path folder /edb is appended to your backup path. The /edb path is to distinguish new V10.0.7.0 backups, from your previous V10.0.6.0 backups.

Update backup settings before upgrade

V10.0.7.0 supports only backups to an S3 object-store for the management database. If your V10.0.6.0 deployment uses SFTP or local backups, then you must reconfigure your management backup settings to use an S3 object-store.

Upgrade to V10.0.7.0 is blocked if management database backups are not configured to use an S3 object-store. To update your backup settings, see the topic for your platform:

- Reconfigure management backup settings on Kubernetes.
- Reconfigure management backup settings on OpenShift.

If you do not require management database backups, you can enable an opt-out parameter to override the upgrade block:

- Kubernetes and OpenShift individual subsystem installations: Add the following annotation to your management CR:

  ```
  metadata:
    annotations:
  ```

```
    apiconnect-operator/backups-not-configured: "true"
```

- Cloud Pak for Integration and OpenShift top-level CR installations: Add the following annotation to your APIConnectCluster CR:

```
metadata:
  annotations:
    apiconnect-operator/backups-not-configured: "true"
```

Restore blocked on 2DCDR deployments

V10.0.7.0 and later. Management database restore is blocked on two data center disaster recovery deployments.

From V10.0.7.0, you cannot restore the management database on an API Connect two data center disaster recovery deployment. You must remove the 2DCDR configuration before you can restore the management database. For more information, see the 2DCDR backup and restore documentation for your platform:

- 2DCDR backup and restore considerations on Kubernetes, OpenShift, and Cloud Pak for Integration.
