Tutorials 33

Installing and maintaining IBM API Connect 35
Kubernetes, OpenShift, and Cloud Pak for Integration 35
Planning your deployment 35
Prerequisite skills for administering API Connect 36
Key concepts: Custom Resources, Operators, and Operands 36
Deployment overview for endpoints and certificates 36
Deployment profiles, topologies, and strategies 37
Deployment and component profiles 37
API Connect deployment profiles for OpenShift and Cloud Pak for Integration 38
Component profiles, CPU limits, memory limits, and licensing 39
Management subsystem deployment profile limits 39
Portal component deployment profile limits 47
Analytics component deployment profile limits 49
DataPower gateway deployment profile limits 51
Multiple data center deployment strategies 52
Two data center warm-standby deployment on Kubernetes and OpenShift 53
Two data center deployment examples and diagrams 54
OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration 56
Network requirements for inter-subsystem communication 58
Enable JWT security instead of mTLS 58
In-cluster service communication between subsystems 60
Kubernetes ingress controller prerequisites 60
Persistent Volume (PV) requirements 61
Load balancer configuration 62
Firewall requirements 64
Planning your analytics deployment 67
Key Concepts: Cert-manager, Issuers, and Secrets 68
Webhooks deployed and managed by the API Connect Operator 69
Administering API Connect in your container environment 71
Namespaces in your container environment 71
Custom Resources and Custom Resource Definitions 71
Managing your API Connect CRs 73
Installing API Connect 73
Deployment requirements 73
IBM API Connect Version 10 software product compatibility requirements 76
API Connect licenses 76
Deployment procedures 77
Obtaining product files 77
Verifying the integrity of IBM product files 79
Deploying on Kubernetes 80
Deploying operators and cert-manager 80
Deploying operators in a single-namespace API Connect cluster 81
Deploying operators in a multi-namespace API Connect cluster 83
Installing cert-manager and certificates in a two data center deployment 85
Customizing certificates during installation on Kubernetes 86
Generating custom certificates using cert-manager 90
Generating custom certificates using cert-manager in a two data center deployment 90

Generating custom certificates manually 92
Deploying API Connect subsystems with custom certificates 93
Installing the API Connect subsystems 94
Installing the management subsystem 95
Installing the gateway subsystem 97
Installing the developer portal subsystem 100
Defining multiple portal endpoints for a Kubernetes environment 103
Installing the analytics subsystem 103
Creating the analytics CR 104
Installing analytics 106
Installing a two data center deployment on Kubernetes 107
Converting a single data center to a two data center deployment on Kubernetes 110
Troubleshooting installation on Kubernetes 114
Deploying on OpenShift and Cloud Pak for Integration 115
Configuring FIPS support on OpenShift 115
Preparing for installation 118
Operator, CASE, and platform requirements 119
API Connect configuration settings 120
Basic configuration settings 120
Management subsystem settings 122
Gateway subsystem settings 123
Developer Portal subsystem settings 125
Analytics subsystem settings 126
Additional Kubernetes settings 127
Configuring timeouts for management endpoints 127
Installation procedures with IBM Cloud Pak for Integration 128
Installing API Connect in a single namespace on OpenShift 129
Installing operators 129
Setting up a certificate issuer 133
Installing the management subsystem in a shared namespace 136
Installing the gateway subsystem in a shared namespace 138
Installing the portal subsystem in a shared namespace 142
Installing the analytics subsystem in a shared namespace 145
Installing API Connect subsystems in different namespaces or environments on OpenShift 147
Installing operators 148
Installing the management subsystem 152
Extracting the management ingress-ca certificates 156
Installing the gateway subsystem 156
Installing the portal subsystem 160
Installing the analytics subsystem 164
Installing with the top-level CR on OpenShift 167
Installing operators 167
Installing API Connect 172
Air-gapped installation 174
Installing with a bastion host 175
Installing with a portable computer or storage device 179
Installing a two data center deployment with Cloud Pak for Integration 184
Planning and initial preparation 185
Preparing your active data center 185
Preparing your warm-standby data center 188
Installing API Connect on the active data center 189
Installing API Connect on the warm-standby data center 191
Installing a two data center deployment on OpenShift 193
Planning and initial preparation 194
Preparing your active data center 194
Preparing your warm-standby data center 196
Installing API Connect on the active data center 200
Installing API Connect on the warm-standby data center 202
Enable additional features post-install 204
Enable management CA verification on REST API calls 204
Enable JWT security and disable mTLS between subsystems 205
Troubleshooting installation on OpenShift 205
Upgrading API Connect 207
Upgrading on Kubernetes 207
Planning your API Connect upgrade on Kubernetes 208
Pre-upgrade preparation and checks on Kubernetes 210
Upgrading DataPower Operator and Operand independently of the APIC 212
Upgrading API Connect on Kubernetes 213
Upgrading the management subsystem on Kubernetes 216
Upgrading the portal subsystem on Kubernetes 217
Upgrading the analytics subsystem on Kubernetes 217
Upgrading the gateway subsystem on Kubernetes 219

Troubleshooting upgrades on Kubernetes 219
Enabling gateway peering and verifying cluster status 221
Upgrading on OpenShift and Cloud Pak for Integration 221
Planning your API Connect upgrade on OpenShift 222
Operator, CASE, and platform requirements for upgrading 224
Pre-upgrade preparation and checks on OpenShift 225
Resolving duplicate users before upgrade on Cloud Pak for Integration 227
Pre-upgrade preparation for air-gapped environment using a bastion host 228
Pre-upgrade preparation for air-gapped environment using a portable storage device 232
Upgrading API Connect on OpenShift 236
Troubleshooting upgrade on OpenShift 239
Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9 243
Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.9 244
Maintaining API Connect 246
Advanced configuration 247
Installing License Service 247
Installing the Automated API behavior testing application 248
Installing the toolkit 249
Customizing user-facing certificates 251
Changing deployment profiles on Kubernetes and OpenShift 252
Changing deployment profiles on OpenShift top-level CR 253
Changing the deployment profile on Cloud Pak for Integration 253
Replica override for microservices 254
Enabling Developer Portal feature flags on Kubernetes 255
Enabling Developer Portal feature flags on OpenShift and Cloud Pak for Integration 256
Enabling UI feature flags on Kubernetes 257
Enabling UI feature flags on OpenShift and Cloud Pak for Integration 257
Advanced configuration for the management subsystem 258
Updating management subsystem password, keys, and secrets 259
Changing the cloud administrator password 259
Changing the database encryption key 259
Changing the registration client_id and client_secret for applications 261
Configuring maximum size of client requests to the Management subsystem 263
Setting rate limits for public APIs on the management service for a Kubernetes environment 264
Enabling API discovery on Kubernetes 265
Enabling governance on Kubernetes 266
Enabling API Agent for the management subsystem 268
Configuring monetization on Kubernetes 269
Restarting the Management subsystem pods 270
Disabling the PodDisruptionBudget (PDB) for the management EDB database 271
Postgres database shutdown 271
Shutting down the Postgres database in the Management subsystem on different environments 272
Starting the Postgres database in the Management subsystem on different environments 272
Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later 273
Configuring zone affinity in the management subsystem 275
Postgres database shutdown 271
Shutting down the Postgres database in the Management subsystem on different environments 272
Starting the Postgres database in the Management subsystem on different environments 272
Disabling the status feedback on products page 278
Advanced configuration for the analytics subsystem 278
Advanced configuration for the gateway subsystem 278
Customizing a DataPower deployment 278
Updating the gateway password, secrets, and certificates 279
Changing the gateway administrator password 279
Changing the gateway client secret 280
Updating the gateway peering certificate 280
Updating the gateway director and invocation endpoint profiles 281
Overriding the default DataPower image, version, and license 281
Overriding pod CPU and memory settings 281
Enabling autoscaling of gateway pods 282
Configuring rate limits on the gateway nodes 283
Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment 283
Overriding DataPowerService spec properties 284
Advanced configuration for the portal subsystem 285
Updating portal keys and secrets 285
Changing the secret for portal data and system tools 285
Changing the portal client_secret 286
Backing up, restoring, and disaster recovery 286
Backing up and restoring the management subsystem 287
Taking a management infrastructure configuration backup 287
Configuring management database backups 288
Running an on-demand backup of the management database 290

Restoring from a management database backup 291
Restoring the management database with a backup CR 291
Restoring the management database with a backup ID 292
Recovering from a disaster 293
Troubleshooting management database backup and restore 294
Backing up and restoring the developer portal 296
Taking a portal infrastructure configuration backup 296
Configuring portal database backups 297
Running an on-demand backup of the portal database 299
Managing your remote portal database backups 301
Restoring from a portal database backup 302
Recovering from a disaster 305
Troubleshooting portal database backup and restore 305
Backing up and restoring the analytics subsystem 306
Backing up and restoring on OpenShift top-level CR 306
Backing up your OpenShift top-level CR API Connect deployment 306
Disaster recovery on OpenShift top-level CR 307
Backing up and restoring on Cloud Pak for Integration and OpenShift top-level CR 308
Backing up your Cloud Pak for Integration API Connect deployment 308
Recovering from a disaster on Cloud Pak for Integration 309
Maintaining a two data center deployment 311
Key concepts of 2DCDR and failure scenarios 311
Failing over to the warm-standby 313
Backup and restore requirements for a 2DCDR deployment 316
Removing a two data center deployment 317
Verifying replication between data centers 319
Synchronizing the ingress-ca certificates between sites 320
Troubleshooting a two data center deployment 321
Renewing TLS certificates 323
Renewing cert-manager controlled certificates 324
Renewing the management-ca with the ManagementSecretRotation CR 325
Renewing the portal-ca with the PortalSecretRotation CR 325
Renewing the analytics CA 326
Renewing the ingress-ca 327
Copying renewed ingress-ca to subsystems in different namespaces 328
Renewing end-entity certificates 328
Monitoring cert-manager certificate renewal 329
Renewing custom certificates 330
List of Issuers, CA certificates, and secrets 330
List of ingress certificates 330
List of intra-subsystem certificates 333
V2018 upgrade: List of certificates to update manually 334
Renewing certificates in a two data center deployment on Kubernetes and OpenShift 335
Monitoring and health checks 336
Monitoring on Kubernetes 336
Monitoring subsystems on Kubernetes 337
Monitoring Postgres disk usage 337
Monitoring platform health using Kubernetes events 338
Monitoring on OpenShift 339
Monitoring the API Connect cluster on OpenShift 339
Monitoring Postgres disk usage on OpenShift 340
Monitoring platform health on Red Hat OpenShift using Kubernetes events 342
Monitoring on Cloud Pak for Integration 342
Monitoring the API Connect cluster on Cloud Pak for Integration 342
Monitoring Postgres disk usage on Cloud Pak for Integration 343
Obtaining simple health check data of Developer Portal sites by using a REST API call 346
Monitoring subsystem health checks 346
Logging 347
Gathering logs 347
Changing logging levels 348
Troubleshooting 349
Power-cycling check on OpenShift and Cloud Pak for Integration 349
Uninstalling API Connect 349
Uninstalling API Connect subsystems 350
Removing API Connect 352
Removing API Connect on OpenShift or Cloud Pak for Integration 354
Migrating from v10 to v10 on a different form factor 355
v10 migration overview 355
v10 migration requirements 357
v10 migration steps 359
Preparing the source system 359
Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration 360

Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration 363
Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration 368
Migrating from OpenShift to Cloud Pak for Integration on the same cluster 369
v10 migration troubleshooting 370
The API Connect operations tool: apicops 371
Using Config Sync to replicate consumer-side catalog data 371
Downloading the Config Sync utility 371
Running Config Sync as a standalone binary 371

Configuring and managing your server environment 371
Cloud Manager configuration checklist 372
Activating your Cloud Manager user account 373
Accessing the Cloud Manager user interface 374
Defining your Cloud Manager topology 375
Creating an availability zone 377
Registering a gateway service 377
Registering an event gateway service 380
Registering an analytics service 382
Registering a portal service 383
Associating an analytics service with a gateway service 385
Associating an OpenTelemetry configuration with a gateway service 386
Creating an OpenTelemetry configuration 386
Enabling OpenTelemetry configuration 387
Setting visibility for a service 388
Managing authentication and security 388
User registries overview 389
Configuring an Authentication URL user registry 390
Configuring a shared custom user registry 391
Configuring an LDAP user registry in the Cloud Manager 397
Using the CLI to configure a shared LDAP user registry 399
Configuring a Local User Registry 406
Configuring an OIDC user registry in Cloud Manager 407
Setting visibility for a user registry 413
Deleting a user registry 414
Removing a user from a user registry 414
Removing yourself from a user registry 414
Removing another user from a user registry 415
TLS profiles overview 416
Creating a TLS server profile 418
Creating a TLS client profile 419
Defining elliptic curve cryptographic schemes for a TLS client profile 420
Creating a keystore 421
Creating a truststore 421
Managing TLS profiles, keystores, and truststores 422
Using OpenSSL to generate and format certificates 423
OAuth Provider overview 424
Configuring a native OAuth provider 424
Configuring basic settings for a native OAuth provider 426
Configuring scopes for a native OAuth provider 427
Configuring user security for a native OAuth provider 428
Configuring tokens for a native OAuth provider 429
Configuring token management and revocation for a native OAuth provider 430
Configuring introspection for a native OAuth provider 431
Configuring metadata for a native OAuth provider 432
Configuring the OIDC parameters for a native OAuth provider 432
Editing a native OAuth provider by using the API Editor 433
Configuring a third-party OAuth provider 434
Configuring scopes for a third-party OAuth provider 435
Setting the visibility for OAuth providers 436
OAuth concepts for API Connect 436
OAuth user scenario 437
OAuth introspection for third-party OAuth providers 437
Oauth metadata URL and authentication URL 439
Scope 442
Tokens 446
Refresh tokens 446
OAuth revocation URL 446
Authenticating and authorizing through a redirect URL 448
Token management with the DataPower Gateway (v5 compatible) 450
Token management with the DataPower API Gateway 452
Authentication URL 455
Custom forms for user security 456
Creating a custom HTML login form for user security 456
Creating a custom HTML authorization form for user security 457

Securing an API with a JSON Web Token 458
Troubleshooting OAuth 458
Configuring the cloud settings 458
Change the name of your cloud 459
Configuring an email server for notifications 460
Setting up notifications 460
Customizing email notification templates 461
Configuring invitation timeouts 463
Configuring API key settings 463
Using the CLI to modify cloud settings 464
Configuring Base64 encoding for temporary tokens 465
Configuring the password-reset notification and timeout 465
Selecting user registries for Cloud Manager and API Manager 466
Setting a default user registry for Cloud Manager and API Manager 467
Configuring timeouts for access tokens and refresh tokens 467
Viewing platform and UI endpoints 468
Configuring the default gateway services for Catalogs 468
Managing the public/private key pairs for signing tokens 469
Configuring public/private key pairs for tokens 470
Configuring governance in the Cloud Manager 471
The governance ruleset lifecycle in the Cloud Manager 475
Updating rulesets and rules with the toolkit CLI 475
Administering provider organizations 477
Creating a provider organization 477
Editing a provider organization 478
Deleting a provider organization 479
Viewing current provider organizations 479
Sending messages to provider organization owners 480
Administering members and roles 481
Creating roles in the admin organization 481
Editing roles in the admin organization 482
Configuring LDAP group mappings on Cloud Manager user roles 482
Deleting roles in the admin organization 484
Viewing members and roles 485
Adding members to the admin organization 485
Assigning roles to members 486
Deleting a member 487
Role Defaults overview 487
Managing role defaults for provider organizations 487
Monitoring the cloud 488
Accessing and configuring analytics 488
Configuring audit logging to monitor user operations 488
Configuring the audit settings 492
Reviewing processing status and downloading gateway logs 495
Changing your Cloud Manager password and profile information 497
Resolving login problems by increasing HTTP header size 498
Onboarding a new admin for Cloud Pak for Integration 499
Extending the Gateway server behavior 500
Gateway extension guidelines - DataPower Gateway (v5 compatible) 500
Gateway extension guidelines - DataPower API Gateway 501
Gateway extensions manifest 502

Externally linked support topics 1703
Management database changes from V10.0.7 1703
Restore blocked on 2DCDR deployments 1704

API Connect overview

IBM® API Connect is an integrated API management offering, with capabilities and tooling for all phases of the API lifecycle. IBM API Connect 10.0.11.0 is s the latest 10.0.x Continuus Delivery (CD) release, and is the follow-on release to the prior 10.0.10.0 Support Cycle-2 (SC-2) release. If you're looking for a different version of API Connect, use the Change version list in the navigation pane to select the version that you require.

Key steps of the API lifecycle include create, secure, manage, socialize, monetize, and analyze. IBM API Connect Version 10 delivers enhanced capabilities for the market-leading IBM API management solution. In addition to the ability to deploy in complex, multi-cloud topologies, this version provides enhanced experiences for developers and cloud administrators in your organization.

IBM API Connect has two main focuses: the first is providing best in class API Management tooling, and the second is having a cloud-native solution. This allows users to create, manage, and secure applications that are deployed across a variety of on-premises and cloud environments.

The following table explains the key phases in the API lifecycle in more detail.

Table 1. Key phases of the API lifecycle

Lifecycle Phase	Description
Create	Develop and write API definitions from an API development environment, eventually bundling these APIs into consumable products, and deploying them to production environments. For tutorials, walk-throughs, and in-depth guides for building, testing, and deploying APIs and Products in API Connect, see Tutorials, and Developing your APIs and applications.
Secure	Leverage the best-in-class API Gateway, gateway policies, and more, to manage access to your APIs and back-end systems. To learn more about adding security to your API, see *Enforcing security requirements on an API* for the OpenAPI version that you are working with: • OpenAPI 2.0: Enforcing security requirements on an API • OpenAPI 3.0: Enforcing security requirements on an API To learn more about how to add API Gateway policies to your API, see API policies and logic constructs.
Manage	Governance structures are built in to the entire API lifecycle, from managing the view/edit permissions of APIs and Products being deployed, to managing what application developers can view and subscribe to when APIs are deployed. To understand and leverage API Connect management and governance controls along the API lifecycle, see Managing your APIs.
Socialize	API Connect comes with an advanced Developer Portal that streamlines the onboarding process of application developers, and can be completely customized to an organization's marketing standards. To understand more about using the Developer Portal, see Developer Portal: Socialize your APIs.
Monetize	Bundle APIs into Products and Plans with monetization schemes that are built into those Plans, thereby opening up digital revenue streams. To understand more about how to leverage monetization strategies in API Connect, see Monetizing your Products.
Analyze	Developers and Product Managers alike are given the tooling in API Connect to understand their API traffic patterns, latency, consumption, and more to make data driven insights into their API initiatives. To learn more about how to leverage API Connect analytics tooling, see API Analytics.

API Connect has four major components: API Manager, Analytics, Developer Portal, and Gateway. These four components can be deployed in a variety of hybrid and multi-cloud topologies. The API Connect infrastructure can either be deployed and managed by an IBM team in an IBM Cloud environment, or it can be deployed and managed by the customers in their own dedicated environment or third-party cloud. There is also the option for having hybrid scenarios, for example, with the API Connect Reserved Instance Offering, users are able to have their API Manager and Developer Portal running in the IBM Cloud, but then place remote gateways next to their back-end services.

Configuration of customer deployed API Connect clouds is done through the Cloud Manager. For in-depth guides and instructions see Configuring and managing your server environment.

For information about the API Connect components that provide these capabilities, and details about the strategy for packaging and publishing APIs for use by API consumers, see:

- Packaging strategy and terminology in API Connect
- API Connect components

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the API Connect v10.x Whitepaper.

What's new in the latest release (version 10.0.11.0)

Find out about the newest features and the latest updates in API Connect.

IBM® API Connect 10.0.11.0 is s the latest 10.0.x Continuus Delivery (CD) release, and is the follow-on release to the prior 10.0.10.0 Support Cycle-2 (SC-2) release.

IBM API Connect 10.0.11.0 CD includes the following enhancements.

Product files and release notes

- Access the latest files from IBM Fix Central by searching for the API Connect product and your installed version. Full installation files for IBM API Connect can be downloaded from Passport Advantage.
- For details on the specific APARs that are included in this release, and links to downloads, blogs, and conference notices, see the IBM API Connect 10.0.11.0 Support Announcement page.
- For more details about support lifecycle policies at IBM, such as Support Cycle-2, see IBM Software Support Lifecycle Policies.

Upgrading to API Connect 10.0.11.0

API Connect 10.0.11.0 supports upgrade only from 10.0.10.0 and 10.0.8.4.

Note: Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema.

- Customers upgrading from 10.0.10.0 will lose all previous scan history.
- To preserve critical information, archive or export important scan results before starting the upgrade.

What's new for Developers

Download all APIs from Product Detail view
: After publishing any product with APIs, you can now download all associated APIs as a ZIP file directly from the product page in the portal. The ZIP file supports downloading APIs of all types, including SOAP, WSDL, REST, and GraphQL, with API names and versions preserved. This enhancement simplifies bulk API management and improves accessibility for developers working across multiple services.

Scan functionality refactored
: The scanning process has been redesigned to reduce high memory consumption during large scans.

Optimized backup size
: Daily backup sizes are now significantly smaller, typically within a few hundred MBs, improving storage efficiency.

What's new for API product managers

New initiator fields added to audit event payloads
: To provide enhanced visibility into the source of audit events, the following fields are now included in audit event payloads:

  - `initiator.host`
  - `initiator.host.agent`
  - `initiator.host.address`

  For more information, see Audit events.

Improved audit logging experience
: A new audit logging UI is now available, providing a comprehensive view of all audit events.

Default saved query for Analytics tab
: You can now set a default saved query that automatically loads when you open the analytics tab. For more information, see Analytics dashboards.

New Engagement destination option
: Engagement now supports Amazon Simple Notification Service. For more information, see Amazon SNS.

What's new in Version 10.0.10.0

This page details the enhancements in IBM® API Connect Version **10.0.10.0** since the previous release.

For details on the specific APARs that are included in this release, and links to downloads, blogs, and conference notices, see the IBM API Connect 10.0.10.0 Support Announcement page.

Upgrading from API Connect 10.0.8.x and 10.0.9.0

API Connect 10.0.10.0 supports upgrade only from 10.0.9.0, 10.0.8.2-ifix1, 10.0.8.1, and 10.0.8.0.

What's new for Developers

Accelerate your API Journey with GenAI-powered API Agent
: Built on agentic framework, API Agent can plan, reason, understand, and run tasks from natural language request. Available as a Visual Studio Code plug-in, the API Agent is trained on API Connect's platform APIs to discover, create, govern and test APIs easily. For more information, see API Agent.

AI Gateway functionality on DataPower® API Gateway
: Previously, there was a restriction that prevented you from enabling AI Gateway if your own gateway-extension was deployed on the gateway, and vice-versa. This limitation has now been removed.

  With this change, you can now deploy your own gateway-extension and enable AI Gateway on the same gateway instance without any restrictions

  For more information, see Using the AI Gateway to support APIs for AI applications.

Out-of-the-Box (OOTB) gateway policy deployment
: For this release, when a DataPower API Gateway is created (registered) in IBM API Connect, the system will automatically deploy out-of-the-box (OOTB) gateway policies.

  The following OOTB policy is deployed upon gateway registration: Token Mediation policy.

  When upgrading to IBM API Connect 10.0.10.0, all existing DataPower API Gateways will automatically receive the new OOTB policy(ies) after the API Management subsystem upgrade.

AI Gateway feature adds support for Azure OpenAI
: API Connect now provides a policy that enables your API to send requests to Azure OpenAI, and supports the following operations:

  - `POST /chat/completions`
  - `POST /embeddings`
  - `GET /models/[model-id]`
  - `GET models`

  For more information, see Using the AI Gateway to support Azure OpenAI APIs.

AI Gateway feature adds support for Gemini
: API Connect now provides a policy that enables your API to send requests to Gemini, and supports the following operations:

  - `POST models/[model]:generateContent`
  - `POST models/[model]:countTokens`
  - `POST models/[model]:embedContent`
  - `POST models/[model]:batchEmbedContents`
  - `GET models/[model]`
  - `GET models`

  For more information, see Using the AI Gateway to support Gemini APIs.

Enhanced API path search with wildcard support
: You can now perform flexible searches across the full path of APIs published to a catalog using the new **`full_path`** query parameter in the **`apis:list`** and **`apis:list-all`** commands. For more information, see API development and management commands.

Support for Product and API sync for API Connect Config Sync
: You can now enable or disable the Product and API sync, as per your requirement. For more information, see Using Config Sync to replicate catalog data.

Support for Noname collector configuration for API discovery
: You can now use the Noname collector to discover APIs from the Noname environment. For more information, see Configuring Noname collector for API discovery.

Technology previewGovernance enforcement
: Use the new governance enforcement feature in IBM API Connect to add the APIs and Products rulesets for enforced validation before publishing APIs and Products to catalogs. For more information, see Using governance enforcement for validation.

Optional environment setting to disable product-level feedback
: A new environment-level setting has been introduced for customers who prefer not to receive product-level feedback. When this feature is disabled, visibility into the product state beyond the API Manager is no longer available. This allows greater control over the information displayed within the environment. For more information, see Disabling the status feedback on products page.

What's new for API product managers

Summary API Event Record Field Reference Now Available
: You can now access a comprehensive reference for the fields stored in a Summary API event record. For more information, see Summary API Event Record Field Reference.

Support added for email as a destination for alert notifications
: Analytics now supports email notifications as a built-in destination type for alert rules. This capability uses the centralized send email API from API Connect, which is also used by other subsystems. This approach ensures consistent behavior and removes the need for custom SMTP configuration. Users can select Email as a destination and must provide values for the subject, recipient (To), and email body fields. The CC and BCC fields are optional.

  Analytics handles the rest behind the scenes via a secured internal webhook. For more information, see Creating a notification task.

Analytics retention enforcement improvement
: A serviceability enhancement was introduced to enforce correct retention and rollover policies on the **`api-event`**, **`summary`**, and **`all-content-count`** OpenSearch indices. For more information, see Retention and rollover.

Full data support
: You can now use the Full data as CSV and Full data as JSON options to export all raw event data directly from the Discover table. To access these options, click the Actions menu at the upper-right side of the Discover table and select the required option. This enables exporting complete datasets in JSON or CSV formats to provide greater flexibility for data analysis and reporting. Previously, the export options were limited to the displayed fields. For more information, see Accessing analytics in the API Manager UI.

Audit Logging updates
: You can now configure API Connect to send audit events to a registered Analytics service. For more information see Configuring audit logging to monitor user operations and Configuring the audit settings.

Selective offload for API events or audit events
: You can now offload API events or audit events selectively by updating the offload filters. If API Connect is configured to send audit events to a registered analytics service, then the default offload includes both API events and audit events. Filtering helps to avoid offloading unintended events. For more information, see Configuring offload on Kubernetes and Red Hat OpenShift.

Automatic recovery of rollover failure
: An automated forced rollover is now attempted if a rollover is in the *failed* state for more than 36 hours. If this attempt is unsuccessful, the following error message is displayed in the analytics director pod logs:

  ```
  Error triggering forced rollover
  ```

  For more information, see Retention and rollover.

Enhanced engagement permissions
: The following permission are now added to enable access to Engagement-related features in the new user interface:

  - `engagement:view`: Allows users to view engagement-related content.
  - `engagement:manage`: Enables users to manage engagement content.

  For more information, see Using Engagement.

New Engagement destination options
: Engagement now supports the following destination options:

  - PagerDuty
  - Slack

  For more information, see Create a destination.

New Engagement datasource
: Engagement now supports audit event based engagement rules. You can now configure engagement rules to respond to audit events. For more information, see Audit events.

What's new for Developer Portal site administrators

Drupal 11 upgrade
: The Drupal version has been upgraded from v10 to v11. All the existing Developer Portal sites are upgraded to Drupal 11. The core modules and themes are automatically made compatible as part of the upgrade. For more information, see Guidelines on upgrading your Developer Portal from Drupal 10 to Drupal 11.

Alphabetical sorting to enhance the consumer organization selection
: The drop-down menu located at the top right of the portal to select the consumer organizations now sorts the organizations in alphabetical order, making it easier to find and select an organization quickly.

Safe Links for enhanced security
: The Safe Links feature in Microsoft is now used to enhance the safety of the unlock links sent via emails. When a user receives an email containing an unlock link, the Safe Links feature modifies the URL to route it through Microsoft's security checks. Before the user clicks the link, Safe Links performs a background request to verify its safety.

What's new for DevOps

What's new for IT architects

What's new for security practitioners

What's new in Version 10.0.9.0

This page details the enhancements in IBM® API Connect Version **10.0.9.0** since the previous release.

For details on the specific APARs that are included in this release, and links to downloads, blogs, and conference notices, see the IBM API Connect 10.0.10.0 Support Announcement page.

Upgrading from API Connect 10.0.8.x

API Connect 10.0.9.0 supports upgrade only from 10.0.8.0 and 10.0.8.1

What's new for Developers

Change in behavior when creating an OpenAPI 3 draft API from an existing OpenAPI service
: Creating an OpenAPI 3 draft API from an existing OpenAPI service now correctly parses the server URL, allowing it to be published and invoked on the gateway without any further modification to the OpenAPI definition, just as it works with OpenAPI 2. In previous versions, it generated URLs that included the hostname from the incoming API, which prevented invocation on the gateway.

OpenTelemetry support
: You can now configure and associate Gateway services with your OpenTelemetry (OT) instance, hosted by your organization. For more information, see Creating an OpenTelemetry configuration and Associating an OpenTelemetry configuration with a gateway service.

AI Gateway functionality on DataPower® API Gateway

Enabling this feature activates AI Gateway policies on the DataPower API Gateway, allowing you to create REST proxies that utilize the AI Gateway to control access to AI models. For more information, see Using the AI Gateway to support APIs for AI applications.

Bulk import feature for AsyncAPIs from EEM

A bulk import feature is now available, enabling users to select and import multiple AsyncAPI definitions from Event Endpoint Manager (EEM) into API Connect. For more information, see Importing an AsyncAPI from Event Endpoint Management.

New statuses for tracking product lifecycle operations.

You can now track product lifecycle operations for DataPower® API Gateway-compatible products using new statuses. For more information, see Publishing a draft product.

Enhanced `apis:validate` and `products:validate` commands

Enhanced `apis:validate` and `products:validate` commands enable the validation of API and Product definitions with the Toolkit CLI. The commands now work when a Swagger/OpenAPI 3.0 or Product YAML definition is directly passed into the relevant CLI command.

Periodic subsystem health checks

The system now performs periodic health checks for each subsystem and reports warnings or errors that might require your attention. For more information, see Monitoring subsystem health checks.

Governance service updates

The following updates to the governance service are now available:

- The governance service is now available from the main navigation bar by clicking the Governance icon  . Previously, the governance service was accessed from the Resources section.
- You can now run scans on your catalogs and spaces to validate the APIs that they contain by using Spectral rulesets. For more information, see Scanning your catalogs and spaces.
- The ability to create and manage product rulesets, as well as API rulesets, is now available; see Configuring governance in the Cloud Manager, and Configuring governance in the API Manager.
- You can now also run validation scans on your product documents, as well as on your API documents. For more information, see Validating an API or product document by using the governance service.
- Spectral 2.0.1 is now supported.

What's new for API product managers

New consumption report and gateway services call volume leaderboard

The analytics reports now include a consumption report and gateway services call volume leaderboard. For more information, see Accessing analytics in the Cloud Manager UI and Accessing analytics in the API Manager UI.

New analytics filter operators

Analytics filters now include two new operators: `isset` and `isnotset`.

- `isset`: This filter displays only fields that have any value, including non-empty strings, numbers, or any other non-null value.
- `isnotset`: This filter displays fields that contain `empty` strings or `null` values.

For more information, see Filtering displayed data

New engagement feature to create complex workflows and automate tasks

You can use the new engagement feature on the API Manager to trigger external HTTP(S) endpoints when specific criteria are met within IBM API Connect. This helps you to create complex workflows that automate tasks enhancing the overall API management experience. The engagement resources are provisioned within a specific provider organization or catalog that enables targeted access and management. For more information, see Using engagement to automate notification tasks.

What's new for API consumers

New analytics charts in the Developer Portal

The Developer Portal analytics view has two new charts at both application and consumer organization scope:

- Top APIs over time.
- Top products over time.

API Product recommendation for consumers

The new API Product Recommendations block on the Developer Portal displays product recommendations for the API consumers. The API products are suggested to the users based on the current subscription plan and browsing history. For more information, see Configuring API product recommendations.

New features in Consumer Catalog

The Consumer Catalog now supports the following:

- Local user registry, OIDC user registry,or LDAP registry
- Ability to view analytics for an application
- Ability to delete consumer accounts

For more information, see Consumer Catalog and Developer Portal considerations

What's new for Developer Portal site administrators

New Case Studies Module in the Developer Portal

The Developer Portal now has a new module which introduces a new content type called **Case Modules**. This will help community managers and API Product business owners to promote and highlight API Products socialized in the Developer Portal. For more information, see Adding a case study.

Limiting API details visibility for non-authenticated users

In the previous releases, both the authenticated and non-authenticated users can view all the API details if the respective API product is viewable. Now, you can limit the API details visibility for non-authenticated users by selecting the **`Show API details to anonymous users`** setting in the Developer Portal. For more information, see Configuring the API details visibility for non-authenticated users.

Additional options for selecting email recipients in the Portal mailing wizard
The Portal users can now select a consumer organization or groups of consumer organizations in mailing wizard. For more information, see Emailing consumer organizations.

Admin Portal updated to Drupal 10.3
The Admin Portal has been updated to Drupal 10.3 which uses a new Admin navigation. The portal tutorials and other Drupal admin related docs are updated to reflect the new Admin navigation.

What's new for DevOps

Support for restricted pod security enforcement using namespace labels
API Connect 10.0.9.0 on Kubernetes supports deploying subsystems in namespaces configured with the **`"enforce=restricted"`** policy.

VMware support exception
The API Connect 10.0.9.0 is not supported to run on VMware.

Configuring analytics offload plugins with a password-protected keystore
You can now use a secret to provide the password to be used with a password-protected keystore for storing the CA certificate for the target offload server instead of providing the password in plain text. For more information, see Configuring offload server certificates on Kubernetes and OpenShift.

Configure user limit for consumer organization and invitation resend interval
The maximum number of users allowed per consumer organization and the interval of invitation resend are now configurable. For more information, see Configure user limit and invitation resend interval for Consumer organization.

What's new for IT architects

What's new for security practitioners

Language versions offered by API Connect

API Connect is offered in several languages, as enabled by the operating platform on which the product is installed.

Note: When API Connect is deployed as a Cloud Pak for Integration capability, it is translated to the same set of languages as the Cloud Pak for Integration product.

- Brazilian Portuguese
- Chinese (Simplified)
- Chinese (Traditional)
- Czech
- Dutch
- English
- French
- German
- Italian
- Japanese
- Korean
- Polish
- Spanish
- Turkish

Known limitations

This page describes the known limitations for API Connect 10.0.7.0 and later.

Note: The limitations that are documented on this page will be removed as they are addressed in the API Connect product. For the most up-to-date list of product limitations, visit the English version of this page.

Analytics

Instana AutoTrace and Dynatrace injection are not supported in certain subsystems
Instana AutoTrace is not supported in the Management, Analytics, Developer Portal, and Gateway subsystems. Using Instana AutoTrace in these subsystems can cause corruption; additionally, Dynatrace injection is not supported in the Developer Portal subsystem and can cause corruption. For more information, see Instana AutoTrace.

Note:

- OpenTelemetry based tracing from the DataPower® API Gateway is supported and is the recommended method. For more information, see Enabling OpenTelemetry configuration.
- This issue originates from the Instana integration and is not related to API Connect.

Analytics command restrictions

The following `--mode analytics` commands work only when the flag `--return_format` is set to either `json` or `yaml`:

- `clustermgmt:catAllocation`
- `clustermgmt:catIndices`
- `clustermgmt:catNodes`
- `clustermgmt:catRecovery`
- `clustermgmt:catShards`
- `clustermgmt:catAliases`

The following commands don't currently work on the Toolkit CLI, as they return only `text/plain`:

- `clustermgmt:getNodesHotThreads`
- `clustermgmt:getNodesHotThreadsById`

Consumer rate limit notifications are not available in Version 10
: The ability to configure notifications for applications so that API consumers are alerted when the usage of an API is nearing its rate limit is not available.

API governance

Validating from within a ruleset shows all rules
: In the governance service, if you click Validate from within a ruleset, the list of rules shown includes rules that are not part of the selected ruleset. To work around this, manually select the rules that you want to use for the validation.

API Manager

An OAuth provider fails if the resources that it references aren't enabled in the Catalog
: If you enable an OAuth provider in a Catalog then any resources that it references, such as API user registries or TLS client profiles, must be enabled in the same Catalog; if not, then although the OAuth provider might publish successfully it will fail at run time. For information on enabling resources in a Catalog, see Creating and configuring Catalogs.

Truststore and keystore settings in a shared TLS client profile are not reflected in API Manager
: If you create a shared TLS client profile in the Cloud Manager user interface and assign a truststore and a keystore, these truststore and keystore settings are not reflected in that TLS client profile in the API Manager user interface and cannot be set there. Furthermore, the TLS client profile list views display the value shared for the truststore and keystore rather than the correct values. To workaround this problem, create the truststore, keystore, and TLS client profile separately for each provider organization in the API Manager user interface, then enable the TLS client profile in your Catalogs as required.

Incorrect UI behavior if API changes are not saved before creating a new API version
: If you make changes to an API definition and then attempt to create a new API version without first saving your changes, you are not prompted to save your changes until after you have completed the new version creation operation. If you click OK in the prompt, your new version is created but your original changes are lost; to create your new version and retain your original changes, you should click Cancel in the prompt, then click Save to save your original changes.

Simultaneous editing of the same API by multiple users might result in changes being overwritten
: If one user saves changes to an OpenAPI 3.0 API, another user who has the same API open in the API editor might have their changes overwritten.

An existing user cannot be added to a Space
: If you attempt to add an existing user to a Space, the operation cannot be completed because the Create button is not enabled. Instead, use the invitation mechanism. For details, see Managing Space membership.
Note: The invited user must use the Sign in option on the activation form, rather than completing the registration details and using Sign up.

A published API whose assembly contains a catch block with an invalid policy will now correctly fail to republish
: Previously, policies in an assembly catch block were not validated, so if an incorrect policy configuration was coded in the OpenAPI source for an API, within an assembly catch block, the API would still publish successfully. Now, policies in an assembly catch block are validated, so such an API will fail to republish and will first need to be corrected.

Cloud Manager

Adding members to a provider organization might fail
: When adding members to a provider organization, the Cloud Manager user interface lists the current owner and members as well. If existing members are selected, the add action will fail.

Cloud Pak for Integration

Cannot add an API to the Asset Repository
: If you are using API Connect as a component of Cloud Pak for Integration, you cannot add an API to the Asset Repository from API Connect.

Problem importing from Asset repository when user remains inactive
: If there is no user activity on the page while importing an API from the Cloud Pak for Integration Asset repository, the user might see the following error: `could not add asset, parent window missing`
Work around the issue by reloading the Import API page and then opening the Asset repository again.

Configuration update mistakes cause admission webhook errors in OpenShift and Cloud Pak for Integration
: In OpenShift and Cloud Pak for Integration, configuration update errors can cause the `APIConnectCluster` instance to go into the Pending state with an underlying component throwing an admission webhook error.

```
oc get apiconnectcluster -n APIC_namespace

NAME    READY  STATUS    VERSION            RECONCILED VERSION   AGE
m1      admission webhook "vmanagementcluster.kb.io" denied the request:
ManagementCluster.management.apiconnect.example.com "m1-mgmt" is invalid: [spec.databaseBackup.restartDB.accept: Invalid

```

Gateway

WebSocket support

API Connect provides basic WebSocket functionality through the **`websocket-upgrade`** policy. However, there are important limitations to consider when designing APIs that use WebSocket communication.

1. General limitations
   - The maximum reliable message payload is less than 1 KB.
   - Sending several messages in rapid succession may exceed cumulative limits. For example, three consecutive 500-byte messages may fail.
   - Messages up to 100 bytes can be reliably transmitted if sent with at least a 10 millisecond delay between them.
   - Send data at intervals greater than 10 milliseconds to prevent dropped connections or gateway issues.
   - WebSocket compression and streaming modes are not supported.
2. Error handling limitations
   - When a server closes a connection using status code 1000, 1006, or 1008, the client receives code 1006, regardless of the actual cause.
   - If the server crashes, the client does not receive a close event or error message from the DataPower Gateway.
   - Errors can be caught:
     - In the main assembly before the **`websocket-upgrade`** policy is executed.
     - In sub assemblies during message processing after the upgrade that originate from a subassembly action.
   - Errors during WebSocket connections or after disconnection cannot be detected once the upgrade is complete.
3. Opcode and data type support
   - Only text frames are supported.
   - Binary frames are not supported.
4. Policy restrictions after upgrade
   - After the WebSocket upgrade, the following actions and properties are not supported in the sub assemblies:
     - client security
     - generate JWT
     - user security
     - validate JWT
     - client identification
     - activity log
     - HTML page
     - WebSocket upgrade
     - Parse:
       - use content type
       - warn on empty input
   - No actions are allowed in the main assembly after the upgrade.
   - Only sub assemblies that use supported properties can process messages after the upgrade.

Gateway pod might show as not ready after upgrade

Gateway pods might fail to display as READY after upgrading to IBM® API Connect 10.0.8.0. The pods will show as RUNNING, but 0/1 READY, as in the following example:

```
$ kubectl get pods -n <namespace>
NAME                                                              READY   STATUS      RESTARTS      AGE
...
gwv6-0                                                             1/1     Running     0             1h
gwv6-1                                                             1/1     Running     0             1h
gwv6-2                                                             0/1     Running     0             1h
...
```

To work around this behavior, use the following command delete the pod that is not ready:

```
$ kubectl delete pod gwv6-2 -n <namespace>
```

If there are multiple gateway pods in the cluster, the delete operation will not result in any service disruption.

Gateway services that span data centers

If you want to configure a gateway service that consists of gateways in different data centers, then note the following points:

- This configuration should be used only if TMS is required and an external OAuth provider cannot be used.
- Network latency between sites must be less than 30 ms.
- For the analytics service to span data centers, network latency between data centers must be less than 10 ms. If you want to associate an analytics service with your gateway service, and cannot meet this latency requirement, then choose one of the data centers to host the analytics service.

Gateway timeout when validating very large API documents with the API governance service

If you are validating very large API documents (5 MB, or 100,000 lines, or more), with all of the rulesets selected by default, the API governance service is likely to take longer than 60 seconds to run, and this can result in an HTTP 504 gateway timeout. To workaround this issue, you can take the following actions:

- Validate the API document by using only one ruleset at a time.
- Increase your component deployment profile, for example to a three replica profile. For more information, see Deployment and component profiles, and Planning your deployment topology and profiles on VMware.

Redact on invalid XPath fails after converting to DataPower API Gateway

`Redact` on invalid XPath fails after converting to DataPower API Gateway. ApplicationManagement Unit (AMU) version 10.0.8.0-R0 support the conversion of the Redactpolicy, but only to Redact version 1.5.0, not 2.0.0.

Redact conditions within **`switch`**, **`operation-switch`**, or **`if`** policies might not execute after converting to DataPower API Gateway

If an API Connect v5-compatible **`redact`** policy is found within a **`switch`**, **`operation-switch`**, or **`if`** policy, the migration utility does not move the **`redact`** policy to the beginning or end of the assembly. The difference in the response between API Connect v5 and DataPower API Gateway may prevent data from being redacted in the DataPower API Gateway.

For example, if an assembly includes a **switch** policy containing four redact conditions followed by an **invoke** policy, each redact condition redacts the response data. After porting to the API Gateway, the redact conditions remain inside the **switch** policy and target the **message.body** property for redaction. These redactions fail to execute because the **message.body** property has not yet been retrieved by the **invoke** policy. To correct this problem, you must move the **invoke** policy before the **switch** policy in the assembly.

Developer Portal

Customized application view is reset to the default after upgrade if forums are also disabled

When upgrading API Connect version 10.0.5.0 or earlier to version 10.0.5.1 or later, if you have disabled forums on your Developer Portal site, and you have customized the application view, the customized application view will be reset to the default after the upgrade. To work around this issue, you can save the customized application view before running the upgrade, and then import the view into the upgraded Developer Portal.
To save the customized application view, run the following commands:

```
mkdir /tmp/tmp_config_<site-alias>
drush @<site-alias> config-get views.view.applications > /tmp/tmp_config_<site-alias>/views.view.applications.yaml
```

Where *<site-alias>* is the alias of your Developer Portal site.
To import the saved view after the upgrade, put the views.view.applications.yaml file inside a directory where it's the only file, and then run the following command:

```
drush @<site-alias> config-import --partial --source=/tmp/tmp_config_<site-alias>/
```

The 'strict' SameSite cookie causes incorrect invitations to consumer organizations

Using the 'strict' SameSite cookie might cause invitation links from emails to send users to a registration page where they are asked to create a new consumer organization instead of joining the organization they were invited to.
The workaround is to using the 'Lax' SameSite Cookie attribute.

Platform

New ibm-apiconnect-operator pod fails to start due existing terminating ibm-apiconnect-operator pod holding lock

The IBM APIConnect operator uses leader election (leader-for-life) to ensure that only one operator/controller pod is running/active at a time. This relies on Kubernetes garbage collection to clean up the lock when the old operator pod is deleted. The new ibm-apiconnect operator pod fails to start if an existing terminating ibm-apiconnect operator pod is still holding the lock.
If you suspect you are encountering this issue, verify it by running the following command:

```
kubectl -n <namespace> logs <new-ibm-apiconnect-pod-name> | grep "LockOwner"
```

If the lock is the problem, the log contains a message similar to the following example:

```
existing lock","LockOwner":"ibm-apiconnect-xxxxxx held by
terminating pod
```

Resolve the issue by completing one of the following options:

- Force delete the terminating pod by running the following command:

  ```
  kubectl -n <namespace> delete pod <terminating-ibm-apiconnect-pod-name> --force --grace-period=0
  ```

  Kubernetes deletes the lock when the pod is deleted.

- Remove the lock manually by running the following command:

  ```
  kubectl delete cm ibm-apiconnect-lock
  ```

Sometimes the completion of an SFTP restore on the Management subsystem does not restore the actual data.

There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

New gateways cannot connect to existing gateways after the gateway peering certificates are changed

Changing the gateway peering SSL certificates after gateway installation causes new gateways to be unable to connect to existing gateways, resulting in an outage. A full restart of the gateway StatefulSet (by deleting all the StatefulSet pods) is required for the gateways to come back online.

Kubernetes might excessively evict pods

In Kubernetes, if insufficient memory, CPU, or storage resources are provided then pods are evicted randomly. To avoid this problem, allocate sufficient resources to the pods. In addition, there are known issues with log rotation in Kubernetes that are documented here: https://github.com/kubernetes/kubernetes/issues/59902. The lack of log rotation can cause logs to grow, limited only by the amount of storage on the node, eventually causing pods to restart. Therefore ensure that appropriate log levels are configured for all API Connect components.
You may also follow the instructions described here https://success.docker.com/article/how-to-setup-log-rotation-post-installation to set the maximum size of the log before it is rolled (max-size) and the maximum number of log files that can be present (max-files). More information about the Docker JSON File logging driver is available here: https://docs.docker.com/config/containers/logging/json-file/.

Requests that take longer than the value of the nginx timeout cause a 409 error

Requests that take longer than the value of the **nginx** timeout can cause a 409 error, such as:

```
Another request is operating on portal-subsystem-03729230-4df7-4419-94c9-e7691b616382 with the same name,
please try again.
```

The error occurs because the ingress controller is sending a repeat request when the previous one timed out. Your request will still continue processing in the background.

Setting resource limits in Kubernetes can cause containers to behave oddly at run time

In Kubernetes, you can set resource limits for each container. However, limiting CPU means that the container processes might slow down if they try to use too much. Limiting memory means that the Kubernetes code kills processes that try to allocate memory that would take the container over its limit. These limits can result in odd behavior such as the containers continually trying to start a daemon process, such as nginx or node, and exiting with success immediately.

When scaling down a Kubernetes cluster of DataPower gateways, the cluster might enter an unrecoverable state if the peering primary instance is lost

If you are scaling down a Kubernetes cluster of DataPower gateways, you must first complete the following steps to ensure that the peering primary instance is not lost:

1. List the pods in the cluster; for example:

```
$ kubectl get pods -n apiconnect --selector
app.kubernetes.io/component=datapower,crd.apiconnect.ibm.com/instance=gwv6
NAME      READY   STATUS    RESTARTS   AGE
gwv6-0    1/1     Running   0          3h31m
gwv6-1    1/1     Running   0          3h32m
gwv6-2    1/1     Running   0          3h34m
```

2. Enter the DataPower admin CLI for gateway 0, by entering the following command and logging in at the prompt; for example:

```
$ kubectl attach -n apiconnect -it gwv6-0
```

3. Switch to the API Connect domain and enter config mode:

```
idg# switch apiconnect
idg[apiconnect]# config
Global mode
```

4. Show the gateway peering status; for example:

```
idg[apiconnect](config)# show gateway-peering-status
```

```
Address         Configuration name  Pending updates  Replication offset  Link status  Primary
--------------  ------------------  ---------------  ------------------  -----------  -------
1.2.3.1         gwd                 0                18331896            ok           no
1.2.3.1         rate-limit          0                3091219             ok           no
1.2.3.1         subs                0                3150127             ok           no
1.2.3.1         tms                 0                3063575             ok           no
1.2.3.2         gwd                 0                18330948            ok           no
1.2.3.2         rate-limit          0                3091067             ok           no
1.2.3.2         subs                0                3149975             ok           no
1.2.3.2         tms                 0                3063257             ok           no
1.2.3.3         gwd                 0                18330948            ok           yes
1.2.3.3         rate-limit          0                3091067             ok           yes
1.2.3.3         subs                0                3149975             ok           yes
1.2.3.3         tms                 0                3063257             ok           yes
```

5. For each of the configuration names, set gateway 0 to be the peering primary instance:

```
idg[apiconnect](config)# gateway-peering-switch-primary gwd
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary rate-limit
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary subs
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary tms
The instance is now the primary in the peer group.
```

6. Show the gateway peering status to confirm the changes; for example:

```
idg[apiconnect](config)# show gateway-peering-status
```

```
Address         Configuration name  Pending updates  Replication offset  Link status  Primary
--------------  ------------------  ---------------  ------------------  -----------  -------
1.2.3.1         gwd                 0                19067953            ok           yes
1.2.3.1         rate-limit          0                3218172             ok           yes
1.2.3.1         subs                0                3277032             ok           yes
1.2.3.1         tms                 0                3189160             ok           yes
1.2.3.2         gwd                 0                19067953            ok           no
1.2.3.2         rate-limit          0                3218172             ok           no
1.2.3.2         subs                0                3277200             ok           no
1.2.3.2         tms                 0                3189160             ok           no
1.2.3.3         gwd                 0                19069241            ok           no
1.2.3.3         rate-limit          0                3218172             ok           no
1.2.3.3         subs                0                3277508             ok           no
1.2.3.3         tms                 0                3189312             ok           no
```

Toolkit

API Designer with Local Test Environment (LTE) fails to log in using https://localhost with the error message "Incorrect username, password, or credentials"

If you use the API Designer with the Local Test Environment and attempt to log in using the localhost, the login fails. You can work around the issue by configuring API Designer credentials to with the local host. Complete the following steps:

1. Download and extract API Designer, then install the credentials file as explained in steps 1, 2, and 6 in Installing the toolkit.

2. Edit the designer_credentials.json file and configure the following settings:
   - `"endpoint": "https://localhost"`
   - `"manager_endpoint": "https://localhost/manager"`
   - `"client_id": Client Id`
     The client ID displays on the console when you start the LTE platform-apic-lte. For more information, see Testing an API with the Local Test Environment.
   - `"client_secret": Client Secret`
     The client secret displays on the console when you start the LTE platform-apic-lte. For more information, see Testing an API with the Local Test Environment.

3. Start API Designer and log in with the LTE using https://localhost as the Host URL (the management endpoint).

API Designer might hang while activating a large imported API

When you import a large API using API Designer and attempt to activate the API in the import wizard, the process might hang. If you encounter this issue, you can work around the problem by completing the following steps:

1. On your local file system, locate the autoproduct file called API-NAME-auto-product_API-VERSION.yaml.
2. Delete the file.
3. In API Designer, edit the newly imported API and activate it by clicking the Online toggle.

In general, it is best practice to activate an API using the Online toggle or by publishing the API with the Publish option.

API Designer on Windows: APIs that use WSDL might encounter errors, or fail to activate, publish, or update.

If you activate, publish, or update a REST or SOAP API that uses a WSDL file, the operation might fail and never complete. Work around the issue by using the autopublish API feature in the API editor.

Permission restrictions in the API Designer UI

The API Designer UI currently has the following permission restrictions:

- Developers that have been given only View permissions cannot see the Test tab in the API editor. For developers to be able to see the Test tab, they must be given a different permission level. For information about the default permission levels available, see API Connect user roles.
- Users with API-Drafts permissions, but who don't have any Sandbox Catalog permissions, cannot see the Test preferences in the Sandbox Catalog. For these users to be able to see the Test preferences, they must be given the Developer or Administrator role on the Sandbox Catalog.

Deleted security requirements might remain in the API source

Security requirements that are deleted from APIs in the API Designer and API Manager UIs, might still remain in the source. To work around this issue, click the Source icon </> in the API editor, and manually remove the security requirements.

Cannot add comments to APIs by using the Source view in the API Designer and API Manager UIs

Comments cannot be added to APIs in the API Designer and API Manager UIs by clicking the Source icon </>, and using the hashtag symbol.

Changing Product visibility from Custom to Public doesn't automatically remove the Consumer organizations and groups

In the API Designer and API Manager UIs, changing Product visibility from Custom to Public doesn't automatically remove the consumer organizations and groups, so the Product publish will fail. To work around this issue, manually remove all of the consumer organizations and groups.

The "Select compatible gateway services" option in Test Preferences causes a "404 POST undefined" error while testing the API

In the Test Preferences > Target gateway services setting, selecting Select compatible gateway services and choosing a specific gateway results in a "404 POST undefined" error when you test the API in the API Explorer or the Test tab.
Workaround: To avoid this problem, select the Use all compatible gateway services target gateway option instead.

Limitations to the OpenAPI 3.0 support

IBM API Connect supports the OpenAPI 3.0 specification, with some limitations. For information about what is supported, see OpenAPI 3.0 support.

A GraphQL API that contains a `graphql-input-type-cost` rate limit fails to publish

A GraphQL API created in releases earlier than IBM API Connect Version 10.0.3.0 might contain a `graphql-input-type-cost` rate limit, which is no longer supported. If you attempt to use the automatic activation mechanism to publish the API, or manually add the API to a Product and attempt to publish that Product, the publish operation will fail. You can resolve this problem in either of the following ways:

- Remove the rate limit definition from the OpenAPI source for the API. For example, if the source is in YAML format, remove the following lines:

  ```
  - name: graphql-input-type-cost
    operation: consume
  ```

- Edit the source for the Product and define a `graphql-input-type-cost` rate limit in all of the Plans that include the API.
  Note: You can edit only a manually created Product, not a Product that is generated by the automatic activation mechanism.

Update WSDL option is not supported in the API Designer UI

The Update WSDL option to update the configuration of an existing SOAP API from a WSDL file or a .zip archive, is supported only in the API Manager UI, or by using the developer toolkit. This option is not supported in the API Designer UI.

Cannot publish an API that has duplicate security definition entries

The API Designer and API Manager user interfaces allow you to add duplicate security definitions to an API. However, attempts to publish the API will fail with OpenAPI validation errors. Ensure that the security definitions in an API are unique.

No option to bulk delete APIs or Products

In the API Designer and API Manager user interfaces, there is currently no option to delete multiple APIs or Products in a single operation; in the user interfaces, APIs and Products must be deleted individually. However, you can bulk delete APIs and Products by using the REST API or CLI interfaces.

Field validation for the Client security policy is incorrect

When configuring a Client Security policy in an API assembly in the API Designer or API Manager user interfaces, there is the following incorrect validation behavior:

- The ID Name field is required, but the API definition can be saved without entering a value in the field.
- The Secret Name field is required only when the Secret Required option is selected, but the user interface indicates that the Secret Name field is required regardless. Furthermore, when the field is required, the API definition can be save without entering a value.
- If the Authenticate Client Method is set to Third party, the User Registry Name field is required, but the API definition can be saved without entering a value in this field.

API Designer user interface might not open correctly if there are badly formed OpenAPI YAML files in the startup directory

If, when launching the API Designer user interface, the startup directory that you select contains one or more badly formed OpenAPI YAML files, the interface might fail to load correctly, with an error such as the following:

```
Cannot read property 'type' of null
```

To resolve this problem, remove any invalid OpenAPI YAML files from the startup directory, then restart the API Designer user interface.

The `apic cloud-settings:mail-server-configured` command response is incorrect

If you use the `apic cloud-settings:mail-server-configured` without a `--format` parameter, it returns only the string `MailServerConfigured` rather than a boolean value to indicate whether an email server has been configured in the cloud settings. To retrieve the correct response, include the `--format` parameter, with a value of either `yaml` or `json` as required.

An OpenAPI definition that contains regular expression syntax fails validation

IBM API Connect supports the GO regular expression syntax. When you import an OpenAPI definition into the API Designer or API Manager user interfaces, or validate one with the `apic validate`, the validation will fail if the OpenAPI source contains unsupported regular expression syntax, with errors that include `Does not match format 'regex'`; for example:

```
- Must validate at least one schema (anyOf) (context:
(root).paths./example/types.post.parameters.0.schema.properties.items, line: 0, col: 0)
- Must validate one and only one schema (oneOf) (context: (root).paths./example/types.post.parameters.0, line: 46164, col:
21)
- paths./example/types.post.parameters.0.schema.properties.items.properties.pattern Does not match format 'regex'
(context: (root).paths./example/types.post.parameters.0.schema.properties.items.properties.pattern, line: 0, col: 0)
```

Validate policy limitations when GraphQL response contains a GraphQL server error

When a GraphQL response contains a GraphQL server error and no data, the assembly Validate policy generates an error on the missing data and overwrites the payload. When the response contains partial data and an error, the assembly Validate action validates the data and overwrites the payload. To work around this limitation, use the condition `$not($exists(message.body.errors))` in an assembly switch condition to skip the assembly Validate policy when the response contains errors.

An API developed for IBM API Connect Version 2018.4.1 that uses an `apim.getvariable('message.body')` function call fails in IBM API Connect Version 10

With the DataPower API Gateway in IBM API Connect Version 2018.4.1, the type of object returned, for XML payloads, by an `apim.getvariable('context_name.body')` function call in a GatewayScript policy in an API assembly depends on how the variable is stored in the gateway context, as follows:

- If the variable is stored as a Buffer (because the variable data was written as an XML string), an XML Nodelist is returned provided that `contextname.headers.content-type` is an XML type.
- If the variable is stored as a parsed XML Document (because the variable data was written as parsed XML, either as an XML document or an XML Nodelist), an XML document is returned.

With the DataPower API Gateway in IBM API Connect Version 10 however, the same function call always returns an XML Nodelist provided that `contextname.headers.content-type` is an XML type. Therefore, such an API developed for Version 2018.4.1 will fail in Version 10 if it is configured to expect an XML document, and will need to be reconfigured appropriately.

The problem does not occur with such an API migrated from IBM API Connect Version 5 because, with that release, `apim.getvariable('context_name.body')` also returns an XML Nodelist for XML payloads, nor does it occur if you are using the DataPower Gateway (v5 compatible).

context_name could be `message`, `request`, or the name of the output from an `invoke` policy.

For a secured GraphQL API, GraphQL subscriptions cannot be tested by using the Test tab in the user interfaces

For a GraphQL API that is secured by client ID, GraphQL subscriptions cannot be tested by using the Test tab in the API Designer or API Manager user interfaces. The API can still be published and used in production.
You can test GraphQL subscriptions in either of the following alternative ways:

- Remove client ID security from the API, for testing purposes, then use the Test tab.
- Use an external test tool.

The `apic cloud-settings:topology` command doesn't return a topology object

If you use the `apic cloud-settings:topology` command without a `--format` parameter, it returns only the string `CloudTopology` rather than the cloud topology. To retrieve the topology object, include the `--format` parameter, with a value of either `yaml` or `json` as required.

User Interface

Stale cache can result in unexpected behavior in the Cloud Manager and API Manager UI

Having a stale cache in your browser can result in unexpected behavior in the Cloud Manager and API Manager UI, such as fetch errors, incorrect data being displayed, and blank pages. To work around this issue, particularly if you have just upgraded your deployment, complete the following actions:

- Reload the browser window.
- If there is still an issue, clear the browser cache and then log back in to the UI.
- Try using a private browser window.
- If possible, try a different browser type.

If issues persist, contact IBM Support.

Limitations to the updated schema editor for API definitions

The Definitions section of the API editor for the API Manager and API Designer UIs was updated in API Connect 10.0.6.0. However, the `OneOf`, `AllOf`, and `Enum` schema structures aren't handled properly by the UI. You can work around this issue by editing the source YAML of your API document.

Options menus in the Catalog might be hidden

In a Catalog, in any of the different tabs such as Consumers, or Subscriptions, when clicking on the options icon ⋮ the menu items might be hidden. To work around the issue, reload the page and the menu items will appear.

Override plan rate limits are not displayed in the Endpoint tab

Any override plan rate limits that have been added to your API for individual operations are not displayed in the API Endpoint tab in the UI. Only the plan rate limit is displayed.

A Product republish, with the Preserve Subscriptions option, fails after a consumer organization group has been removed from the visibility settings

If you remove a consumer organization group from the custom visibility settings for a Product, and that group contains a consumer organization with an application that is subscribed to the Product, an attempt to republish the Product with the Preserve Subscriptions option will fail even if that consumer organization is then added to the custom visibility settings individually.

Pagination setting is global across the API Connect user interfaces
: If you set the Items per page value on any page in the Cloud Manager or API Manager user interface, that setting is then applied to all pages in both user interfaces in the same browser session. If you want to set the value separately for a specific page, open it in a private browser window. Such a setting in a private browser window is specific to that window and is lost when the window is closed.

Logging in to the API Connect user interfaces fails when using the Safari web browser
: If you are using the Safari web browser and a Basic Authorization header exists for the same DNS domain in which API Connect is running, attempts to log in to the API Connect user interfaces, or to sign up by using an activation link, fail. To avoid this problem, use an alternative web browser.

Login to the Cloud Manager or API Manager user interfaces might fail with error 431 if the browser has a large number of cookies
: Attempts to login to the Cloud Manager or API Manager user interfaces might fail if the HTTP header or cookie size is larger than 32 KB, a limitation that is imposed for security reasons. To resolve this problem, either clear the browser cache and cookies, or open a private window, then retry.

Numerical Handling in YAML Configurations and Precision Constraints in API Manager UI

- In the API Manager UI YAML configurations, numbers in exponential notation (for example 1e20) are handled differently based on their exponent value. Numbers with an exponent less than or equal to 20 are converted to their full integer form (for example 1e20 becomes 100,000,000,000,000,000,000) for display and processing. Numbers with an exponent greater than 20 stay in exponential notation (for example 1e21). Numbers that exceed the range of integers that are supported by DataPower JSON schema validation (-9,007,199,254,740,992 to 9,007,199,254,740,992) result in validation errors or unexpected behavior.
- JavaScript's inherent precision limitations truncate floating-point numbers to approximately 17 significant digits. For example:
  - Input: 0.12345678901234567890123456789O
  - Processed Value: 0.12345678901234568

User interfaces are not supported in Microsoft Edge
: The API Manager and Cloud Manager user interfaces are not supported in the Microsoft Edge web browser. To work in the user interfaces, use a different browser.

API Connect concepts

To help you get started, read about the API Connect concepts and obtain a high-level understanding of the API management solution.

- **Who does what in API Connect?**
  Review the different functions that users can perform in API Connect, the typical set of tasks that is performed by each type of user, and the documentation that is most often used for each task.
- **Packaging strategy and terminology in API Connect**
  API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.
- **API Connect components**
  The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.
- **API Connect support**
  If you experience a problem with IBM API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.

Who does what in API Connect?

Review the different functions that users can perform in API Connect, the typical set of tasks that is performed by each type of user, and the documentation that is most often used for each task.

Systems administrators

If you deploy API Connect on premises, then your company manages the systems. Because API Connect comprises multiple servers even in an on-premises deployment, the collection of servers and services is referred to as a (local) cloud. This is unrelated to any servers and systems that are deployed in IBM® Cloud.

In an on-premises deployment, there are two roles for managing your deployment:

- Cloud owner: There is one cloud owner for a deployment, and that person adds other people to the server management team.
- Cloud administrator: Your deployment needs at least one cloud administrator; your company will probably assign multiple people to perform this role. Cloud administrators manage the deployment and configuration of API Connect servers and software.

In the API Connect documentation, cloud owners and administrators are primarily interested in the following sections, which introduce concepts and explain how to deploy, maintain, and configure the components of an on-premises deployment.

Users

At the highest level, API Connect users belong to organizations, which are groups of people. A *provider organization* (often shortened as *p-org*) is a group of people who create, publish, and maintain APIs that are then used by people in a *consumer organization*. Consumers develop their own applications that call the APIs created by providers. A single customer can create multiple provider organizations and consumer organizations. For example, different divisions within a large company might work with different technologies and create entirely different sets of APIs, so it makes sense to group them into different p-orgs. Each provider organization publishes their APIs to a Developer Portal that uses consumer organizations to manage the customers who use those APIs.

At a minimum, you need one provider organization if you want to publish and manage APIs with API Connect, and one consumer organization for each customer.

Provider organization

A provider organization performs many tasks during the lifecycle of an API, from developing, publishing, and maintaining APIs to managing the membership of the organization itself. Each p-org can be as large or as small as needed. A large company might create a p-org for each product team, or for each department but a small company might use a single p-org.
A person can be a member of multiple provider organizations and receive a different set of permissions for each. When the user logs in to API Connect, they select the organization whose resources they will use, and receive the appropriate permissions for that organization for the duration of the session.

The following roles are commonly associated with a provider organization but are not necessarily represented by different people. In a small company, one person might perform all of the API maintenance tasks while in a larger company, several people might take on separate roles.

- Organization Owner: Every provider organization requires one owner to ensure that a user account is associated with the organization. The organization owner has full access to all of the p-org's resources (APIs, Products, Catalogs, and so on) and role cannot be deleted. The organization owner can add people to the organization manager role.
- Organization Manager: Maintaining the organization account is the job of the organization manager. In a large company, several people might share this role. Organization managers add *members* to provider organizations and assign them the permissions needed to perform their jobs. Organization owners and managers typically use the docs on administering provider orgs and administering members and roles.
- API Developer: In API Connect, an API developer creates new APIs and updates existing APIs as needed. The API developer can configure *policies* that define security restrictions, logging rules, and quotas that control access to your company's resources. The API developer might be assigned to work with a specific *Catalog* that manages a subset of APIs, or they might receive access to all of the p-org's Catalogs and the *Spaces* within each. API developers are usually most concerned with documentation related to developing APIs, managing API settings, and authoring policies for APIs.
- API Administrator: After an API developer creates a set of APIs, the API administrator manages the distribution. The API administrator defines *Plans* that determine access to the APIs, collects related APIs into *Products*, and publishes them to the consumer Developer Portals. To complete these tasks, the API administrator uses documentation focused on managing API syndication and working with Products.
- Product Manager: A product manager controls access to the Developer Portal where customers subscribe to APIs and then tracks API usage and performance. For each customer, the product manager creates a consumer organization, assigns a customer representative as the owner, and manages the relationship between the provider organization and each consumer organization. The product manager can customize the appearance of Developer Portal for their p-org as well as provide forums and blogs for their consumers. The product manager uses the API Connect Analytics service to track API usage and performance so that the p-org knows when APIs should be updated or retired. The product manager typically uses documentation on administering consumer organizations, using the Developer Portal, and reviewing API analytics.

Consumer organization

A consumer organization creates applications that use the APIs that are developed by provider organizations. Each provider's APIs are made available to each consumer organization in the API Connect Developer Portal. Members of a consumer organization typically perform two functions:

- Consumer Organization Owner: The consumer organization owner also manages the organization by inviting other members and assigning permissions to each. This role additionally has permissions to customize the Developer Portal where members access APIs that the organization is subscribed to.
- Application Developer: Create applications that invoke APIs shared through the Developer Portal.

The only API Connect feature that API consumers use is the Developer Portal, which is managed by the API provider. There is no need for consumers to read the API Connect documentation.

- **API Connect user roles**
  The IBM API Connect solution provides an infrastructure, tools, and facilities that allow users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.

API Connect user roles

The IBM® API Connect solution provides an infrastructure, tools, and facilities that allow users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.

The roles described here are the default API Connect roles. In the API Manager user interface, you can create custom roles; for more information, see: Creating custom roles.

The following sections describe the roles and permissions for each of the API Connect user interfaces:

- User roles in the Cloud Manager UI.
- User roles in the API Manager UI.
- User roles in the Developer Portal UI.

The roles are as follows:

- Member role given to any user that is on boarded without another role and is the minimum role that allows user to login only.
- Owner and Admin roles have all permissions and their cannot be modified.
- Custom roles can be created in the Admin organization and in Provider organizations, but not in Consumer organizations.

Note: In Cloud Manager and API Manager, the Owner role has full access and Member role has read only access. Both Owner and Member roles cannot be edited or deleted. All other roles, including custom roles, can be deleted. If a role was removed from the member, the membership for the user still remains in API Connect, enabling you to add a role to the member at a future date.

User roles and permissions in the Cloud Manager UI

The following table describes the Cloud Manager UI user permissions as configured in the base product. Certain roles can edited as indicated in Table 2, and custom roles can be created. For instructions on how to create custom roles for the Admin organization (Cloud Manager users), see Creating roles in the admin organization.

Table 1. Cloud Manager UI permissions

Permission	Action	Description
Cloud Settings	View	View all items in the Cloud Manager > Settings menu including roles and default roles
	Manage	Manage all items in the Cloud Manager > Settings menu including roles and default roles
Provider	View	View the list of provider organizations in the Cloud Manager > Provider organizations menu

Permission	Action	Description
organization	Manage	Add, edit, and delete provider organizations and invite owners from the Cloud Manager > Provider organizations menu
Analytics	View	View analytics in the Cloud Manager UI and includes create, update, duplicate, delete, share, and unshare saved queries
Audit	View	View audit events
Settings	View	View roles in the Cloud Manager > Settings > Roles menu
	Manage	Manage roles in the Cloud Manager > Settings > Roles menu which includes configuring Governance
Member	View	View members on the members list in the Cloud Manager > Members

	Manage	Add and invite members from the Cloud Manager > Members menu
		Note: By default, a user with Member > Manage permission can assign to themselves or to another user, any role with any permission regardless of the permissions that they themselves have. However, you can apply a restriction such that, for a user to assign a role, they must themselves have at least all of the permissions that are applied to that role. To apply that restriction, complete the following steps:
		1. Log in to your management server from the toolkit CLI as a member of the cloud administration organization; for details, see Logging in to management server.
		2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):
		`apic cloud-settings:update --server mgmt_endpoint_url -`
		where *mgmt_endpoint_url* is the platform API endpoint URL.
		3. Enter the following data, followed by a new line:
		`restrict_member_manage_permission: true`
		4. Press **CTRL D** to terminate the input.

Topology	View	View items in the Cloud Manager > Topology menu
	Manage	Add, edit, and delete the items in the Cloud Manager > Topology menu
Engagement	View	View all items in the Engagement section including rules, tasks, destinations, and engagement configurations. With this permission, you can monitor alert conditions, view notification settings, and track engagement activities across the system.
	Manage	View and modify all items in the Engagement section including creating, updating, and deleting rules, tasks, destinations, and engagement configurations. With this permission, you can configure alert conditions, set up notification channels, and manage the complete engagement workflow.

The following table lists the various Cloud Manager UI roles and the permissions that are assigned to them.

Table 2. Cloud Manager UI roles

Role	Actions	Provides access to	Description
Administrator	View, Manage	All menus	Administers the admin organization
Owner	View, Manage	All menus	Owns and administers the admin organization
Member	View	Organization	Minimum role. Member role is automatically assigned to any user on boarded without a role. It allows them to login but does not provide access to any menus.
Organization Manager	View, Manage	Organization and provider organization	Manages provider organizations.
Topology Administrator	View	Organization, Topology, and Settings	Administers the cloud topology. This role can only manage Topology and Settings
Viewer	View	All menus	Views the admin organization

User roles and permissions in the API Manager UI

The following tables describe the API Manager UI user permissions.

A user with Roles permission can change the permission assignments, and can create custom roles; for more information, see Creating custom roles in the section, Managing your APIs.

Table 3. Organization permissions

Permissions	Action	Description
App-Approval	View	View application approvals, for requests to promote a development application to a production application
	Manage	Manage (approve or decline) requests for approval to promote a development application to a production application
Subscription	View	View application plan subscriptions that have been created by consumer organizations in the Developer Portal
	Manage	Manage the application plan subscriptions that have been created by consumer organizations in the Developer Portal Note: The Manage permission includes ability to migrate a subscription to another plan.
Subscription-Approval	View	View application plan subscription approvals
	Manage	Manage (approve or decline) application plan subscriptions
Consumer-Onboard-Approval	View	View consumer onboard approvals
	Manage	Manage (approve or decline) consumer onboard approvals
API-Analytics	View	View analytics data, as well as access and apply saved analytics queries
	Manage	Create, update, duplicate, delete, and share saved analytics queries including view permission
Child	View	View catalogs in the provider organization level and spaces in the catalog level
	Create	Create catalogs in the provider organization level and spaces in the catalog level
	Manage	Manage catalogs in the provider organization level and spaces in the catalog level Note: Management tasks include deleting a catalog or space, or transferring ownership of a catalog or space.
API-Drafts	View	View draft APIs
	Edit	Edit draft APIs and API tests, view draft products, and API testing
API-Agent	All	Use conversational API Agent

Permissions	Action	Description
Governance-Enforcement-Approval	View	View all items in the Governance enforcement approval tasks section. With this permission, you can view all tasks created as part of governance enforcement flow, that require approval by catalog administrator
	Manage	View and modify all items in the Governance enforcement approval tasks section. With this permission, you can view and update all tasks (approve or reject) created as part of governance enforcement flow, that require approval by catalog administrator
Product	View	View product
	Stage	Stage product
	Manage	Manage product
Product-Approval	View, Manage	View and manage products, which includes viewing product lifecycle changes, and performing actions such as: • stage • manage • publish • supersede • replace • deprecate • retire
Consumer organization	View	View consumer organization and developers
	Manage	Manage consumer organization and developers
App	View	View both production and development applications
	Manage	Manage both production and development applications Note: A member with this permission can also request the promotion of a development app to a production app. This request triggers a task that needs approval by a member with the App-approval Manage permission.
App-Dev	Manage	View and manage the development applications
Audit	View	View audit events
Settings	View	• View an organization's configuration settings, including roles, TLS profiles, and user registries. • View configuration settings for a catalog or space, including policies and OpenAPI extensions.
	Manage	• Manage an organization's configuration settings, including roles, TLS profiles, user registries, Governance, API tests, and Discovery. • Manage configuration settings for a catalog or space, including policies and OpenAPI extensions.
Member	View	View the members of an organization

	Manage	Manage the members of an organization
		Note: By default, a user with Member > Manage permission can assign to themselves or to another user, any role with any permission regardless of the permissions that they themselves have. However, you can apply a restriction such that, for a user to assign a role, they must themselves have at least all of the permissions that are applied to that role. To apply that restriction, complete the following steps:
		1. Log in to your management server from the toolkit CLI as a member of the cloud administration organization; for details, see Logging in to management server.
		2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):
		`apic cloud-settings:update --server mgmt_endpoint_url -`
		where *mgmt_endpoint_url* is the platform API endpoint URL.
		3. Enter the following data, followed by a new line:
		`restrict_member_manage_permission: true`
		4. Press `CTRL D` to terminate the input.

Topology	View	View or manage services associated with the organization, including Gateways, Developer Portal, and Analytics.
	Manage	Manage services associated with the organization, including Gateways, Developer Portal, and Analytics.
Engagement	View	View all items in the Engagement section including rules, tasks, destinations, and engagement configurations. With this permission, you can monitor alert conditions, view notification settings, and track engagement activities across the system.
	Manage	View and modify all items in the Engagement section including creating, updating, and deleting rules, tasks, destinations, and engagement configurations. With this permission, you can configure alert conditions, set up notification channels, and manage the complete engagement workflow.
Product-Drafts	View	View draft APIs and products
	Edit	View draft APIs and edit draft products

A user with Settings > Manage permission can change the permission assignments, and can create custom roles; for more information, see Creating custom roles in the section, Managing your APIs.

Table 4. Default API Manager UI roles and the default permissions assigned to those roles.

Role	Action	Provides access to	Description
Administrator	View, Manage	All menus	Administers the API provider organization
API Agent User	View	All menus	By default, an API Agent chat user has only view permission. To perform all actions for the API Agent, you need to have the API-Agent permission
Owner	View, Manage	All menus	Owns and administers the API provider organization
Viewer	View	All menus	Views the API provider organization
API Administrator	View, Manage	All menus, but cannot manage the following: Member, Settings, Topology, Organization, and Child	Manages the lifecycle of APIs and publish APIs for discovery and use

Role	Action	Provides access to	Description
Community Manager	View, Manage	All menus, but cannot manage the following: Member, Settings, Topology, Organization, Product, Product-Approval, and Child	Manages the relationship between the provider organization and consumer organizations, provides information about API usage, and provides support to consumer organizations
Member	View	Organization	Minimum role. Member role is automatically assigned to any user on boarded without a role. It allows them to login but does not provide access to any menus
Developer	View, Manage	All menus, but cannot manage the following: Menu, Settings, Topology, and Org. For product and Product-Approval the developer role can do the following actions: view, stage, publish, supersede, replace, deprecate, retire, and archive	API developers design and develop APIs and applications for the provider organizations to which they belong. Note: The developer role allows the creation of products and APIs, and the staging and publishing of products to a catalog or space, when assigned to a user at the provider organization level but not when assigned to a user who is a member only of a catalog or space within a provider organization. A developer in a catalog or space can manage products that are staged or published to the catalog or space.

Note: Owners and administrators have the full permission to use API Agent. See API Agent user roles for more information.

User roles in the Developer Portal UI

The following table describes the various Developer Portal UI roles that relate to working with APIs and applications.

Table 5. Developer Portal UI roles

Role	Action	Provides access to	Description
Owner	View, Manage	Organization member	Owns and administers the consumer organizations and view or manage the application plan subscriptions that have been created by consumer organizations in the Developer Portal. The manage permission includes ability to migrate a subscription to another plan.
	View, Manage	Organization settings	
	View	Organization view	
	View	Consumer product	
	View, Manage production or development applications	Consumer application	
	Manage development application	Consumer organizations	
	View, Manage production or development applications	Consumer subscription	
	View	Consumer application analytics	
Administrator	View, Manage	Organization member	Administers the consumer organizations and view or manage the application plan subscriptions that have been created by consumer organizations in the Developer Portal. The manage permission includes the ability to migrate a subscription to another plan.
	View, Manage	Organization settings	
	View	Organization	
	View	Consumer product	
	View, Manage production or development applications	Consumer application	
	Manage development applications	Consumer organizations	
	View, Manage	Consumer subscription	
	View application analytics	Consumer application analytics	
Viewer	View	Organization member	Viewer of the consumer organizations
	View	Organization settings	
	View	Organization	
	View	Consumer product	
	View applications	Consumer application	
	View production applications	Consumer production application	

Role	Action	Provides access to	Description
	View application analytics	Consumer application analytics	
Developer	View	Organization member	API developers are responsible for building and managing applications within their respective developer organizations. View or manage the application plan subscriptions that have been created by consumer organizations in the Developer Portal. The manage permission includes ability to migrate a subscription to another plan.
	View	Organization settings	
	View	Organization	
	View	Consumer product	
	View, Manage production or development applications	Consumer application	
	Manage development applications	Consumer organizations	
	View, Manage	Consumer subscription	
	View application analytics	Consumer application analytics	
Member	View	Organization	Member of the consumer organizations

Note: A user who is called admin is created automatically, with full administrator access to the Developer Portal site. The admin user can view products and APIs but has no access to use APIs. The admin user assumes the email address of the owner of the provider organization that is associated with the Developer Portal.

Packaging strategy and terminology in API Connect

API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.

The packaging strategy supports API providers in meeting the requirements of the API consumers. An understanding of the concepts and terminology behind the packaging strategy is required before developing and deploying APIs by using IBM® API Connect.

The following sections describe the concepts and terminology behind the packaging strategy for IBM API Connect:

- APIs
- Plans and products
- Catalog and Spaces
- Organizations and users
- Sample provider organization with two Catalogs

APIs

An Application Programming Interface (API) is an industry-standard software technology. An API is a set of routines, protocols, and tools for building software applications. An API specifies how software components interact and provides quick access to common assets and processes. APIs can be public (such as offered on GitHub), can require client credentials, or can be kept private within an application. Thus, APIs are classified as external (public), partner (protected), or internal (private), based on how they are consumed.

An API is composed of operations, called methods, which are offered in one of the following styles in API Connect:

- A REST API is structured according to the principles of Representational State Transfer. REST APIs use HTTP or HTTPS requests to PUT, GET, POST, and DELETE data (also referred to as CRUD operations). REST identifies resources using URIs. Data can be described in a variety formats (XML, HTML, JSON, TXT, etc.), with JSON being the popular choice. REST APIs specify MIME (Multipurpose Internet Mail Extensions) types. REST is platform- and language-independent and works across firewalls using HTTPS. REST APIs leverage HTTP standards for security, caching, and status codes. HTTP clients and servers are available for all major programming languages and operating system/hardware platforms. REST implementations are easily scaled due to use of HTTP and browsers as a uniform interface.
- A SOAP (Simple Object Access Protocol) API is a web service that is exposed as an API. SOAP interfaces are described in WSDL (Web Services Description Language) format. The WSDL is an XML document describing the structure for headers, messages, URL endpoints, and datatypes used to access a web service. SOAP is considered more secure than REST as it supports WS-Security as well as SSL. SOAP also contains WS-Reliable Messaging for reliability, rather than relying on retrying the operation (as does REST). SOAP requires a client application and is better suited for enterprise applications that require secure transactions.

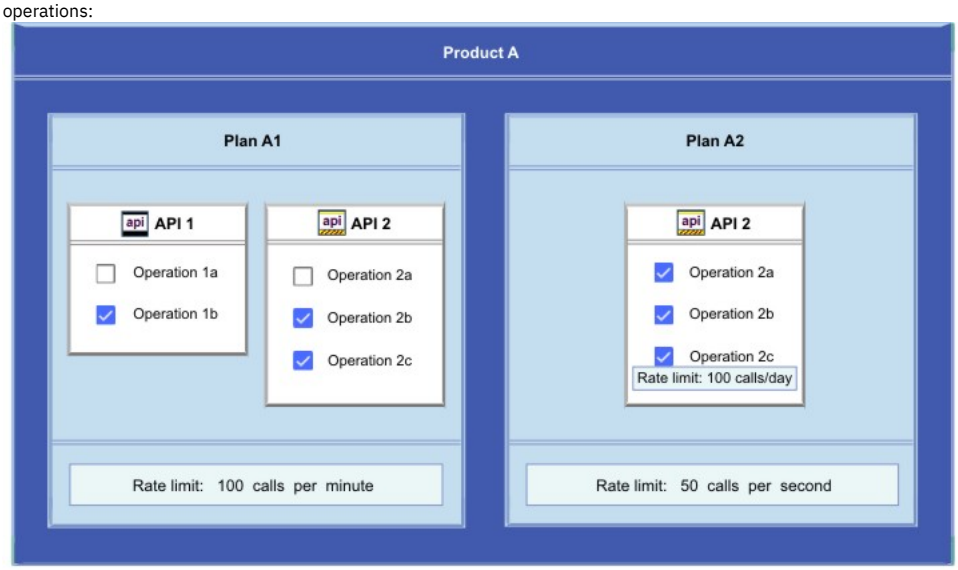
APIs can be versioned and packaged into multiple products for distribution to API consumers on the Developer Portal. For information about creating and managing APIs, see Developing your APIs and applications and Managing your APIs.

Plans and products

Plans and products are proprietary packaging constructs that are unique to API Connect. API providers use products to offer one or more APIs to the application developers who will consume the APIs (API consumers). The providers use plans to control access to APIs and to manage API usage. Products are packages that contain both the APIs and the accompanying plans. See Working with Products.

To make an API available to an application developer, it must be included in at least one product and at least one plan.

Plans perform the following functions:



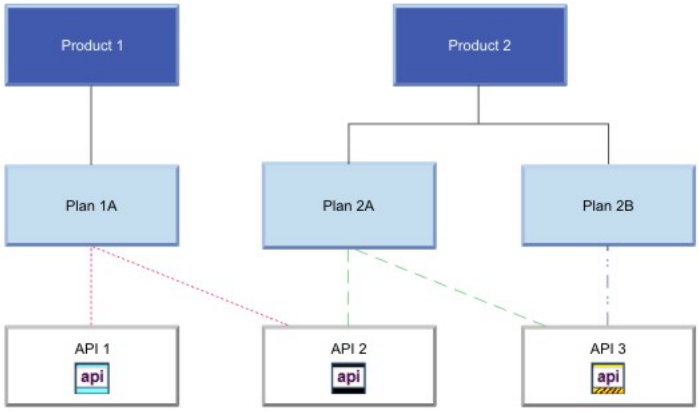
- Control which APIs an application developer can use
- Make available a collection of operations from one or more APIs
- Apply rate limits to APIs to differentiate between offerings
- Implement different rate limits to specify how many requests a consuming application is allowed to make during a specified time interval

A rate limit can be implemented as a default rate that is shared across all operations in a plan, or can be set for specific operations of an API. Plans can use differing rate limits to provide different levels of service to API consumers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

A product in API Connect bundles a set of APIs and plans into one offering that is intended for a particular use. You can create plans only within products, and these products are then published in a Catalog. The following rules apply for the relationship between products and plans:

- A plan can belong to only one product.
- A product can have multiple plans that each contain a different set of APIs.
- A plan in one product can share APIs with plans from any other product.

Multiple plans within a single product provide different levels of performance for the same offering. For example, a product can include a "Demo Plan" that makes a single API available, and a "Full Plan" that makes several APIs available.
The following diagram illustrates how plans can be used to make operations from one or more APIs available, and to set rate limits on both plans and individual operations:



The diagram illustrates the following concepts:

- Product A contains two APIs and two plans.
- Both APIs are included in Plan A1.
- Plan A2 includes only API 2, which is also included in Plan A1. Operation 2a for API 2 is excluded from Plan A1. All operations in API 2 are included in Plan A2.
- Different rate limits are set for the two plans at the plan level. For API 2 in Plan A2, a rate limit is also set specifically for Operation 2c to override the rate limit set at the Plan level.

Products are used to manage the lifecycle of the APIs they contain. The states in the Product lifecycle include draft, staged, published, deprecated, and retired. A product in draft state is moved to the staged state when it is staged to a *Catalog*. A product moves to the published state when the product is published. The APIs in a product become accessible to API consumers when the product is in the published state and they then become visible on a *Developer Portal*. After a product is published, application developers can use the Developer Portal to gain access to its APIs by registering applications to one or more plans in the product.

The following diagram illustrates the hierarchy of products, plans, and APIs.

For more information about managing the lifecycle of products, see Working with Products in the API Manager.

Catalogs and Spaces

A Catalog contains a collection of products. Catalogs are staging targets through which products (together with the accompanying plans and APIs) are published on a Developer Portal. Catalogs are used to separate products and APIs for testing before publishing them on a Developer Portal. In a typical workflow, an API provider uses a development Catalog when developing and testing APIs, and uses a production Catalog for publishing APIs that are ready for external use. Each Catalog has an associated

Developer Portal for exposing the published products. A Catalog includes runtime capability through an associated gateway service that handles any API requests for the APIs in that Catalog.

API Connect includes a syndication feature that enables API providers to partition a Catalog into multiple staging targets (or *Spaces*) for API development purposes. Each API provider development team can use its own dedicated Space to manage its products independently of other teams. A Space has its own set of capabilities relating specifically to the products and APIs that are created and published to that Space. Products and APIs in all Spaces in a given Catalog are published to the same Developer Portal. Spaces are not visible on the Developer Portal. Application developers who consume the APIs on the Developer Portal are unaware of the Space configuration used by the API Developers. On the Developer Portal, the APIs are seen as a coordinated offering within a Catalog.

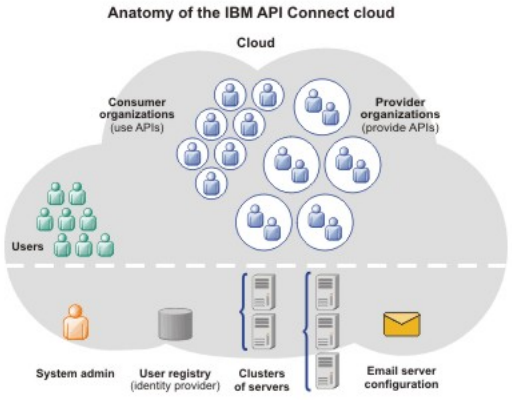
For more information about Catalogs and Spaces, see Working with Catalogs and Using syndication to partition Catalogs into Spaces.

Organizations and users

In the context of API Connect, there are two types of organizations: provider and consumer. An organization can encompass a project team, department, or division.

A provider organization owns APIs, and associated plans and products, and can additionally own *provider* applications that are called by APIs. To complete the various functions in the API lifecycle, a provider organization assigns responsibilities for certain tasks. Some standard responsibilities within a provider organization include:

- A provider organization owner who has the full set of access permissions to API Connect functions, and can also commission APIs and track their business adoption.
- API developers who design and develop APIs and applications for the provider organizations to which they belong.
- An administrator who manages the lifecycles of APIs and publishes APIs for discovery and use.
- A "community" manager who manages the relationship between the provider organization and application developers, provides information about API usage, and provides support to application developers.



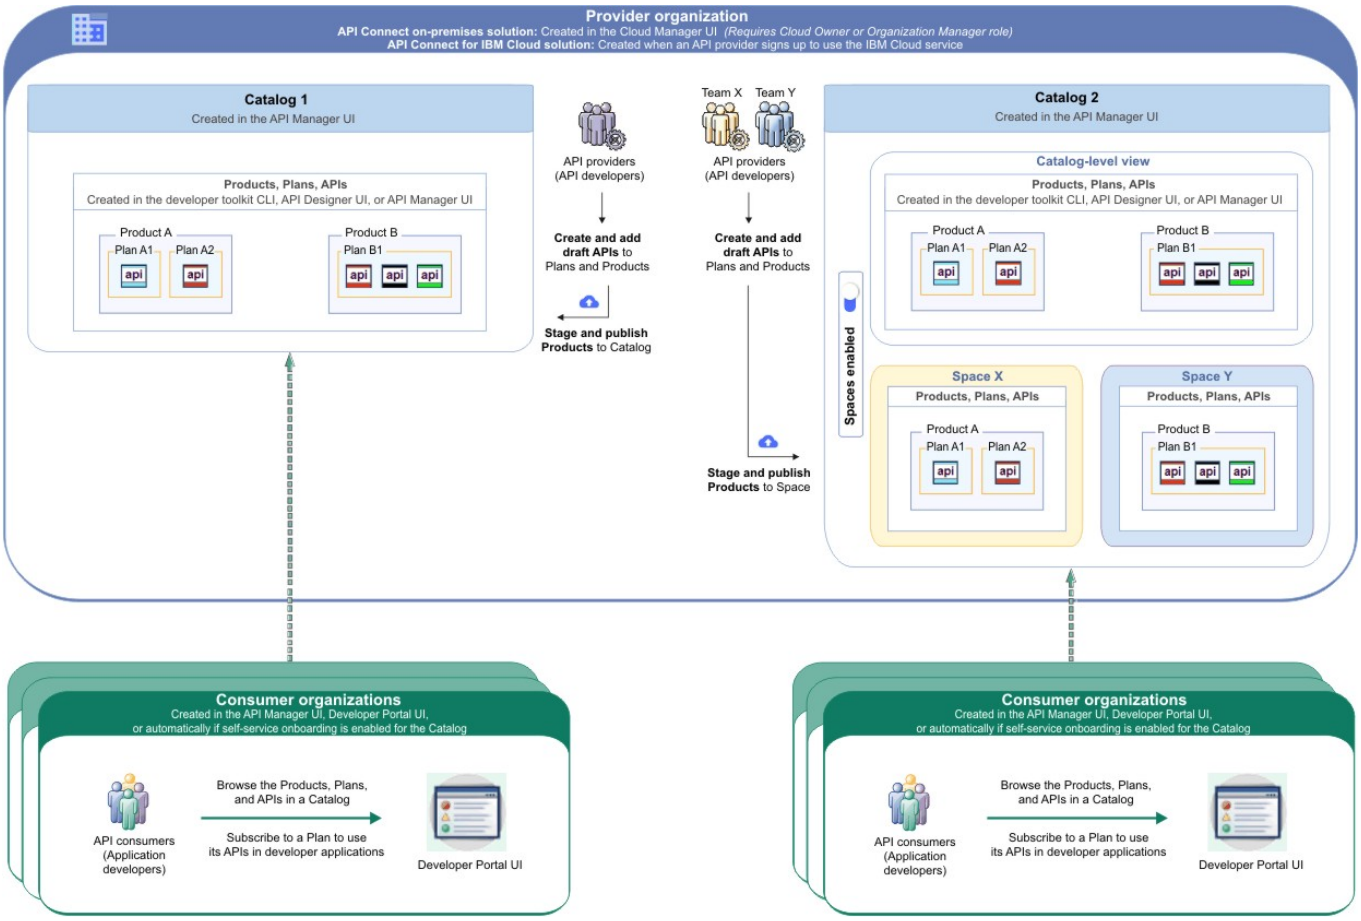
A consumer organization owns only *developer* applications, and consumes the APIs and applications produced by the provider organization. Standard responsibilities within a consumer organization include:

- A consumer organization owner who adds application developers to the consumer organization, views the products and APIs that the provider organization has made available on the Developer Portal, and subscribes to APIs to use them in applications.
- Application developers who view the products and APIs that the provider organization has made available on the Developer Portal, and subscribe to use these APIs in applications.

The provider and consumer organization responsibilities map to *roles* within API Connect. Some roles are independent of an organization; for example, an administrator who manages the cloud infrastructure and keeps the system running. For information about the full set of defined roles and access permissions, see API Connect user roles.

Users have an existence in the API Connect ecosystem that is independent of an organization. A user can be a member of more than one provider or consumer organization.

There can be multiple provider organizations in one API Connect cloud, to provide an API development environment for each line of business of an enterprise. The API Connect cloud is a collection of servers that comprise an API Connect installation, including the configuration information and metadata that they contain. The cloud infrastructure is shared by all organizations, and managed independently of them (by a cloud or system administrator). The following diagram shows the relationship between the provider organizations, consumer organizations, and users. The clusters shown are logical groupings of servers with the same capability.



For more information about organizations, see Administering provider organizations and Administering consumer organizations.

Sample provider organization with two Catalogs

The following diagram shows an example for how APIs, plans, products, Catalogs, and Spaces fit within provider and consumer organizations. In this example, two Catalogs are created in the provider organization to act as staging targets for different sets of requirements.

- Catalog 1 does not require separation of the products for use by individual provider development teams, and so does not have Spaces enabled. API developers with access to this Catalog create draft APIs, and stage and publish them as products to the Catalog. Several consumer organizations are granted permission to explore, discover, and use the published products and APIs. In each of the consumer organizations, the published products and APIs from Catalog 1 are exposed on a single Developer Portal.
- Catalog 2 is partitioned into two Spaces (X and Y) so that two provider development teams can manage their products independently. These teams stage and publish their APIs (as products) separately to the individual Spaces, to make them accessible to application developers in multiple consumer organizations. In each

of the developer organizations, the published products and APIs from both Spaces are exposed in the same Developer Portal, and application developers who access this portal will see the APIs from both Spaces as a coordinated offering.

- **Understanding rate limits for APIs and Plans**
  In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

Understanding rate limits for APIs and Plans

In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

What are rate limits and burst limits?

A rate limit is the maximum number of calls that you want to allow in a particular time interval. Setting rate limits enables you to manage the network traffic for your APIs and for specific operations within your APIs. API Connect supports two types of rate limiting:

Rate limit
: A specified number of calls to be accepted within a defined time period; for example, 100 calls per minute. In API Connect, rate limits can be defined as unlimited, or with a specified number of calls per second, minute, hour, day, or week.

  Rate limits can be "hard" (enforced) or "soft". If the rate limit is hard and a call exceeds the limit, then the call is aborted and an error is returned. A soft rate limit allows the call to complete but logs a warning message. When a hard rate limit is reached, no more calls are accepted from that customer until the beginning of the next time period. For example, you might want to permit a total of 1000 calls per hour (rate limit). If a customer makes 1000 calls in the first 10 minutes, they cannot complete any more calls until the hour has expired.

Burst limit
: A rate limit that is applied to a small time period. In API Connect, burst limits are defined for multiples of seconds or minutes. Burst limits are always hard. When a burst limit is reached, calls are not accepted until the time period has expired. Once that pause is over, calls continue to be accepted until a hard rate limit is reached. Configuring a burst limit prevents usage spikes and ensures that the rate limit is evenly spread across its overall time period. For example, you might want to permit a total of 1000 calls per hour (rate limit) and a maximum spike of 50 calls per second (burst limit).

Note:
The system clock determines the start time for rate, and burst limits. The intervals are configured as follows:

- 1-second interval starts at each new second.
- 1 minute interval starts at the beginning of each minute.
- 1 hour interval starts at the beginning of each hour.
- 1 day interval starts at midnight UTC.
- 1 week interval starts on Thursday at 00:00:00 UTC.

Where can you apply rate limits?

You can configure rate limiting at several levels of an API and the Plan containing it. Each of the rate limits is tracked separately and when a hard limit is exceeded, calls at that point are no longer accepted until the start of the next time period.

The following list explains where you can configure rate limits:

Plan: all APIs
: You can define a general rate limit at the Plan level, and it affects all of the consumer orgs that use that Plan. When a rate limit is enforced for a Plan, the limit is checked before every call that involves any API contained in that Plan. If the rate limit is exceeded, APIs are not even called. For information on setting a rate limit for a Plan, see Editing a draft Product.
Note: If the subscriber changes to a different Plan, only the Plan-level rates limit are reset. If there is a hard rate limit that is specified in the API's definition or assembly, that rate limit is still enforced under the new Plan.

Plan: API path and operation
: You can define a rate limit for a specific path and operation of an API within a Plan; for example, you might allow unlimited calls to a GET operation but enforce a limit on PUT operations for the same API. You can even define multiple rate limits on the same path and operation. If the rate limit is enforced, then the limit is checked before every call that involves the API's path and operation. For more information on configuring rate limits on API paths and operations within a plan, see the following topics:

  - Defining rate limits for an API operation
  - Describing Plans in your Product

API definition
: You can define a rate limit on an API in the API definition (the Design page in the user interface). This rate limit applies to all calls involving the API, from all consumer orgs. If the containing Plan allows the call but the API definition has a hard limit set, the call is aborted. For more information on setting a rate limit on an API definition, see Changing an API rate limit.

API assembly
: When you apply a rate limit to an API assembly, the limit only affects calls at that point in the assembly. This allows you to define a more granular rate limit than if you set it on the API definition. If the Plan and the API definition allow a call to proceed but a hard limit that is set on the assembly is exceeded, the call is aborted at the point in the process flow where the rate limit is set. Any actions that appear in the assembly's process flow before the rate limit policy are executed. Only the actions that appear in the flow after the rate limit policy are aborted. For more information on configuring assembly-level rate limits, see the following topics:

  - Rate Limit policy
  - GatewayScript policy
  - Using context variables in a GatewayScript policy

How can you test rate limits?

When you're ready to test rate limits on an API or Plan, execute a larger number of calls than specified by your rate limit, within a shorter period. If you set soft rate limits, check for warning messages that indicate when each limit is exceeded. If you set hard limits, you can tell that it was enforced when the API call fails. You can also check the error messages to verify which calls exceeded the limits.

For more information on creating and configuring catalogs, see Working with Catalogs.

API Connect components

The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.

- Cloud Manager
- The developer toolkit
- API Manager
- API Gateways
- Runtime
- Developer Portal
- API Analytics
- Typical tasks per interface component
- API Connect server requirements

Cloud Manager

The API Connect Cloud Manager component is used to manage the API Connect on-premises cloud. The Cloud Administrator uses this UI to:

- Define the cluster of *Management servers*, *Gateway servers*, and *containers* that are required in the cloud, and configure the topology. For information about Management servers and Gateway servers, see API Connect server requirements. For information about containers, see Runtime.
- Manage (modify, move, remove, restart, reboot) the servers in the cloud.
- Monitor the health of the cloud.
- Define and manage the provider organizations that develop APIs. (Assigned managers or owners of provider organizations can also complete this task.)
- Define additional cloud administrators, or set up users with roles that enable access to specific capabilities.
- Add user registries for authenticating users and securing APIs, and configure the secure transmission of data (for example, through websites).

For more information about the Cloud Manager, see Managing your cloud.

The developer toolkit

The developer toolkit provides the tools for modeling, developing, and testing APIs. The developer toolkit includes a command-line interface (CLI) and a corresponding graphical user interface, the API Designer.

API developers use the API management functions in the API Designer or the CLI to create draft API definitions for REST and SOAP APIs, or for OAuth provider endpoints that are used for OAuth 2.0 authentication. The API definitions can be configured to add the API to a Product, add a policy assembly flow (to manipulate requests/responses), and to define security options and other settings. APIs can then be tested locally prior to publishing, to ensure they are defined and implemented correctly.

Draft APIs (in their containing Products) that are created by using the API Designer, or CLI are published to Catalogs.

The developer toolkit is installed locally, for offline API and application development. For more information about the developer toolkit, see Developing your APIs and applications.

API Manager

The API Manager provides a user interface that facilitates promotion and tracking of APIs that are packaged within Products and Plans. API providers can move the Products through their lifecycle, and manage the availability and visibility of APIs and Plans.

Catalogs and Spaces are created in the API Manager to act as staging targets through which APIs, Plans, and Products are published to consumer organizations. API providers can stage their Products to Catalogs or Spaces, and then publish them to make the APIs in those Products visible on a *Developer Portal* for external discovery.

To control access to the available API management functions, users in the provider organization can be set up in the API Manager UI with assigned roles and permissions. API providers can also use the UI to manage the consumer organizations that sign up to access their APIs and Plans. Developer *communities* can also be created as a way of grouping together a collection of consumer organizations to whom a particular set of Products and Plans can be made available.

The API Manager UI also includes functions to manage the security of the API environment, and provides access to analytics information about API invocation metrics within customizable dashboard views.

For more information about the API Manager, see Managing your APIs.

API Gateways

Gateways enforce runtime policies to secure and control API traffic, provide the endpoints that expose APIs to the calling applications, and provide assembly functions that enable APIs to integrate with various endpoints. They also log and report all API interactions to the API Connect analytics engine, for real-time and historical analytics and reporting.

API Connect supports the following types of API gateways:

- DataPower Gateway (v5-compatible)
  The DataPower® Gateway is an enterprise API Gateway that is built for departments and cross-enterprise usage. In V10 API Connect, the DataPower Gateway is compatible with the V5 DataPower Gateway, so it is referred to in documentation as the "v5-compatible" (or "v5c") gateway. The v5-compatible gateway provides a comprehensive set of API policies for security, traffic management, mediation, acceleration, and non-HTTP protocol support.

- DataPower API Gateway
  The DataPower API Gateway was designed with the same security focus as the DataPower Gateway (v5-compatible). Where DataPower Gateway (v5 compatible) is built for flexibility, DataPower API Gateway is built specifically for the API use case, with resulting performance benefits.DataPower API Gateway is optimized for the cloud. Use this gateway if you are running applications in a public or private cloud and want to expose them as APIs.

Your API Connect deployment can include a virtual DataPower Gateway. Support for a physical DataPower Gateway is also available, subject to certain conditions.

For more information about the gateways, and a comparison of their features, see Gateway types.

Runtime

You can run applications and API implementations in API Connect in a containerized runtime.

Containerized runtime
: A containerized runtime environment provides a lightweight deployment location for APIs and applications. A container wraps an application in a complete file system that includes everything it needs to run, such as code, runtime, system tools, and system libraries. You can use Docker Swarm or Kubernetes containers to run your APIs and applications being managed by API Connect.

Developer Portal

The Developer Portal provides a customizable self-service web-based portal to application developers to explore, discover, and subscribe to APIs.

When API providers publish APIs in the API Manager, those APIs are exposed in the Developer Portal for discovery and usage by application developers in consumer organizations. Application developers can access the Developer Portal UI to register their applications, discover APIs, use the required APIs in their applications (with access approval where necessary), and subsequently deploy those applications.

The Developer Portal provides additional features, such as forums, blogs, comments, and ratings, for socialization and collaboration. API consumers can also view analytics information about the APIs that are used by an application, or used within a consumer organization. For more information, see Developer Portal: Socialize your APIs.

API Analytics

API Connect provides the capability to filter, sort, and aggregate your API event data. This data is then presented within correlated charts, tables, and maps, to help you manage service levels, set rate limits, establish controls, set up security policies, manage communities, and analyze trends. API analytics is built on the OpenSearch open source real-time distributed search and analytics engine. For more information, see Analytics: understand your API usage.

API Connect server requirements

From an on-premises cloud, you can create, promote, use, and track APIs. An on-premises cloud is composed of various appliances, where each appliance is a server of a specific type. The collection of servers defines your cloud and determines how to distribute the work of managing, analyzing, routing, and storing data.

Your on-premises cloud can be a combination of new and existing physical appliances and virtual appliances, or can be entirely composed of virtual appliances. The type and quantity of servers in an API Connect environment are determined by the individual needs of each enterprise, but the minimum requirement is one Management server, one Analytics server, one Gateway server, and one server to host the Developer Portal.

The API Connect on-premises cloud includes the following server types:

- Management server. Stores all of the cloud configuration, and controls communication between the other servers within API Connect. Manages the operations of the various servers in the API Connect cloud and provides the tools to interface with the various servers. The Cloud Manager and API Manager user interfaces run on the Management server.
- Analytics server. Provides analytic functions that collect and store information about APIs and API users.
- Gateway server. Processes and manages security protocols and stores relevant user and appliance authentication data. The Gateway server also provides assembly functions that enable APIs to integrate with various endpoints, such as databases or HTTP-based endpoints.
- **Developer Portal server**. Provides a customizable social developer portal with a full-featured content management system, and includes clustering capability. Enables API providers to build portals for their application developers, and provides the interface for application developers to discover APIs and subscribe to usage Plans contained in the published Products for use in their applications.

Note: All Management appliances in an API Connect cloud must run at the same firmware level as each other. Gateway appliances can run on different firmware levels to each other, but it is recommended that all of the Gateway appliances run on the same level as each other.

Typical tasks per interface component

API Connect offers both command line and graphical user interfaces. Provider and consumer organizations use different interfaces for completing typical tasks. Refer to the following table to locate the interface that corresponds to a specific task.

Table 1. API Connect Tasks per interface component

Organization Type	Interface Component	Tasks
API Provider	Command Line Interface (CLI)	Create APIs, Plans, and Products
	API Designer UI	Create APIs, Plans, and Products
	API Manager UI	Create Catalogs and Spaces; Create Consumer Organizations
	Cloud Manager UI	Create Provider Organizations
API Consumer (application developer)	Developer Portal	Access APIs to create and run applications; Create Consumer Organizations

If self-service onboarding is enabled for a Catalog, a consumer organization is automatically created when an application developer signs up or is invited by the API provider to a Developer Portal, and the application developer then becomes the owner of that consumer organization.

- **Gateway types**
  IBM API Connect provides the different types of gateways for use with your deployment.

Related concepts

- Packaging strategy and terminology in API Connect

Gateway types

IBM® API Connect provides the different types of gateways for use with your deployment.

DataPower API Gateway

The DataPower® API Gateway has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible). Where DataPower Gateway (v5 compatible) was built for flexibility, DataPower API Gateway is built specifically for the API use case, with resulting performance benefits.

DataPower API Gateway was built and optimized for the cloud. Use this gateway if you are running applications in a public or private cloud and want to expose them as APIs.

DataPower Gateway (v5 compatible)

DataPower Gateway (v5 compatible) provides compatibility with the IBM DataPower Gateway that was provided with IBM API Connect Version 5 and earlier releases.

Consider using DataPower Gateway (v5 compatible) if you are an existing DataPower user and want to use your DataPower resources and knowledge.

DataPower gateway comparison

The following table compares support for features between the gateway types.

Table 1. Comparison of the DataPower Gateway (v5 compatible) and DataPower API Gateway

Feature	DataPower Gateway (v5 compatible)	DataPower API Gateway
Native policies	No	Yes
OAuth provider	Full OAuth 2.0 Support	Full OAuth 2.0 Support
OAuth policy	No	Yes
OpenID Connect	Supported through a template	Supported natively
Invoke policy	Yes	Yes

Feature	DataPower Gateway (v5 compatible)	DataPower API Gateway
Custom policies	Yes	Yes
Conditional policies	if, operation-switch, switch	switch
Activity logging	Implicitly executed at the end of API assembly	Configured in the API design, outside of the API assembly.
GatewayScript	Yes	Yes
Parse policy (threat detection)	No	Yes
Gateway extensions	Yes	Yes
Support for mutual TLS (mTLS)	Yes	Yes

Attention: Version 5-compatible gateways and DataPower API Gateways have different mechanisms for interacting with the API context for GatewayScript and XSLT policies, or if you are authoring user-defined policies. Ensure that you are using the correct mechanisms for your gateway type:

- For v5-compatible gateways and v5 compatibility for APIs created for the API Gateway, see GatewayScript code examples and XSLT policy examples.
- For DataPower API Gateway, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Event Gateway

Event Endpoint Management provides the capability to describe and catalog your Kafka topics as event sources, and to grant access to application developers within the organization. Application developers can discover event endpoints and configure their applications to access them through the event gateway. With Event Endpoint Management, developers can control access to the event endpoints, and also control what data can be produced to them or consumed from them.

For more information on Event Endpoint Management, see the Event Endpoint Management introduction in the IBM Event Automation documentation.

API Connect support

If you experience a problem with IBM® API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.

For the most recent API Connect technical information, see the IBM Support Community.

If you cannot find a resolution, before you contact IBM Support, you must gather information about the problem. For details of the information you must gather before contacting IBM Support, see MustGather - Collecting data: API Connect problem determination.

Providing IBM Support with a good description of the problem together with the details of your API Connect configuration, helps to expedite the problem resolution.

API Connect glossary

The IBM® API Connect and Cloud Manager glossary of terms and definitions.

API Administrator (role)
: Manages the API product lifecycle for the Provider Organizations for which they are a member.

API Event
: An event that is captured for use by API Connect Analytics or third-party analytics, such as response time, HTTP response code, payload of the request and response body . An API event is logged each time an API operation is invoked via the Gateway server.

API Gateway
: Service that acts as a single entry point or “front door” for provider APIs and back-end services. An API Gateway accepts and processes concurrent API calls, and performs traffic management, authorization and access control, monitoring, and API version management. See also IBM DataPower Gateway.

API Manager
: Graphical tool in API Connect that enables you to manage catalogs, Spaces, and APIs, users, and roles in the Provider organization, consumer organizations and communities, publish Products to the Developer Portal, and analyze API usage.

API Designer
: Graphical tool that runs locally on a laptop or desktop system that enables you to create and modify APIs, and publish them to IBM Cloud or container runtimes.

API operation
: REST API calls consisting of an HTTP verb and a URL path (endpoint). For example, **`GET http://myserver.com/api/users`** that returns a list of users.

Application
: Software that consumes (calls) an API. One or more Applications are registered by a consumer organization to subscribe to APIs. The application is allocated the client ID and client secret credentials that it supplies when invoking API calls.

assembly
: Makes side calls to external services and then transforms and aggregates the response before a response is relayed to the calling application.

Availability zones
: In API Connect these are logical groupings of API Connect services that will typically reflect the deployment environment. For example, you might have availability zones that are named **`internal`** and **`external`** to reflect the APIs published in each. Or they might be defined by the geographic location the services are running in.

Catalog
: A staging target that behaves as a logical partition of the gateway and the Developer Portal. The URLs for API calls and for the Developer Portal are specific to a particular catalog.

client ID
: A piece of information that identifies an individual application. An application can invoke an API only if it passes an application key that is recognized by the IBM API Connect system and is granted access to the API. The application key is passed by the client by using an HTTP query parameter.

client secret
: A piece of information used together with the application key to verify the identity of an application. An API can be configured to require that client applications supply their client secret with their client ID. The client secret functions effectively as a password known only to the application. The client secret is passed by the client by using an HTTP query parameter.

Cloud Manager (tool)

Graphical tool in API Connect on-premises installation that enables you to define servers, administer and scale system resources, monitor runtime health and create Provider organizations. The Cloud Administrator is the primary user of the Cloud Manager.

Cloud Administrator (role)
: Manages the configuration of resources, regions, and availability zones for the Admin Organization of an on-premises installation.

cluster
: A collection of one or more servers that provide a specific function.

Cold standby
: A deployment configuration in which failover servers are in a stopped state until a failover is required, resulting in a longer time window to restore the normal operation of the solution.

community
: A collection of consumer organizations. It is used as a grouping construct when publishing APIs. Communities are used to restrict the visibility and accessibility of APIs. An API can be published to selected communities, which means that only application developers within those organizations can see the API.

Community Manager (role)
: Manages application developer communities for the Provider Organizations for which they are a member.

Consumer organization
: Within a catalog, representation of a business entity that wants to consume APIs exposed by the catalog. For example, a third-party application development company would register themselves as a consumer organization (via the Developer Portal). Each developer in their company can then be registered as a user inside that consumer organization.

IBM DataPower® Gateway
: API Gateway service component of API Connect that helps provide security, control, integration, and optimized access to APIs. Due to its security and hardening, it is suited for a deployment in the demilitarized zone (DMZ) for externally facing production scenarios. Available in physical, virtual, cloud, Linux and Docker form factors. There are two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway; for details, see Gateway types.

Developer (role)
: Creates and configures APIs, Products, and policies for the Provider Organizations for which they are a member. An API Developer can be a member of one or more Provider Organizations. The API Developer focuses on the technical implementation of APIs more than they do on the business relationship with application developers.

Development catalog
: Catalog used for testing APIs that are under development and in which approvals are bypassed for publishing and lifecycle actions. Pending approvals are canceled when a non-Development catalog is converted to a Development catalog.

Developer Portal
: Component of API Connect that provides a customizable graphical web portal for developers to discover APIs, register applications that consume APIs, subscribe to usage plans, and test and use APIs.

Developer Toolkit
: Locally installed package that includes API Designer and the `apic` command-line tool that enables you to create, edit, manage, and publish APIs and apps.

Gateway
: See API Gateway.

Gateway service
: API Connect service that provides API gateway functionality, such as microgateway or IBM DataPower.

Hot standby
: A deployment configuration in which a set of servers are actively running ready to instantaneously take over in the event of a failure, but not actively serving traffic until that failover.

Identity provider
: Provides identifiers for users looking to interact with a system, assert to such a system that such an identifier that is presented by a user is known to the provider, and possibly provide other information about the user that is known to the provider. API Connect supports LDAP, AuthURL, and Local User Registries.

Integrations
: Third-party tools to build on and improve your API Connect workflow; for example, Slack, Auth0, and so on.

Integration profile
: Standard API that you can use to integrate with management services for things like identity, notifications, API analytics.

Keystore
: A repository of security certificates, either authorization certificates or public key certificates, and corresponding private keys, which are used in SSL encryption. The keystore file has a `.jks` extension.

Management server
: Stores all of the cloud configuration, and controls communication between the other servers within API Connect.

Management service
: Consists of one or more Management servers.

Member (role)
: The default role for all users in both the Admin and Provider Organization. All users are assigned the Member role in addition to other roles that they may require.

microservice
: Modular, independently deployable application service that communicates with other microservices through a REST API. Microservices are typically organized around capabilities, for example, recommendation, inventory, shipping, or billing.

Mutual authentication
: Process in which both entities on a network authenticate each other. In a network environment, the client authenticates the server and vice-versa. It is optional for TLS. Also called two-way authentication.

Notification settings
: How you configure notifications for API Connect users (API providers and consumers).

Notification services
: Integrations that provide notification capabilities, such as email.

Notification templates
: The configuration of the message format and wording for a notification service.

OAuth provider
: The OAuth provider supplies the OAuth authentication for logins. API Connect supports both Native and Third Party OAuth providers. Some common third-party OAuth providers are Google and Facebook.

OpenAPI Components
: Part of API specification that contains a set of reusable objects for aspects of an API specification, such as schemas, responses, reqeustBodies, and headers. For more information, see [OpenAPI v3 specification](https://github.com/OAI/OpenAPI-Specification/blob/OpenAPI.next/versions/3.0.md#components-object).

organization
: The entity that owns APIs or applications that use APIs. A provider organization owns APIs and associated Plans, and can also own applications. A consumer organization owns only applications. An organization has at least one owner. An organization can be a project team, department, or division.

Organization Manager (role)
: The Organization Manager manages Provider Organizations for the Admin Organization.

Path
: Defines the route through which users access REST APIs. A path consists of one or more HTTP operations such as GET or POST.

Plan
: The packaging construct by which APIs are made available to developers. A Plan makes a collection of operations from one or more APIs available, and is published to communities of application developers. Application developers gain access to APIs by registering applications to access Plans. A Plan carries with it a collection of policy settings. In the simplest form, a Plan defines a single quota policy that applies to all the API operations that are accessed through the Plan. In more advanced cases, additional policies can be associated with a Plan.

policy
: A configuration that controls a specific aspect of processing in the Gateway server during the handling of an API invocation at run time. Policies are the building blocks of assembly flows. Policies provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

Product
: Provide a method by which you can group APIs into a package that is intended for a particular use. Also, they contain Plans, which can be used to differentiate between different offerings. You can create Plans only within Products, and these Products are then published in a catalog.

Provider Organization Owner
: Owns and administers API provider organizations, manages application developer communities, authors APIs and defines products, manages the API product lifecycle. Owners are invited by the Cloud Administrator to join API Connect as an owner of a provider organization.

proxy
: Application programming interface that forwards requests to a user-defined back-end resource and relays responses back to the calling application.

Region
: A physical location (site or data center) hosting infrastructure that is isolated from other locations, with independent power and networking connectivity. A region may or may not have further subisolation characteristics such as semi-independent pods or availability zones.

Resources (User registries, TLS Profiles, notifications)
: Resources supply necessary functions for the API Connect cloud, such as user authentication, SSL security, and sending system-generated emails.

role
: Defines permissions that can enable functionality for users. Each role has a different set of permissions.

security definition
: Specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

server
: A single appliance, such as an IBM WebSphere IBM DataPower appliance.

service
: A user-configurable element that is implemented through one or more server processes in the API Connect runtime, such as microgateway, Analytics, IBM DataPower, and Developer Portal.

SNMP
: The simple Network Management Protocol (SNMP) is a protocol for network management. It is used for collecting information from, and configuring, network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP) network. The SNMP hosts are configured in the API Connect Cloud Manager.

Space
: A subdivision of a catalog. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

SSL (TLS) Profile
: An SSL/TLS profile is used to secure the transmission of data through web sites. SSL certificates guarantee that information you submit to web sites will not be stolen or tampered with.

subscription
: The means by which an application developer gains access to the resources provided by an API. An application developer uses the Developer Portal to subscribe to the plan in which the API is published.

TLS
: Transport Layer Security - a cryptographic protocol that provides secure communication over a network to prevent eavesdropping and tampering. It is a successor to SSL and runs over TCP.

TLS Profiles
: The Cloud Manager and API Manager use TLS profiles to secure transmission of data through web sites. TLS certificates guarantee that information you submit to websites will not be stolen or tampered with. A TLS Profile consists of Server name, Protocol used (SSL or TLS), and whether Mutual Authentication is required.

Toolkit
: See Developer Toolkit.

Topology administrator (role)
: Configures gateway services for the Admin Organization.

Truststore
: Stores certificates from trusted Certificate authorities(CA), which are used to verify certificates presented by Server in SSL/TSL Connection. While a keystore stores a server's credentials, the truststore stores certificates from a third-party CA.

User registry
: A database or other collection containing credentials for users such as provider organization members, consumer organization members, and API Connect administrators. The users are authenticated by an identity provider such as LDAP. User registries authenticate users at login time when accessing the Cloud Manager or API Manager applications. User registries are also be used to protect APIs so that user credentials must be supplied when an API is called.

vendor extension
: An extension to OpenAPI (Swagger) specification required by a particular use case.

Visibility
: Setting visibility determines whether a Provider Organization has access to an Availability Zone, or other service.

Accessibility features for IBM API Connect

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in IBM® API Connect Enterprise. You can use screen-reader software to hear what is displayed on the screen.

- Supports keyboard-only operation.
- Supports interfaces commonly used by screen readers.

Tip: This product documentation, and its related publications, are accessibility-enabled for the IBM Home Page Reader. You can operate all features by using the keyboard instead of the mouse.
If you are reading a PDF file with a screen reader, the default reading option typically returns the best results. Sometimes, how the PDF file is generated might require you to select one of the other reading options. For example, Use reading order in raw print stream.

Keyboard navigation

This product uses standard Linux® and Microsoft Windows navigation keys.

For more information about the commitments that IBM makes toward accessibility, see the IBM Accessibility Center.

Legal information

Notices, and terms and conditions for information centers.

- **Tracking API volume for auditing and compliance**
  For client security reasons, IBM entrusts its clients with monitoring their own API volume and helping ensure that it is within the limits of the contract.
- **Notices**
  This information was developed for products and services that are offered in the U.S.A.
- **Terms and conditions for information centers**
  Permissions for the use of these publications are granted subject to the following terms and conditions.

Tracking API volume for auditing and compliance

For client security reasons, IBM entrusts its clients with monitoring their own API volume and helping ensure that it is within the limits of the contract.

If you purchased IBM API Connect with a license metric of "API Calls", the count of total API Calls must be collected and archived by the client for audit and compliance. This includes, but is not limited to, licensed programs: "IBM API Connect Hybrid Entitlement" and "IBM Cloud Pak for Integration - API Calls".

Usage archiving

You **are required to regularly** record the number of your API calls from the Analytics **system** to maintain a record of **monthly** usage. To ensure the most accurate results, capture the counts of API Calls daily. For information about viewing API call counts and creating a query that counts API calls for **all** response status codes and for a specified time range, see Counting total API calls for your analytics service.

Overage charging

If you exceed your allotted usage, it is your responsibility to report this to IBM in the form of a CSV file so that the correct overage charge can be applied. IBM has the right to audit customer usage data at any time. If unreported overages are found, there are severe penalties.

Overage is based on the measurement period. For example, overage for a contract might be measured by the year. If your API volume exceeds the entitlement after 6 months, you must either pay overages for the remaining period or purchase additional volume.

Notices

This information was developed for products and services that are offered in the U.S.A.

IBM® may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering the subject matter that is described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.
1623-14,
Shimotsuruma,

Yamato-shi
Kanagawa
242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Therefore, some states do not allow disclaimer of express or implied warranties in certain transactions this statement may not apply to you.

This information might include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who want to have information about it for enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information that has been exchanged, should contact:

IBM United Kingdom Laboratories,
Mail Point 151,
Hursley Park,
Winchester,
Hampshire,
England
SO21 2JN

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program that is described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program license Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results that are obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements are the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility, or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports that are used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses that are used by an actual business enterprise is entirely coincidental.

COPYRIGHT license:

This information contains sample application programs in the source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing, or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:

© (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs. © Copyright IBM Corp. _enter the year or years_. All rights reserved.

Trademarks

IBM, the IBM logo, and ibm.com® are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Copyright and trademark information page at https://www.ibm.com/legal/copytrade.shtml.

Java™ and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Linux® is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Kubernetes is a trademark of the Linux Foundation in the United States, other countries, or both.

Microsoft and Windows are trademarks of Microsoft Corporation in the United States, other countries, or both.

OpenShift® is a trademark of Red Hat®, Inc. in the United States, other countries, or both.

VMware is a registered trademark or trademark of VMware, Inc. in the United States and other jurisdictions.

Other company, product, and service names might be trademarks of IBM or other companies.

Privacy Policy Considerations

IBM Software products, including software as a service solutions, (*Software Offerings*) may use cookies or other technologies to collect product usage information to help improve the user experience to tailor interactions with the user or for other purposes. Often no personally identifiable information is collected by the Software Offerings.

Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth in the following paragraphs.

Depending upon the configurations deployed, this Software Offering may use session and persistent cookies that collect each user's session ID for purposes of session management, or functional purposes. These cookies can be disabled, but disabling them will also eliminate the functionality that they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, See IBM's Privacy Policy at https://www.ibm.com/privacy and IBM's Online Privacy Statement at https://www.ibm.com/privacy/details the section entitled *Cookies, Web Beacons, and Other Technologies* and the *IBM Software Products and Software-as-a-Service Privacy Statement* at https://www.ibm.com/software/info/product-privacy.

Terms and conditions for information centers

Permissions for the use of these publications are granted subject to the following terms and conditions.

Applicability

These terms and conditions are in addition to any terms of use for the IBM® website.

Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or as determined by IBM, the aforementioned instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

IBM API Connect Considerations for GDPR Readiness

Information about features of IBM® API Connect that you can configure, and aspects of the product's use that you should consider to help your organization with GDPR readiness.

For PID(s): 5725-Z22 5725-Z63

Notice:

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of API Connect that you can configure, and aspects of the product's use that you should consider to help your organization with GDPR readiness. This information is not an exhaustive list, due to the many ways that clients can choose and configure features, and the large variety of ways that the product can be used in itself and with third-party applications and systems.

Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that may affect the clients' business and any actions the clients may need to take to comply with such laws and regulations.

The products, services, and other capabilities described herein are not suitable for all client situations and may have restricted availability. IBM does not provide legal, accounting, or auditing advice or represent or warrant that its services or products will ensure that clients are in compliance with any law or regulation.

10. Capability for Restricting Use of Personal Data

GDPR

General Data Protection Regulation (GDPR) has been adopted by the European Union ("EU") and applies from May 25, 2018.

Why is GDPR important?

GDPR establishes a stronger data protection regulatory framework for processing of personal data of individuals. GDPR brings:

- New and enhanced rights for individuals
- Widened definition of personal data
- New obligations for processors
- Potential for significant financial penalties for noncompliance
- Compulsory data breach notification

Read more about GDPR

- Complete guide to GDPR compliance
- IBM GDPR website

Product Configuration - considerations for GDPR Readiness

The following sections provide considerations for configuring API Connect to help your organization with GDPR readiness.

Configuration to support data handling requirements

The GDPR legislation requires that personal data is strictly controlled and that the integrity of the data is maintained. This requires the data to be secured against loss through system failure and also through unauthorized access or via theft of computer equipment or storage media.
IBM API Connect stores identity data in a local database. This encompasses both clients' employee identity data and users' identity data. Direct access to this database is not available. Identity information that is collected is protected in transit; refer to Creating a TLS Server Profile for details on configuring TLS profiles.

API Connect supports various user registry types for authenticating users. Refer to Authenticating by using your enterprise user directory for details. When using a local user registry, passwords are stored in encrypted form in the local API Connect database. If you want alternative password management, use a non-user registry option to manage passwords.

Administrators, that you define, can view identity information. Administrators can take backups that include identity information. It is your responsibility to protect these backups.

A core component for an API Connect deployment is the gateway. Refer to the section on API Gateways (in the *API Connect components* topic) for details about gateways. DataPower® Gateways are commonly used; refer to the DataPower Gateway documentation for details. Refer to the DataPower Gateway deployment guidelines document for considerations for configuring DataPower Gateways to help your organization with GDPR readiness.

Configuration to support Data Privacy

For Developer Portal, you can customize the privacy policy statement. Refer to Customizing the privacy policy statement for details.

Configuration to support Data Security

To learn about securing your solution, use this API Connect product documentation and search for "security".

Data Life Cycle

GDPR requires that personal data is:

- Processed lawfully, fairly and in a transparent manner in relation to individuals.
- Collected for specified, explicit, and legitimate purposes.
- Adequate, relevant, and limited to what is necessary.
- Accurate and, where necessary, kept up to date. Every reasonable step must be taken to ensure that inaccurate personal data are erased or rectified without delay.
- Kept in a form that permits identification of the data subject for no longer than necessary.

API Connect manages the life cycle of user-related data in the following ways:

User account information

API Connect collects and stores identity information, including first and surname, and email address, for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where nonlocal user registries are used, only the email address is copied from the LDAP registry. Developer Portal user accounts can be deleted; refer to Deleting your Developer account for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.
Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to Developer Portal: socialize your APIs to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details.

API analytics

API Connect optionally logs information that is related to API invocations. This capability in API Connect is known as API Analytics. Refer to Analytics: understand your API usage for details.
The API Analytics log information can optionally include unknown / unclassified information such as query headers and request and response information that is related to API calls -- you control defining the APIs and data that is associated with API invocations.

The retention period for storing Analytics data in API Connect is configurable; refer to Retention and rollover for details. Backup capability for this information is not available.

To disable API Analytics, disassociate it from the gateway that collects event data. For information, refer to Associating an analytics service with a gateway service.

System logs

Event-logging preferences can be configured at the API level, refer to Activity Log for details.

API Connect logs collect technical information that is related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms that are used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs.You can configure log settings and download the logs as explained in Logging.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

Data Collection

Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details. You can also customize the privacy policy statement for Developer Portal; refer to Customizing the privacy policy statement for details.

Types of Data Collected

API Connect collects and stores identity information (including given name, surname, and email address) for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where nonlocal user registries are used, only the email address is copied from LDAP registry. Developer Portal user accounts can be deleted; refer to Deleting your Developer account for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.

Data Storage

Identity data is stored in the API Connect local data store. There is no direct access available to this data store.

API Analytics uses the OpenSearch real-time distributed search and analytics engine for storage of logged data. There is no direct access available to this data store.

Identity data is included in backups; refer to Backing up and restoring for details on taking backups. It is your responsibility to protect and discard backups.

Data Accesses

Identity information can be viewed by administrators that you define.

Analytics information can be accessed through various means. Refer to Access your analytics data for details.

Analytics information can be offloaded to third-party systems. Refer to Offloading to third-party systems for details. It is your responsibility to protect offloaded data.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

API Connect logs collect technical information related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs.You can configure log settings and download the logs as explained in Logging.

Data Processing

Data collected by API Connect or to gateways via API invocations is protected by TLS in transit. Refer to Creating a TLS Server Profile for details.

Data is stored in API Connect local database on the API Connect appliances. There is no direct access available to this data.

Cloud Manager and API Manager administrators (defined by you) have read access to identity data.

Data Deletion

Right to Erasure

Article 17 of the GDPR states that data subjects have the right to have their personal data removed from the systems of controllers and processors -- without undue delay -- under a set of circumstances.

Data Deletion characteristics

Users can delete their own Developer Portal user accounts -- refer to Deleting your Developer account for details. Cloud Manager and API Manager user account identity data can be anonymized by the users to remove association with the account data.
Technical information related to service use collected in logs is rolled over based on size and time criteria.

To disable API Analytics, disassociate it from the gateway that collects event data. For information, refer to Associating an analytics service with a gateway service.

The retention period for storing Analytics data in API Connect is configurable; refer to Retention and rollover for details. Backup capability for this information is not available.

Analytics information can be offloaded to third-party systems. Refer to Offloading to third-party systems for details. You are responsible for the security of offloaded data.

Identity information for accounts is included in system backups. You manage the deletion of system backups.

Data Monitoring

Customers should regularly test, assess, and evaluate the effectiveness of their technical and organizational measures to comply with GDPR. These measures should include ongoing privacy assessments, threat modeling, centralized security logging, and monitoring

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

Capability for Restricting Use of Personal Data

Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to Developer Portal: socialize your APIs to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs.

You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details. You can also customize the privacy policy statement for Developer Portal; refer to Customizing the privacy policy statement for details.

Developer Portal users can modify their own account information, and can delete their account.

Essential reading

These articles by IBM® API Connect product specialists provide a wealth of supporting information on APIs and the API economy.

Why Become a Digital Business?
: Running a Digital Transformation to become a Digital Business is among the hottest initiatives now – crossing both business and IT. But, is this just the new buzzword or is there something to this that is different? Do you know **why** you must become a “Digital Business”?

Creating A Digital Ecosystem – Past, Present, and Future
: The ability to create a digital enivironment is critical to digital transformation success. Your success is your network reach.

Agile integration
: Your business needs a modern, agile approach to integration. It must empower extended teams to create integrations, uses a complete set of integration styles and capabilities, and increases overall productivity.

What is an API? and What is the API Economy?
: Businesses start to consider APIs and the API Economy at various times. Many are long down their API journeys, while others are still considering whether to start. This article looks at some of the basics that companies considering APIs might want to know.

What is API Management?
: APIs are not new. Software and hardware have had APIs (application programming interfaces) for decades. However, *having* an API and *managing* an API are not the same thing.

Providing APIs or Managing APIs – There is a Big Difference
: A discussion of the potential for confusion between APIs that are provided and APIs that are managed.

Recommendations for an API Economy Center of Excellence
: What roles are required to drive a successful API initiative, how must this fit in the current organization, and how do these roles relate to existing roles in the company?

Focus on the API Developer
: A productive developer is a happy developer. One of the most frequently discussed topics in the API economy is focusing on the needs of the Application developer – the consumer target for your APIs.

Agile API development
: Agile API Development Customer expectations and behavior are continuously changing. To deliver exceptional customer experience, a business must be nimble to adapt to these changing needs.

API Products – Who, What, Where, When, Why and How”
: An API Product is an API offering made available for consumer use that is offered to a target market to satisfy a customer’s needs.

Changing Culture – How Committed Are You?
: How do we change the culture in our organization to create an API culture?

Plan Ahead! Don’t Build an API Superhighway into a Cul-de-sac
: Without proper planning, a business can start their API initiatives, build incredible excitement quickly, but find that the path that leads them into a cul-de-sac (or dead end) that cannot handle the demand that they created.

IBM API Connect v10.x Deployment WhitePaper
: A technical in-depth analysis on the deployment options for IBM API Connect.

Principles for API Security - White Paper
: API security is of paramount importance in gaining the promised benefits without exposure to negative consequences.

Can you trust your APIs?
: As enterprises are continuously expanding their digital footprint, they must help ensure that the APIbehavior is intact, as it has a far-reaching effect on an application's execution and user experience.

Istio Service Mesh and APIConnect/DataPower Gateway integration
: What is Istio, and how can DataPower API Gateway integrate in an Istio Service Mesh.

Best Practice – Monetizing API Products
: Ultimately the goal for almost all API initiatives is Monetization in the broad sense that crosses multiple modes from Free - to Indirect - to Direct. Most businesses by using APIs successfully are monetizing APIs by speeding offerings to market, reaching new markets and new customers, innovating, and sharing assets better inside their enterprise.

Tutorials

These tutorials guide you through the steps typically required to set up, configure and run an API Connect cloud.

Introduction

These tutorials are arranged according to the desired goal, such as creating and publishing an API, or managing catalogs of products, or consuming published API products. These goals can be grouped into categories as follows.

Table 1. Tutorial Categories

Category	Description
Cloud Administration	Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.
API Provider Administration	Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.
API Product Promotion and Usage	Managing the Developer Portal presentation and user administration, as well as consuming published API products as an external developer.

Time required

Each tutorial should take approximately 20 - 30 minutes to finish. If you explore other concepts that are related to this tutorial, it might take longer.

Use the links in the following sections to access the tutorials that fit your goals.

Cloud Administration

Table 2. Cloud Administration Tasks. Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.

Category	Tutorials
Initial Configuration	• Initial Cloud Configuration
Provider Organization	• Creating a Provider Organization

API Provider Administration

Table 3. API Provider Tasks. Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.

Category	Tutorials
Developer Portal Set Up	• Creating the Portal • Register a Consumer Application

API Product Development and Management

Table 4. API Development. Developing and publishing APIs, products and plans, managing product life cycles.
Note: All tutorials listed here use the API Manager interface. The user experience using the API Designer may differ.

Category	Tutorials
Getting Started	• Invoke a REST API • Create a SOAP API from WSDL • Import an API
Building APIs	• Expose SOAP as REST API • Mapping JSON Content
Security	• Using OAuth Password Grant Tokens • Tutorial: Implementing OIDC Security • Using OpenID Connect security • Tutorial: Implementing OAuth Security • Generating a JSON Web Token (JWT) • Validating a JSON Web Token (JWT)
Managing APIs	• Tutorial: Supersede a Product • How to monetize an API Product • Tutorial: Creating a Client Application

API Product Promotion and Usage through the Developer Portal

There are many tutorials available for the Developer Portal from getting started to advanced customization. For more information, see Developer Portal tutorials.

Prerequisites

- You must have a web browser available, whether you are working online or offline.
- When publishing Products in any of the tutorials you must have the permissions of an Organization Manager or Administrator. However, you can complete several of the tutorials with fewer permissions. For more information about user roles, see Administering user access.

Installing and maintaining IBM API Connect

To ensure that your IBM® API Connect cloud functions, your cloud must have the necessary system requirements to support the installation. During the installation process, the components of IBM API Connect can be configured to satisfy your requirements.

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the IBM API Connect v10.x Deployment White Paper .

- **Kubernetes, OpenShift, and Cloud Pak for Integration**
  Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.
- **Migrating from v10 to v10 on a different form factor**
  Migrate an API Connect v10 deployment from one form factor to a different form factor.
- **The API Connect operations tool: apicops**
  Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.
- **Using Config Sync to replicate consumer-side catalog data**
  Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

Kubernetes, OpenShift, and Cloud Pak for Integration

Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.

- **Planning your deployment**
  Review the following topics to plan your API Connect deployment.
- **Installing API Connect**
  Use these instructions to install a deployment of API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.
- **Upgrading API Connect**
  Upgrade API Connect on Kubernetes and OpenShift platforms to a newer version.
- **Maintaining API Connect**
  You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.
- **Uninstalling API Connect**
  You can uninstall a Kubernetes deployment of API Connect.

Planning your deployment

Review the following topics to plan your API Connect deployment.

- **Prerequisite skills for administering API Connect**
  The background knowledge and skills that are required to install and manage an API Connect deployment.
- **Key concepts: Custom Resources, Operators, and Operands**
  API Connect uses Custom Resources (CRs) and the Kubernetes Operator pattern.
- **Deployment overview for endpoints and certificates**
  When deploying API Connect, you must define endpoints for the subsystems. TLS certificates are automatically generated for all endpoints, but you can configure custom certificates for the user-facing endpoints.
- **Deployment profiles, topologies, and strategies**
  Review the available deployment topologies, profiles, and strategies for high-availability and disaster recovery, and choose the best option for your organization.
- **Kubernetes ingress controller prerequisites**
  Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.
- **Persistent Volume (PV) requirements**
  Review the persistent volumes (PVs) required by your API Connect installation.
- **Load balancer configuration**
  When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.
- **Firewall requirements**
  Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes or OpenShift.
- **Planning your analytics deployment**
  Plan your API Connect analytics deployment by reviewing options for deployment profile and estimating required persistent storage space.
- **Key Concepts: Cert-manager, Issuers, and Secrets**
  By default API Connect uses an open source product that is called cert-manager to handle the issuing and renewal of the certificates that are used by API Connect. The cert-manager has its own Kubernetes pods and runs in its own namespace. The cert-manager adds some additional resources to the Kubernetes environment. The API Connect administrator needs to be familiar with these additional resources:
- **Webhooks deployed and managed by the API Connect Operator**
  The API Connect Operator deploys and manages various Kubernetes API webhooks in the cluster to assist in management of its custom resources.
- **Administering API Connect in your container environment**
  How to manage your API Connect subsystems in Kubernetes and OpenShift environments.

Prerequisite skills for administering API Connect

The background knowledge and skills that are required to install and manage an API Connect deployment.

The following list provides an idea of the concepts and technologies that the API Connect administrator should be familiar with:

- The container platform where API Connect is to be installed, either:
  - Kubernetes
  - OpenShift

  How to manage pods, PVCs, namespaces in your container platform.
- Linux: File permissions, editing files with the vi editor, redirecting command output to file.
- Network concepts: FQDNs, ports, firewalls.
- TLS: CAs, certificate chains, mTLS.

The examples in this list do not include all background knowledge that is required, but are intended to give a general idea of the skills that are needed to plan, install, and maintain an API Connect deployment.

Key concepts: Custom Resources, Operators, and Operands

API Connect uses Custom Resources (CRs) and the Kubernetes Operator pattern.

- Kubernetes: https://kubernetes.io/docs/concepts/extend-kubernetes/operator/
- OpenShift: https://developers.redhat.com/articles/2021/06/11/kubernetes-operators-101-part-1-overview-and-key-features.

Below are some key points to understand about how API Connect implements this pattern:

- An API Connect instance is composed of two main operators and the API Connect subsystems that they manage, which in Kubernetes terminology are known as the Operands.
- The operator is responsible for monitoring the API Connect operands, ensuring that they are running as expected.
- API Connect operands can continue running without their operator, in an unmanaged state. However, this is not a supported configuration.
- The API Connect operator manages the Management Server, Portal, and Analytics subsystems. On Kubernetes each of these subsystems has its own Custom Resource, so each of these is an Operand. On Openshift and Cloud Pak for Integration there is also the option of having a top-level Custom Resource which manages all subsystems as a single Operand.
- The DataPower operator manages the Gateway operand.
- A single API Connect operator can manage multiple API Connect instances if the operator is installed globally and the API Connect operands are in individual namespaces. This is the recommended configuration where multiple API Connect instances are required, as opposed to a separate operator in each namespace.
- There can be only one instance of the API Connect operator in your Kubernetes or OpenShift environment. You cannot have multiple namespaces each with their own API Connect operator.

Deployment overview for endpoints and certificates

When deploying API Connect, you must define endpoints for the subsystems. TLS certificates are automatically generated for all endpoints, but you can configure custom certificates for the user-facing endpoints.

Configuring endpoints

The endpoints are defined for each subsystem during installation. See Installing API Connect.

Subsystem	Endpoints	Description	Certificates
Management	admin	Endpoint on the management server for communication with the Cloud Manager user interface.	cloud-admin-ui
	manager	API Manager URL endpoint on the management server for communication with the API Manager user interface.	api-manager-ui
	consumer	Platform REST API endpoint for running consumer APIs on the management server.	consumer-api
	api	Platform REST API endpoint for running admin and provider APIs on the management server.	platform-api
	consumer catalog	Consumer Catalog URL endpoint on the management server for communication with the Consumer Catalog UI.	consumer-catalog
	hub	Automated Testing Behavior API endpoint. External Ingress, port 443	hub-endpoint
Portal	api.portal	Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS
	portal	Portal Web site URL entered in Cloud Manager. Used publicly to access Portal.	portal-www-ingress
Analytics	ai	The analytics-ingestion endpoint is used by the Gateway service to push data to the Analytics service. Requires a TLS profile configured with mutual TLS.	mutual TLS
Gateway	rgwd (API Gateway) gwd (v5-compatible Gateway service)	This is the endpoint the gateway uses for network communication. Enter this endpoint as the Management Endpoint entered in Cloud Manager.	apic-gw-service-ingress

Configuring certificates

The certificates are configured automatically by cert-manager. The certificates for the user-facing endpoints can be customized, see Customizing user-facing certificates.

Configuring mutual TLS

Mutual TLS is used for communication between API Connect subsystems. Configure inter-subsystem communication in your TLS profiles in the Cloud Manager UI. See Creating a TLS Server Profile.

Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see Configuring a proxy.

Deployment profiles, topologies, and strategies

Review the available deployment topologies, profiles, and strategies for high-availability and disaster recovery, and choose the best option for your organization.

- **Deployment and component profiles**
  Decide on whether to deploy three replica or one replica API Connect subsystems, and the memory and CPU resources to allocate to the subsystems.
- **Multiple data center deployment strategies**
  Strategies for deploying API Connect across multiple data centers.
- **OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration**
  You can install API Connect subsystems separately by using individual subsystem CRs, or you can deploy them all together with a top-level CR. You can also deploy API Connect as part of Cloud Pak for Integration. The differences between each installation type are described in this topic.

Deployment and component profiles

Decide on whether to deploy three replica or one replica API Connect subsystems, and the memory and CPU resources to allocate to the subsystems.

API Connect is composed of three components: Management, Portal, and Analytics, and a supporting program: the DataPower Gateway, see API Connect components.
Note: Throughout this document, the DataPower Gateway supporting program is also referred to as a "component" or a "subsystem". The Management, Portal, and Analytics components are also referred to as "subsystems".
The Management, Portal, Analytics, and Gateway each have a set of capacity and HA profiles, called component profiles. OpenShift and Cloud Pak for Integration also have API Connect deployment profiles that define the component profiles that are used by each component of a complete API Connect deployment.

The naming convention of the profiles is `nAxcB.mC` where:

- **nA** indicates the number (A) of replicas of each pod, where each replica must run on a different worker node.
- **cB** indicates the minimum number of virtual cores (B) required on the worker node to deploy the profile.
- **mC** indicates the minimum amount of memory (C) in GB required by the profile on the worker node.

Component profiles

Each API Connect component has a defined set of profiles that it can be deployed with. For information on the resource settings defined for each component profile, see Component profiles, CPU limits, memory limits, and licensing.

Key points of component profiles:

- One replica profiles are denoted by `n1`, and provide a single replica of each pod. The one replica profiles can be deployed on a single worker node.
- Three replica profiles are denoted by `n3`, and provide three replicas of each pod. At least three worker nodes must be available to deploy a three replica profile. If one replica pod fails, then the other two replicas continue serving requests, providing high availability.
- Component profiles do not have to be the same for each component. For example, you can have a three replica deployment of the Management component that is configured with a one replica deployment of the Portal component.
- It is possible to change component profile after installation see Advanced configuration.
- Multiple Portal, Analytics, and Gateway component instances can be added with either configuration. For example, you can have a three replica Management component that is configured with two Portal services: a one replica Portal component, and a three replica Portal component.

OpenShift and Cloud Pak for Integration API Connect deployment profiles

API Connect deployment profiles define a complete API Connect deployment, specifying the component profiles for the Management, Portal, Analytics, and Gateway components to be used in that deployment.

Key points of API Connect deployment profiles:

- The API Connect deployment profiles apply to top-level CR installations only. If you want to deploy your API Connect components individually, then select the component profiles from Component profiles, CPU limits, memory limits, and licensing. For more information about the top-level CR installation, see OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration.
- The API Connect deployment profile is selected by the user in the installation steps on OpenShift and Cloud Pak for Integration.
- API Connect deployment profiles provide one instance of the Portal, Analytics, and Gateway components.
- For details of each API Connect deployment profile, see: API Connect deployment profiles for OpenShift and Cloud Pak for Integration

- **API Connect deployment profiles for OpenShift and Cloud Pak for Integration**
  Details of the API Connect deployment profiles that are provided for OpenShift and Cloud Pak for Integration.

- **Component profiles, CPU limits, memory limits, and licensing**
  Available component profiles, their CPU and memory limits, and how the CPU-based licensing works.

API Connect deployment profiles for OpenShift and Cloud Pak for Integration

Details of the API Connect deployment profiles that are provided for OpenShift and Cloud Pak for Integration.

API Connect provides various profiles to suit your capacity and availability requirements.

The API Connect deployment profiles provide one Management component instance, and one instance of the Portal, Analytics, and Gateway components.

On Cloud Pak for Integration:

- The available deployment profiles are presented as tiles in the Platform UI.
- The Portal, Analytics, and Gateway components are automatically registered with the Management component during installation.

n1xc7.m48: Small - One replica

Best suited for light, noncritical workloads such as small team development and testing. Deploys 1 replica of the Management, Developer Portal, Analytics, and Gateway components with a minimal footprint.

Table 1. n1xc7.m48

Component name	Component profile
Management	n1xc2.m16
Portal	n1xc2.m8
Analytics	n1xc2.m16
Gateway	n1xc1.m8

n1xc16.m72: Medium - One replica

Ideal for medium workloads such as organizational development, testing, and production when in alignment with business availability requirements. Deploys 1 replica of the Management, Developer Portal, Analytics, and Gateway components.

Table 2. n1xc16.m72

Component name	Component profile
APIM	n1xc4.m16
Portal	n1xc4.m16
Analytics	n1xc4.m32
Gateway	n1xc4.m8

n1xc12.m64: Medium - One replica - Remote Gateway

Ideal for medium workloads such as organizational development, testing, and production when in alignment with business availability requirements. Must be configured for use with existing or independently deployed Gateways. Deploys 1 replica of the Management, Developer Portal, and Analytics components.

Table 3. n1xc12.m64

Component name	Component profile
APIM	n1xc4.m16
Portal	n1xc4.m16
Analytics	n1xc4.m32

n3xc16.m64: Large - Three replicas

Ideal for heavy workloads when business requires redundancy for greater availability & capacity. Deploys 3 replicas of the Management, Developer Portal, Analytics, and Gateway components.

Table 4. n3xc16.m64

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m32
Gateway	n3xc4.m8

n3xc12.m56: Large - Three replicas - Remote Gateway

Ideal for heavy workloads when business requires redundancy for greater availability & capacity. Must be configured for use with existing or independently deployed Gateways. Deploys 3 replicas the Management, Developer Portal, and Analytics components.

Table 5. n3xc12.m56

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m32

Deprecated profiles

The API Connect deployment profiles presented here existed in previous releases, but are now in a deprecated state and should not be used for new installations.

Table 6. n3xc11.m48
DEPRECATED

Component name	Component profile
APIM	n3xc2.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc1.m8

Table 7. n3xc14.m48
DEPRECATED

Component name	Component profile
APIM	n3xc2.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc4.m8

Table 8. n1xc10.m48
DEPRECATED

Component name	Component profile
APIM	n1xc2.m16
Portal	n1xc2.m8
Analytics	n1xc2.m16
Gateway	n1xc4.m8

Table 9. n3xc16.m48
DEPRECATED

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc4.m8

Table 10. n3xc12.m40
DEPRECATED

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16

Component profiles, CPU limits, memory limits, and licensing

Available component profiles, their CPU and memory limits, and how the CPU-based licensing works.

API Connect is licensed based on the CPU usage of your deployment. Each component profile sets specific CPU and memory limits on each of the containers that comprise API Connect.

API Connect operator

The API Connect operator container uses the same CPU and memory requests and limits for all profiles, and is not a container that requires license entitlement.

Table 1. Operator container CPU and memory requirements

Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits	PVC Size	Number of replicas	License entitlement required
ibm-apiconnect	ibm-apiconnect	75	1000	128	1Gi		1	No

The CPU and memory usage tables for each API Connect component profile are shown in the following pages.

- **Management subsystem deployment profile limits**
  Review the CPU, memory limits, and PVC space that are required for each management profile.
- **Portal component deployment profile limits**
  The CPU and memory limits that are defined for each Portal deployment profile.
- **Analytics component deployment profile limits**
  The CPU and memory limits that are defined for each analytics deployment profile.
- **DataPower gateway deployment profile limits**
  The CPU and memory limits that are defined for each Gateway deployment profile.

Management subsystem deployment profile limits

Review the CPU, memory limits, and PVC space that are required for each management profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>**. For example, for the **n3xc2.m16** profile:

- The three licensed containers are **apim**, **postgres**, and **taskmanager**.
- These three containers have CPU limits of 625, 750, and 625.
- This profile is a three replica (n3) profile.

The total CPU limit of the licensed containers then is: (625 + 750 + 625) * 3 = 6000

All management subsystem deployment profiles have job pods that complete tasks during startup, upgrade, backup, and restore operations. The job pods do not have any licensed containers, and their CPU/memory requests and limits are the same for all profiles.

Table 1. Management job pods CPU and memory requirements

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
management-up-apim-schema	management-up-apim-schema-0-to-<nnn>-<xx>-<yy>	apim-schema	50 m	500 m	128 Mi	256 Mi
management-up-apim-data-populate	management-up-apim-data-populate-0-to-<nnn>-<xx>-<yy>	apim-data-populate	50 m	600 m	256 Mi	4096 Mi
management-up-lur-schema	management-up-lur-schema-0-to-<nnn>-<xx>-<yy>	lur-schema	50 m	500 m	128 Mi	256 Mi
management-up-lur-data-populate	management-up-lur-data-populate-0-to-<nnn>-<xx>-<yy>	lur-data-populate	50 m	500 m	128 Mi	256 Mi
management-apim-restore-<xxx>	management-apim-restore-<xxx>-<yyy>	apim-restore	50 m	500 m	128 Mi	256 Mi
management-up-compliance-schema	management-up-compliance-schema-0-to-<nnn>-<xx>-<yy>	compliance-schema	50 m	500 m	128 Mi	256 Mi
management-up-compliance-data-populate	management-up-compliance-data-populate-0-to-<nnn>-<xx>-<yy>	compliance-data-populate	50 m	500 m	128 Mi	256 Mi
management-agent-schema	management-agent-schema-<nnn>	agent-schema	50 m	100 mm	256 Mi	512Mi
management-gic-schema	management-gic-schema-<nnn>	sic-schema	50 m	100 mm	256 Mi	512Mi

The following tables show the pod resource and license requirement for each management component deployment profile. A separate table shows the requirements for optional features.
Important: The tables for the three replica profiles show the usage for a single replica in the three replica deployment. Except for containers that are indicated to be one replica, multiply by three to get the total usage.

n1xc2.m16

Table 2. n1xc2.m16 profile resource and licensing requirements

Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits	PVC Size	Number of replicas	License entitlement required

Note: The following components have the following ephemeral storage requirements:

- **java-tech-connectors**: 1 Gi (requests) or 1 Gi (limits).
- **connectivity-pack-proxy**: 150 Mi (requests) or 1 Gi (limits).
- **action-connectors**: 1 Gi (requests) or 1 Gi (limits).

Portal component deployment profile limits

The CPU and memory limits that are defined for each Portal deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **`<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>`**

All Portal component deployment profiles have a **`sync-backup`** job pod that completes tasks that are related to scheduled portal backups. The **`sync-backup`** job pod does not have any licensed containers, and its CPU/memory requests and limits are the same for all profiles.

Table 1. Portal job pods resource and licensing requirements

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
<portal-instance-name>-sync-backup	*<portal-instance-name>*-sync-backup-*<jobuuid>*	sync-ptl-backup-schedule	1m	1m	100Mi	100Mi

n1xc2.m8

Table 13. n3xc8.m16 Containers for optional features, resource and licensing requirements

Feature	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits	PVC Size	Number of replicas	License entitlement required
2DCDR	db-remote	tunnel	75m	500m	160Mi	256Mi	1Gi	3	
	www-remote	tunnel	75m	500m	160Mi	256Mi	1Gi	3	
	tunnel	server	100m	500m	256Mi	512Mi	1Gi	3	

Note: For 2DCDR deployments, if the remote site is deployed with a one replica profile, the `db-remote` and `www-remote` pods have one replica, to match the remote site.

Analytics component deployment profile limits

The CPU and memory limits that are defined for each analytics deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>**

All analytics component deployment profiles have an **osinit** job pod that is run on startup and completes tasks that are related to initialization. The **osinit** job pod does not have any licensed containers, and its CPU/memory requests and limits are the same for all profiles.

You can choose different storage types with the three replica profiles, and so the pods deployed differ depending on the storage option chosen: Analytics storage type. If you choose storage type **shared**, then your analytics deployment has 1 storage pod, called **storage**. If you choose storage type **dedicated**, then your analytics deployment has 2 storage pods, called **storage** and **storage-os-master**. The tables for the three replica profiles indicate in parentheses after the pod name which storage type the pod applies to, for example "storage (shared)".

Table 1. Analytics job pods

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
<analytics-instance-name>-osinit	*<analytics-instance-name>*-osinit-*<podid>*	osinit	8 m	100 m	128 Mi	256 Mi
<analytics-instance-name>-oscron	*<analytics-instance-name>*-oscron-*<jobid>*-*<podid>*	oscron	8 m	100 m	128 Mi	256 Mi

The PVC sizes that are specified in the tables are the defaults. Review the planning and installation documentation to decide on the sizes to allocate for your deployment: Planning your analytics deployment.

DataPower gateway deployment profile limits

The CPU and memory limits that are defined for each Gateway deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **`<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>`**.
Note: All profiles show PVC size as 30Gi, this is only required if the Token Management Service (TMS) is enabled. If TMS is not enabled, there is no PVC requirement.

Multiple data center deployment strategies

Strategies for deploying API Connect across multiple data centers.

If you want to deploy API Connect across multiple data centers, then several options are available and are detailed in this topic.

Note:
You can install the subsystems that make up an API Connect deployment in different data centers, but it is not recommended to install a single API Connect subsystem across data centers. For example, if you are deploying a three replica analytics subsystem, then all analytics subsystem replicas should run in the same data center. Splitting a three replica deployment across data centers is only supported when the network latency between the data centers is less than 10 ms.

For the gateway service, if TMS is required and an external OAuth provider cannot be used, then the gateways can be located in different data centers if network latency between data centers is less than 30 ms.

Remote gateway deployment

To provide high availability for your published APIs, you can deploy one or more gateway services in different data centers, and register them with the management subsystem in your main data center. If your main data center has an outage, then your remote gateways continue to process calls to your published APIs.

Remote gateway deployment is the simplest way to take advantage of multiple data centers. The main disadvantage is that you cannot update any published APIs during the main data center outage (because your management subsystem is in the main data center).

To install API Connect with remote gateways, follow the multi-namespace installation procedures for your platform:

- OpenShift: Installing API Connect subsystems in different namespaces or environments on OpenShift.
- Kubernetes: Deploying operators in a multi-namespace API Connect cluster.

Cold-standby deployment

In a cold-standby deployment, API Connect is installed and running in your main data center. In your cold-standby data center, API Connect is ready to be installed and has access to the API Connect backup files from your main data center.

If your main data center has an outage, then you install API Connect in your cold-standby data center, and restore your most recent subsystem database backups to your cold-standby deployment.

Requirements for cold-standby configuration:

- The API Connect deployment in the cold-standby data center must use the same deployment profile as the main data center.
- The API Connect network endpoints that you define in your main data center must be valid in your cold-standby data center.
  For example, if the network endpoint for your Cloud Manager UI is `cloud-admin.apicinstall.example.com`, this endpoint must route correctly to the management subsystem you install in your cold-standby data center.

  Every network endpoint that you configure during API Connect installation and configuration in your main data center must be valid in your cold-standby data center.

- Ensure that subsystem backups are regularly copied from your main data center to your cold-standby. Backups must include both your infrastructure configuration (CR and secret YAML files), and subsystem database backups. See Backing up, restoring, and disaster recovery.

The steps for failing over to your cold-standby data center are:

1. Install API Connect in your cold-standby data center, by using the infrastructure configuration backup YAML files from your main data center.
2. Restore your API Connect subsystem database backups.
3. Update network routing so that user traffic is directed to your cold-standby data center.

Steps 1 and 2 are essentially the same as the disaster recovery steps to restore API Connect, see Backing up, restoring, and disaster recovery.
The advantage of the cold-standby deployment over the remote gateway deployment is that your full API Connect deployment is available in the cold-standby site. Management and portal subsystem users can update APIs and view analytics data while your main site is unavailable.

Warm-standby deployment

In the warm-standby deployment, the management and portal subsystems continually replicate their databases to a warm-standby API Connect deployment in a separate data center.

The advantage of the warm-standby deployment over cold-standby is that the failover process is faster, and the management and portal databases in the warm-standby site are fully up to date. With the cold-standby strategy, your management and portal databases are only as recent as the last backup you took from your main site.

The disadvantage of the warm-standby deployment is that it adds extra complexity to the API Connect installation process, and all ongoing maintenance procedures such as upgrade. Use the warm-standby deployment strategy only when the following are essential requirements:

- Minimal management and portal subsystem downtime.
- No management and portal data loss, when restoration of data from the last backup that was taken of your active site is not sufficient.

Requirements for warm-standby configuration:

- The API Connect deployment in the warm-standby data center must use the same deployment profile as the main data center.
- The API Connect network endpoints that you define in your main data center must be valid in your warm-standby data center.
  For example, if the network endpoint for your Cloud Manager UI is `cloud-admin.apicinstall.example.com`, this endpoint must route correctly to the management subsystem you install in your warm-standby data center.

  Every network endpoint that you configure during API Connect installation and configuration in your main data center must be valid in your warm-standby data center.

The warm-standby deployment configuration is referred to in this documentation as two data center disaster recovery (2DCDR). For more information about 2DCDR, see Two data center warm-standby deployment on Kubernetes and OpenShift.

- **Two data center warm-standby deployment on Kubernetes and OpenShift**
  An overview of the two data center disaster recovery deployment strategy with a warm-standby data center.
- **Two data center deployment examples and diagrams**
  Examples of two data centers deployment options.

Two data center warm-standby deployment on Kubernetes and OpenShift

An overview of the two data center disaster recovery deployment strategy with a warm-standby data center.

The two data center disaster recovery warm-standby deployment configuration (referred to as 2DCDR) provides continuous replication of the management and portal subsystem databases to a warm-standby deployment in another data center.
Important: The 2DCDR deployment adds complexity to the API Connect installation procedures, and all subsequent maintenance procedures such as backup, restore, and upgrade. Before you decide to use the 2DCDR deployment strategy, review the Multiple data center deployment strategies to see whether any of the alternatives are better suited to your requirements.

Key points of the two data center disaster recovery (DR) solution

- Two data center DR is an active/warm-standby deployment for the management and portal subsystem, and must use manual failover.
- Two DataPower® Gateway subsystems must be deployed to provide high availability for the gateway service. However, this scenario doesn't provide high availability for the analytics service.
- If high availability is required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.
- Data consistency is prioritized over data availability.
- Each data center must be setup within its own Kubernetes or OpenShift cluster.
- Latency between the two data centers must be less than 80 ms.
- Port 443 must be open between data centers for API Connect database replication.
- Replication of the management database is asynchronous, so it is possible that the most recent updates do not transfer to the warm-standby data center if there is an active data center failure.
- Replication of the portal database is synchronous, and therefore the latency is limited to 80 ms or less.
- The management and portal subsystems in the two data centers must use the same deployment profile.
- The deployment in each data center is effectively an instance of the same API Connect deployment - therefore, the endpoints, certificates, and Kubernetes secrets must all be the same.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a two data center disaster recovery configuration.

Deployment architecture

A two data center deployment model is optimized for data consistency ahead of data availability, and must use manual failover when a fault occurs. For high availability of management and portal subsystems ensure that you use a three replica deployment profile. For more information on deployment profiles, see: Deployment and component profiles.

For a single Kubernetes cluster to span multiple data centers the network latency must be no more than a few milliseconds, typically less than 10 ms. This low latency is often unachievable between geographically separated data centers. For this reason, the two data center disaster recovery solution requires that each data center is set up

with its own Kubernetes cluster. The management and portal subsystem databases are continually replicated from the active datacenter to the warm-standby datacenter, this requires a network latency between the two data centers of less than 80 ms.

To achieve high availability for the DataPower Gateway, you must deploy two gateway subsystems. One subsystem in the active data center, and a separate subsystem in the warm-standby data center. Publish all Products and APIs to both gateway subsystems. The gateway subsystems are independent, and so are insulated if an issue occurs in one of them. A global dynamic router can then be used to route traffic to one gateway subsystem or the other. If high availability is also required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration portal analytics isn't possible.

There can be multiple portal services in an API Connect deployment (although still only one portal site per Catalog).

The deployment in each data center is effectively an instance of the same API Connect deployment – as the database is replicated, all of the configuration is also shared. Therefore, the endpoints, certificates, and secrets all need to be the same.

Dynamic routing
: Note: A dynamic routing device, such as a load balancer, is required to route traffic to either data center. However, neither this device nor its configuration is part of the API Connect offering. Contact IBM Services if you require assistance with configuring a dynamic router.
The dynamic router configuration must handle the traffic between the subsystems and between the data centers. For example, the consumer API calls from the portal to the management subsystem must transfer through a dynamic router so that the portal can use a single endpoint regardless of which data center the management subsystem is active in. The same is needed for calls to the Platform and Admin APIs from the other subsystems, as well as for incoming UI traffic for the portal UI, Cloud Manager UI, and API Manager UI.

: The dynamic router must support SSL passthrough, so that it routes the Mutual TLS (mTLS) connections between the management subsystem and the portal, and between the management subsystem and the DataPower Gateway. The router should not do TLS termination, it should do layer 4 based routing by using SNI.

: If you do not want to use mTLS between API Connect subsystems, you can Enable JWT security instead of mTLS.

Service status
: When a failure occurs, it is common practice to display an interstitial system outage web page. The dynamic router can be configured to display this web page when there is a failure, while the manual failover to the warm-standby data center is taking place.

Deployment-profiles
: Both one replica and three replica deployment profiles can be used with two data center DR, but they must be the same at each data center. For more information about the deployment-profiles, see Deployment and component profiles on Kubernetes.

For more information about a two data center DR deployment, see the following topics:

Kubernetes and OpenShift

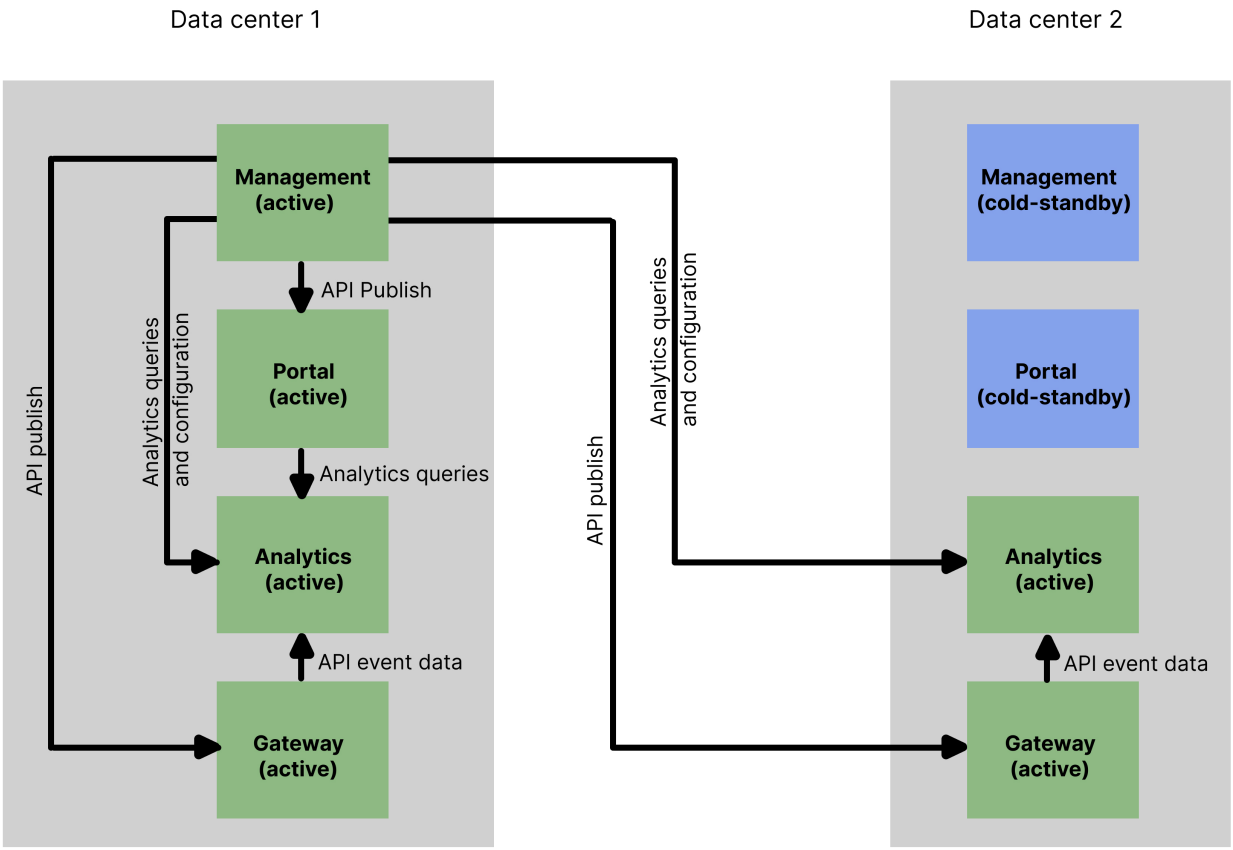
- Installing a two data center deployment on Kubernetes
  - Converting a single data center to a two data center deployment on Kubernetes
- Maintaining a two data center deployment

Two data center deployment examples and diagrams

Examples of two data centers deployment options.

The descriptions on this page refer to a deployment of API Connect across two data centers. The data centers are referred to as DC1 and DC2. API Connect subsystems in each data center are referred to as **<subsystemname>_<dc>**, for example: **management_dc1** refers to the management subsystem in DC1.

Remote gateway



With a remote gateway deployment, DC1 has a complete API Connect installation (management, portal, analytics, gateway), and DC2 has one or more gateways deployed that are registered with the management subsystem in DC1. All APIs published in DC1 are also published to the gateways in DC2. If DC1 has a failure, then the gateways in DC2 can continue processing API calls.

The steps to install and configure a remote gateway deployment are:

1. Install all API Connect subsystems in DC1.
2. Install one or more gateways in DC2.
3. In the Cloud Manager UI, register your DC2 gateways with **management_dc1**.
4. Associate your **analytics_dc1** subsystem with **gateway_dc1** and **gateway_dc2**.
5. Provider organization owners must configure all catalogs to publish to both **gateway_dc1** and **gateway_dc2**.

Cold-standby

In the cold-standby topology, all API Connect subsystems are installed normally in DC1. In DC2 the analytics and gateway subsystems are installed and running, but the management and portal subsystems are in a ready-to-install state (cold-standby). If a failure occurs in DC1, then the management and portal subsystems in DC2 are installed, and the latest database backups from the DC1 management and portal subsystems are restored to them.

Key points of the cold-standby topology:

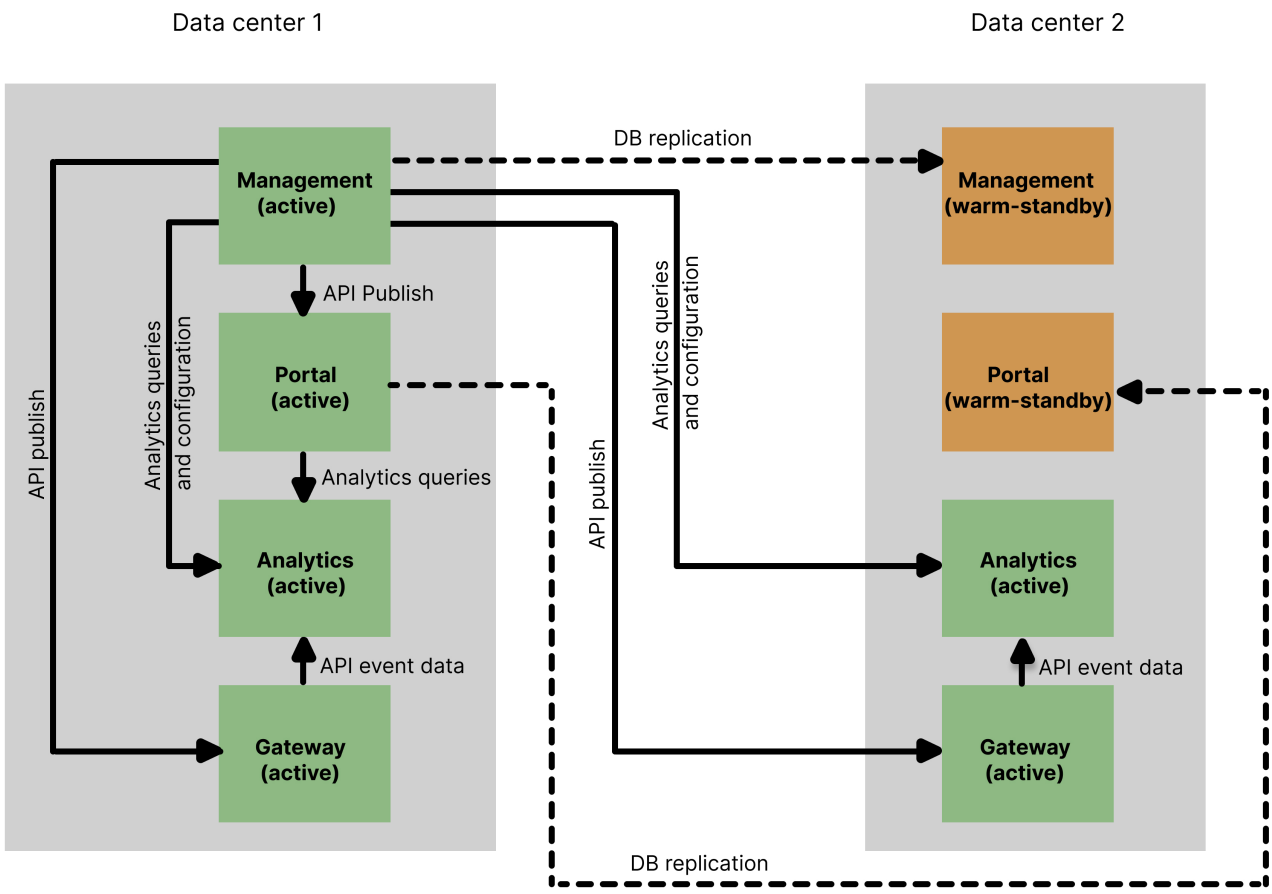
- During a failure of DC1, **`gateway_dc2`** continues to process API calls. Configure your load-balancer to direct all calls to **`gateway_dc2`** if **`gateway_dc1`** stops responding.
- Ensure that the latest management and portal subsystem backups are accessible from DC2. This includes your infrastructure configuration backups, and your database backups. See Backing up, restoring, and disaster recovery.
- The recovery point for the management and portal subsystems is the last time a backup of these subsystems was taken. If you have a low recovery point objective (RPO) for management and portal, then schedule frequent backups.
- Portal sites cannot show analytics data from either data center.

The installation and configuration procedure for cold-standby is:

1. Install all API Connect subsystems in DC1.
2. Prepare the API Connect installation in DC2, but do not install the management and portal subsystems. Install only the API Connect operator, the gateway, and the analytics subsystems in DC2.
3. Copy the **`ingress-ca`** secret from DC1 to DC2. See Synchronizing the ingress-ca certificates between sites.
4. In the Cloud Manager UI in DC1, register the DC1 subsystems and also the DC2 gateway and analytics subsystems. Associate **`analytics_dc2`** with **`gateway_dc2`**.
5. In the API Manager UI in DC1, configure all catalogs to use both **`gateway_dc1`** and **`gateway_dc2`**. Ensure that all products are published to both gateway services.
6. Configure scheduled backups of your management and portal subsystems in DC1, at a frequency sufficient for your recovery point objective. Ensure that backups are copied to a location that is accessible from DC2.
7. Configure your load-balancer to route all API traffic to **`gateway_dc2`** if **`gateway_dc1`** fails to respond.

The failover procedure for cold-standby, where all subsystems in DC1 are unavailable is:

1. Ensure that all API Connect traffic is directed to DC2.
2. Install the management and portal subsystems in DC2.
3. Restore the management and portal subsystem databases in DC2, with the most recent backups taken from DC1.



Reverting to DC1 after recovery:

- Ensure that you have recent backups from management and portal in DC2.
- Restore the recent DC2 database backups to the management and portal subsystems in DC1. If you modified any of the subsystem YAML files or certificates while running management and portal in DC2, then make those same updates on DC1.
- Update your network configuration to route management and portal traffic to DC1.
- Uninstall the management and portal subsystem from your cold-standby data center. See Uninstalling API Connect subsystems.

If you want to be able to see analytics data from both data centers in the Cloud Manager and API Manager UIs, then see Replicating analytics data to a remote data center.

Warm-standby with analytics in both data centers

The management and portal subsystems are deployed in both data centers using the active/warm-standby configuration: Two data center warm-standby deployment on Kubernetes and OpenShift. An analytics subsystem is deployed in each data center to receive API event data from the gateways in that data center. Unlike the management and portal subsystems in the warm-standby data center, the gateway and analytics subsystems are running and communicate with the management subsystem in the active data center.

The steps to install the 2DCDR warm-standby deployment are:

1. Follow the installation instructions for 2DCDR on your platform: Installing API Connect. Install the management and portal subsystems as active in DC1, and as warm-standby in DC2.
2. Install gateway and analytics subsystems in both data centers.
3. In the Cloud Manager UI of DC1, register all gateways and analytics subsystems from both data centers. Associate `analytics_dc1` with `gateway_dc1`, and `analytics_dc2` with `gateway_dc2`.
4. Provider organization owners must set all catalogs to publish to both `gateway_dc1` and `gateway_dc2`.
5. API calls can be directed to both `gateway_dc1` and `gateway_dc2`, and the API events they log are sent to the analytics subsystems that they are associated with.

Failover steps if DC1 fails:

1. Promote `management_dc2` and `portal_dc2` to active.
2. Direct all API Connect traffic to DC2.
3. New APIs that are published are sent to `gateway_dc2`, and queued for `gateway_dc1`.

If you want to be able to see analytics data from both data centers in the Cloud Manager and API Manager UIs, then see Replicating analytics data to a remote data center.

Advanced deployment scenarios

For more advanced multi-data center deployment options, see the API Connect white paper: IBM API Connect v10.0.8.x WhitePaper.

OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration

You can install API Connect subsystems separately by using individual subsystem CRs, or you can deploy them all together with a top-level CR. You can also deploy API Connect as part of Cloud Pak for Integration. The differences between each installation type are described in this topic.

Before you review this topic, make sure that you understand the Key concepts: Custom Resources, Operators, and Operands of API Connect.

Deploying with individual subsystem CRs

Deploying API Connect using individual subsystem CRs means that you must install each subsystem separately, either with the OpenShift UI, or by manually applying YAML files for each subsystem. The portal, analytics, and gateway subsystems must then be manually registered with the management subsystem, as described in Defining your Cloud Manager topology.

Individual subsystem CRs: Key points

- Deploying with individual subsystem CRs allows more flexibility than the alternative top-level CR deployment, and can be simpler to manage.
  - Subsystems in the same API Connect cluster can be installed in different namespaces.
  - Updates to subsystem CRs are made directly in the subsystem CR. When the top-level CR is used, all configuration updates must be made in the top-level CR, which can require copying sections from the subsystem CR and pasting them into the top-level CR.
  - Custom certificates can be used for inter-subsystem communication.
  - The two data center disaster recovery deployment topology is simpler to manage and more flexible when individual subsystem CRs are used.
- The individual subsystem CR installation is preferable for deployments where you plan to have multiple portal and analytics services, or subsystems in different namespaces, and where you do not require the other capabilities of Cloud Pak for Integration.
- Individual subsystem CR installation does not integrate as fully with Cloud Pak for Integration as the top-level CR installation. See the next section.

Deploying with the top-level CR

Deploying with the top-level CR automates the deployment of each subsystem. To install, you select 'API Connect' in either the OpenShift console or the Cloud Pak for Integration Platform UI, enter some properties such as namespace, click 'Create', and all the subsystems that make up an API Connect instance are automatically installed. You still have individual CRs for each subsystem, but they are all managed by the top-level CR. The top-level CR is called **`APIConnectCluster`**.

Top-level CR: Key points to consider

- All API Connect subsystems are managed by the top-level CR. You edit the top-level CR YAML when you want to update your API Connect configuration.
- With the top-level CR, the subsystem CRs still exist but should not be edited directly. Any changes made to them get overwritten by the top-level CR.
- Installation with the top-level CR requires fewer steps, but subsequent management of subsystems and configuration of advanced features can be more complicated than it is with an individual subsystem deployment.
- The top-level CR deployment provides one of each subsystem service: management, portal, analytics, and gateway. If you want additional portal, analytics, or gateway services, do not use the top-level CR.
- For a quick proof-of-concept demonstration, the top-level CR is ideal due to the automated installation of subsystems.
- The top-level CR deployment integrates fully with Cloud Pak for Integration. For top-level CR installation instructions on Cloud Pak for Integration, see *Deploying an instance by using the Platform UI* and *Deploying all API management subsystems by using the CLI* in the Cloud Pak for Integration documentation.

Deploying with Cloud Pak for Integration

Cloud Pak for Integration includes API Connect as one of its many capabilities. For information on everything Cloud Pak for Integration provides, see https://www.ibm.com/docs/en/cloud-paks/cp-integration.

Key points of a Cloud Pak for Integration API Connect installation:

- Cloud Pak for Integration provides a UI, called the Platform UI, which can be used to install and manage your API Connect deployment.
- When installing API Connect with the Cloud Pak for Integration Platform UI, the top-level CR deployment is used. All the same key points of the top-level CR apply to Cloud Pak for Integration installations that use the top-level CR.
- If Cloud Pak for Integration is already installed in your environment, and you install API Connect with the Cloud Pak for Integration Platform UI, then API Connect automatically incorporates and attempts to use Cloud Pak features.
  You can prevent Cloud Pak for Integration incorporating your API Connect installation by setting **`metadata.annotations.apiconnect-operator/cp4i`** to **`false`** in the top-level CR before installation.

  If you are not installing API Connect with the Cloud Pak for Integration Platform UI and you want your API Connect deployment incorporated with Cloud Pak for Integration, then you can set the API Connect **`metadata.annotations.apiconnect-operator/cp4i`** annotation to **`true`** in your top-level CR (or management CR if not using the top-level CR) before installation.

  It is not possible to change the value of **`metadata.annotations.apiconnect-operator/cp4i`** after installation. If you want to do this, then you must reinstall API Connect.

- It is not possible to uninstall Cloud Pak for Integration and retain any API Connect instance that it is managing. Nor can a Cloud Pak for Integration API Connect instance be converted to a stand-alone instance. If you want to change to a non-Cloud Pak for Integration deployment, see Migrating from v10 to v10 on a different form factor.
- You can migrate an existing top-level CR installation to be incorporated into Cloud Pak for Integration. See see Migrating from OpenShift to Cloud Pak for Integration on the same cluster.
  Note: The reverse of this operation is not supported.
- In a Cloud Pak for Integration installation, if the Platform UI is detected and the top-level CR deployment is used, the API Connect operator runs a job that is called the **`configurator`**, which registers all API Connect subsystems with the management service after installation. This means that your API Connect installation is ready for you to immediately start configuring provider organizations.
- Cloud Pak for Integration does mean a higher computing resource requirement in your environment, when compared to a stand-alone API Connect installation.
- The planning requirements for API Connect such as available PVs and Firewall settings that are described in Planning your deployment, also apply when you install API Connect with Cloud Pak for Integration.

Which deployment type should you choose?

For long-term ease of maintenance and maximum flexibility, choose Deploying with individual subsystem CRs.

For integration with the App Connect, Asset Repo, Platform UI, and other Cloud Pak for Integration features, choose Deploying with Cloud Pak for Integration.

For quick installation of API Connect that is suitable for demonstrations and testing, choose Deploying with the top-level CR.

Network requirements for inter-subsystem communication

Plan how to secure the network communications between your API Connect subsystems.

API Connect provides various configuration options that are related to inter-subsystem communication.

Support load-balancer TLS termination by disabling mTLS and enabling JWT security

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.
Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on load-balancers.
The following communication flows can be secured with JWT:

- Management initiated communication to portal, analytics, and gateway subsystems.
- Analytics ingestion: The flow of API event records from the gateway to the analytics subsystem.
  Note: If the gateway is under a high transaction load and sending many API events to the analytics subsystem, the enablement of JWT might impact the performance of your analytics subsystem. It is recommended to run performance tests under your expected analytics load before you decide to use JWT for the analytics ingestion path.

With JWT enabled, the portal, gateway, and analytics subsystems verify the JSON Web Token (JWT) sent from the management subsystem when it initiates communication with them. The analytics subsystem verifies the JWT sent from the gateway with incoming API event data. The subsystems that receive the token contact a JSON Web Key Set (JWKS) URL to verify it. The JWKS URL is hosted by the management subsystem, in a subpath of the management subsystem's platform REST API.
For more information about this feature, see Enable JWT security instead of mTLS.

Use services instead of routes (OpenShift) or ingresses (Kubernetes)

Note: This feature is available on Kubernetes and OpenShift® deployments where the API Connect subsystems are within the same cluster. It is not available on two data center disaster recovery deployments: Two data center warm-standby deployment on Kubernetes and OpenShift.
For inter-subsystem communication, API Connect uses routes on OpenShift and Ingresses on Kubernetes. Both routes and ingresses require the exposure of external HTTPS endpoints. On API Connect deployments where all subsystems are in the same cluster, you can use services instead of routes or ingresses for inter-subsystem communication. When API Connect is configured to use services, all inter-subsystem communications are kept within the cluster, providing greater security and reduced load on external network infrastructure such as load-balancers.

In the context of inter-subsystem communication, the use of routes or ingresses is referred to as **`external`** communication, and the use of services is referred to as **`in-cluster`** communication.

You select whether to use **`external`** or **`in-cluster`** communication when you register your portal, gateway, or analytics subsystems with the management subsystem.

For more information about this feature, see In-cluster service communication between subsystems.

Enabling mTLS on management to gateway communication

On Kubernetes and on OpenShift installations where the top-level CR is not used, mTLS can be enabled for management to gateway communication. To enable mutual TLS between the management client and the gateway service's manager endpoint, add **`mtlsValidateClient`** to the **`spec`** section:

```
spec:
  mtlsValidateClient: true
```

This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under **`gatewayManagerEndpoint.hosts.secretName`**. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under **`gateway.client.secretName`**.
Note: If you do not want to use mTLS, the you must enable JWT instead.
Note: On Cloud Pak for Integration and OpenShift where the top-level CR is used, mTLS enablement for management to gateway communication is not supported.

Certificates used to secure inter-subsystem communication

TLS keystores and truststores for the management subsystem are configured in the Cloud Manager UI, see TLS profiles overview.

TLS configuration on the portal, analytics, and gateway subsystems is configured at the Kubernetes level.

For information about the default certificates that are used in the TLS and mTLS communications between subsystems, see Key Concepts: Cert-manager, Issuers, and Secrets.

Enable JWT security instead of mTLS

When and how to use JWT security instead of mTLS.

Most of the network interactions between API Connect subsystems use mTLS.The communication flows in API Connect that are secured with mTLS are as follows:

- Management to portal.
- Management to analytics.
- Management to API gateway.
- Management to v5 compatible gateway.
- Management to Event gateway. Cloud Pak for Integration only.
- API gateway to analytics.

- V5 compatible gateway to analytics.
- Event gateway to analytics.

All other inter-subsystem communication uses TLS. For the communication routes that use mTLS, it is a requirement that all network infrastructure such as load-balancers that are located between API Connect subsystems implement TLS passthrough (and not TLS termination).

Use of JSON Web Token (JWT) security instead of mTLS allows for the deployment of API Connect in network infrastructures where TLS termination is enabled on load-balancers that are located between subsystems. JWT provides application layer security between API Connect subsystems. The typical use-case for this feature is when payload inspection of all network communications is required at network boundaries. The communication flows that support JWT security are:

- Management to portal.
- Management to analytics.
- Management to API gateway.
- Management to v5 compatible gateway.
- API gateway to analytics.
  Note: It is not possible to use JWT and disable mTLS on the V5 compatible gateway to analytics message flow.

The management subsystem always sends a JWT when it initiates communication with the other subsystems, but by default the subsystems do not verify this JWT. When JWT security is enabled, the subsystems verify the JWT by making a REST call to the JSON Web Key Set (JWKS) URL. The JWKS URL is hosted on the management subsystem's platform REST API.

To enable JWT verification on management initiated communication, update the subsystem CRs to specify the JWKS URL. To disable JWT verification, update the subsystem CRs and delete the value of the JWKS URL (leave it unset).

To enable JWT verification on gateway to analytics communication, enable the Use JWT switch when you register the gateway in the Cloud Manager UI.
Note: For OpenShift® users - The example steps in this document use the Kubernetes **`kubectl`** command. On OpenShift, use the equivalent **`oc`** command in its place. If you are using a top-level CR (**`APIConnectCluster`**), make sure that the **`spec.gateway`** section is included. If it is not included already, you must add the **`spec.gateway`** section before adding the required property within it.

Disabling mTLS and enabling JSON Web Token (JWT) security

If you disable mTLS, you must enable JWT. It is not possible to configure API Connect with both mTLS and JWT disabled.

You disable mTLS on the portal, gateway (for management to gateway communication), and analytics subsystems by setting the **`mtlsValidateClient`** property to false in the Custom Resources (CRs) of each subsystem.

When **`mtlsValidateClient`** is set to false, the subsystem does not verify the client's TLS credentials, but it does check for a valid JWT configuration. For example, to disable mTLS and enable JWT for management to portal communication, edit the portal CR and set:

```
spec:
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the **`jwksUrl`** specified in the management subsystem CR **`status.endpoints`** section.

Using registration of the portal service in the Cloud Manager UI as an example, JWT works as follows:

1. Management subsystem establishes a TLS connection to the portal subsystem on the portal director admin endpoint, and sends a JWT to the portal.
2. Before the portal trusts the management subsystem, it first verifies the JWT it received. The JWT is verified by a call to a JSON Web Key Set (JWKS) URL.
3. The management subsystem receives the JWT verification request from the portal on its platform REST API, and responds that the JWT is valid.
4. The portal receives confirmation that the JWT is valid, and so it can trust the management subsystem and continue the registration process.

To disable JWT security for management initiated communication, either remove the **`jwksUrl`** property from the CR, or leave its value empty. If you disable JWT, you must enable mTLS by setting **`mtlsValidateClient`** to true.

To disable JWT security for gateway to analytics communication, disable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Configuring the JWKS URL

The JWKS URL is defined as the platform API hostname with the following subpath appended: **`api/cloud/oauth2/certs`**. You can see what the JWKS URL is from the **`status.endpoints`** section of the management CR, for example:

```
status:
...
  endpoints:
...
    - name: jwksUrl
      secretName: api-endpoint
      type: API
      uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

Note: The JWT feature is intended for environments where the are load-balancers located between subsystems. If you are using the in-cluster communications feature Use services instead of routes (OpenShift) or ingresses (Kubernetes), then you cannot have load-balancers between subsystems, and so disabling mTLS and enabling JWT is not necessary. However, if you do want to use the JWT feature with in-cluster communications then the JWKS URL can be obtained following these steps:

1. Describe any API Connect pod:

   ```
   kubectl describe pod <apic-pod>
   ```

2. In the pod describe output, search for **`APIC_PLATFORM_API_SVC_ENDPOINT`**:

   ```
   Containers:
     apim:
       Environment:
         APIC_PLATFORM_API_SVC_ENDPOINT:  https://management-juhu.acme-v1005-020323.svc:2000/api
   ```

3. The JWKS URL is the value of **APIC_PLATFORM_API_SVC_ENDPOINT** with **/cloud/oauth2/certs** appended to it. If the APIC_PLATFORM_API_SVC_ENDPOINT is missing the **/api** at the end, add **api/cloud/oauth2/certs** instead. The path of the JWKS URL must always be **api/cloud/oauth2/certs**.

Key points and limitations of JWT security

- Changing the JWKS URL on portal, and analytics subsystems causes pods to restart, and so a short subsystem outage. The gateway pod does not restart when the JWKS URL is changed.
- On new installs of Cloud Pak for Integration and top-level CR OpenShift deployments, the JWKS URL is set automatically for the portal, gateway, and analytics subsystems.
- You can have both mTLS and JWT enabled, although the analytics subsystem does not verify the JWT if mTLS is enabled.
- The v5c gateway does not send a JWT to the analytics subsystem. This flow is secured by mTLS, which cannot be disabled.
- If you enable JWT for gateway to analytics communication, the ingestion of analytics data becomes dependent on the availability of the management subsystem (so that the JWT can be verified). For more information about this limitation, see: JWT usage between gateway and analytics subsystems.
- Under high analytics ingestion loads, JWT enablement might impact the performance of the analytics subsystem. It is recommended to complete a performance test under your expected analytics load before you decide to use JWT for gateway to analytics communication.

JWT usage between gateway and analytics subsystems

Because the analytics subsystem makes a REST call to the management subsystems to verify the JWT it receives from the gateway, analytics ingestion depends on the management subsystem when JWT is enabled. The analytics subsystem caches the response from the JWKS URL so that it does not need to make a REST call to the management subsystem every time API event data is received from the gateway. But the JWT verification cache does expire after 24 hours, and a new REST call to the management subsystem is made to refresh the cache. The JWT dependency on the platform REST API means that an outage of the management subsystem does eventually prevent the analytics subsystem from accepting new analytics API event records.

In-cluster service communication between subsystems

Key points and limitations of **in-cluster** inter-subsystem communication.

- In-cluster communication is only possible between subsystems that are in the same cluster.
- In-cluster communication cannot be used in two data center disaster recovery deployments, Two data center warm-standby deployment on Kubernetes and OpenShift.
- If you are adding new subsystems to an upgraded deployment you can set the subsystems to use **in-cluster** communication, but you must use different certificates and secrets for the subsystem endpoints. The default certificate and secret names for the subsystem endpoints are:
  - Analytics: **ai-endpoint**.
  - Portal: **portal-admin**.
  - Gateway: **gwv6-manager-endpoint** or **gw-gateway-manager**

  Do not use these same certificate and secret names if your additional subsystems are in the same namespace.
- If you customize any TLS certificates used for inter-subsystem communication, then to use **in-cluster** communication the TLS certificates must include the service hostname in the DNS section of the SAN, for example:

```
X509v3 Subject Alternative Name: critical
                DNS: ptladmin.mydomain.com, DNS: portal.apic.svc, DNS: portal.apic.svc.cluster.local
```

- On Cloud Pak for Integration, all subsystems are registered automatically during deployment with **external** communication specified.

Kubernetes ingress controller prerequisites

Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.

Before you begin

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes. Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see https://kubernetes.io.

Kubernetes/ingress-nginx ingress controller **ingress-config.yml** settings

A Kubernetes deployment for IBM API Connect requires the **kubernetes/ingress-nginx** ingress controller implementation (see https://github.com/kubernetes/ingress-nginx) with SSL passthrough enabled.

API Connect v10 does not require Helm, so it is recommended to use Helm3 for the installation of the ingress controller. Follow these steps:

1. Create a file **ingress-config.yaml** where the following values are required:
   Specify at least one SSL protocol; separate multiple protocols with a comma as shown in the example.

```
controller:
  watchIngressWithoutClass: true
  admissionWebhooks:
    enabled: false
  config:
    ssl-protocols: "TLSv1.2 TLSv1.3"
  extraArgs:
```

```
    annotations-prefix: ingress.kubernetes.io
    enable-ssl-passthrough: true
```

You may use the following sample ingress-config.yml file to configure the ingress controller:

```
controller:
  watchIngressWithoutClass: true
  admissionWebhooks:
    enabled: false
  config:
    hsts-max-age: "31536000"
    keepalive: "32"
    log-format: '{ "@timestamp": "$time_iso8601", "@version": "1", "clientip": "$remote_addr",
      "tag": "ingress", "remote_user": "$remote_user", "bytes": $bytes_sent, "duration":
      $request_time, "status": $status, "request": "$request_uri", "urlpath": "$uri",
      "urlquery": "$args", "method": "$request_method", "referer": "$http_referer",
      "useragent": "$http_user_agent", "software": "nginx", "version": "$nginx_version",
      "host": "$host", "upstream": "$upstream_addr", "upstream-status": "$upstream_status"
      }'
    main-snippets: load_module "modules/ngx_stream_module.so"
    proxy-body-size: "0"
    proxy-buffering: "off"
    server-name-hash-bucket-size: "128"
    server-name-hash-max-size: "1024"
    server-tokens: "False"
    ssl-ciphers: HIGH:!aNULL:!MD5
    ssl-prefer-server-ciphers: "True"
    ssl-protocols: "TLSv1.2 TLSv1.3"
    use-http2: "true"
    worker-connections: "10240"
    worker-cpu-affinity: auto
    worker-processes: "1"
    worker-rlimit-nofile: "65536"
    worker-shutdown-timeout: 5m
  daemonset:
    useHostPort: false
  extraArgs:
    annotations-prefix: ingress.kubernetes.io
    enable-ssl-passthrough: true
  hostNetwork: true
  kind: DaemonSet
  name: controller
rbac:
  create: "true"
```

2. Run the commands:

```
helm3 repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
helm3 repo update
helm3 install ingress-controller ingress-nginx/ingress-nginx --namespace kube-system --values ingress-config.yaml
```

Kubernetes/ingress-nginx ingress controller `config.map` settings

To ensure that the IBM API Connect services have time to start, increase the *proxy-read-timeout* and *proxy-send-timeout* values, which are in seconds, in the **kubernetes/ingress-nginx** ingress controller *config.map* to at least the following:

- proxy-read-timeout: "240"
- proxy-send-timeout: "240"

Depending on your environment, you might need to increase these further if the IBM API Connect services do not start. If there is a load balancer in front of the worker nodes, then the load balancer configuration might also need to have extended timeouts.

System and Software Requirements

The system and software requirements are described in the Software Product Compatibility Reports. See Detailed system requirements for a specific product

Persistent Volume (PV) requirements

Review the persistent volumes (PVs) required by your API Connect installation.

The PV requirements for API Connect subsystems vary according to the number of subsystem nodes that are deployed, whether you are using two datacenter disaster recovery (2DCDR) Two data center warm-standby deployment on Kubernetes and OpenShift, and other subsystem specific options.

Management subsystem

Management subsystem PV requirements depend on what database backup configuration is used, and if the API discovery feature is enabled.

Table 1. Management PV requirements

Deployment profile	Database backup	Discovery enabled	Number of PVs required
Single replica (n1)	local	yes	4
Three replica (n3)	local	yes	12
Single replica (n1)	local	no	3
Three replica (n3)	local	no	9
Single replica (n1)	sftp	yes	4
Three replica (n3)	sftp	yes	12
Single replica (n1)	sftp	no	3
Three replica (n3)	sftp	no	9
Single replica (n1)	object-store	yes	3

Deployment profile	Database backup	Discovery enabled	Number of PVs required
Three replica (n3)	object-store	yes	9
Single replica (n1)	object-store	no	2
Three replica (n3)	object-store	no	6

Gateway subsystem

Only required where `tokenManagementService` is enabled:

```
tokenManagementService:
  enabled: true
  storage:
    storageClassName: $STORAGE_CLASS
    volumeSize: 30Gi
```

Portal subsystem

Table 2. Portal PV requirements

Deployment profile	Number of PVs required
Single node (n1), one datacenter	6
Three nodes (n3), one datacenter	18
Single node (n1), two datacenter	9 per datacenter
Three nodes (n3), two datacenter	27 per datacenter
Single node (n1), two datacenter, where other datacenter is three node (n3)	13 in n1 datacenter, 23 in n3 datacenter
Three node (n3), two datacenter, where other datacenter is single node (n1)	30 in n3 datacenter, 15 in n1 datacenter

The amount of persistent storage space that is used by the developer portal depends on the following factors:

- The number of portal sites you create. Each portal site uses space in the `webVolumeClaimTemplate` and `databaseVolumeClaimTemplate` PVCs. 3 backups of each portal site are stored in the `backupVolumeClaimTemplate` PVC.
- The content that you add to your portal sites, such as custom images and documents that you attach to your sites.
- If debugging tools such as Drupal logs are enabled.

Note: In Openshift disk performance increases with disk size, for example, a 200 Gi PVC has better performance than a 30 Gi PVC. It is recommended that the `databaseVolumeClaimTemplate` is kept above 200 Gi to avoid performance issues.

Analytics subsystem

The number of PVs needed depends on if you disable local storage, and if you have backups that are configured .

Table 3. Analytics PV requirements

Deployment profile	Local storage disabled (ingestion only)	Local storage enabled	Local storage and backups enabled
Single node (n1)	1	2	3
Three node (n3)	3	6	9

To understand how much storage capacity your analytics subsystem needs, see Estimating storage requirements.

Load balancer configuration

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.

Before you begin

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer and the ingress endpoints defined during installation of API Connect can remain unchanged.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for mTLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4.

If you do not want to use mTLS between API Connect subsystems, you can Enable JWT security instead of mTLS.

Set endpoints to resolve to the load balancer

When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node.

Note: The example deployment in the page is a Kubernetes deployment. The same principles apply to an OpenShift deployment.

Procedure

- **Kubernetes cluster with wildcard DNS**
  In this example, API Connect is deployed to a Kubernetes cluster with three master and six worker nodes. The master nodes have the Kubernetes API server listening on port 6443. The Kubernetes API Server is used for communicating with the kubectl command line interface. Note that it is generally not necessary for the Kubernetes API server (on port 6443 in this example) to be exposed outside the cluster through the load balancer, this is just one possible setup shown here.

  The kubernetes/ingress-nginx ingress controller is deployed as a daemonset, so that every worker node in the cluster has an ingress controller pod listening on port 443. The API Connect subsystems (API Manager, Developer Portal, Analytics and Gateway) are all deployed on this same cluster.

  Note:
  - When you configure a load balancer in front of a management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

    The default timeout is typically 50 or 60 seconds, which is not long enough to avoid **`409 Conflict`** or **`504 Gateway Timeout`** errors. The **`409 Conflict`** error can occur when the time needed to complete an operation is sufficiently long that a second request gets issued.

    For example, to specify 240 seconds when using HAProxy as a load balancer, set **`timeout client`** and **`timeout server`** to **`240000`**.

    Best practice is to ensure that the same values are specified for the timeout settings for the load balancer and for the Kubernetes ingress controller. The ingress controller timeout settings are set in the ingress controller config.map. For more information, see the **`proxy-read-timeout`** and **`proxy-send-timeout`** settings in Kubernetes ingress controller prerequisites .

  - Ensure that the load balancer is configured to support the cipher **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**.
    When the Developer Portal, as a client, calls back to platform-api-endpoint or consumer-api-endpoint of the management subsystem, it sends only a single cipher in the Client Hello. The cipher is **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**. The SSL Handshake will fail if this cipher is not configured (supported) on the client's load balancer.

  A host running HAProxy acts as the load balancer, with a configuration for proxies in the HAProxy configuration file such as:

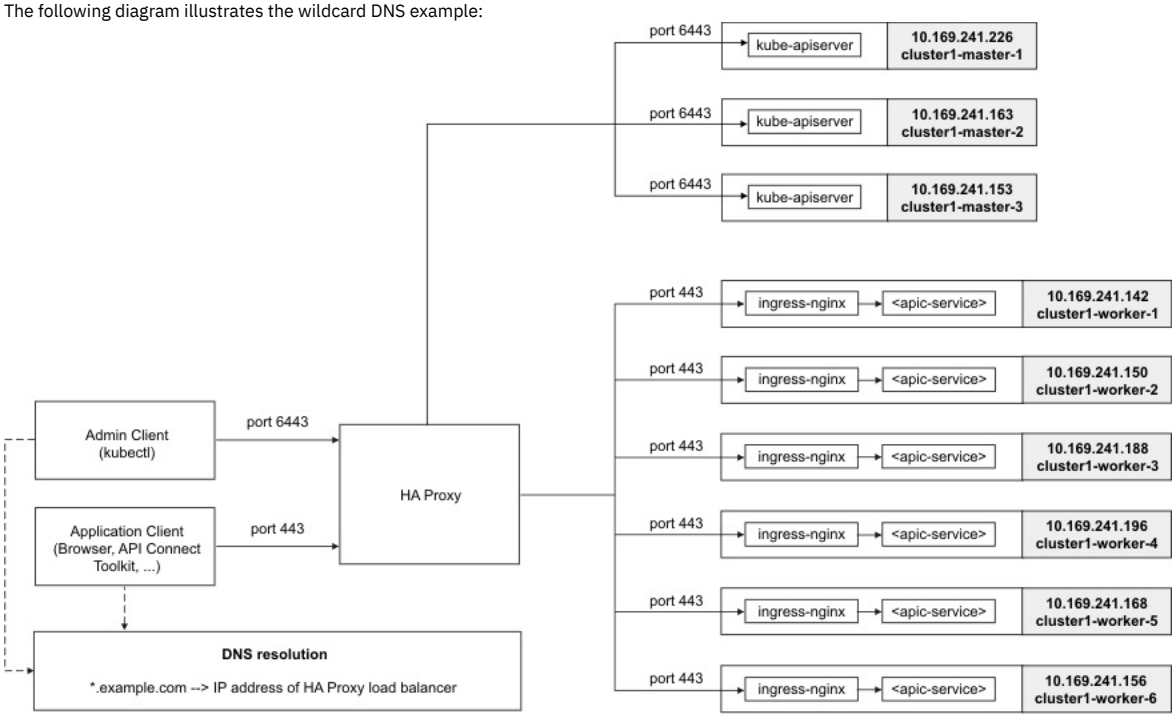
```
defaults
        log     global
        mode    http
        option  httplog
        option  dontlognull
        timeout connect 5000
        timeout client  240000
        timeout server  240000
        errorfile 400 /etc/haproxy/errors/400.http
        errorfile 403 /etc/haproxy/errors/403.http
        errorfile 408 /etc/haproxy/errors/408.http
        errorfile 500 /etc/haproxy/errors/500.http
        errorfile 502 /etc/haproxy/errors/502.http
        errorfile 503 /etc/haproxy/errors/503.http
        errorfile 504 /etc/haproxy/errors/504.http

frontend apiservers
        bind *:6443
        mode tcp
        option  tcplog
        option forwardfor
        default_backend k8s_apiservers

frontend ingress
        bind *:443
        mode tcp
        option  tcplog
        option forwardfor
        default_backend k8s_ingress

backend k8s_apiservers
        mode tcp
        option  tcplog
        option ssl-hello-chk
        option log-health-checks
        default-server inter 10s fall 2
        server cluster1-master-1 10.169.241.226:6443 check
        server cluster1-master-2 10.169.241.163:6443 check
        server cluster1-master-3 10.169.241.153:6443 check

backend k8s_ingress
        mode tcp
        option  tcplog
        option ssl-hello-chk
        option log-health-checks
        default-server inter 10s fall 2
        server cluster1-worker-1 10.169.241.142:443 check
        server cluster1-worker-2 10.169.241.150:443 check
        server cluster1-worker-3 10.169.241.188:443 check
        server cluster1-worker-4 10.169.241.196:443 check
        server cluster1-worker-5 10.169.241.168:443 check
        server cluster1-worker-6 10.169.241.156:443 check
```



A wildcard DNS record allows the resolution of **`*.example.com`** to the IP address of the HAProxy host.

The ingress endpoints are defined in the CRs (custom resources) for each API Connect subystem. During configuration of each subsystem, you define the endpoint by specifying a host name **`$STACK_HOST`** in the CR. For configuration instructions, see Installing the API Connect subsystems.

You can view the endpoint definitions in sample CRs:

- Installing the management subsystem
- Installing the developer portal subsystem
- Installing the analytics subsystem
- Installing the gateway subsystem

The following diagram illustrates the wildcard DNS example:

- **Kubernetes cluster without wildcard DNS**
  This example uses the same topology as the previous one, except that there is no wildcard DNS resolution. Instead, individual DNS records are added, all pointing to the IP address of the load balancer. For example: **`portal.example.com`** and **`admin.portal.example.com`** resolve to the IP address of the load balancer.
- **Kubernetes cluster with `xip.io` or `nip.io`**
  This example uses the same topology as the first one, except that there is no specific DNS resolution configured and instead a service such as **`xip.io`** or **`nip.io`** provides wildcard DNS resolution. It is not recommended to use this approach for a production setup, as the ingress endpoints configured during installation of API Connect would be tied to the IP address of the load balancer. This approach can be useful when configuring a test deployment in situations where access to DNS records is not practical or would introduce delay in the deployment.

Firewall requirements

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes or OpenShift.

Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

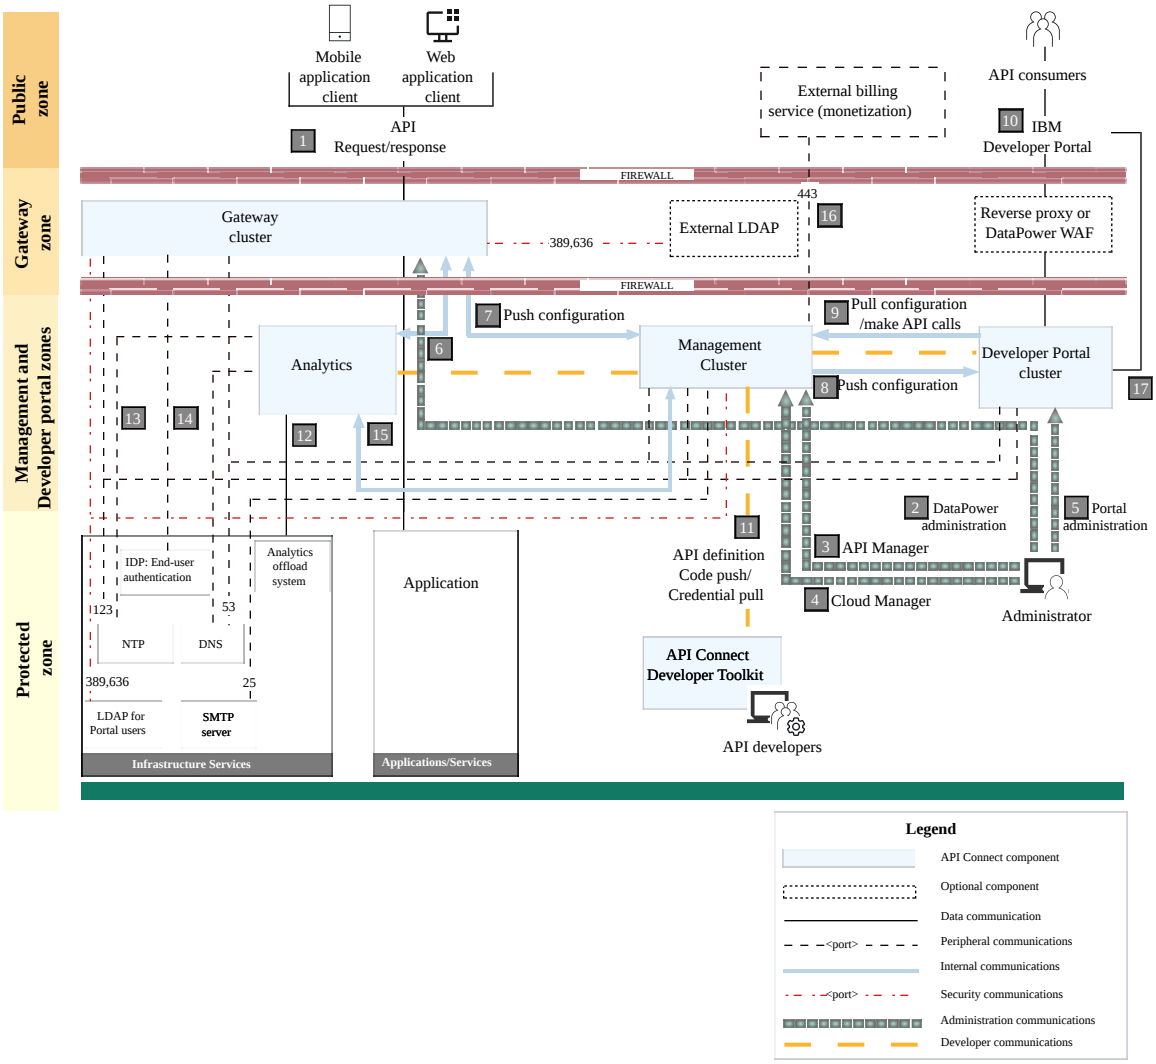


Table 1. Key for the network diagram example.
The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 and 443 HTTPS Management servers to and from Gateway servers for webhook delivery. Port 3000 is the default port for apic-gw-service, and this is the port Management uses to communicate with Gateway. Port 443 is the default port for the platform-api endpoint, which apic-gw-service uses to communicate with Management.
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed.
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP

	Usage description	Default port number
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	External billing service – Management cluster connecting to external billing service (when configured for billing). If you are using Stripe as your external billing service, you must enable connections with the Stripe API at: https://stripe.com/files/ips/ips_api.json. You can also view the Stripe IP addresses at the following URL: https://stripe.com/docs/ips.	443 HTTPS from Management zone to Public zone
17	Developer Portal cluster must be able to access its own site endpoints.	443 HTTPS from Portal zone to Public zone

Firewall port requirements

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not. • 22 (outbound) Used for SFTP backups on Management and Portal subsystems • 53 (outbound) DNS • 123 (outbound) NTP • 443 (inbound and outbound) Used by all subsystems for communication with other subsystems

Each subsystem uses ports in addition to the ports in Table 2. See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
Management Service	Management Service uses the ports in Table 2 plus: • 22 remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. • 161 (inbound) SNMP • LDAP server port (if using LDAP user registry), typically 389 (outbound) • 3007 (outbound) LDAP The Automated test behavior application must be able to invoke (outbound) any port that a test system might present an API on. It can be bound to a particular port (if it is the same in all environments) or to a range of ports (to cover all of the ports it might invoke).
Developer Portal	The Developer Portal uses the ports listed in Table 2, plus: • 22 - A remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. See Configuring portal database backups.
Analytics	The Analytics subsystem uses the ports listed in Table 2. Analytics port usage considerations: • 161 for SNMP is required for both non-clustered and clustered deployments • In a non-clustered deployment, no additional ports are required. • Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open.
Gateway Server	The Gateway Server uses these ports in both non-clustered and clustered deployments: • 161 (inbound and outbound) SNMP • 162 (outbound) SNMP traps • 3000 (inbound) Gateway Service local port (configurable) • 5550 (inbound) XML management port (configurable) • 5554 (inbound) REST management port (if enabled; configurable) • 9022 (inbound) Gateway SSH (if enabled; configurable) • 9090 (inbound) Web GUI console (if enabled; configurable) • 9443 (inbound) Gateway local port (configurable)

Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.
- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

Port requirement for Stripe billing service

All Management servers and Developer Portal servers must be able to communicate HTTPS content with the external billing service when billing is configured. If you are using Stripe as your external billing service, you must enable HTTPS communication on port 443 with the Stripe API: https://stripe.com/files/ips/ips_api.json.
Note: API Connect does not support using webhooks with Stripe. You can see a list of the Stripe IP addresses at: https://stripe.com/docs/ips.

Planning your analytics deployment

Plan your API Connect analytics deployment by reviewing options for deployment profile and estimating required persistent storage space.

Deployment profile

Decide which deployment **`profile`** you want to use, the available profiles are:

- For Kubernetes and OpenShift® (individual subsystem) installations: Analytics deployment profiles.
- For Cloud Pak for Integration and Red Hat OpenShift top-level CR installations: API Connect deployment profiles.

For a scalable analytics deployment, choose a three replica profile. If you do not expect a high API transaction rate and plan to keep a limited amount of analytics data, then a one replica profile is sufficient.

Storage class

Before you install analytics, you must choose a storage class. **`Ceph`**, **`Block`**, and **`Local Volume`** are all supported; however, **`Local Volume`** is the most suitable for analytics. The analytics subsystem provides internal data replication and HA support, so the additional HA capabilities that **`Ceph`** or **`Block`** storage might give you are not needed. In addition, analytics require a high throughput of disk I/O operations to successfully handle the analytics data load from the gateway. **`Local Volume`** is the best-performing storage class for disk I/O.

Note: GlusterFS, NFS, Rook-CephFS, or any shared file system storage class is not supported for analytics. If you use these storage classes, you might encounter severe performance degradation, pod crashloops, and possibly loss of data.

Storage type

Note: Storage type selection is available on three replica deployments only.
To make an informed choice on which storage type is best for you, first read and understand the OpenSearch concepts that are described in OpenSearch nodes, indices, shards, and replicas.
API Connect provides two OpenSearch storage types:

- **Shared storage**
  A single pod provides data storage and OpenSearch cluster management. Shared storage is the only option on a one replica deployment.
- **Dedicated storage**
  OpenSearch data storage and cluster management functions are split, and run in separate pods on each worker node:
  - The **`storage-os-master`** pod runs an OpenSearch "manager eligible" node that manages the OpenSearch cluster, but does not store any API event data.
  - The **`storage`** pod runs an OpenSearch "data" node that stores API event data.

  Dedicated storage is the default storage type for three replica deployments.

Dedicated storage facilitates horizontal scaling to support greater analytics data storage and throughput. Add worker nodes and increase the number of **`storage`** pod replicas to scale horizontally (you do not need to increase the number of **`storage-os-master`** replicas). Dedicated storage also provides greater stability and allows some OpenSearch configuration changes to be made without downtime.
You can change storage type after installation, see Dedicated storage and scaling up.

Disabling internal storage

The analytics subsystem provides a complete solution for routing, storing, and viewing the analytics data. However, you might not need the internal storage and viewing solution if you are using a third-party system for data offloading. In this scenario, you can greatly reduce your CPU and memory costs by disabling the internal storage and viewing components.

When you disable internal storage for analytics data, the following microservices are disabled:

- **`osinit`**
- **`storage`**

Important:
If you disable local storage, the analytics views in your API Connect UIs remain accessible, but are empty.

Configure local storage disablement before installation. It is not possible to disable or re-enable internal storage after installation.

You can enable offload of analytics data to third-party systems after installation.

For the steps to disable internal storage, see Disable local storage.

Persistent storage space

Based on your expected API transaction rate, you can estimate how much storage space your analytics subsystem requires. See Estimating storage requirements.

Inter-subsystem communication security

By default the network communication from the management and gateway subsystems, to the analytics subsystem uses Kubernetes ingresses or Red Hat OpenShift routes, and is secured with mTLS. You can configure alternative network communication options if your environment requires. For more information, see Network requirements for inter-subsystem communication.

Kubernetes operating map counts

When the analytics service is configured to store data, it uses OpenSearch, which requires map counts higher than the operating system defaults. The minimum recommended value is `262144`. Unless you plan to disable local storage, increase the default map count on every Kubernetes worker node:

1. To change the map counts on the live system, run the following command on every Kubernetes node:

   ```
   sudo sysctl -w vm.max_map_count=262144
   ```

2. To persist this change when node restarts occur, add the following setting to the /etc/sysctl.conf file:

   ```
   vm.max_map_count = 262144
   ```

For more information, see Important settings in the OpenSearch documentation.

PV requirements

The number of PVs needed depends on if you disable local storage, and if you have backups that are configured .

Table 1. Analytics PV requirements

Deployment profile	Local storage disabled (ingestion only)	Local storage enabled	Local storage and backups enabled
Single node (n1)	1	2	3
Three node (n3)	3	6	9

To understand how much storage capacity your analytics subsystem needs, see Estimating storage requirements.

Firewall requirements

The analytics firewall requirements are documented here: Firewall requirements

Key Concepts: Cert-manager, Issuers, and Secrets

By default API Connect uses an open source product that is called cert-manager to handle the issuing and renewal of the certificates that are used by API Connect. The cert-manager has its own Kubernetes pods and runs in its own namespace. The cert-manager adds some additional resources to the Kubernetes environment. The API Connect administrator needs to be familiar with these additional resources:

Issuers

Issuers play the part of certificate authorities (CAs) in the local environment and issue the certificates. Issuers reside in the API Connect namespace. There are two types of Issuers:

- Self-Signed - This issuer provides the self-signed certificates, for example a root CA.
- CA - This issuer can be either the root certificate authority or an intermediate certificate authority.

Here is an example of the issuers that can be found on the management subsystem:

```
kubectl get issuers -n <management namespace>
NAME                 READY   AGE
abc-management-ca    True    96d
selfsigning-issuer   True    96d
```

- `selfsigning-issuer` This is a SelfSigned Issuer that provides the root certificate for all default certificates that are used in API Connect.
- `abc-management-ca` This is a CA Issuer that signs all the end-entity certificates that are used for communication between the management subsystem pods. It is in effect an intermediate CA between the root (`selfsigning-issuer`) and the end-entity certificates.

Certificates

A certificate is a Kubernetes resource that contains a pointer to a Kubernetes secret. The Kubernetes secret contains the actual TLS certificate. Certificate objects contain other information such as the issuer, expiry date, and status. Run `kubectl get certificate` to see the certificates on an API Connect subsystem:

```
kubectl get certificate -n <management namespace>
NAME                                READY   SECRET                              AGE
abc-management-ca                   True    abc-management-ca                   96d
abc-management-client               True    abc-management-client               96d
```

```
abc-management-natscluster-mgmt           True    abc-management-natscluster-mgmt           96d
abc-management-server                     True    abc-management-server                     96d
...
```

The first certificate in the list `abc-management-ca` is the intermediate CA certificate that is used for signing the other certificates that are shown in the output. If you describe this certificate you can see that the `selfsigning-issuer` is its issuer:

```
kubectl describe certificate abc-management-ca -n <management namespace>
...
Spec:
  ...
  Issuer Ref:
    Kind:  Issuer
    Name:  selfsigning-issuer
```

Describing the other management subsystem certificates, observe that the `abc-management-ca` certificate is the issuer:

```
kubectl describe certificates abc-management-client -n <management namespace>
...
Spec:
  ...
  Issuer Ref:
    Kind:  Issuer
    Name:  abc-management-ca
```

Key points:

- The certificates with '-ca' on the end are all CA Certificates, and they sign all the other subsystem certificates whose names do not end with '-ca'.
- The CA certificates are also known as Issuer certificates.
- Certificates that CA certificates sign are known as end-entity certificates.
- When a CA certificate is updated, all end-entity certificates that it signs must also be updated.

For a complete list of the certificates in an API Connect installation, see API Connect certificates reference.

Secrets

Secrets are the Kubernetes resource for storing credentials. In API Connect, secrets are where the TLS certificates are stored. Every Kubernetes certificate object has a corresponding secret of the same name. The Kubernetes certificate contains a property that refers to its corresponding secret:

```
kubectl describe certificates abc-management-client -n <management namespace>
...
Spec:
  ...
  Secret Name:        abc-management-client
```

The default output of `kubectl get certificate` includes a column that is labeled `SECRET`, which shows the secret name.

```
kubectl get certificate -n <management namespace>
NAME                                      READY   SECRET                                    AGE
abc-management-ca                         True    abc-management-ca                         96d
abc-management-client                     True    abc-management-client                     96d
abc-management-natscluster-mgmt           True    abc-management-natscluster-mgmt           96d
abc-management-server                     True    abc-management-server                     96d
...
```

The `kubectl describe` output of a secret shows that it contains the TLS certificates:

```
kubectl describe secret abc-management-client -n <management namespace>
...
Name:         abc-management-client
Namespace:    default
Labels:       app.kubernetes.io/instance=abc-management
              app.kubernetes.io/managed-by=ibm-apiconnect
              app.kubernetes.io/name=abc-management-client
Annotations:  cert-manager.io/alt-names:
              cert-manager.io/certificate-name: abc-management-client
              cert-manager.io/common-name: abc-management-client
              cert-manager.io/ip-sans:
              cert-manager.io/issuer-group:
              cert-manager.io/issuer-kind: Issuer
              cert-manager.io/issuer-name: abc-management-ca
              cert-manager.io/uri-sans:

Type:  kubernetes.io/tls

Data
====
ca.crt:   1107 bytes
tls.crt:  1139 bytes
tls.key:  1675 bytes
```

The full TLS certificate strings can be seen with:

```
kubectl get -o yaml secret <secret name> -n <namespace>
```

For more details about cert-manager, and a full list of all the certificates that are created and used in an API Connect deployment, see API Connect certificate reference.

Webhooks deployed and managed by the API Connect Operator

The API Connect Operator deploys and manages various Kubernetes API webhooks in the cluster to assist in management of its custom resources.

The webhooks included admission controllers and conversion webhooks.

Defaulting webhook

- Purpose
  The defaulting webhook is a type of Mutating Admission Webhook which runs against Custom Resources (CRs) at **CREATE** or **UPDATE** time to populate default values in the CR's **spec**.

- Creation
  Currently the defaulting webhook runtime is part of the API Connect Operator runtime, that is it exists within the API Connect Operator pod and container. When the operator boots, it creates **MutatingWebhookConfiguration** resources for each CRD (listed below). This **MutatingWebhookConfiguration** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

  The name for the **MutatingWebhookConfiguration** resource for each CRD will take the following form:

  ```
  <namespace>.<crd-name>.defaulter[.<component>].apiconnect.ibm.com
  ```

  The following CustomResourceDefinitions utilize a defaulting webhook:

  ```
  AnalyticsCluster
  ApiconnectCluster
  GatewayCluster
  ManagementCluster
  ManagementDBUpgrade
  ManagementRestore
  PortalCluster
  ```

- Lifecycle
  While the defaulting webhook runtime itself lives within the API Connect Operator pod, the **MutatingWebhookConfiguration** is a cluster-scope resource and is stand-alone. When it is created, an **ownerReference** is set on it that references the API Connect Operator's **ClusterRole**. Thus, the lifecycle of the **MutatingWebhookConfiguration** resources will be linked with the **ClusterRole**, which is linked with the installation of the operator itself.

  When the operator is uninstalled, the **MutatingWebhookConfiguration** resources for that operator instance are also removed.

- Example
  The below output shows the defaulting webhook configurations created for an operator deployed in the **apiconnect-operator** namespace. One can be seen for each CRD.

  ```
  $ oc get mutatingwebhookconfiguration
  NAME                                                                    WEBHOOKS   AGE
  apiconnect-operator.analyticsclusters.defaulter.analytics.apiconnect.ibm.com       1          4d4h
  apiconnect-operator.apiconnectclusters.defaulter.apiconnect.ibm.com                1          4d4h
  apiconnect-operator.gatewayclusters.defaulter.gateway.apiconnect.ibm.com           1          4d4h
  apiconnect-operator.managementclusters.defaulter.management.apiconnect.ibm.com    1          4d4h
  apiconnect-operator.managementdbupgrades.defaulter.management.apiconnect.ibm.com  1          4d4h
  apiconnect-operator.managementrestores.defaulter.management.apiconnect.ibm.com    1          4d4h
  apiconnect-operator.portalclusters.defaulter.portal.apiconnect.ibm.com             1          4d4h
  ```

Validating webhook

- Purpose
  The validating webhook is a type of ValidatingAdmissionWebhook which runs against Custom Resources (CRs) at **CREATE** or **UPDATE** time to validate the CR contains a configuration which will yield an operable cluster. The CustomResourceDefinitions use OpenAPI schema validation for basic property checks (such as integer bounds and non-empty strings), but more complex validation of the configuration is done via the webhook.

- Creation
  Currently the validating webhook runtime is part of the API Connect Operator runtime, i.e. it exists within the API Connect Operator pod and container. When the operator boots, it creates **ValidatingWebhookConfiguration** resources for each CRD (listed below). This **ValidatingWebhookConfiguration** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

  The name for the **ValidatingWebhookConfiguration** resource for each CRD will take the following form:

  ```
  <namespace>.<crd-name>.validator[.<component>].apiconnect.ibm.com
  ```

  The following CustomResourceDefinitions utilize a validating webhook:

  ```
  AnalyticsCluster
  ApiconnectCluster
  GatewayCluster
  ManagementCluster
  ManagementDBUpgrade
  ManagementRestore
  PortalCluster
  ```

- Lifecycle
  While the validating webhook runtime itself lives within the API Connect Operator pod, the **ValidatingWebhookConfiguration** is a cluster-scope resource and is stand-alone. When it is created, an **ownerReference** is set on it that references the API Connect Operator's **ClusterRole**. Thus, the lifecycle of the **ValidatingWebhookConfiguration** resources will be linked with the **ClusterRole**, which is linked with the installation of the operator itself.

  When the operator is uninstalled, the **ValidatingWebhookConfiguration** resources for that operator instance are also removed.

- Example
  The below output shows the validating webhook configurations created for an operator deployed in the **apiconnect-operator** namespace. One can be seen for each CRD.

```
validatingwebhookconfiguration
NAME                                                                    WEBHOOKS   AGE
apiconnect-operator.analyticsclusters.validator.analytics.apiconnect.ibm.com       1          4d4h
apiconnect-operator.apiconnectclusters.validator.apiconnect.ibm.com                1          4d4h
apiconnect-operator.gatewayclusters.validator.gateway.apiconnect.ibm.com           1          4d4h
apiconnect-operator.managementclusters.validator.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.managementdbupgrades.validator.management.apiconnect.ibm.com  1          4d4h
apiconnect-operator.managementrestores.validator.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.portalclusters.validator.portal.apiconnect.ibm.com             1          4d4h
```

Administering API Connect in your container environment

How to manage your API Connect subsystems in Kubernetes and OpenShift environments.

On all container platforms, your API Connect subsystems can be entirely managed from the command line, by using the Kubernetes **kubectl** command. On OpenShift, you can use the equivalent **oc** command instead of **kubectl**. However, since the **kubectl** command is recognized in OpenShift, the **kubectl** command is used in most example commands throughout this documentation.

On OpenShift, some administration operations can be done through the OpenShift console, and on Cloud Pak for Integration also through the Platform UI.

- **Namespaces in your container environment**
  How to administer API Connect in a namespace-scoped container environment.
- **Custom Resources and Custom Resource Definitions**
  Information about the Custom Resources (CRs) that make up API Connect.
- **Managing your API Connect CRs**
  How to update the API Connect CRs in your deployment.

Namespaces in your container environment

How to administer API Connect in a namespace-scoped container environment.

Namespaces are used in Kubernetes to allow separate groups of resources to run in the same Kubernetes cluster without interfering with each other. For example, you can have two Kubernetes pods with an identical name if they are in different namespaces.

When you install API Connect, you can use an existing namespace or create a new namespace for your API Connect installation to run in.

Cluster-scoped resources are Kubernetes resources that operate across multiple namespaces. The API Connect operator is installed at cluster-scope, and can manage multiple API Connect installations that are installed in different namespaces.

Whenever you run the **kubectl** command, you must specify which namespace the command is to run in. For example:

```
kubectl -n <namespace> get pods
```

where `-n <namespace>` defines the namespace to run the command in. If you specify the wrong namespace, the **kubectl** command fails:

```
kubectl -n wrong-ns get pod mypod
Error from server (NotFound): namespaces "wrong-ns" not found
```

Kubernetes and OpenShift have a default namespace that is used if no namespace is specified in **kubectl** commands. It is not recommended to install API Connect in the default namespace. Always create a dedicated namespace for each API Connect installation.

Throughout this document, **kubectl** commands are provided to run the various installation and maintenance operations that are used to manage your API Connect installation. For brevity, the `-n <namespace>` is not included in the example commands where the namespace to specify is clear from the context.

If you need to run a sequence of `kubectl` commands in the same namespace, you can set the default namespace so that you do not need to include `-n <namespace>` in the commands. To set the default namespace, run the following command:

- Kubernetes:

  ```
  kubectl config set-context --current --namespace=<namespace>
  ```

- OpenShift:

  ```
  oc project <namespace>
  ```

Custom Resources and Custom Resource Definitions

Information about the Custom Resources (CRs) that make up API Connect.

Custom Resources (CRs) are sets of Kubernetes resources (such as pods) that you can interact with using the **kubectl** command. An API Connect installation has a distinct CR for each API Connect subsystem: management, portal, gateway, and analytics.

Custom Resource Definitions (CRDs) are the Kubernetes resource that is used to define CRs. API Connect has a CRD for each subsystem:

- ManagementCluster
- PortalCluster
- GatewayCluster
- AnalyticsCluster

API Connect on Cloud Pak for Integration or on OpenShift with the top-level CR, has an extra CRD for the top-level CR:

- APIConnectCluster

Each API Connect subsystem CR defines the system-level properties for its subsystem such as endpoints, secrets, backup settings, and storage allocations. The properties are defined in YAML format. The syntax to view the properties of an API Connect CR are:

```
kubectl -n <namespace> get <API Connect CRD name> <API Connect CR name> -o yaml
```

Example output:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  annotations:
    ...
  creationTimestamp: "2023-12-06T17:37:28Z"
    ...
  name: management
  namespace: apic
  ...
  uid: 9e67df02-d044-4a5b-8fb5-93391722ae97
spec:
  adminUser:
    secretName: management-admin-pass
  ...
  analytics:
    client: {}
    ingestion:
      secretName: management-a7s-ing-client
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: management-ingress-issuer
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: management-api-manager-apic.apps.ibm.com
      secretName: management-api-manager
    ...
  databaseBackup:
    ...
  databaseVolumeClaimTemplate:
    storageClassName: rook-ceph-block
    ...
  version: 10.0.x.y
  ...
status:
  conditions:
  - lastTransitionTime: "2023-12-06T17:47:47Z"
    message: All services ready
    reason: na
    status: "True"
    type: Ready
...
```

To refer to a specific property in the CR, dot notation is used, so the property:

```
metadata:
  annotations:
```

is referred to as `metadata.annotations`. In the example output shown previously, some properties of interest are highlighted in bold:

- **`kind: ManagementCluster`**. The **`kind`** property refers to the CRD that defines the CR.
- **`name: management`**. The name of the CR itself. When you want to run a kubectl operation on the CR, you specify the CR name in the command.
- **`namespace: apic`**. The name of the namespace the CR exists in.
- **`spec:`** The **`spec`** section contains the properties of your API Connect subsystem, such as URLs for the endpoints and scheduled database backup settings.
- **`spec.apiManagerEndpoint.hosts.name`** is where you define the URL of the API Manager UI.
- **`status:`** The **`status`** section shows information about the current state of the subsystem, including any errors or warnings.

You can have multiple portal, analytics, and gateway CRs in the same namespace, each registered with the management subsystem as separate services. You cannot have multiple management CRs in the same namespace. To list all the installed CRs for a portal, analytics, or gateway CRD, run:

```
kubectl get <CRD name>
```

where *<CRD name>* is **`PortalCluster`**, **`GatewayCluster`**, or **`AnalyticsCluster`**. Example output:

```
kubectl get PortalCluster
```

```
NAME        READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                                AGE
ptl_1       3/3     Running   10.0.x.y   10.0.x.y-3968        Ready for API Cloud Manager service registration   6d22h
ptl_2       3/3     Running   10.0.x.y   10.0.x.y-3968        Ready for API Cloud Manager service registration   9d12h
```

The output shows two portal CRs. To get just information on one of the CRs, specify that CR name in the **kubectl get** command:

```
kubectl get PortalCluster ptl_2
```

```
NAME        READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                                AGE
ptl_2       3/3     Running   10.0.x.y   10.0.x.y-3968        Ready for API Cloud Manager service registration   9d12h
```

Tip: Instead of typing the full CRD names **ManagementCluster**, **PortalCluster**, **GatewayCluster**, or **AnalyticsCluster**, you can use the following shorter alternatives:

- **mgmt** for **ManagementCluster**
- **ptl** for **PortalCluster**
- **gw** for **GatewayCluster**
- **a7s** for **AnalyticsCluster**

To see all the API Connect CRs in a namespace, use the **kubectl get apic** command:

```
kubectl get apic -n <namespace>
NAME                                                    READY   STATUS    VERSION    RECONCILED VERSION   AGE
analyticscluster.analytics.apiconnect.ibm.com/test-a7s   n/n     Running   10.0.x.y   10.0.x.y-2248        5d

NAME                                                 READY   STATUS    VERSION    RECONCILED VERSION   AGE

Managing your API Connect CRs

How to update the API Connect CRs in your deployment.

Updating an API Connect CR requires editing the CR and adding, updating, or deleting individual properties or entire sections of the CR. Two methods exist to edit a CR:

- Edit the CR manually with the **kubectl** edit command. The **kubectl** edit command opens the CR in an editor, where standard **vi** operations can be used to update the CR:

  ```
  kubectl edit ptl <portal cr name>
  ```

  Make the changes that you want in the CR, for example update the value of **spec.databaseBackup.schedule**, then save and exit.
  Note: You can omit the CR name in the edit command. To open all portal CRs in the namespace for editing, run:

  ```
  kubectl edit ptl
  ```

  For brevity, the CR name is often omitted where **kubectl** edit commands are provided in this documentation.

- Use the **kubectl** **patch** operation to update the CR in a single command, for example:

  ```
  kubectl patch managementcluster <mgmt cr name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
  ```

  In this example, the patch operation removes the entire **spec.multiSiteHA** section from the management CR.

  Patch operations that require updating multiple properties in the same CR can be done by creating a YAML file that contains all the properties to change, for example:

  ```
  kubectl patch mgmt <mgmt cr name> --type merge --patch "$(cat <YAML file>)"
  ```

  where *<YAML file>* is the file that contains the properties to update.
  Note: With **patch** operations, you must always specify the CR name, even if you have only one CR of the CRD type in the namespace.

Both methods for updating CRs are used throughout this documentation.

Installing API Connect

Use these instructions to install a deployment of API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.

To deploy API Connect, complete the tasks in the sequence below.

- **Deployment requirements**
  Describes the system requirements for deploying into the Kubernetes, OpenShift, and Cloud Pak for Integration runtime environments.
- **Deployment procedures**
  You can use these procedures to deploy API Connect on either native Kubernetes or OpenShift.

Deployment requirements

Describes the system requirements for deploying into the Kubernetes, OpenShift, and Cloud Pak for Integration runtime environments.

Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software might change and this information might become outdated.
Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure.
For more information, see https://kubernetes.io.

These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes.

About this task

Review all the requirements listed in the following steps before starting your API Connect deployment.

Note: If you plan to install the Automated API behavior testing application, review the *Before you begin* section in Installing the Automated API behavior testing application because the requirements might have an impact on your deployment choices for API Connect.

Procedure

1. Verify that you have supported software.
   - Refer to the IBM Software Product Compatibility Reports site for detailed requirements for operating systems, supporting software, and other prerequisites. See Detailed system requirements for a specific product
   - For new installations, the API Connect operators and operands must be at compatible versions. This requirement applies to native Kubernetes and OpenShift installations.
     - Note that the API Connect operator version *number* does not match the API Connect release version *number*. You can view a mapping of API Connect release number to API Connect operator version numbers in Deploying operators and cert-manager.
     - For API Connect operands (Management, Portal, Analytics, and Gateway subsystems), the version number matches the API Connect release version number.

2. Verify that your Kubernetes environment is running and meets the configuration requirements for API Connect:
   - When using IBM Cloud Kubernetes Service, ingress-nginx is required.
   - Specify settings for the ingress controller for a Kubernetes runtime environment. See Kubernetes ingress controller prerequisites.
   - The timezone for API Connect pods is set to UTC. Do not change the timezone for the pods.
   - To ensure the API Connect services have time to start, we recommend increasing the *proxy-read-timeout* and *proxy-send-timeout* values in the *config.map* used to configure the kubernetes/ingress-nginx ingress controller. The following settings should be increased:
     - proxy-read-timeout: "240"
     - proxy-send-timeout: "240"

     240 seconds (4 minutes) is a recommended minimum; actual value will vary depending upon your environment. If there is a load balancer in front of the worker node(s), then the load balancer configuration may also need to have extended timeouts.
   - Storage type:
     When selecting storage type, review the following considerations:

     - Management subsystem requires block storage.
     - Developer Portal subsystem supports block storage or local volume storage.
     - Analytics subsystem supports block storage or local volume storage.

     Supported storage types
     - Block storage
       Select a block storage format of your choosing in order for API Connect components to be supported. Supported block storage types include, but are not limited to:

       - Rook Ceph
         Note: cephrbd (RADOS Block Device) is recommended over cephfs file system

       - OpenShift Container Storage
       - Portworx
       - IBM Cloud Block Storage
       - AWS: the gp2, gp3, io1, and io2 types of Elastic Block Storage (EBS) are supported.
       - Azure Premium Storage
       - GCE Persistent Disk

       See also the **API Connect v10.0.8.x Deployment WhitePaper** for information on limitations observed with other block storage solutions: https://community.ibm.com/community/user/integration/viewdocument/ibm-api-connect-v1008x-deploymen?CommunityKey=2106cca0-a9f9-45c6-9b28-01a28f4ce947&tab=librarydocuments

     - Local volume storage

       Management subsystem and Developer Portal subsystem
       Local volume storage is not recommended for the Management subsystem and Developer Portal subsystem because it has severe performance impacts for high availability deployments, and for pod allocation.
       Note also that local volume storage is not available in most cloud environments, and might incur limitations in disaster recovery scenarios, since it is tied to the node on which the pod is run. This means that use of LVS might be adequate for deployments with a one replicaprofile, but inadequate for deployments with a three replica profile.

       Analytics subsystem
       For Analytics subsystems, transactions per second (TPS) is three times faster with local volume storage than with Ceph block storage. In a production scenario, you will have multiple analytics-storage (OpenSearch) nodes forming a storage cluster. OpenSearch will manage data replication across its cluster and ensure high availability, thus mitigating possible local volume storage drawbacks with disaster recovery.

     Non-supported storage
     - NFS
       API Connect v10 cannot be deployed on NFS.

     - GlusterFS
       GlusterFS is not recommended as a storage option due to severe performance degradation and in some cases, loss of data. There are known GlusterFS issues that affect OpenSearch (which is used in the API Connect analytics service), the Developer Portal and the Management subsystem

     - IBM Spectrum Scale

This storage class does not support block storage.

- Storage class configuration:
  In your Kubernetes cluster configuration, you must create storage classes with the setting:

  ```
  volumeBindingMode: WaitForFirstConsumer
  ```

  This setting is needed to avoid volume node **affinity** conflicts, such as those caused by **requiredPodAntiAffinity** restrictions. If **WaitForFirstConsumer** is the binding mode, PVCs (PersistentVolumeClaims) are only bound once the pod is actually created.

  By contrast, when the binding mode is immediate (**volumeBindingMode: Immediate**), the PVCs are bound to PVs (PersistentVolumes) as soon as the PV is created.

  Example: When deploying to a multi-zone cluster, you must use StorageClass with **WaitForFirstConsumer** because when binding mode is immediate, successful deployment is indeterminate because of interactions between pod/node affinity and the Kubernetes provisioning of the PV on the right node where the pod is being provisioned.

  For more information, see "Volume Binding Mode" on https://kubernetes.io/docs/concepts/storage/storage-classes/.

  Note: During deployment, you are required to specify the name of the storage class you created. You can either use the setting **storageClassName: $STORAGE_CLASS** in the applicable CR (such as apiconnect top-level CR or an individual subsystem CR), or you can use a configuration UI such as Platform Navigator UI or OpenShift Container Platform (OCP) UI.
- When the Analytics service is configured to store data, (that is, it is not configured for ingestion-only), the service depends on OpenSearch, which requires map counts higher than the operating system defaults. See: Installing the analytics subsystem.
  If you are deploying on OpenShift, the map count is preconfigured (**vm.max_map_count = 1027580**) with a value that is sufficiently large for OpenSearch so you do not need to modify this setting.

- Ensure that your Kubernetes deployment addresses known security vulnerabilities with SSH to prevent the use of weak SSH Message Authentication Code (MAC) and Key exchange algorithms (KexAlgorithms) with TCP over port 22. Use of weak algorithms can allow an attacker to recover the plain text message from the encrypted text. If you have not yet addressed the security vulnerabilities with weak MACs and KexAlgorithms, update your configuration manually by adding the following lines to /etc/ssh/sshd_config:

  ```
  KexAlgorithms curve25519-sha256@libssh.org,diffie-hellman-group-exchange-sha256
  MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
  ```

- IBM API Connect requires a number of container registry repositories to be added to your container registry service if automatic repository creation is not supported. Follow the procedure in Step 4 of Obtaining product files.

- Logging:
  - Configure a remote server for logging. See Logging. Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.
  - Configure the log rotation by setting the **max-size** and **max-files** values to a setting appropriate for your deployment. In a Kubernetes deployment, insufficient values for max-size and max-files can cause logs to grow too large and eventually force pods to restart.
    For more information, visit the Docker documentation and search for "JSON File logging driver".

3. Ensure your deployment meets the DNS requirements for API Connect domain names, host names, and endpoints.
   You specify endpoints when you edit the custom resource templates for each subsystem, and when you use the Cloud Manager UI to configure the services for your cloud. The domain names you use for the endpoints must be recognized by your DNS configuration. DNS entries must meet these requirements:

   Important: For API Connect on native Kubernetes and OpenShift, do not use coredns 1.8.1 through 1.8.3. These releases have a defect that can prevent pods for Developer Portal from starting. See https://coredns.io/.
   - Endpoints cannot contain the underscore character `"_"` or uppercase characters.
   - Host names that are used to create endpoints cannot contain the underscore character `"_"` or uppercase letters.
   - DNS must be configured with domain names that correspond to the endpoints configured at installation time for each subsystem.
   - Host names and DNS entries may not be changed on a cluster after the initial installation.
   - Kubernetes ingress limits the character set for DNS names to not support the underscore character `"_"`. This means you cannot specify underscores in domain names that are used as endpoints. For example, **my_domain.abc.com** and **my.domain_abc.com** are not supported for **<xxx>.<hostname>.<domainname>**, and will cause an error:

     ```
     Invalid value: "my_domain.abc.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.',
     and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is
      '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*')
     ```

   - We recommend that you keep a record of the DNS entries and endpoint names, as you will need to map the DNS entries and use the same endpoints when restoring a backup of the management database. Note that endpoints are FQDNs, entered in all lowercase.
   - Specifying domain names when deploying CRs (custom resources) for each subsystem:
     The custom resource templates provide endpoint settings that consist of a default endpoint prefix and a variable **$STACK_HOST** that you set to specify your domain name, as part of Installing the API Connect subsystems.

   Table 1. Endpoints with domain names that must be configured in DNS

Default endpoint name	Description
admin.$STACK_HOST	Cloud Manager URL endpoint for the Management subsystem
manager.$STACK_HOST	API Manager URL endpoint for the Management subsystem
api.$STACK_HOST	Platform REST API Endpoint for admin and provider APIs
consumer.$STACK_HOST	Platform REST API Endpoint for consumer APIs for the Management subsystem.
rgw.$STACK_HOST	Gateway Endpoint for API invocation for DataPower API Gateway
rgwd.$STACK_HOST	Gateway Management Endpoint for DataPower API Gateway
gw.$STACK_HOST	Gateway Endpoint for API invocation for DataPower Multi-Protocol Gateway (v5-compatible)
gwd.$STACK_HOST	Gateway Management Endpoint for DataPower Multi-Protocol Gateway (v5-compatible)
ai.$STACK_HOST	Analytics ingestion endpoint for the Analytics subsystem
api.portal.$STACK_HOST	Developer Portal admin endpoint
portal.$STACK_HOST	Developer Portal UI endpoint

- Specifying endpoints using the Cloud Manager interface
  After initial deployment of the Kubernetes custom resource for each subystem, you will also enter the endpoints in the Cloud Manager user interface when defining each service as part of Defining your topology.

4. The Cloud Provider for the target Kubernetes platform must provide Ingress Controller support for SSL Passthrough.
   For example, if the Cloud Provider uses or suggests the use of the NGINX Community Ingress, then the **`--enable-ssl-passthrough`** flag would need to be provided at runtime, as described at https://kubernetes.github.io/ingress-nginx/user-guide/tls/#ssl-passthrough. For IBM Cloud Kubernetes Service, see https://cloud.ibm.com/docs/containers?topic=containers-ingress-user_managed..
5. If you plan to deploy API Connect on Kubernetes with DataPower Gateway in a *non-Kubernetes* environment, such as a DataPower appliance, review the API Connect requirements for operation with DataPower Gateway:
   - When deploying with a DataPower appliance, configure a Gateway Service Management Endpoint and API invocation Endpoint in DataPower. See *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.
   - Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
     Note:
     Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.
6. If you plan to deploy the API Connect management subsystem and the DataPower Gateway subsystem on a Kubernetes deployment, managed by the DataPower and API Connect Operators, you can use any combination of API Connect 10.0.8.x with DataPower Gateway 10.6.0.y or DataPower API Gateway 10.6.0.y.
7. Observe namespace restrictions:
   - OpenShift
     Only one top level CR (APIConnectCluster) can be deployed in each namespace.
   - Cloud Pak for Integration
     In the Platform Navigator UI, only one APIConnect capability can be deployed in each namespace.
   - Native Kubernetes
     Only one instance of a subsystem can be deployed in each namespace. Deploying multiple similar subsystems in a single namespace is not supported. For example, there is no support for deploying two management subsystems, **`mgmt1`**, **`mgmt2`** in a single namespace where API Connect operator is installed.
8. The following kernel or Kubernetes node limits for the Developer Portal subsystem must be set correctly:
   - Ensure that your kernel or Kubernetes node has the value of its **`inotify`** watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a **`non-ready`** state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of **`inotify`** watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take **`inotify`** watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.
   - Ensure that your kernel or Kubernetes node has a value of **`nproc`** (maximum number of processes) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow all of the portal processes to execute. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls, you might need as many as 125205. If the number is too low, you will see errors like **`"fork: retry: Resource temporarily unavailable"`** in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.
   - Ensure that your kernel or Kubernetes node has a value of **`nofiles`** (maximum number of open file descriptors) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow the portal to open all of the files that it requires. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls and portal web sites, you might need as many as 1048576. If the number is too low, you will see errors like **`"too many open files"`** in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.

- **IBM API Connect Version 10 software product compatibility requirements**
  Ensure that you install the minimum API Connect operating system requirements. Use the IBM Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- **API Connect licenses**
  When you install a new version of API Connect, you must accept a license for the API Connect program that you purchased.

IBM API Connect Version 10 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

Generating a Software Product Compatibility Report

To generate an API Connect requirements report, complete the following steps:

1. Open the Detailed system requirements for a specific product page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.
5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

API Connect licenses

When you install a new version of API Connect, you must accept a license for the API Connect program that you purchased.

When you install or upgrade API Connect, the procedures include instructions for specifying your license. Be sure to specify a license ID from the version of API Connect that you are installing or are upgrading to.

The licenses in Table 2 are used as the master mod-level license for all API Connect Fix Pack and security roll-up releases in this stream. There are no changes to license terms, only updates to open source notices documented in the notes for each.

Table 1. API Connect 10.0.11.0 licenses

License ID	Program Name	URL
L-KYAL-S3RCBM	IBM API Connect Enterprise V10.0.11.0	https://ibm.biz/BdbdMg
L-JVUW-LSTB9R	IBM Cloud Pak for Integration - API Calls 16.1.2	https://ibm.biz/BdnM2T
L-SBZZ-CNR329	IBM webMethods Hybrid Integration Subscription 11.2	https://ibm.biz/BdnaFK

Deployment procedures

You can use these procedures to deploy API Connect on either native Kubernetes or OpenShift.

- **Obtaining product files**
  Obtain the product files, upload the images to a Docker registry, and decompress the operators and templates.
- **Deploying on Kubernetes**
  Use the procedures in this section to install API Connect on native Kubernetes distributions.
- **Deploying on OpenShift and Cloud Pak for Integration**
  You can install API Connect in an OpenShift environment or as the API Management capability in IBM Cloud Pak for Integration.

Obtaining product files

Obtain the product files, upload the images to a Docker registry, and decompress the operators and templates.

Before you begin

- Ensure you have supported hardware and software. See IBM API Connect Version 10 software product compatibility requirements.
- Complete the Deployment requirements
- Install and run Docker on the local machine being used for API Connect installation. Log in to your image registry.

About this task

From the IBM Fix Central site, download the Docker image-tool file of the API Connect subsystems. Next, you will upload the image-tool file to your Docker local registry. If necessary, you can populate a remote container registry with repositories. Then you can push the images from the local registry to the remote registry.

You will also download the Kubernetes operators, API Connect Custom Resource (CR) templates, and Certificate Manager, for use during deployment configuration.

Note: If you have API Connect installed and want to upgrade your release version, follow the upgrade instructions in Upgrading on Kubernetes.

Procedure

1. Obtain the API Connect files:
   a. Go to the What's New in the latest version information page.
   b. Locate the Note: *You can access the latest files from <URL link>*. Select the *<URL link>* to go directly to the Announce page on Fix Central, where you can download files for the *latest version* of API Connect.

   The following files are used for initial deployment on native Kubernetes:

   IBM API Connect *<version>* for Containers
   : Docker images for all API Connect subsystems

   IBM API Connect *<version>* Operator Release Files for Containers
   : Kubernetes operators and API Connect Custom Resource (CR) templates

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command line utility. Packaged standalone, or with API Designer:
     - IBM API Connect *<version>* Toolkit for *<operating_system>*
     - IBM API Connect *<version>* Toolkit Designer for *<operating_system>*

     Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment. See Testing an API with the Local Test Environment

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files that you can use to verify the integrity of your downloads.

2. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
3. Load the image-tool image in your Docker local registry. The image is contained in the IBM API Connect *<version>* for Containers file. For example:

   ```
   docker load < apiconnect-image-tool-<version>.tar.gz
   ```

   Ensure that the registry has sufficient disk space for the files.

4. If your Docker registry requires repositories to be created before images can be pushed, create the repositories for each of the images listed by the image tool. (If your Docker registry does not require creation of repositories, skip this step and go to Step 5.)

a. Run the following command to get a list of the images from image-tool:

```
docker run --rm apiconnect-image-tool-<version> version  --images
```

b. From the output of each entry of the form `<image-name>:<image-tag>`, use your Docker registry repository creation command to create a repository for `<image-name>`.
For example in the case of AWS ECR the command would be for each `<image-name>`:

```
aws ecr create-repository --repository-name <image-name>
```

5. Upload the image:
   - If you do not need to authenticate with the docker registry, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url>
     ```

   - Otherwise, if your docker registry accepts authentication with username and password arguments, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url> --username <username> --password <password>
     ```

     Tip: On AWS, where the password can be a long string, you can substitute *<password>* with

     ```
     `aws ecr get-login-password --region region`
     ```

   - Otherwise, such as with IBM Container Registry, if you need the image-tool to use your local Docker credentials, first authenticate with your Docker registry, then upload images with the command:

     ```
     docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
     ```

     Note: The previous command does not work on macOS if Docker is configured to use the `osxkeychain` credential store. In this case, complete the following steps:
     - Disable **Docker > Preferences... > Securely store Docker logins in the macOS keychain**.
     - Inspect `~/.docker/config.json` to make sure that it does not contain `"credSstore": "osxkeychain"`, as some versions of Docker-for-mac may handle the setting correctly per https://github.com/docker/for-mac/issues/4192.
     - Authenticate with the Docker registry you intend to upload to.
     - Run the command:

       ```
       docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
       ```

     - Once the upload of images is successful you may enable **Docker > Preferences... > Securely store Docker logins in the macOS keychain**.

Docker authentication notes:
- Both HTTPS and HTTP are supported. Best practice for Docker registry security is to use HTTPS by utilizing standard Docker load tools, to ensure your images and platform are protected. However, when necessary you can use HTTP by specifying the `--tls-verify=false` flag.
- When using a Docker registry on `localhost`, you might encounter that the image-tool Docker container is on the Docker network and typically without access to `localhost`. You can workaround this issue by using the `--network host` argument to the Docker command. Note that `--network host` is a Docker argument, not an image-tool argument.
- Example of using `--network host` and `--tls-verify=false`:

  ```
  $ docker run -d -p 5000:5000 --name registry registry:2
  ...
  $ docker run --rm --network host apiconnect-image-tool-<version> upload localhost:5000 --tls-verify=false
  ...
  ```

Providing a certificate for verification, or disabling TLS verification

See the sample output of the tool usage for options to provide a certificate for verification or to disable TLS verification:

```
$ docker run --rm apiconnect-image-tool-<version> upload --help
upload docker images

Usage:
  image-tool upload REGISTRY [flags]

Flags:
      --cert-dir string   Directory with destination registry certificate tls.crt file
      --username string   User name
  -h, --help              help for upload
      --password          password for <username>
      --tls-verify        Verify TLS on destination registry (default true)

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Notes:

- `--username=<username>` and `--password=<password>` can be used to specify credentials for authentication with the destination Docker registry.
- `--tls-verify=false` can be used to disable verification of the destination Docker registry certificate
- `--cert-dir <path>` can be used to provide a `tls.crt` file to be used for validation of the destination Docker registry certificate. For example:

  ```
  docker run --rm -v <path-to-folder-with-tls.crt-file>:/cert apiconnect-image-tool-<version> upload <registry> --
  cert-dir /cert
  ```

6. Download the file IBM® API Connect *<version>* Operator Release Files for Containers
   a. Decompress the downloaded Operator Release Files for Containers
   Contents:

   - API Connect Operator operator custom resource definition (CRDs).
   - API Connect Operator Deployment and required resources CRDs.

- API Connect Operator Deployment and required resources CRDs, for multiple-namespace installations.
- DataPower Gateway Operator operator custom CRDs.
- API Connect custom resource templates, and Certificate Manager

The Operator Release Files for Containers files will be used later in deployment instructions.

Note: The Operator Release files may include catalog and operator source for OpenShift. These files are not used when deploying on native Kubernetes.

b. To access the API Connect custom resource templates and Certificate Manager, decompress the archive **helper_files.zip**.
The zip file contains custom resource templates for:

- Deployment of each subsystem.
- Backup and restore of each subsystem
- Custom certificates, both external and internal, for either standard deployments or 2-site HA deployments
- Certificate support for multi-namespace deployments
- Multi-site secret generation in a two data center deployment on Kubernetes.
- Ingress Issuer and Subsystem Certificates Resources, for either standard deployments or 2-site HA deployments
- Setting an administrator secret for DataPower Gateway

The templates will be used later in deployment instructions.

What to do next

Continue with Deploying operators and cert-manager.

- **Verifying the integrity of IBM product files**
  You can verify the integrity of files to ensure that they originated from IBM and are not modified.

Verifying the integrity of IBM product files

You can verify the integrity of files to ensure that they originated from IBM and are not modified.

Before you begin

Import the public key so you can use it to verify files. You only need to import the public key once.

1. Install **gpg** (GNU Privacy Guard), available at https://www.gnupg.org/.
2. Create a file called PRD0003216key.pub.gpg and copy the following content into the file:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

mQINBGP+Fr0BEADz5ppiT+RhdOw+PihTcMirn4umuinsTU66qpWZES+aLmSjw3Ik
BUlD0GQkJDn6qqZyMhYUwaLVicTtLrChykzfkd3Cdzis0WRsCJNdpuLIV9OS8L9a
zCMn09lHQgaf4+eYpDYOm5OBmRP+wqP3iJrC9dVho8oRaFUBmWi30Hak+YE8xBDU

=1Zs0
-----END PGP PUBLIC KEY BLOCK-----
```

3. Run the following command to import the public key to **gpg**:

```
gpg --import PRD0003216key.pub.gpg
```

For example:

```
$ gpg --import PRD0003216key.pub.gpg
gpg: key 020ED6B5DBE65F3B: public key "APIConnect <psirt@us.ibm.com>" imported
gpg: Total number processed: 1
gpg:               imported: 1
```

4. Run the following command to verify that the key was imported successfully:

```
gpg --list-key --fingerprint APIConnect
```

Make sure that the output of the command matches the following information:

```
$ gpg --list-key --fingerprint APIConnect
pub   rsa4096 2023-02-28 [SCE]
      39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
uid           [ unknown] APIConnect <psirt@us.ibm.com>
```

Procedure

Complete the following steps to verify product files for API Connect:

1. Visit IBM Fix Central and download the appropriate signatures_*<version>*.zip file for the version of API Connect that you will install or upgrade to. Extract the signatures_*<version>*.zip file to the folder containing the files that you want to verify.
2. Verify individual API Connect files to compare each file's signature with the fingerprint of the public key. To verify a file, run the following command:

   ```
   gpg --verify <file_to_verify>.asc
   ```

   For example, to verify helper_files.zip, ensure that it is stored in the same folder as the signatures file and run the following command:

   ```
   gpg --verify helper_files.zip.asc
   ```

   Example of a successful verification:

   ```
   $ gpg --verify helper_files.zip.asc
   gpg: assuming signed data in 'helper_files.zip'
   gpg: Signature made Mon 28 Sep 17:35:17 2020 PDT
   gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
   gpg: Good signature from "APIConnect <psirt@us.ibm.com>" [unknown]
   gpg: WARNING: This key is not certified with a trusted signature!
   gpg:          There is no indication that the signature belongs to the owner.
   Primary key fingerprint: 39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
   ```

   Example of a failed verification:

   ```
   gpg: assuming signed data in 'helper_files.zip'
   gpg: Signature made Tue 11 Jul 2023 09:28:02 PM PDT
   gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
   gpg: BAD signature from "APIConnect <psirt@us.ibm.com>" [unknown]
   ```

Deploying on Kubernetes

Use the procedures in this section to install API Connect on native Kubernetes distributions.

- **Deploying operators and cert-manager**
  Deploy the Kubernetes operator files and install cert-manager.
- **Installing the API Connect subsystems**
  Deploy the API Connect subsystem custom resources.
- **Installing a two data center deployment on Kubernetes**
  Additional installation instructions for a two data center disaster recovery (2DCDR) deployment on Kubernetes.
- **Troubleshooting installation on Kubernetes**
  Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on Kubernetes

Deploying operators and cert-manager

Deploy the Kubernetes operator files and install cert-manager.

Before you begin

You must have completed the following installation tasks before you deploy the operators:

1. Review the installation requirements. See Deployment requirements.
2. Obtain the API Connect product files. See Obtaining product files.

About this task

Table 1 lists the operators used for installing and upgrading API Connect.

Table 1. Operators and operands for API Connect

API Connect version	API Connect Operator version	DataPower Operator version
10.0.11.0	6.2.0	1.16.0

Note: There can be only one instance of the API Connect operator in your Kubernetes environment. You cannot have multiple namespaces each with their own API Connect operator.

You can run the API Connect operator and subsystems at different versions. The following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version

API Connect Operator version	API Connect version
6.2.0	• 10.0.11.0
6.1.0	• 10.0.10.0
6.0	• 10.0.9.0
5.3-sc2	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

The deployment procedures differ depending on whether your deployment cluster uses a single namespace or multiple namespaces. Follow the instructions that apply to your deployment cluster:

- **Deploying operators in a single-namespace API Connect cluster**
  Deploy the Kubernetes operator files in a single namespace cluster.
- **Deploying operators in a multi-namespace API Connect cluster**
  Deploy the Kubernetes operator files in multi-namespace cluster.
- **Installing cert-manager and certificates in a two data center deployment**
  Additional instructions explaining how to install a cert-manager and certificates in a two data center disaster recovery deployment on Kubernetes.
- **Customizing certificates during installation on Kubernetes**
  How to customizing your user-facing and internal API Connect certificates during installation.

Deploying operators in a single-namespace API Connect cluster

Deploy the Kubernetes operator files in a single namespace cluster.

Before you begin

- Ensure you completed the prerequisite tasks for installing operators. See Deploying operators and cert-manager.
- Be sure to review your strategy for using certificates with API Connect. See Deployment requirements.

Note: If you are deploying a multi-namespace API Connect cluster, do not use these instructions. Instead, go to Deploying operators in a multi-namespace API Connect cluster.

Procedure

1. Ensure `KUBECONFIG` is set for the target cluster:

   ```
   export KUBECONFIG=<path_to_cluster_config_YAML_file>
   ```

   An example path is **`/Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml`**

2. Decide on a namespace to be used for installation.
   Create a new namespace in the Kubernetes cluster for your API Connect deployment, and avoid using the default **`namespace`** to ensure a successful installation.

   Run the following command to create a new namespace, replacing **`<namespace>`** with the name for your namespace:

   ```
   kubectl create ns <namespace>
   ```

   Note: Do not use the following reserved namespaces for your installation:
   - `default`
   - `openshift-*`
   - `kube-*`
3. Install a cert-manager.
   Cert-manager adds convenience to the generation and management of API Connect certificates. For more information about cert-manager, see Key Concepts: Cert-manager, Issuers, and Secrets.

   Note: If you are deploying a two data center disaster recovery deployment on Kubernetes, then do not do this step, follow the steps in Installing cert-manager and certificates in a two data center deployment, then return here.
   a. Obtain the certificate manager.
      API Connect uses cert-manager v1.18.2 of cert-manager, which is a native Kubernetes certificate management controller.

      You can obtain cert-manager v1.18.2 from the API Connect v10 distribution **`helper_files.zip`** archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.18.2

      b. Apply the CR:

      ```
      kubectl apply -f cert-manager-1.18.2.yaml
      ```

      Do not specify a custom namespace.

      See https://cert-manager.io/docs/release-notes/release-notes-1.18/.

      c. Wait for `cert-manager` pods to enter `Running 1/1` status before proceeding. To check the status:

      ```
      kubectl get po -n cert-manager
      ```

      There are 3 `cert-manager` pods in total.
4. Create a registry secret with credentials to be used to pull down product images.

Use the following command, replacing **<namespace>** with the namespace for your deployment, and replacing **<registry_server>** with the location of the Docker Registry where the installation product images were pushed:

```
kubectl create secret docker-registry apic-registry-secret
--docker-server=<registry_server>
--docker-username=<username@example.com> --docker-password=<password> --docker-email=<username@example.com> -n <namespace>
```

5. Create a registry secret for the DataPower registry with the credentials to be used to pull down product images.
   Use the following command, replacing **<namespace>** with the desired namespace for the deployment:

   ```
   kubectl create secret docker-registry datapower-docker-local-cred
   --docker-server=<docker_server> --docker-username=<username@example.com> --docker-password=<password> --docker-email=
   <username@example.com> -n <namespace>
   ```

6. Create a DataPower admin secret.
   Use the following command, replacing **<namespace>** with the desired namespace for the deployment:

   ```
   kubectl create secret generic datapower-admin-credentials --from-literal=password=admin -n <namespace>
   ```

   The admin secret will be used for **$ADMIN_USER_SECRET** when deploying the gateway CR.

7. If you are using a namespace other than the default, open **ibm-apiconnect.yaml** in a text editor. Replace each occurrence of **namespace:** default with **namespace: <namespace>**, where **<namespace>** is the name of the namespace you created for your API Connect deployment.
   For example, if your namespace is **api-connect-namespace**, you can replace **namespace:** default with **namespace: api-connect-namespace**.
8. Open **ibm-apiconnect.yaml** in a text editor. Replace the value of each **REPLACE-DOCKER-REGISTRY** with the location of the API Connect operator images, either uploaded to your own registry or pulled from a public registry.
   Additionally, update the **imagePullSecrets** section by replacing **DEFAULT_IMAGE_PULL_SECRET** with the registry secret name that was created in step 4

   For example, if your registry location is **my-registry.com** and your registry secret name is **apic-registry-secret**, you need to make the following changes:
   - Replace each occurrence of **REPLACE-DOCKER-REGISTRY** with **my-registry.com**.
   - Replace **DEFAULT_IMAGE_PULL_SECRET** with **apic-registry-secret**.

   ```
   serviceAccountName: ibm-apiconnect
   imagePullSecrets:
   - name: apic-registry-secret
   initContainers:
   - name: ibm-apiconnect-init
     image: my-registry.com/ibm-apiconnect-operator-
   init@sha256:0d3bbac7c67372ad013407a8049c69dbd08b1559b59a7606fcd87eb0f4519ce1
   ...
   containers:
   - name: ibm-apiconnect
     image: my-registry.com/ibm-apiconnect-operator@sha256:a7473ee26c252fca4931b682cd95d73b4149e4b5b773834408f9f22d0246a76c
   ```

9. If you want to include DataPower Gateway in your installation and are using a namespace other than the default, open **ibm-datapower.yaml** in a text editor. Replace each occurrence of namespace: default with **namespace: <namespace>**, where **<namespace>** is the name of the namespace you created for your API Connect deployment.
   For example, if your namespace is **api-connect-namespace**, you need to replace **namespace:** default with **namespace: api-connect-namespace**.
10. Open **ibm-datapower.yaml** in a text editor.
    a. Replace the placeholder **REPLACE-DOCKER-REGISTRY** with the location of the DataPower operator image, either uploaded to your own registry or pulled from a public registry.
       For example, if your registry location is **my-registry.com**, you need to replace **REPLACE-DOCKER-REGISTRY** with **my-registry.com**.
    b. Update the **IBM_ENTITLED_REGISTRY**, **IBM_FREE_REGISTRY_DATAPOWER**, and **IBM_FREE_REGISTRY_CPOPEN** values in the environment section with the registry address where the images were uploaded using the image-tool in Obtaining product files.
       For example, if you uploaded the images to **my-registry.com**, you need to update the values as follows:

       ```
       - name: IBM_ENTITLED_REGISTRY
         value: "my-registry.com/cp/datapower"
       - name: IBM_FREE_REGISTRY_DATAPOWER
         value: "my-registry.com/cp/datapower"
       - name: IBM_FREE_REGISTRY_CPOPEN
         value: "my-registry.com/cp/cpopen"
       ```

       Note:
       - The **IBM_ENTITLED_REGISTRY** value represents the registry address for the entitled DataPower images.
       - The **IBM_FREE_REGISTRY_DATAPOWER** value represents the registry address for the free DataPower images.
       - The **IBM_FREE_REGISTRY_CPOPEN** value represents the registry address for the CP Open images.
11. Install the ibm-apiconnect CRDs.

    ```
    kubectl apply --server-side --force-conflicts -f ibm-apiconnect-crds.yaml
    ```

12. Install the ibm-apiconnect Kubernetes deployment.

    ```
    kubectl apply -f ibm-apiconnect.yaml
    ```

13. If DataPower Gateway is desired in this installation, install the ibm-datapower Kubernetes deployment for DataPower Gateway, with the following command, replacing **<namespace>** with the desired namespace for the deployment (**-n <namespace>** may be omitted if default namespace is being used for installation):

    ```
    kubectl apply -f ibm-datapower.yaml -n <namespace>
    ```

    Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting install.

14. Install the **ingress-ca** Issuer to be used by **cert-manager**.
    Note:

If you are installing a two data center disaster recovery deployment, skip this step, and follow the steps in: Installing cert-manager and certificates in a two data center deployment.

a. Use the following command, replacing `<namespace>` with the desired namespace for the deployment:

```
kubectl apply -f ingress-issuer-v1.yaml -n <namespace>
```

The file `ingress-issuer-v1.yaml` is included in the release files contained in `helper_files.zip`

b. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

Example output indicating success:

```
NAME                          READY   SECRET                        AGE
analytics-ingestion-client    True    analytics-ingestion-client    70s
gateway-peering               True    gateway-peering               69s
gateway-service               True    gateway-service               69s
ingress-ca                    True    ingress-ca                    71s
portal-admin-client           True    portal-admin-client           71s
portal-tunnel-client          True    portal-tunnel-client          70s
```

The list of certificates might vary based on your deployment.

15. Continue with Installing the API Connect subsystems.

Deploying operators in a multi-namespace API Connect cluster

Deploy the Kubernetes operator files in multi-namespace cluster.

Before you begin

- Ensure you completed the prerequisite tasks for installing operators. See Deploying operators and cert-manager.
- Be sure to review your strategy for using certificates with API Connect. See Deployment requirements.

About this task

Note: If you are deploying a single-namespace API Connect cluster, do not use these instructions. Instead, go to Deploying operators in a single-namespace API Connect cluster.

- These instructions apply only to native k8s deployments. They do not apply to OpenShift deployments.
- The API Connect operator is deployed as a cluster-scoped operator which watches every namespace in the cluster. The API Connect operator can be installed in any namespace, although it is recommended that the operator is installed in its own dedicated namespace.
- The DataPower operator must be deployed in a namespace where gateway subsystem install is planned.
- Single `ingress-ca` certificate must be installed and used across the various namespaces where subsystems will be installed.

Procedure

1. Prepare your environment:
   a. Ensure `KUBECONFIG` is set for the target cluster:

   ```
   export KUBECONFIG=<path_to_cluster_config_YAML_file>
   ```

   An example path is `/Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml`

   b. Create namespaces for the subsystems that will be installed:
   - API Connect operator namespace
   - Gateway subsystem namespace
   - Management subsystem namespace
   - Portal subsystem namespace
   - Analytics subsystem namespace

   Note: The following namespaces are reserved and must not be used for your installation:
   - `default`
   - `openshift-*`
   - `kube-*`

   The following example values and deployment are used throughout these instructions:

   - An apiconnect operator is installed in `operator` namespace
   - A DataPower operator and gateway subsystem is installed in `gtw` namespace
   - The Management subsystem is installed in `mgmt` namespace
   - The Portal subsystem is installed in `portal` namespace
   - The Analytics subsystem is installed in `a7s` namespace

   c. Multi-namespace templates are provided in `helper_files.zip`, inside the `release_files.zip` you downloaded in Obtaining product files:

   ```
   helper_files_unpack/multi-ns-support/
   ```

2. Install cert-manager and configure certificates:
   Cert-manager adds convenience to the generation and management of API Connect certificates. For more information about cert-manager, see Key Concepts: Cert-manager, Issuers, and Secrets.

You can obtain cert-manager v1.18.2 from the API Connect v10 distribution **helper_files.zip** archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.18.2.

a. Install cert-manager v1.18.2, do not specify a custom namespace as cert manager will be installed in its own namespace.
Note: If you are deploying a two data center disaster recovery deployment on Kubernetes, then do not do this step, follow the steps in Installing cert-manager and certificates in a two data center deployment, then return here.

i. `kubectl apply -f cert-manager-1.18.2.yaml`

ii. Wait for cert-manager pods to enter `Running 1/1` status before proceeding. Use the following command to check:

```
kubectl -n cert-manager get po
```

There are 3 cert-manager pods in total.

b. Install `ingress-ca` certificate:
i. Locate `ingress-ca` certificate at `helper_files/multi-ns-support/ingress-ca-cert.yaml`
ii. Create `ingress-ca` certificate in one of the subsystems. For example, if we choose `mgmt` namespace:

```
kubectl -n mgmt apply -f ingress-ca-cert.yaml
```

c. Install common issuers on all the namespaces:
i. Locate `common-issuer.yaml` in `helper_files/multi-ns-support/`
ii. Create `common-issuer.yaml` in all namespaces:

```
kubectl create -f common-issuer.yaml -n mgmt
kubectl create -f common-issuer.yaml -n gtw
kubectl create -f common-issuer.yaml -n ptl
kubectl create -f common-issuer.yaml -n a7s
```

d. Obtain the `ingress-ca` secret created by cert manager and create the secret on all namespaces:
Note: The instructions in this step result in having a `selfsigning-issuer` in every namespace. This issuer is typically referenced by an API Connect CR in the namespace with:

```
...
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
...
```

This issuer (and associated root certificate) does not need to be the same in every namespace, nor does it need to be the same for 2 CRs in the same namespace. Each subsystem can use its own **selfsigning-issuer**, because it is only used for certificates that are internal to the subsystem.

To ensure that the ingress-issuer is in sync across namespaces, it should be backed by the same **ingress-ca** certificate. This enables, for example, APIM to use a client certificate that matches the CA of the portal-admin ingress endpoint. The sync is achieved by copying around the **ingress-ca** certificate in each namespace, as shown in the following steps. It does not matter that it is the same issuer, or whether it has a different name. However it is important is that the ingress-ca is the same for the all the "ingress-issuer" that are going to be used by the subsystems.

i. Make sure `ingress-ca` certificate READY status is set to true:

```
kubectl get certificate ingress-ca -n mgmt
NAME         READY   SECRET       AGE
ingress-ca   True    ingress-ca   9m24s
```

ii. Cert-manager creates a secret called `ingress-ca` in `mgmt` namespace which represents the certificate we created in Step 2.c.
iii. Use the following command to obtain the yaml format of the secret:

```
kubectl get secret ingress-ca -n <namespace-where-ingress-ca-cert-is-created> -o yaml > ingress-ca-secret-in-cluster.yaml
```

iv. Remove unwanted content from the secret yaml:

```
cat ingress-ca-secret-in-cluster.yaml | grep -v 'creationTimestamp' | grep -v 'namespace' | grep -v 'uid' | grep -v 'resourceVersion' > ingress-ca-secret.yaml
```

v. Create the secret using the YAML that you prepared in previous step on rest of the subsystem namespaces. In this example, in the `gtw`, `a7s` and `ptl` namespaces.

```
kubectl create -f ingress-ca-secret.yaml -n gtw
kubectl create -f ingress-ca-secret.yaml -n ptl
kubectl create -f ingress-ca-secret.yaml -n a7s
```

e. Install management certs in management namespace:
i. Locate `management-certs.yaml` in `helper_files/multi-ns-support/`
ii. Create `management-certs.yaml` in the `mgmt` namespace:

```
kubectl create -f management-certs.yaml -n mgmt
```

f. Install gateway certs in the gateway namespace:
i. Locate `gateway-certs.yaml` in `helper_files/multi-ns-support/`
ii. Create `gateway-certs.yaml` in the `gtw` namespace:

```
kubectl create -f gateway-certs.yaml -n gtw
```

3. Install the API Connect operator:
a. Install the ibm-apiconnect CRDs with the following command. Do not specify a namespace:

```
kubectl apply --server-side --force-conflicts -f ibm-apiconnect-crds.yaml
```

b. Create a registry secret with the credentials to be used to pull down product images with the following command, replacing **<*namespace*>** with the desired namespace for the API Connect operator deployment.

```
kubectl -n <namespace> create secret docker-registry apic-registry-secret
              --docker-server=<registry_server>
              --docker-username=<username@example.com> --docker-password=<password>
              --docker-email=<username@example.com>
```

- For example, replace **<*namespace*>** with **operator**.
- **docker-password** can be your artifactory API key.
- **-n <namespace>** may be omitted if **default** namespace is being used for installation

c. Locate and open **ibm-apiconnect-distributed.yaml** in a text editor of choice. Then, find and replace each occurrence of **$OPERATOR_NAMESPACE** with **<namespace>**, replacing **<namespace>** with the desired namespace for the deployment. In this example, the namespace is **operator**.

d. Also in **ibm-apiconnect-distributed.yaml**, replace all the instances of the placeholder string **REPLACE-DOCKER-REGISTRY** with the docker registry host location of the apiconnect operator image (either uploaded to your own registry or pulled from the public registry).

e. Install **ibm-apiconnect-distributed.yaml** with the following command

```
kubectl apply -f ibm-apiconnect-distributed.yaml
```

4. Install DataPower operator:
Deployment of the DataPower operator is only needed if you have at least one API Connect v10 Gateway subsystem (whether v5 compatible or not) to upgrade. If you are using DataPower in a different form factor such as an Appliance, you will not have an API Connect v10 Gateway subsystem to upgrade, and will not need the DataPower operator for your upgrade.

   Note: The DataPower Operator supports multiple instances of DataPower in the same cluster, separated by namespace. When deploying into multiple namespaces, ensure that any cluster-scoped resources are created with unique names for separate installations, such that they are not overwritten by subsequent installations. For example, DataPower cluster-scoped resources include **ClusterRoleBindings**.

   a. Create a registry secret for the DataPower registry with the credentials to be used to pull down product images with the following command, replacing **<namespace>** with the desired namespace for the deployment .(In this case **gtw**):

```
kubectl -n <namespace> create secret docker-registry datapower-docker-local-cred
              --docker-server=<registry_server>
              --docker-username=<username@example.com> --docker-password=<password>
              --docker-email=<username@example.com>
```

   - For example, replace **<*namespace*>** with **gtw**.
   - **docker-password** can be your artifactory API key.
   - **-n <namespace>** may be omitted if **default** namespace is being used for installation

   b. Create a DataPower admin secret, replacing **<namespace>** with the desired namespace for the deployment. For example, **gtw**. This secret will be used for **$ADMIN_USER_SECRET** later in the Gateway CR:

```
kubectl -n <namespace> create secret generic datapower-admin-credentials --from-literal=password=admin
```

   -n
   <namespace> may be omitted if **default** namespace is being used for installation.

   c. Locate and open **ibm-datapower-distributed.yaml** in a text editor of choice. Then, find and replace each occurrence of **default** with **<namespace>**, replacing **<namespace>** with the desired namespace for the deployment. For example, **gtw**.

   d. Install **ibm-datapower-distributed.yaml** with the following command:

```
kubectl -n <namespace> apply -f ibm-datapower-distributed.yaml
```

   Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting install.

5. Next, install the subsystems. Continue with Installing the API Connect subsystems.
Note: Unless otherwise stated, when performing the individual subsystem upgrades the **<*namespace*>** value of example **kubectl** commands for a given subsystem should be set to the namespace for the particular subsystem component they are acting on.

Installing cert-manager and certificates in a two data center deployment

Additional instructions explaining how to install a cert-manager and certificates in a two data center disaster recovery deployment on Kubernetes.

Before you begin

Before you install a cert-manager, you should know your strategy for using certificates with API Connect. Review the certificate requirements in Deployment requirements.

You should also have already completed Obtaining product files.

About this task

You must create certificates and keys for API Manager and the Developer Portal on both data centers, dc1 and dc2, and ensure that they match on both.

Use these instructions to install the supplied cert-manager and **ingress-issuer-v1.yaml**.

Note that **ingress-issuer-v1.yaml** is supplied by cert-manager.

Procedure

1. Install cert-manager.
Cert-manager adds convenience to the generation and management of API Connect certificates. For more information about cert-manager, see Key Concepts: Cert-manager, Issuers, and Secrets.

a. Obtain the certificate manager.
API Connect v10 uses cert-manager v1.18.2 of cert-manager, which is a native Kubernetes certificate management controller.

You can obtain cert-manager v1.18.2 from the API Connect v10 distribution **helper_files.zip** archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.18.2

b. Apply the CR:

```
kubectl apply -f cert-manager-1.18.2.yaml
```

Do not specify a custom namespace.

See https://cert-manager.io/docs/release-notes/release-notes-1.18/.

c. Wait for **cert-manager** pods to enter **Running 1/1** status before proceeding. To check the status:

```
kubectl get po -n cert-manager
```

There are 3 **cert-manager** pods in total.

2. Use the following steps to allow **ingress-ca** secrets to be the same on both data centers.
   a. On DC1 apply the file **ingress-issuer-v1-dc1.yaml**:

```
kubectl -n <namespace> apply -f ingress-issuer-v1-dc1.yaml
```

   b. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

   c. Export **ingress-ca** secret as a yaml from DC1:

```
kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
```

   d. Edit the **ingress-ca.yaml** file to remove all **annotations**, **labels**, **creationTimestamp**, **managedFields**, **manager**, **operation**, **time**, **resourceVersion**, **selfLink**, and **uid**. Also, if you are using a different **namespace** in DC2, then update the **namespace** field.
   e. Copy the **ingress-ca.yaml** from DC1 to DC2 and apply that file on DC2:

```
kubectl -n <namespace> apply -f ingress-ca.yaml
```

   f. On DC2 apply the file **ingress-issuer-v1-dc2.yaml**:

```
kubectl -n <namespace> apply -f ingress-issuer-v1-dc2.yaml
```

   g. Use the following commands to test that they are the same, on DC1 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d
> /tmp/ingress.pem.dc1
```

   h. On DC2 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d
> /tmp/ingress.pem.dc2
```

   i. To see the differences run:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

   The files should be the same.
   j. On DC2, to ensure that the certificates are working correctly and that they are using the **ingress-ca** secret. First, get the **portal-admin-client crt** file:

```
kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/admin-client.crt
```

   k. Test that it is working by using OpenSSL:

```
openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
```

   If it is working, you should see:

```
/tmp/admin-client.crt: OK
```

3. Continue with Deploying operators and cert-manager.

Customizing certificates during installation on Kubernetes

How to customizing your user-facing and internal API Connect certificates during installation.

Note: The recommended best practice is to not customize your internal certificates, and to customize your user-facing certificates after API Connect is installed. If you do customize certificates, then you are responsible for maintaining those certificates. Ensure that your custom certificates meet the requirements that are defined in the Certificate reference tables (which are subject to change in future fix packs), and that you renew them before they expire. Follow the topics in this section only if you must customize internal certificates.
To deploy API Connect with custom internal certificates, some additional preparation and steps are required before any API Connect subsystem CRs are created. Review the topics in this section before you start the installation process.

Remember: As per the DNS specification, wildcard certificates apply only to one level of subdomain and not more than that. For example, a certificate for ***.example.com** is not valid for **foo.bar.example.com**.
Customization of the following certificates is supported:

Table 1. Management subsystem certificates

Certificate name	Issuer	Description

`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have:
		• The same CA as the server certificate `analytics-ai-endpoint` on the analytics subsystem.
		• The common name must match the `spec.clientSubjectDN` in the analytics CR:
		`kubectl describe cert analytics-admin-client`
		`Spec:`
		`  Common Name:  a7s-ing-client`
		`kubectl get a7s -o yaml`
		`  spec:`
		`    clientSubjectDN: CN=a7s-ing-client`
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical.
		To update this certificate, use kubectl. Restart the `apim`, `taskmanager`, and `analytics-proxy` pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
		This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service.

`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have:
		• The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem.
		• The common name must match the `spec.adminClientSubjectDN` in the portal CR:
		`kubectl describe cert portal-admin-client`
		`Spec:`
		`  Common Name:  ptl-adm-client`
		`kubectl get ptl -o yaml`
		`  spec:`
		`    adminClientSubjectDN: CN=ptl-adm-client`
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
		This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service.

`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the `apim` and `taskmanager` pods after update. This certificate must have the same CA as the `gwv6-manager-endpoint or gw-gateway-manager` certificate on the gateway. This certificate is loaded by the management subsystem into the `Gateway management client TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the gateway, then create a new profile and specify it when you register the gateway service.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.

Table 2. Analytics subsystem certificates

Certificate name	Issuer	Description
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint in the `mtls-gw` pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the `analytics-ai-endpoint` certificate. If this certificate is updated, restart the `mtls-gw` pod for the update to take effect.

Table 3. Gateway certificates

Certificate name	Issuer	Description
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on the management subsystem If you update this certificate, then all gateway pods are restarted automatically.

Certificate name	Issuer	Description
`gwv5-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The **`gatewayManager`** endpoint certificate for the v5 compatible gateway. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the **`gateway-client-client`** certificate on management subsystem If you update this certificate, then all gateway pods are restarted automatically.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.
`gwv5-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.

Table 4. Portal subsystem certificates

Certificate name	Issuer	Description
`portal-admin or ptl-director or portal-director`	`ingress-issuer`	Server certificate used on the **`portalAdminEndpoint`**. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the **`portal-admin-client`** certificate. This certificate must have the same CA as the **`portal-admin-client`** certificate on the management subsystem. This certificate is used by the **`portal-nginx`** pod.
`portal-web`	`ingress-issuer`	The server certificate used on the **`portalUIEndpoint`**. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default **`portal-web`** certificate is issued by the **`ingress-issuer`**, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the **`portal-web`** ingress (**`portal-web`** route on OpenShift®).

Table 5. Internal intra-subsystem certificates

Certificate name	`spec.customCertificates` name	Description
`management-ca`	`caCertificate`	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using **`in-cluster`** communication. See In-cluster service communication between subsystems
`portal-ca`	`caCertificate`	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.
`analytics-ca`	`caCertificate`	The issuer for the **`analytics-client`** and **`analytics-server`** certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If you update this certificate, you must then update the **`analytics-client`** and **`analytics-server`** server certificates, and then ensure that the following pods are restarted: • **`storage`**- Restarts automatically. • **`warehouse`**- Restarts automatically. • **`ingestion`**- Restarts automatically. • **`director`**- Restart manually.
`management-client`	`clientCertificate`	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
`portal-client`	`clientCertificate`	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.
`analytics-client`	`clientCertificate`	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, then the **`storage`**, **`warehouse`** and the **`ingestion`** pods restart automatically. You must manually restart the **`director`** pod.
`management-server`	`serverCertificate`	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate. Required DNS names within the SAN section are: **`*.<namespace>`** **`*.<namespace>.svc`** **`*.<namespace>.svc.cluster.local`** **`*.<instance name>-server.<namespace>.svc`** **`*.<instance name>-server.<namespace>.svc.cluster.local`** **`<instance name>-server`**

Certificate name	spec.customCertificates name	Description
portal-server	serverCertificate	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. Required DNS names within the SAN section are: *.<namespace> *.<namespace>.svc *.<namespace>.svc.cluster.local *.<instance name>-server.<namespace>.svc *.<instance name>-server.<namespace>.svc.cluster.local <instance name>-server *.<instance name>-<site name>-db-all.<namespace>.svc *.<instance name>-<site name>-www-all.<namespace>.svc *.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local *.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local *.<namespace>.svc.cluster.local <instance name>-db #<remote portal CR name>-db # For 2DCDR only. <*instance name*> and <*remote portal CR name*> are truncated if more than 15 characters. This certificate is used by all portal pods.
analytics-server	serverCertificate	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. Required DNS names within the SAN section are: *.<namespace> *.<namespace>.svc *.<namespace>.svc.cluster.local *.<instance name>-server.<namespace>.svc *.<instance name>-server.<namespace>.svc.cluster.local <instance name>-server <instance name>-storage <instance name>-director <instance name>-ingestion <instance name>-mtls-gw <instance name>-storage-os-master <instance name>-warehouse If this certificate is updated, then the **storage**, **warehouse** and **ingestion** pods restart automatically. Manually restart the **director** pod.
db-server	dbServerCertificate	Intra-subsystem certificate for the management database.
natscluster-mgmt	NATSTLSCertificate	Intra-subsystem certificate for the **nats** pods.
db-client-postgres	dbClientPostgres	Intra-subsystem certificate for the management database subsystem.
db-client-apicuser	dbClientApicuser	Intra-subsystem certificate for the management database subsystem.

To see the complete list of TLS certificates, see API Connect TLS certificates.

Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.
You can replace the default certificates with certificates that you already own, for example DigiCert certificates, or generate new custom certificates by using software such as cert-manager.

- If you have your own certificates, see Generating custom certificates manually.
- If you do not have your own custom certificates, and you want to use cert-manager to generate custom certificates, see Generating custom certificates using cert-manager.

If you want to customize API Connect internal certificates (the certificates for communication within API Connect components), then you must customize all of them, but you do not need to create all of them yourself. Any custom internal certificates that are not named in your subsystem CRs are generated automatically during installation. You cannot convert an existing API Connect installation to use custom internal certificates, these certificates must be configured at installation.

Setting an encryption-secret for the management database using OpenSSL

You can optionally create an encryption-secret for the management database. If you do not create an encryption-secret, then it is created automatically for you.

1. The encryption-secret is a secure random bytes password that is used for field level encryption in the management database. You can generate 128 random bytes using the following command in OpenSSL:

   ```
   openssl rand -out /path/to/secret/encryption-secret.bin 128
   ```

2. Use kubectl to put the generated secret into **management-encryption-key**:

   ```
   kubectl create secret generic management-encryption-key -n <namespace>
         --from-file=/path/to/secret/encryption_secret.bin
   ```

   where **<namespace>** is the namespace where the management CR is going to be created)

3. Make sure that in management_cr.yaml, **encryptionSecret.secretName** points to the name of the secret created in the previous step.

Important: Back up the encryption-secret.bin file to a safe location. If this file is lost, then it is not possible to access the management database or its backups.

  Steps to configure API Connect subsystem CR YAML files to deploy them with custom certificates.

Generating custom certificates using cert-manager

Generate custom certificates using cert-manager.

About this task

If you do not have your own custom certificates that you can provide for the installation, you can prepare a YAML file with certificate definitions that cert-manager can use to generate the required certificates.
Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.

Procedure

1. Download and install cert-manager v1.18.2 from https://github.com/cert-manager/cert-manager/releases/tag/v1.18.2.
2. Open the helper_files/custom-certs-external.yaml in an editor.
   To locate the custom-certs-external.yaml file, see Obtaining product files.
3. In custom-certs-external.yaml, replace all instances of `example.com` with the domain for your API Connect deployment.
4. Apply the custom-certs-external.yaml file in your API Connect namespace.

   ```
   kubectl -n <namespace> apply -f custom-certs-external.yaml
   ```

5. Optional: If you want to customize the internal certificates with cert-manager, then follow these steps.
   Note: It is not recommended to customize internal certificates because it adds complexity and increases the maintenance overhead of your API Connect deployment. It is not possible to customize a subset of the internal certificates in a subsystem CR. If you want to customize any of the internal certificates in a subsystem CR, then you must customize them all.
   Use the custom-certs-internal.yaml file, which can be found in the `helper_files` installation archive. For more information, see Obtaining product files.

   a. Decide on a site name for your management subsystem. The `db-server-certificate` requires a site-name. Update the custom-certs-internal.yaml file with your site name and namespace.
   b. Apply the updated custom-certs-internal.yaml file in your API Connect namespace:

      ```
      kubectl -n <namespace> apply -f custom-certs-internal.yaml
      ```

6. Verify that the certificates and their corresponding secrets were created:

   ```
   kubectl -n <namespace> get certificate
   kubectl -n <namespace> get secret
   ```

What to do next

Configure your subsystem CR YAML files to use your custom certificates: Deploying API Connect subsystems with custom certificates.

Generating custom certificates using cert-manager in a two data center deployment

Generate custom certificates using cert-manager in a two data center disaster recovery deployment on Kubernetes.

About this task

The following example of providing custom certificates uses cert-manager to generate them.

Procedure

1. Set `KUBECONFIG` for the target cluster:

   ```
   export KUBECONFIG=<path_to_cluster_config_YAML_file>
   ```

   Example path:

   ```
   /Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml
   ```

2. Install cert-manager:
   a. Download v1.18.2 from https://github.com/cert-manager/cert-manager/releases/tag/v1.18.2.
   b. Install cert-manager. Do not specify a namespace:

      ```
      kubectl apply -f cert-manager.yaml
      ```

   c. Check the status of the `cert-manager` pods:

      ```
      kubectl -n cert-manager get pods
      ```

Wait for **cert-manager** pods to enter **Running 1/1** status before proceeding. Cert-manager has 3 pods in total.

3. Set up the customized external certificates:
   For quick setup, you can use the provided YAML files that are included in the **helper_files**, see Deploying operators and cert-manager. The YAML for the active data center (DC1) is called **custom-certs-external-dc1.yaml** and the YAML for the warm-standby data center (DC2) is called **custom-certs-external-dc2.yaml**.

   a. Open **custom-certs-external-dc1.yaml** and **custom-certs-external-dc2.yaml** in a text-editor. Find and replace each occurrence of **example.com** with the ingress subdomain for your API Connect deployment.
   b. Ensure that the management CR for DC1 is ready to be installed. Make a note of the **hostname** of the site.
   c. In **custom-certs-external-dc1.yaml** find **spec.dnsNames**
      For example, in DC1:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: dc1-mgmt-replication
spec:
  commonName: dc1-mgmt-replication
  secretName: dc1-mgmt-replication
  dnsNames:
  - <INSERT SITE HOSTNAME HERE. THIS WILL BE THE SAME VALUE AS IN THE MANAGEMENT CR spec.multiSiteHA.hosts.name for
site 1>
  issuerRef:
    name: ingress-issuer
  usages:
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

   d. Replace the line that begins **- <INSERT SITE HOSTNAME HERE** with - *hostname of the site*.
   e. Ensure that the management CR for DC2 is ready to be installed. Make a note of the **hostname** of the site.
   f. In **custom-certs-external-dc2.yaml** find **spec.dnsNames** and replace the line that begins **- <INSERT SITE HOSTNAME HERE** with - *hostname of the site*.
   g. Ensure that the portal CR for DC1 is ready to be installed. Make a note of the **hostname** of the site.
   h. In **custom-certs-external-dc1.yaml** find **spec.dnsNames**
      For example, in DC1:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: dc1-ptl-replication
spec:
  commonName: dc1-ptl-replication
  secretName: dc1-ptl-replication
  dnsNames:
  - <INSERT SITE HOSTNAME HERE. THIS WILL BE THE SAME VALUE AS IN THE PORTAL CR spec.multiSiteHA.hosts.name for site
1>
    issuerRef:
    name: ingress-issuer
  usages:
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

   i. Replace the line that begins **- <INSERT SITE HOSTNAME HERE** with - *hostname of the site*.
   j. Ensure that the portal CR for DC2 is ready to be installed. Make a note of the **hostname** of the site.
   k. In **custom-certs-external-dc2.yaml** find **spec.dnsNames** and replace the line that begins **- <INSERT SITE HOSTNAME HERE** with - *hostname of the site*.

4. Use the following steps to synchronize the **ingress-ca** secrets across the data centers.
   a. On DC1 apply the file **custom-certs-external-dc1.yaml**:

```
kubectl -n <namespace> apply -f custom-certs-external-dc1.yaml
```

   b. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

   c. Export **ingress-ca** secret as a YAML file from DC1:

```
kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
```

   d. Edit the **ingress-ca.yaml** file to remove all labels, annotations, **creationTimestamp**, **resourceVersion**, **uid**, and **selfLink**.
   e. Copy the **ingress-ca.yaml** from DC1 to DC2 and apply that file on DC2:

```
kubectl -n <namespace> apply -f ingress-ca.yaml
```

   f. On DC2 apply the file **custom-certs-external-dc2.yaml**:

```
kubectl -n <namespace> apply -f custom-certs-external-dc2.yaml
```

   g. Use the following commands to test that they are the same, on DC1 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/ingress.pem.dc1
```

h. On DC2 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/ingress.pem.dc2
```

i. To see the differences run:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

The files should be the same.

j. To verify that the certificates are working correctly and that they are using the `ingress-ca` secret, get the `portal-admin-client crt` file:

```
kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/admin-client.crt
```

k. Use OpenSSL to verify the certificate:

```
openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
```

If it is valid, you should see:

```
/tmp/admin-client.crt: OK
```

What to do next

Configure your subsystem CR YAML files to use your custom certificates: Deploying API Connect subsystems with custom certificates.

Generating custom certificates manually

Generate custom certificates for API Connect without using cert-manager.

About this task

Note: If you want to customize only your user-facing endpoint certificates, then you do not need to configure them at installation. Install API Connect normally and then update the certificates following the steps in Customizing user-facing certificates.
If you choose to create your certificates manually, then you lose some of the management features of cert-manager. For example, you must manually update your certificates before they expire.

Requirements for manually created certificates:

- Extended Key Usage (EKU) must be either `serverAuth` or `clientAuth` depending upon the type of certificate. Certificates of the type *Server* must have an Extended Key Usage with `serverAuth` purpose. Certificates of the type *Client* must have an Extended Key Usage with `clientAuth` purpose.
- Subject Alternative Name (SAN) for the required hosts.
- If a certificate is signed by an internal or custom CA, include the full chain in the end certificate. If you omit the full chain, then a user who uses OpenSSL to access the endpoint gets the following error: `error:num=20:unable to get local issuer certificate`
  The following example shows the full chain for an end certificate (signed by a custom CA):

```
-------BEGIN CERTIFICATE -----
Cert contents for end-cert
--------END CERTIFICATE ----------
-------BEGIN CERTIFICATE -----
Cert contents for Intermediate-CA
--------END CERTIFICATE ----------
-------BEGIN CERTIFICATE -----
Cert contents for Root CA
--------END CERTIFICATE ----------
```

Procedure

1. Generate your custom certificates with the appropriate EKU and SAN. You must have the private key, public certificate, and CA certificates in non-password-protected PEM format. Following is an example for how to generate a certificate with an EKU `serverAuth` and SAN using OpenSSL:

```
openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
platform-api-cert -sha256
-extfile <(cat /etc/ssl/openssl.cnf <(printf
"\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth"))
-extensions SAN
```

where

- `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint that the certificate applies to.
- `platform-api-example.csr` is the file name for the certificate signing request.

The following is an example for how to generate a certificate (portal-client) with an EKU `clientAuth` and SAN using OpenSSL:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
portal-client-cert
-sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,
digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,
CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

Note:
When you prepare your custom certificates, certain pairs of certificates must be signed by the same certificate authority, as noted in the description of each certificate: API Connect TLS certificates.

If you're installing a two data center disaster recovery configuration, and are using custom certificates, then the subject names of any client certificates must be the same in both data centers, as noted in the description of each certificate: API Connect TLS certificates. For example, the subject names in both data centers might both be **CN=portal-admin-client**, or they might both be **CN=ptl-adm-client, O=cert-manager**, but they must be identical.

2. Create a Kubernetes secret for each custom certificate.
   Create Kubernetes secrets for each of your custom certificates. The secrets must be of type **kubernetes.io/tls** and must contain the following **data** items: **ca.crt**, **tls.crt**, and **tls.key**.

   ```
   kubectl create secret generic my-tls-secret --from-file=tls.crt=<path_to_cert_file> --from-file=tls.key=<path_to_key_file>
   --from-file=ca.crt=<path_to_cacert_file>
   ```

   When you create each secret, it's helpful to reference its purpose or its corresponding certificate in the secret name, to ensure that you specify the correct secret for each custom certificate.

What to do next

Configure your subsystem CR YAML files to use your custom certificates: Deploying API Connect subsystems with custom certificates.

Deploying API Connect subsystems with custom certificates

Steps to configure API Connect subsystem CR YAML files to deploy them with custom certificates.

Before you begin

Create the custom certificates that you want to use, either creating the certificates manually or using cert-manager.
For a two data center disaster recovery deployment, follow the steps in Generating custom certificates using cert-manager in a two data center deployment.

About this task

This task covers the steps to configure your API Connect CR YAML files to use the custom certificates that you created.

Procedure

1. Edit the helper_files/ingress-issuer-v1.yaml file and delete the default definitions for the certificates that you are customizing.
   The ingress-issuer-v1.yaml file is provided as part of the installation **helper_files** archive. See Obtaining product files.

   This file is used for generating the default certificates. To use a custom certificate, you must delete the default definition so that API Connect uses your certificate instead of the default certificate. If you customize all the default certificates and delete those definitions from the file, then you don't need to use the file during installation.

2. Update the user-facing endpoint definitions in the subsystem CRs, for all the endpoints where you created a custom certificate.
   Note: If you want to customize only your user-facing endpoint certificates, then you do not need to customize them at installation. You can install API Connect normally and then update the certificates following the steps in Customizing user-facing certificates.
   For each custom endpoint certificate, delete the annotation that specifies the default issuer, and replace the secret name with your own custom secret name.

   a. Open the subsystem CR for editing and locate the endpoint definition.
      For example, the following snippet shows the definition for the **cloudManagerEndpoint** in the management CR:

      ```
      cloudManagerEndpoint:
        annotations:
          cert-manager.io/issuer: ingress-issuer
        hosts:
        - name: admin.example.com
          secretName: cm-endpoint
      ```

   b. Delete the annotation for the **cert-manager.io/issuer**.
      Delete the field name and the value; you can leave the **annotations:** label in place.

   c. Replace the default secret name with the name of the Kubernetes secret that you created for that endpoint's custom certificate.
      In the following example, **cm-endpoint** is the default secret name, which must be replaced. Make sure to reference the correct secret for the custom certificate.

      ```
      cloudManagerEndpoint:
        annotations:
        hosts:
        - name: admin.example.com
          secretName: my_cm-endpoint
      ```

3. Customize internal (CA, inter, and intra-subsystem) certificates.
   a. Open the subsystem CR for editing.
   b. Set the **spec.microServiceSecurity** property to **custom**.
      By default, the setting is configured for **certManager** as shown in the following example:

      ```
      microServiceSecurity: certManager
      certManagerIssuer:
          name: selfsigning-issuer
          kind: Issuer
      ```

   c. Delete the **spec.certManagerIssuer** block.
      In the following example, **microServiceSecurity** is set to **custom** and the **certManagerIssuer** block is commented out:

```
microServiceSecurity: custom
#certManagerIssuer:
#    name: selfsigning-issuer
#    kind: Issuer
```

4. Add the **spec.customCertificates** block and list the secret name for each internal custom certificate that you created for the subsystem. See the Table 5 table for the certificate names.

   You do not have to provide a custom certificate for every certificate supported by the subsystem. Put the custom certificates that you created; any certificates that you omit from the list are generated automatically during installation.

   For example, your **customCertificates** list for the management subsystem might look like the following:

```
customCertificates:
   - name: caCertificate
     secretName: management-ca
   - name: clientCertificate
     secretName: management-client
   - name: serverCertificate
     secretName: management-server
   - name: dbServerCertificate
     secretName: db-server-certificate
   - name: NATSTLSCertificate
     secretName: management-natscluster-mgmt
   - name: dbClientPostgres
     secretName: db-client-postgres
   - name: dbClientReplicator
     secretName: db-client-replication
   - name: dbClientApicuser
     secretName: db-client-apicuser
   - name: S3ProxyTLSCertificate
     secretName: management-s3proxy-all
```

What to do next

Complete the installation of API Connect:

- If you did not deploy the API Connect operator yet, proceed to Deploying operators in a single-namespace API Connect cluster or Deploying operators in a multi-namespace API Connect cluster.
- If you already deployed the operator, proceed to Installing the API Connect subsystems.

Installing the API Connect subsystems

Deploy the API Connect subsystem custom resources.

Before you begin

Attention: API Connect is not supported on a FIPS-enabled environment.
Before you install the subsystems, verify that you completed the following prerequisite tasks:

1. Obtaining product files
2. Deploying operators and cert-manager

About this task

Use the CR (custom resource) files to install the Management, Gateway, Analytics, and Portal subsystems for your API Connect cloud. CRs are extensions of the Kubernetes API. API Connect installs its subsystems using individual CRs. One CR is deployed per one managed subsystem. The API Connect operator manages the lifecycle of the subsystem CRs and deploys and manages the microservice for each one.

CR templates are provided in the **helper_files** archive to install each API Connect subsystem. You uncompressed these files into an installation folder of your choosing in Obtaining product files.

- The API Connect operators and operands must be at compatible versions of API Connect.
- You can deploy multiple instances of API Connect into the same cluster by using different namespaces.
- Deploying multiple similar subsystems in a single namespace is not supported. For example, deploying two management subsystems, **mgmt1**, **mgmt2** in a single namespace where API Connect operator is installed.
- For more information on Custom Resources in Kubernetes see https://kubernetes.io/docs/concepts/extend-kubernetes/api-extension/custom-resources/.
- For details on how the API Connect operator manages the CRs using the Kubernetes operator pattern, see https://kubernetes.io/docs/concepts/extend-kubernetes/operator/.
- For guidance on choosing object names and IDs in Kubernetes, see https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names.

Procedure

Complete each of the following instructions:

1. Installing the management subsystem.
2. Installing the gateway subsystem.
3. Installing the developer portal subsystem.
4. Installing the analytics subsystem.
5. When all subsystems are running, verify you can access the API Connect Cloud Manager. Enter the Cloud Manager endpoint URL in your browser.
   Tip:

You can find your Cloud Manager endpoint URL as follows:

The property **cloudManagerEndpoint** is specified in the management CR (**management_cr.yaml**). When you edited the template, you specified a value for ***$STACK_HOST***:

```
cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.$STACK_HOST
      secret: cm-endpoint
```

The template URL is **https://admin.<*STACK_HOST*>/admin**. The **/admin** suffix at the end is the name of the Cloud Manager administrator.

For example, if ***$STACK_HOST*** is **myhost.subnet.example.com**, the Cloud Manager endpoint URL is:

```
https://admin.myhost.subnet.example.com/admin
```

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See Accessing the Cloud Manager user interface.

What to do next

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

- **Installing the management subsystem**
  Install the management subsystem in your Kubernetes environment.
- **Installing the gateway subsystem**
  Install the DataPower gateway subsystem
- **Installing the developer portal subsystem**
  Install the developer portal subsystem.
- **Installing the analytics subsystem**
  Install the API Connect analytics subsystem.

Installing the management subsystem

Install the management subsystem in your Kubernetes environment.

Before you begin

Before you start this task, you should have already:

- Reviewed the Kubernetes requirements in Pre-installation requirements
- Completed Deploying operators and cert-manager

About this task

Edit the custom resource template for the management system, apply the resource, verify that the pods are up and running, and verify that you can connect to the API Connect Cloud Manager.

Procedure

1. Edit the **management_cr** template CR, to replace the placeholders with values for your deployment.

   $APP_PRODUCT_VERSION
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.11.0

   $SECRET_NAME
   Use for image pull.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   $PROFILE
   Specify your management subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

   $DOCKER_REGISTRY
   The host name of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **ingressclass.kubernetes.io/is-default-class:**

`true` is used. If such an ingress class does not exist in the Kubernetes environment, then `nginx` is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system. For example:

```
spec:
...
 cloudManagerEndpoint:
    #ingressClassName: $INGRESS_CLASS
```

Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

`$STACK_HOST`

The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress host names to use and just replace all instances of `STACK_HOST` to be the desired ingress subdomain for the API Connect stack. For example, if your host is `myhost.subnet.example.com`:

  ```
  cloudManagerEndpoint:
        < ... >
    hosts:
    - name: admin.myhost.subnet.example.com
      secret: cm-endpoint

  apiManagerEndpoint:
        < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secret: apim-endpoint

  platformAPIEndpoint:
        < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secret: api-endpoint

  consumerAPIEndpoint:
        < ... >
    hosts:
    - name: consumer.myhost.subnet.example.com
      secret: consumer-endpoint

  consumerCatalogEndpoint:
        < ... >
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secret: consumer-catalog-endpoint
  ```

- Complete hostname customization
  Change both the predefined prefixes and the `STACK_HOST` subdomain to match your desired hostnames.

  For example, for `cloudManagerEndpoint`, you can replace `admin.$STACK_HOST` with `my.cloudmgr.myhost.subnet.example.com`, where `my.cloudmgr` replaces `admin`, and `myhost.subnet.example.com` replaces `STACK_HOST`. For example:

  ```
  cloudManagerEndpoint:
        < ... >
    hosts:
    - name: my.cloudmgr.myhost.subnet.example.com
      secret: cm-endpoint
  ```

  You can do this for some or all of the host names, depending on your customization requirements.

`$STORAGE_CLASS`

The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: `kubectl get sc`.

```
storageClassName: local-storage
```

2. Edit the `license:` setting:
   a. Set `accept:` to `true` to accept the license. Note that the default value is `false`. If you do not accept the license, the Operator will not install the subsystem.
   b. Set `metric:` to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

   c. Set `use:` to either `production` or `nonproduction`, to match the license you purchased.
   d. Set `license:` to the License ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

   ```
   license:
     accept: true
     metric: PROCESSOR_VALUE_UNIT
     use: production
     license: L-RJON-BZ5LSE
   ```

3. If installing with custom internal certificates, specify a site name.
   - The site name is used as the identifier for the PostgreSQL database cluster used by API Connect. This name should already have been decided upon and used to update the `custom-certs-internal.yaml` file as described in Generating custom certificates using cert-manager.
   - You must now add your chosen site name to `management_cr.yaml`, by creating a `siteName` property anywhere inside the `spec` block, set to the chosen site name:

```
  siteName: <site_name>
```

Replace <site_name> with your chosen site name.

4. It is recommended to allocate 100Gi for write-ahead logging (WAL) storage.
   The default storage is:

   - One replica profile - 30Gi
   - Three replica profile - 47Gi

   For best performance, edit the CR to add the following entries, and set **volumeSize:** to 100Gi:

```
spec:
  dbArchiveVolumeClaimTemplate:
    storageClassName: <storage-class>
    volumeSize: <volume-size>
```

5. Optional: If you are installing as part of a two data center disaster recovery set up, complete the steps in Installing a two data center deployment on Kubernetes before you apply the edited file.
6. Install the management Custom Resource, replacing **<namespace>** with the target installation namespace in the Kubernetes cluster.

```
kubectl apply -f management_cr.yaml -n <namespace>
```

7. Verify that the management subsystem is fully installed:

```
kubectl get ManagementCluster -n <namespace>
```

   The installation has completed when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (e.g. **9/9**). For example:

```
NAME          READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
management    True    16/16      <version>   <version-build>      7m17s
```

8. Check your connection to the Cloud Manager user interface on the management subsystem on your Cloud Manager endpoint.
   For example, if you accepted the default prefix of **admin**, and you set ***$STACK_HOST*** to **myhost.subnet.example.com**, the Cloud Manager endpoint URL is:

```
https://admin.myhost.subnet.example.com/admin
```

   The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. For further details, see Accessing the Cloud Manager user interface.

9. Backup your management subsystem database and infrastructure configuration: Backing up and restoring the management subsystem.
10. For more information about advanced configuration for Postgres components, see Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Installing the gateway subsystem

Install the DataPower® gateway subsystem

Before you begin

Important: When you install the gateway subsystem, you must configure the gateway subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
If you plan to install the gateway subsystem in a remote cluster, be sure to satisfy the following requirements:

- Install both the API Connect and the DataPower operators.
  The versions of the operators on the remote cluster and the version of the gateway operand must exactly match the versions used in the main cluster.
- Make sure the remote cluster has the certificates:
  - If you are using certificate manager, ensure that the ingress-ca is synced between sites.
  - If you are not using certificate manager, copy the client gateway certificates to the remote cluster and reference them in the gateway CR.

About this task

Note: An alternate deployment scenario is to use a physical DataPower appliance for the gateway. If you are using an appliance for the gateway, do not install using API Connect Kubernetes CRs, since you do not need to configure a gateway subsystem in your Kubernetes cluster when using an appliance. For an appliance-based gateway, you must configure two endpoints in DataPower to be used as the Gateway Service Management Endpoint and the API invocation Endpoint. Enter these endpoints in the Configure Gateway Service screen in Cloud Manager.
The installation folder where the **helper_files.zip** was extracted contains two templates for gateway service. The **v5cgateway_cr.yaml** template is for the v5 compatible gateway, and the **apigateway_cr.yaml** template is for the API Gateway.

Procedure

1. Edit the template CR, either **apigateway_cr.yaml** or **v5cgateway_cr.yaml**, to replace the placeholders with values for your deployment.

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.11.0

$PROFILE
Specify your gateway profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$SECRET_NAME
Use for image pull.

```
imagePullSecrets:
  - apic-registry-secret
```

$DOCKER_REGISTRY
The host name of the Docker Registry to which you uploaded the installation images. For example:

```
my.docker.registry.domain.example.com.
```

$INGRESS_CLASS
The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **ingressclass.kubernetes.io/is-default-class: true** is used. If such an ingress class does not exist in the Kubernetes environment, then **nginx** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system. For example:

```
spec:
...
  gatewayEndpoint:
    ingressClassName: nginx
```

Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and just replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

  ```
  gatewayEndpoint:
      < ... >
    hosts:
    - name: rgw.myhost.subnet.example.com
      secret: gwv6-endpoint

  gatewayManagerEndpoint:
      < ... >
    hosts:
    - name: rgwd.myhost.subnet.example.com
      secret: gwv6-manager-endpoint
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

  ```
  gatewayEndpoint:
      < ... >
    hosts:
    - name: my.gateway.endpoint.myhost.subnet.example.com
      secret: gwv6-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **kubectl get sc**.

```
storageClassName: local-storage
```

$ADMIN_USER_SECRET
Edit **$ADMIN_USER_SECRET** to set the value you created in Deploying operators and cert-manager.

```
adminUserSecret: $ADMIN_USER_SECRET
```

$PLATFORM_CA_SECRET
Set to **ingress-ca**. The **$PLATFORM_CA_SECRET** contains the CA certificate for the platform REST API endpoint. The gateway makes calls to the platform REST API and this property must be set so that the gateway can verify the server certificate.

```
mgmtPlatformEndpointCASecret:
  secretName: $PLATFORM_CA_SECRET
```

2. Edit the **license:** setting:
   a. Set **accept:** to **true** to accept the license. Note that the default value is **false**. If you do not accept the license, the Operator will not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.

- MONTHLY_API_CALL - Applies only to the IBM API Connect® Hybrid Entitlement program.

For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

c. Set `use:` to either `production` or `nonproduction`, to match the license you purchased.
d. Set `license:` to the License ID for the version of API Connect that you purchased. See API Connect licenses.

Example entry to accept the license for a production system:

```
  license:
    accept: true
    metric: PROCESSOR_VALUE_UNIT
    use: production
    license: L-RJON-BZ5LSE
```

3. Enable or disable `syslogConfig`.

```
syslogConfig:
    enabled: false # if true, provide below details
    # remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
    # remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
    # secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

- To disable syslog, remove the `syslogConfig` block from `apigateway_cr.yaml` and `v5cgateway_cr.yaml`. Alternatively, you can set `syslogConfig.enabled` to `false`.
- To enable `syslogConfig` in the gateways, set the following values in `apigateway_cr.yaml` and `v5cgateway_cr.yaml`:

  enabled
  `enabled: true`
  $DATAPOWER_SYSLOG_TCP_REMOTE_HOST
  `remoteHost: <remote.host>`
  String. The hostname of the server for `syslogConfig`.

  $DATAPOWER_SYSLOG_TCP_REMOTE_PORT
  `remotePort: <remote_port_number>`
  Integer. The port number of the server for `syslogConfig`.

  $DATAPOWER_SYSLOG_TCP_TLS_SECRET
  `secretName: <secret>`
  String. The TLS secret name of the server for `syslogConfig`.

4. Optional: If applicable to your deployment, update the GatewayCluster CR to configure `DataPowerService` APIs to customize your DataPower deployment. See Customizing a DataPower deployment.
5. Configure Management-to-Gateway communication security. You must configure either mutual TLS (mTLS) or JWT for secure communication between the management subsystem and the gateway subsystem.
   a. To enable mutual TLS between the management client and the gateway service's manager endpoint, add `mtlsValidateClient` to the `spec` section:

   ```
   spec:
     mtlsValidateClient: true
   ```

   This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under `gatewayManagerEndpoint.hosts.secretName`. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under `gateway.client.secretName`.

   b. If you want to enable JWT security for communications between the management and gateway, add and set the property `jwksUrl`, and set `spec.mtlsValidateClient` to false.

   ```
   spec:
     ...
     jwksUrl: <JWKS URL>
     mtlsValidateClient: false
   ```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

   ```
   kubectl describe mgmt -n <namespace>
   ...
   status:
     - name: jwksUrl
       secretName: api-endpoint
       type: API
       uri: https://api.apic.acme.com/api/cloud/oauth2/certs
   ```

   For more information about JWT security, see Enable JWT security instead of mTLS.
6. Optional: If you want to use the In-cluster inter-subsystem communication feature, then uncomment the `mgmtPlatformEndpointSvcCASecret` section, and set the `secretName`:

```
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca  # Usually management-ca
```

   Unless you customized your internal certificates, this is always `management-ca`.
7. Optional: Enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
8. Install the gateway Custom Resource by applying the gateway template file:
   For a DataPower API Gateway, run the following command:

   ```
   kubectl apply -f apigateway_cr.yaml -n <namespace>
   ```

   For a DataPower Gateway (v5 compatible), run the following command:

   ```
   kubectl apply -f v5cgateway_cr.yaml -n <namespace>
   ```

9. To verify that the gateway subsystem(s) are fully installed, run the following command:

   ```
   kubectl get GatewayCluster -n <namespace>
   ```

   The installation has completed when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (**2/2**) for all the gateway subsystems that were installed. Example:

   ```
   NAME   READY   SUMMARY   VERSION     RECONCILED VERSION   AGE
   gwv5   True    2/2       <version>   <version-build>      7m31s
   gwv6   True    2/2       <version>   <version-build>      7m32s
   ```

   There is no need to wait for the **READY** status to be **True** before moving on to the next Subsystem installation.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Installing the developer portal subsystem

Install the developer portal subsystem.

About this task

Important: When you install the portal subsystem, you must configure the portal subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Important:

- To enable effective high availability for your portal service, you need a latency that is less than 50 ms between all portal-db pods to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest portal-db pod, as the write actions are synchronous across the cluster of portal-db pods. It is recommended that there are three servers in each cluster of portal-db pods for the high availability configuration. The three servers can be situated in the same availability zone, or across three availability zones to ensure the best availability. However, you can configure high availability with two availability zones.
- The portal does not do certain operations if the free space on certain volumes falls beneath predefined limits. In particular:
  The **databaseVolumeClaimTemplate** needs at least 4GB of free space to create new sites, restore site backups, or upgrade or change the URL of existing sites.

  The **webVolumeClaimTemplate** needs at least 256MB free space to create new sites, restore site backups, or upgrade or change the URL of existing sites.

- Ensure that your kernel or Kubernetes node has the value of its **inotify** watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a **non-ready** state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of **inotify** watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take **inotify** watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.
- Ensure that your kernel or Kubernetes node has a value of **nproc** (maximum number of processes) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow all of the portal processes to execute. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls, you might need as many as 125205. If the number is too low, you will see errors like **"fork: retry: Resource temporarily unavailable"** in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.
- Ensure that your kernel or Kubernetes node has a value of **nofiles** (maximum number of open file descriptors) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow the portal to open all of the files that it requires. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls and portal web sites, you might need as many as 1048576. If the number is too low, you will see errors like **"too many open files"** in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.

The portal endpoints values are used when you configure a portal service in the Cloud Manager. See Registering a Portal service.

- **portalAdminEndpoint** - This is the Management Endpoint that is defined in Cloud Manager, which is used for communicating with API Manager.
- **portalUIEndpoint** - This is the portal website URL defined in Cloud Manager. It determines the URL for the site that is created for each catalog. It is used for public access to the portal from a browser.

Important: The endpoints defined here must be the ones used by the Management subsystem when registering the portal, and portal users when accessing portal sites. Do not attempt to proxy these endpoints. You will not be able to register the portal service nor access portal sites using any other endpoint URLs than those defined here.

Procedure

1. Edit the **portal_cr** template CR to replace the placeholders with values for your deployment.

   $APP_PRODUCT_VERSION
   API Connect application version for the subsystems.

   version: <*version_number*>

   Example version number: 10.0.11.0

   $PROFILE
   Specify your portal subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

   $SECRET_NAME

Use for image pull.

```
imagePullSecrets:
  - apic-registry-secret
```

$DOCKER_REGISTRY
The host name of the Docker Registry to which you uploaded the installation images. For example:

```
my.docker.registry.domain.example.com.
```

$INGRESS_CLASS
The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **ingressclass.kubernetes.io/is-default-class:** **true** is used. If such an ingress class does not exist in the Kubernetes environment, then **nginx** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system. For example:

```
  spec:
...
portalAdminEndpoint:
    #ingressClassName: $INGRESS_CLASS
```

Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **myhost.subnet.example.com**:

  ```
  portalAdminEndpoint:
      < ... >
      hosts:
      - name: api.portal.myhost.subnet.example.com
        secret: portal-admin

    portalUIEndpoint:
      < ... >
      hosts:
      - name: portal.myhost.subnet.example.com
        secret: portal-web
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **portalAdminEndpoint**, you can replace **api.portal.$STACK_HOST** with **my.api.portal.myhost.subnet.example.com**, where **my.api.portal** replaces **api.portal**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

  ```
  portalAdminEndpoint:
        < ... >
      hosts:
      - name: my.api.portal.myhost.subnet.example.com
        secret: cm-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **kubectl get sc**. For example, for local storage:

```
storageClassName: local-storage
```

$PLATFORM_CA_SECRET
Set to **ingress-ca**. The **$PLATFORM_CA_SECRET** contains the CA certificate for the platform REST API endpoint. The portal makes calls to the platform REST API and this property must be set so that the portal can verify the server certificate.

```
mgmtPlatformEndpointCASecret:
  secretName: $PLATFORM_CA_SECRET
```

$CONSUMER_CA_SECRET
Set to **ingress-ca**. The **$CONSUMER_CA_SECRET** contains the CA certificate for the consumer REST API endpoint. The portal makes calls to the consumer REST API and this property must be set so that the portal can verify the server certificate.

```
mgmtConsumerEndpointCASecret:
  secretName: $CONSUMER_CA_SECRET
```

Note:

- The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation. For more information on planning your portal PV requirements, see Portal subsystem.
- The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
- The **certVolumeClaimTemplate** is used by the nginx pod and in 2DCDR mode it is also by the **tunnel**, **db-remote** and **www-remote** pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

2. Edit the **license:** setting:
   a. Set **accept:** to **true** to accept the license. Note that the default value is **false**. If you do not accept the license, the Operator will not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.

- MONTHLY_API_CALL - Applies only to the IBM API Connect® Hybrid Entitlement program.

For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

c. Set `use:` to either `production` or `nonproduction`, to match the license you purchased.
d. Set `license:` to the License ID for the version of API Connect that you purchased. See API Connect licenses.

Example entry to accept the license for a production system:

```
  license:
    accept: true
    metric: PROCESSOR_VALUE_UNIT
    use: production
    license: L-RJON-BZ5LSE
```

3. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties `mtlsValidateClient` and `jwksUrl`.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

4. Optional: If you want to use the In-cluster inter-subsystem communication feature, then uncomment the `mgmtPlatformEndpointSvcCASecret` and the `mgmtConsumerEndpointSvcCASecret` sections, and set the `secretName` for both:

```
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca  # Usually management-ca
  mgmtConsumerEndpointSvcCASecret:
    secretName: management-ca  # Usually management-ca
```

Unless you customized your internal certificates, these secrets are always `management-ca`.

5. Optional: If you are installing as part of a two data center disaster recovery set up, complete the steps in Installing a two data center deployment on Kubernetes before you apply the edited file.
6. Install the portal Custom Resource, replacing `<namespace>` with the target installation namespace in the Kubernetes cluster:

```
kubectl apply -f portal_cr.yaml -n <namespace>
```

7. Verify that the portal subsystem is fully installed:

```
kubectl get PortalCluster -n <namespace>
```

The installation is complete when `STATUS` reports `Running`, `Ready` reports that all services are online (`3/3`), and `MESSAGE` reports "Ready for API Cloud Manager service registration", for example:

```
NAME           READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                      AGE
portal         3/3     Running   <version>  <version>            Ready for API Cloud Manager service registration   2h
```

You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.

8. We highly recommend that you retain the portal subsystem encryption secret in a safe location, in case you need to restore the portal subsystem during a disaster recovery scenario.
The encryption secret is created when the portal subsystem is initially deployed. You can obtain the name of the encryption secret from the portal subsystem custom resource once the installation is complete. For example:

a. Obtain the name of the encryptionSecret:

```
kubectl get ptl portal -o yaml | grep encryptionSecret
encryptionSecret: portal-enc-key
```

The name of encryption secret is `portal-enc-key`.

b. Save the secret yaml in a safe location:

```
kubectl get secret portal-enc-key -o yaml > portal-enc-key.yaml
```

9. Backup the portal installation. See Backing up and restoring the developer portal.
Note:
When you create or register a Developer Portal service, the portal subsystem checks that the portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete the following update:

On Kubernetes, OpenShift®, and IBM® Cloud Pak for Integration
Add the following section to the portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you completed the installation of all the required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

- **Defining multiple portal endpoints for a Kubernetes environment**
  Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

Defining multiple portal endpoints for a Kubernetes environment

Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

About this task

You can override the single endpoint definition for portal-WWW, and the associated **portal-www-ingress** TLS certificate, to support multiple **portal-www** endpoints.

For information about the endpoints for the Developer Portal, see Installing the developer portal subsystem.

Following are the example endpoints for configuring different sites served by the same Developer Portal service, as configured in this task:

- https://banking.example.com/loans
- https://insurance.example.com/vehicle

These unique endpoints allow Developer Portal sites to be defined on the Developer Portal service with different host names and domains. They replace endpoints that distinguish different sites by sub paths, as shown in the following examples:

- https://www.example.com/banking/loans
- https://www.example.com/insurance/vehicle

Procedure

Edit your **portal_cr** template. You can add multiple entries for your endpoints in the **hosts** element:
For example:

```
spec:
    portalUIEndpoint:
        annotations:
          cert-manager.io/issuer: ingress-issuer
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

Installing the analytics subsystem

Install the API Connect analytics subsystem.

Review Planning your analytics deployment to ensure that you understand the choices for configuring the topology, disk space, and other elements of the analytics subsystem.

Note: When the analytics service is configured to store data, it uses OpenSearch, which requires map counts higher than the operating system defaults. The minimum recommended value is **262144**. If you plan to store analytics data locally (that is, do you not intend to disable local storage and offload all data), increase the default map count on every Kubernetes node:

1. To change the map counts on the live system, run the following command on every Kubernetes node:

   ```
   sudo sysctl -w vm.max_map_count=262144
   ```

2. To persist this change when node restarts occur, add the following setting to the /etc/sysctl.conf file:

   ```
   vm.max_map_count = 262144
   ```

For more information, see Important settings in the OpenSearch documentation.

- **Creating the analytics CR**
  Create the installation CR for API Connect analytics so that you can deploy the analytics subsystem.

- **Installing analytics**
  Deploy the analytics CR to install the analytics subsystem in your API Connect deployment.

Creating the analytics CR

Create the installation CR for API Connect analytics so that you can deploy the analytics subsystem.

Before you begin

Important: When you install the analytics subsystem, you must configure the analytics subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Review Analytics preinstallation planning to decide on your deployment options.

About this task

To install the analytics subsystem, define the analytics Custom Resource (CR) in a YAML file. The YAML file contains all of your configuration settings for the analytics deployment. Use the file to install, upgrade, and update the configuration of your analytics subsystem.
Note: The analytics_cr.yaml template file is stored in the directory where you extracted helper_files.zip.

Procedure

1. Create or copy the analytics_cr.yaml file from the helper_files.
2. Edit the CR file and update the following settings:
   You cannot install the analytics subsystem until the placeholders are replaced with real values for your environment.

   `$APP_PRODUCT_VERSION`
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.11.0

   `$PROFILE`
   Specify your analytics subsystem profile, where **`n`** indicates number of replicas, **`c`** number of cores, and **`m`** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.
   Note: The profile that you select influences your storage type options. If you select an **`n1`** profile then you must select the **`shared`** storage type. For more information about storage types, see storage types.

   `$SECRET_NAME`
   The name of the secret used to pull images from the Docker registry.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   `$DOCKER_REGISTRY`
   The hostname of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **`ingressclass.kubernetes.io/is-default-class:`** **`true`** is used. If such an ingress class does not exist in the Kubernetes environment, then **`nginx`** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system. For example:

   ```
   spec:
   ...
    ingestion:
       endpoint:
         #ingressClassName: $INGRESS_CLASS
   ```

   Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

   `$STACK_HOST`
   The ingress subdomain for the API Connect stack. Used for the ingestion endpoint. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:
   - Subdomain customization only
     Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **`$STACK_HOST`** with the ingress subdomain for the API Connect stack. For example, if your host is **`myhost.subnet.example.com`**:

     ```
     ingestion:
       endpoint:
          < ... >
         hosts:
         - name: ai.myhost.subnet.example.com
           secretName: analytics-ai-endpoint
          < .... >
     ```

   `$STORAGE_TYPE`
   If you selected an n1 (one replica) profile in **`$PROFILE`**, then set **`$STORAGE_TYPE`** to **`shared`**. If you selected an n3 (three replica) profile, then set **`$STORAGE_TYPE`** to **`dedicated`**. For more information about analytics storage types, see Storage type.

   `$STORAGE_CLASS`

The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: `kubectl get sc`.

- For shared storage deployments (where you set `$STORAGE_TYPE` to `shared`):

```
storage:
  type: shared
  shared:
    volumeClaimTemplate:
      storageClassName: local_storage
```

- For dedicated storage deployments (where you set `$STORAGE_TYPE` to `dedicated`), set `$STORAGE_CLASS` in two places:

```
storage:
  type: dedicated
  shared:
    volumeClaimTemplate:
      storageClassName: local_storage
      ...
  master:
    volumeClaimTemplate:
      storageClassName: local_storage
      ...
```

$DATA_VOLUME_SIZE

Replace `$DATA_VOLUME_SIZE` with the value that you calculated in Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
  ...
  shared:
    volumeClaimTemplate:
      ...
      volumeSize: 500Gi
```

3. Edit the `license` setting.
   a. Set `accept:` to `true` to accept the license. The default value is `false`. If you do not accept the license, the Operator does not install the subsystem.
   b. Set `metric:` to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM® API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Counting total API calls.
   c. Set `use:` to either `production` or `nonproduction` to match the license you purchased.
   d. Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

```
license:
  accept: true
  metric: PROCESSOR_VALUE_UNIT
  use: production
  license: L-RJON-CEBL97
```

4. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties `mtlsValidateClient` and `jwksUrl`.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.

5. Optional: If you plan to configure analytics database backups, then define the storage that is required for backups:
   Define your backup PVC by adding the `backup.volumeClaimTemplate` property in `spec.storage`. For example:

```
spec:
  storage:
    backup:
      volumeClaimTemplate:
        storageClassName: <storage class>
        volumeSize: <size>
```

   If you are not sure of the volume size that you need, then you can configure the `backup.volumeClaimTemplate` after installation.

6. Save the file.

What to do next

Install your analytics subsystem: Installing analytics.

Important: All analytics advanced configuration options can be added, changed, or removed after installation **except** for disablement or enablement of internal storage. If you want to disable internal storage, you must configure it in the analytics CR before installation: Disable local storage.

Installing analytics

Deploy the analytics CR to install the analytics subsystem in your API Connect deployment.

Before you begin

Now that you have a complete analytics CR file, double-check it for accuracy. In particular, verify that:

- No placeholder values remain in the analytics_cr.yaml file.
- You configured all the topology options that you plan to deploy.
- You configured appropriate volume size for storage.

Procedure

1. Run the following command to apply the analytics_cr.yaml:

   ```
   kubectl apply -f path/to/analytics-cr -n namespace
   ```

   where:
   - ***path/to/analytics-cr*** is the path to your saved analytics_cr.yaml file.
   - ***namespace*** is the name of your namespace.
2. To enable secure communication from Analytics to the Management subsystem, specify the **mgmtPlatformEndpointCASecret** field in the Analytics custom resource (CR).

   ```
   mgmtPlatformEndpointCASecret:
     secretName: ingress-ca
   ```

   Where:

   secretName:
   Specifies the name of the Kubernetes Secret that contains the CA certificate for the platform ingress endpoint. The value must match the name of the Secret.
3. Optional: To enable mTLS-based communication over internal Kubernetes services, set the **mgmtPlatformEndpointSvcCASecret** field in the Analytics CR:

   ```
   mgmtPlatformEndpointSvcCASecret:
     secretName: management-ca  # Typically 'management-ca'
   ```

   Where:

   secretName:
   Specifies the name of the Kubernetes Secret that contains the CA certificate used by the internal Kubernetes service to sign its TLS certificates.

   The **management-ca** Secret is typically generated during the Management subsystem installation and must be copied to the Analytics namespace.
4. Verify that the analytics subsystem is fully installed by running the following command:

   ```
   kubectl get AnalyticsCluster -n namespace
   ```

   where ***namespace*** is the name of your namespace.
   The installation is complete when the **READY** status is **True** and the **SUMMARY** reports that all services are online. Example:

   ```
   NAME        READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
   analytics   True    5/5       <version>   <version-build>       7m39s
   ```

   The **SUMMARY** total count is based on your configured topology. Both numbers are equal when the installation is complete.

Results

Table 1 lists the pods that are expected in the three replica analytics deployment profile.

Table 1. Expected analytics subsystem pods

Expected	Pods	Note
3	director	Always expected.
3	ingestion	Always expected.
3	mtls-gw	Always expected.
3	storage	Not expected if you disabled internal storage.
3	storage-os-master	Not expected if you disabled internal storage. Not expected if shared storage is configured.
3	osinit	Expected to be in completed state.
1	data-warehouse	Expected if backups are enabled. For information about analytics database backups, see configure analytics database backups.

The one replica profile has 1 replica (instead of 3) of each pod.

What to do next

Take a backup of your analytics subsystem and configure scheduled analytics database backups: Analytics backup and restore.

Installing a two data center deployment on Kubernetes

Additional installation instructions for a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Before you begin

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Download the operator files and custom resource definitions for use during installation onto both of your data centers. Ensure that you complete the instructions for Deploying operators and cert-manager, and set the same ingress-ca certificate in both data centers: Installing cert-manager and certificates in a two data center deployment.

Familiarize yourself with the instructions in Installing the API Connect subsystems. Follow these instructions along with the 2DCDR specific steps in this topic.

Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

The following endpoints must be the same on both data centers:

Management subsystem endpoints

- `cloudManagerEndpoint`
- `apiManagerEndpoint`
- `platformAPIEndpoint`
- `consumerAPIEndpoint`
- `consumerCatalogEndpoint`

Portal subsystem endpoints

- `portalAdminEndpoint`
- `portalUIEndpoint`

For more information about how to set the endpoints, see Installing the management subsystem on Kubernetes, Installing the developer portal subsystem on Kubernetes.

About this task

A 2DCDR deployment differs from a standard API Connect deployment in that the custom resources (CRs) for both the management and portal in each data center include a `multiSiteHA` configuration section. The `multiSiteHA` section is used to define which data center is the active and which is the warm-standby.

The following examples show `multiSiteHA` sections in the `PortalCluster` CRs for the active and warm-standby data centers.

```
siteName: dallas
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationdallas.cluster1.example.com
      secretName: dallas-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

```
siteName: raleigh
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

Table 1. `multiSiteHA` configuration properties

Configuration property	Description
`mode`	The state of the data center in the context of the 2DCDR deployment. Valid values are: • `active` - indicates the active data center. • `passive` - indicates the warm-standby data center.

`replicationEndpoint`
`annotations:`
`cert-manager.io/issuer:`
`ingress-issuer`
`hosts:`
`- name:`
`secretName:`
	Contains details of the external ingress name for the subsystem in the current data center in the 2DCDR deployment.
	The hosts `name` is a unique fully qualified hostname that the other data center uses to communicate with the current data center.

`replicationPeerFQDN`	The ingress hostname for the other data center in the 2DCDR deployment. This information is required so that the two data centers can communicate with each other.
`tlsClient:` `secretName`	The TLS client secret for the subsystem.

The `siteName` property is a unique descriptive name for the portal and management subsystems, in each data center. For example, `dallas` in data center 1 (DC1), and `raleigh` in data center 2 (DC2).

- Set a different `siteName` on the active to the one set on the warm-standby data center.

- `siteName` is used in the hostnames, and so can contain only `a-z` and `0-9` characters.
- You can set a `siteName` in the `ManagementCluster` or `PortalCluster` CRs only on installation. You cannot change the name after deployment. If you don't set a `siteName` at first deployment, an automated `siteName` is created for you.

To install a 2DCDR deployment:

1. Set the placeholder properties in the CR file for management and portal subsystems as detailed in Installing the API Connect subsystems, but do not run the final `kubectl apply` operation. Complete the additional 2DCDR configuration steps before you run `kubectl apply`.
2. Set the properties in the `multiSiteHA` section, and synchronize encryption secrets between the data centers as described in the procedure below:

Procedure

- **Installing to an active data center**
  The following example shows how to set the multi-site HA CR values for deploying to the active data center. In this example, the initial active data center is called `dallas` (DC1) and the warm-standby data center is called `raleigh` (DC2).

  1. Set Dallas to be active for the API Manager service on DC1.
     Edit the `ManagementCluster` CR file management_cr for DC1, and set the `multiSiteHA` properties as shown:

     ```
     siteName: dallas
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationdallas.cluster1.example.com
           secretName: dc1-mgmt-replication
       replicationPeerFQDN: mgrreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: dc1-mgmt-replication-client
     ```

  2. Set Dallas to be active for the Developer Portal service on DC1.
     Edit the `PortalCluster` CR file portal_cr for DC1, and set the `multiSiteHA` properties as shown:

     ```
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationdallas.cluster1.example.com
           secretName: dallas-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: ptl-replication-client
     ...
     siteName: dallas
     ```

  3. Create a secret called `ptl-encryption-key` on the active and warm-standby data centers.
     The secret must use the same random string in both data centers. Run the following command:

     ```
     kubectl create secret generic ptl-encryption-key --from-literal=encryption_secret=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  4. When the secrets are created on both DC1 and DC2, update the portal CR on DC1 and DC2 and add the following under the `spec` section:

     ```
     encryptionSecret:
       secretName: ptl-encryption-key
     ```

     Warning: Ensure that you add the secret directly under the `spec` section and not inside the `multiSiteHA` section.
  5. Create a secret called `mgmt-encryption-key` on the active and warm-standby data centers.
     The secret must use the same random string in both data centers. Run the following command:
     Note: Do not use the same random string that you used to create the secret for `ptl-encryption-key`.

     ```
     kubectl create secret generic mgmt-encryption-key --from-literal=encryption_secret.bin=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  6. When the secrets are created on both DC1 and DC2, update the portal CR on DC1 and DC2 and add the following under the `spec` section:

     ```
     encryptionSecret:
       secretName: mgmt-encryption-key
     ```

     Warning: Ensure that you add the secret directly under the `spec` section and not inside the `multiSiteHA` section.
  7. Apply the CR files to the subsystems in DC1.
     For example, to apply the `ManagementCluster` CR file to the DC1 cluster, run the following command:

     ```
     kubectl apply -f management_cr.yaml -n <namespace>
     ```

     Where `<namespace>` is the target installation namespace in the Kubernetes cluster for DC1. Repeat this process to apply the updated `PortalCluster` CR file to DC1.
     You can verify that the installation process is running with the following command:

     ```
     kubectl get ManagementCluster -n <namespace>
     ```

     Note: Until the warm-standby is installed and running, the `haStatus` reports `PeerNotReachable`.

Change ***ManagementCluster*** to ***PortalCluster*** to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

8. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

   Management subsystem endpoints
   - **cloudManagerEndpoint**
   - **apiManagerEndpoint**
   - **platformAPIEndpoint**
   - **consumerAPIEndpoint**
   - **consumerCatalogEndpoint**

   Portal subsystem endpoints
   - **portalAdminEndpoint**
   - **portalUIEndpoint**

- **Installing the warm-standby data center**
  The following example shows how to set the multi-site HA CR values for the remote data center called **raleigh** (DC2) to be the warm-standby. Use the same encryption key on both sites.

  Ensure that the installation of the active data center is complete before you start the installation of the warm-standby data center.

  1. Set Raleigh to be warm-standby for the API Manager service on DC2.
     Edit the **ManagementCluster** CR file management_cr for DC2, and set the **multiSiteHA** properties as shown:

     ```
     multiSiteHA:
       mode: passive
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationraleigh.cluster2.example.com
           secretName: raleigh-mgr-replication-worker-1
       replicationPeerFQDN: mgrreplicationdallas.cluster1.example.com
       tlsClient:
         secretName: mgr-replication-client
     ...
     siteName: raleigh
     ```

  2. Set Raleigh to be warm-standby for the Developer Portal service on DC2.
     Edit the **PortalCluster** CR file portal_cr for DC2, and set the **multiSiteHA** properties as shown:

     ```
     multiSiteHA:
       mode: passive
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationraleigh.cluster2.example.com
           secretName: raleigh-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationdallas.cluster1.example.com
       tlsClient:
         secretName: ptl-replication-client
     ...
     siteName: raleigh
     ```

  3. Apply the CR files to the subsystems in DC2.
     For example, to apply the **ManagementCluster** CR file to the DC2 cluster, run the following command:

     ```
     kubectl apply -f management_cr.yaml -n <namespace>
     ```

     Where ***<namespace>*** is the target installation namespace in the Kubernetes cluster for DC2. Repeat this process to apply the updated **PortalCluster** CR file to DC2.
     You can verify that the installation process is running with the following command:

     ```
     kubectl get ManagementCluster -n <namespace>
     ```

     When installation is complete, **haStatus** reports **Ready**.
     Change ***ManagementCluster*** to ***PortalCluster*** to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

- **Validating your two data center deployment**
  While the management subsystems on the warm-standby and active data centers are synchronizing their databases, the management status reports **Warning**, and the **haStatus** reports **pending**:

  ```
  kubectl get mgmt -n <namespace>
  ```

  ```
  NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
  AGE
  management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in
  CR for details   8m59s
  ```

  ```
  status:
    haStatus
      {
        "lastTransitionTime": "2023-03-31T19:47:08Z",
        "message": "Replication not working, install or upgrade in progress.",
        "reason": "na",
        "status": "True",
        "type": "Pending"
    }
  ```

When the management database replication between sites is complete, the management status reports **Running**, and **status.haStatus** reports **Ready**:

```
oc get mgmt -n <namespace>

NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.11.0-0   10.0.11.0-0          Management is ready. HA status Ready - see HAStatus in
CR for details              8m59s

oc get mgmt -n <namespace> -o yaml

...
status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the **haStatus** output shows the reason, for example::

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.11.0-0   10.0.11.0-0          Management is ready. HA Status Warning - see HAStatus
in CR for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "PeerNotReachable"
   }
```

If the warning persists, see Troubleshooting a two data center deployment.
You can validate that your portal deployments are synchronizing by running **kubectl get pods** on both the active and warm-standby data centers, and confirming that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the **Ready** state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See Failing over to the warm-standby.

- **Converting a single data center to a two data center deployment on Kubernetes**
  Instructions on how to convert a single data center to a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Related concepts

- Maintaining a two data center deployment

Converting a single data center to a two data center deployment on Kubernetes

Instructions on how to convert a single data center to a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Before you begin

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Download the operator files and custom resource definitions for use during installation onto both of your data centers. Ensure that you complete the instructions for Deploying operators and cert-manager, and set the same ingress-ca certificate in both data centers: Installing cert-manager and certificates in a two data center deployment.

Familiarize yourself with the instructions in Installing the API Connect subsystems. Follow these instructions along with the 2DCDR specific steps in this topic.

Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

About this task

You can convert a single data center API Connect to a 2DCDR deployment. Both data centers must have the same **portal-admin** and **portal-www** endpoints. The main difference is that the custom resource (CR) files for both the Management subsystem and the Developer Portal subsystem on each data center must include a **multiSiteHA** configuration section, and it's this section that determines the two data center DR deployment. It's also this section that's used to control the deployment in the future, for example in failover and recovery situations.

The following codeblocks show examples of completed **multiSiteHA** sections in the **PortalCluster** CR files for two data centers, one active and one warm-standby. Both the **ManagementCluster** and the **PortalCluster** CR templates have a **multiSiteHA** section containing the placeholder **$MULTI_SITE_HA**, and it is this placeholder that must be replaced with the values for your deployment.

```
siteName: dallas
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationdallas.cluster1.example.com
      secretName: dallas-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

```
siteName: raleigh
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

The configuration properties are described in the following table.

Table 1. The configuration properties of the multi-site HA section in the CR file

Configuration property	Description
mode	The state of the data center in the context of the two data center deployment. Valid values are: • **active** - indicates the primary data center • **passive** - indicates the warm-standby data center
replicationEndpoint **annotations:** **cert-manager.io/issuer** **hosts:** **- name:** **secretName:**	Contains details of the external ingress name for the subsystem in the current data center in the two data center deployment. The hosts **name** is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
replicationPeerFQDN	The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.
tlsClient: **secretName**	The TLS client secret for the subsystem.
siteName	A descriptive name for the Portal subsystem, and the Management subsystem, in the current data center, for example **dallas**. This name is used in the hostnames, and so can contain only **a-z** and **0-9** characters. Note that you can set a **siteName** in the **ManagementCluster** or **PortalCluster** CR only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set a **siteName** at first deployment, an automated **siteName** is created for you. For example, if you are converting an existing single Management cluster to a two data center Management cluster by adding the multi-site HA values, you will not be able to configure a **siteName** for the existing Management cluster.

To install a two data center disaster recovery deployment, you must set all of the placeholder properties in the CR file for both the Management and the Developer Portal subsystems as detailed in the relevant topics in the Installing the API Connect subsystems section, as well as the properties in the multi-site HA section that are detailed here. Some examples of complete CR files are shown in the Example section.

Procedure

- **Converting a single data center deployment to two data centers**
  When converting a single data center deployment into a two data center deployment, it is best practice to use the existing data center as the active one, and add a new warm-standby data center elsewhere. This practice ensures that the data is retained.
  Remember:
  - Both data centers must have the same **portal-admin** and **portal-www** endpoints.
  - You cannot configure a **siteName** for the existing Management or Portal cluster because the **siteName** property can be configured only at first deployment.

  The following example shows how to update the multi-site HA CR values for making the local data center called **dallas** (DC1) active, and for setting the new remote data center called **raleigh** (DC2) as warm-standby.

- Install cert-manager.
  Note: Run these steps on DC1 only if you don't already have cert-manager running.
  1. Obtain cert-manager.
     API Connect v10 uses cert-manager v1.18.2 of cert-manager, which is a native Kubernetes certificate management controller.

     You can obtain cert-manager v1.18.2 from the API Connect v10 distribution **helper_files.zip** archive, or from https://github.com/cert-manager/cert-manager/releases/tag/v1.18.2.

  2. Apply the CR:

     ```
     kubectl apply -f cert-manager-1.18.2.yaml
     ```

     Do not specify a custom namespace.

     See https://docs.cert-manager.io/en/release-0.10/getting-started/install/kubernetes.html.

  3. Wait for **cert-manager** pods to enter **Running 1/1** status before proceeding. To check the status:

     ```
     kubectl get po -n cert-manager
     ```

     There are 3 **cert-manager** pods in total.
- Use the following steps to allow **ingress-ca** secrets to be the same on both data centers.
  1. On DC1 apply the file **ingress-issuer-v1-dc1.yaml**:

```
kubectl -n <namespace> apply -f ingress-issuer-v1-dc1.yaml
```

2. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

3. Export `ingress-ca` secret as a yaml from DC1:

```
kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
```

4. Edit the `ingress-ca.yaml` file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
5. Copy the `ingress-ca.yaml` from DC1 to DC2 and apply that file on DC2:

```
kubectl -n <namespace> apply -f ingress-ca.yaml
```

6. On DC2 apply the file `ingress-issuer-v1-dc2.yaml`:

```
kubectl -n <namespace> apply -f ingress-issuer-v1-dc2.yaml
```

7. Use the following commands to test that they are the same, on DC1 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/ingress.pem.dc1
```

8. On DC2 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/ingress.pem.dc2
```

9. To see the differences run:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

The files should be the same.

10. To ensure that the certificates are working correctly and that they are using the `ingress-ca` secret. First, get the `portal-admin-client crt` file:

```
kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/admin-client.crt
```

11. Test that it is working by using OpenSSL:

```
openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
```

If it is working, you should see:

```
/tmp/admin-client.crt: OK
```

- **Installing to an active data center**
  The following example shows how to set the multi-site HA CR values for deploying to an active data center (DC). In this instance, we are deploying to a local data center called `dallas` (DC1) that has a remote data center called `raleigh` (DC2).

1. Set Dallas to be active for the API Manager service on DC1.
   As the API Manager service already exists, you cannot set the `siteName` property. Add the multi-site HA section properties to the existing `ManagementCluster` CR file for DC1. For example:

```
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: mgrreplicationdallas.cluster1.example.com
      secretName: dc1-mgmt-replication
  replicationPeerFQDN: mgrreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: dc1-mgmt-replication-client
```

2. Set Dallas to be active for the Developer Portal service on DC1.
   As the Developer Portal service already exists, you cannot set the `siteName` property. Add the multi-site HA section properties to the existing `PortalCluster` CR file for DC1. For example:

```
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationdallas.cluster1.example.com
      secretName: dallas-ptl-replication-worker-1
  replicationPeerFQDN: ptlreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: ptl-replication-client
```

3. Create a secret called `ptl-encryption-key` on the active and warm-standby data centers.
   You must create a secret on the active and warm-standby sites that use the same random string, run the following command:

```
kubectl create secret generic ptl-encryption-key --from-literal=encryption_secret=<RANDOM STRING> -n <namespace>
```

The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

4. When the secrets are created on both DC1 and DC2, update the Portal CR on DC1 and DC2 to include in the `spec` object:

```
 encryptionSecret:
    secretName: ptl-encryption-key
```

Warning: Ensure that you add the secret to the **spec** object and not to the **multiSiteHA** object.

5. Apply the CR files to the subsystems in DC1.
   For example, to apply the **ManagementCluster** CR file to the DC1 cluster, run the following command:

   ```
   kubectl apply -f management_cr.yaml -n <namespace>
   ```

   Where ***<namespace>*** is the target installation namespace in the Kubernetes cluster for DC1. Repeat this process to apply the updated **PortalCluster** CR file to DC1.
   You can verify that the updated CR files have been applied by running the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   You can verify that the installation process is running with the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   Note: Until the warm-standby is installed and running, the **haStatus** reports **PeerNotReachable**.
   Change ***ManagementCluster*** to ***PortalCluster*** to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

6. Set your dynamic router to direct all traffic to DC1.
   This includes setting the four endpoints for the API Manager cluster, and the two endpoints for the Developer Portal cluster.

- **Installing to a warm-standby data center**
  The following example shows how to set the multi-site HA CR values for the remote data center called **raleigh** (DC2), which is being installed as the warm-standby, standby location. You must use the same encryption key on both sites.

  1. Get the encryption key from Dallas the **active** (DC1) site:
     a. Run the command **kubectl get mgmt -o yaml|grep enc** to get the db encryption key on the **active** site, for example:

     ```
     $ kubectl -n <namespace> get mgmt -o yaml|grep enc
     ```

     An example of possible output:

     ```
     encryptionSecret: dallas-enc-key
     ```

     Make a note of the secret name. In this case, it's **dallas-enc-key**.
     b. Run **kubectl get secret dallas-enc-key -o yaml**, an example of possible output:

     ```
     apiVersion: v1
     data:
       encryption_secret.bin:
     VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
     pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
     kind: Secret
     metadata:
       creationTimestamp: "2020-08-28T12:53:41Z"
       labels:
         app.kubernetes.io/instance: m1
         app.kubernetes.io/managed-by: ibm-apiconnect
         app.kubernetes.io/name: dallas-enc-key
       name: dallas-enc-key
       namespace: default
       resourceVersion: "43039"
       selfLink: /api/v1/namespaces/default/secrets/m1-enc-key
       uid: 46c92395-9cc2-4421-b2c4-48e472c0cbb1
     type: Opaque
     ```

     c. Copy the output that you got and put it into a new file. Delete the contents of **metadata:** and add back in a **name:** attribute, in this case **dc1-enc-key**. An example of the format is here:

     ```
     apiVersion: v1
     data:
       encryption_secret.bin:
     VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
     pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
     kind: Secret
     metadata:
       name: dc1-enc-key
     type: Opaque
     ```

     d. Save the file. In this example, it's called **dc1-enc-key.yaml**.
  2. On Raleigh the (DC2) site:
     a. Copy the yaml file that you just saved that contains the **encryption_secret.bin** from Dallas the **active** (DC1) site.
     b. Run **kubectl create -f dc1-enc-key.yaml** to create the same secret with the same key on the Raleigh (DC2) site. For example:

     ```
     $ kubectl  -n <namespace> create -f /tmp/dc1-enc-key.yaml
     ```

     An example of possible output:

     ```
     secret/dc1-enc-key created
     ```

     c. In the management CR for Raleigh the (DC2) site, add the following entry to the **spec**.

     ```
     encryptionSecret:
         secretName: dc1-enc-key
     ```

  3. Set Raleigh to be warm-standby for the API Manager service on DC2.
     Edit the **ManagementCluster** CR file management_cr for DC2, and set the multi-site HA section properties, for example:

     ```
     multiSiteHA:
       mode: passive
       replicationEndpoint:
     ```

```
    annotations:
      cert-manage.io/issuer: ingress-issuer
    hosts:
    - name: mgrreplicationraleigh.cluster2.example.com
      secretName: raleigh-mgr-replication-worker-1
  replicationPeerFQDN: mgrreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: mgr-replication-client
...
siteName: raleigh
```

4. Set Raleigh to be warm-standby for the Developer Portal service on DC2.
   Edit the `PortalCluster` CR file portal_cr for DC2, and set the multi-site HA section properties, for example:

```
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manage.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN: ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
siteName: raleigh
```

5. Ensure that you completed the steps that are in the **Installing to an active data center** section to create a secret called `ptl-encryption-key` on DC1 and DC2, and to update the Portal CR on DC1 and DC2 to include the `ptl-encryption-key` in the `spec` object.
6. Apply the CR files to the subsystems in DC2.
   For example, to apply the `ManagementCluster` CR file to the DC2 cluster, run the following command:

   ```
   kubectl apply -f management_cr.yaml -n <namespace>
   ```

   Where *<namespace>* is the target installation namespace in the Kubernetes cluster for DC2. Repeat this process to apply the updated `PortalCluster` CR file to DC2.
   You can verify that the updated CR files are applied by running the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   You can verify that the installation process is running with the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   When installation is complete, `haStatus` reports `Ready`.
   Change *`ManagementCluster`* to *`PortalCluster`* to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

Related concepts

Troubleshooting installation on Kubernetes

Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on Kubernetes

- DataPower operator fails to start

DataPower operator fails to start

There is a known issue on Kubernetes that can cause the DataPower operator to fail to start. In this case, the DataPower operator pods can fail to schedule, and display the status message: `no nodes match pod topology spread constraints (missing required label)`. For example:

```
0/15 nodes are available: 12 node(s) didn't match pod topology spread constraints (missing required label),
3 node(s) had taint {node-role.kubernetes.io/master: }, that the pod didn't tolerate.
```

You can workaround the issue by editing the DataPower operator deployment and reapplying it, as follows:

1. Delete the DataPower operator deployment, if deployed already:

   ```
   kubectl delete -f ibm-datapower.yaml -n <namespace>
   ```

2. Open `ibm-datapower.yaml`, and locate the `topologySpreadConstraints:` section. For example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: zone
     whenUnsatisfiable: DoNotSchedule
   ```

3. Replace the values for `topologyKey:` and `whenUnsatisfiable:` with the corrected values that are shown in the following example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: topology.kubernetes.io/zone
     whenUnsatisfiable: ScheduleAnyway
   ```

4. Save `ibm-datapower.yaml` and deploy the file to the cluster:

   ```
   kubectl apply -f ibm-datapower.yaml -n <namespace>
   ```

Deploying on OpenShift and Cloud Pak for Integration

You can install API Connect in an OpenShift environment or as the API Management capability in IBM Cloud Pak for Integration.

The recommended configuration is to have a single operator in the global namespace, managing multiple API Connect instances in separate namespaces.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

- **Configuring FIPS support on OpenShift**
  Configure support for FIPS (Federal Information Processing Standards) on the cluster where you will install IBM API Connect.
- **Preparing for installation**
  Set up your OpenShift environment in preparation for deploying API Connect.
- **Installation procedures with IBM Cloud Pak for Integration**
  The API Management capability of IBM Cloud Pak for Integration uses API Connect.
- **Installing API Connect in a single namespace on OpenShift**
  Use individual subsystem CRs to install API Connect subsystems in a shared namespace on OpenShift.
- **Installing API Connect subsystems in different namespaces or environments on OpenShift**
  Install API Connect subsystems in different namespaces, for example Management subsystem in a namespace that is called `apicmgmt`, Gateway in a namespace called `apicgway`. These same steps can also be used for installing subsystems in different environments.
- **Installing with the top-level CR on OpenShift**
  Use the single, top-level `APIConnectCluster` CR to deploy API Connect on OpenShift.
- **Air-gapped installation**
  In a disconnected environment using Red Hat OpenShift Container Platform (OCP), install API Connect by mirroring product images to a bastion host or a portable device and then completing the installation.

  Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Configuring FIPS support on OpenShift

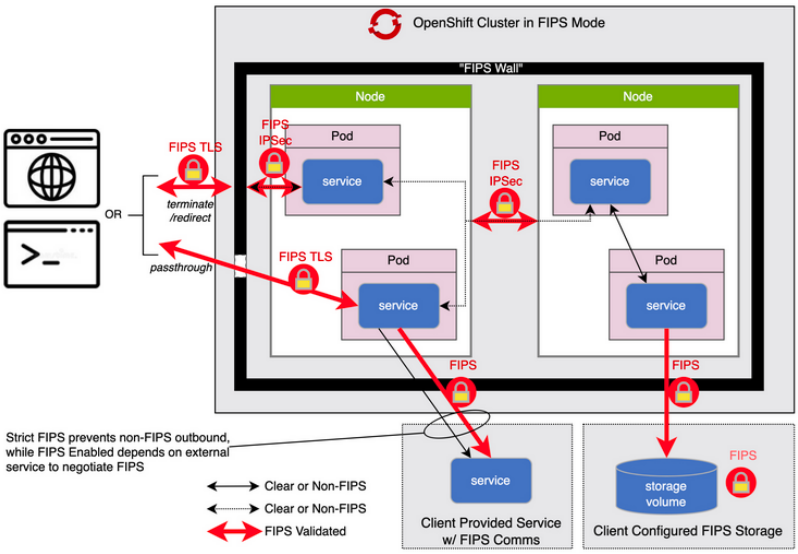
Configure support for FIPS (Federal Information Processing Standards) on the cluster where you will install IBM API Connect.

Before you begin

API Connect supports FIPS with the following limitations:

- Only FIPS version 140-2 is supported
- FIPS must be configured on the cluster before you install API Connect
- You must deploy API Connect 10.0.8.0 or later, with DataPower Gateway 10.6.2 or later
  For DataPower, refer to the following documentation for the most up-to-date information on DataPower FIPS support:
  - Known limitations and restrictions
  - Cloud Pak for Integration - Gateway instance additionally notes the FIPS and FIPS-Wall status

About this task



To be FIPS compliant, an organization must adhere to the various data security and computer system standards outlined in the FIPS requirements. FIPS compliance for API Connect is supported by implementing a "FIPS wall".

What is FIPS?

Federal Information Processing Standards (FIPS) are standards and guidelines issued by the National Institute of Standards and Technology (NIST) for federal government computer systems. The standards are developed when there are compelling federal government requirements for standards, such as for security and interoperability, but acceptable industry standards or solutions do not exist. Government agencies and financial institutions use these standards to ensure that products conform to specified security requirements.
API Connect supports version 140-2 of the FIPS requirements, implemented using the "FIPS wall" approach.

What is a FIPS wall?

The "FIPS wall" is a boundary approach to FIPS compliance that is used by IBM products. All pods in the cluster are FIPS-tolerant (the pods can run without issues on a FIPS-enabled OpenShift cluster), while creating a compliant "boundary" that is secured at external points of contact (known as "touch points").
Traffic inside the boundary is secure because the communication between nodes is automatically encrypted at the OpenShift Container Platform level using the IPSec protocol. Traffic within any node happens in-memory, so it never leaves the node. The following diagram illustrates a typical OpenShift cluster that is configured to support the FIPS wall. In the diagram, the "wall" is represented with a heavy black border. Communications between pods within the border are secured with IPSec encryption, and communications that cross the border to external devices are secured using other means for example, TLS encryption).

What are the cluster requirements to support a FIPS wall?

- FIPS is enabled on the cluster during installation (by setting `fips: true` in the install-config.yaml file)
- FIPS is enabled for node-to-node communication (using the OVN-Kubernetes Container Network Interface cluster network provider, and with IPSec enabled)
- The etcd key-value store is encrypted with `aescbc`
- Storage is encrypted with FIPS ciphers
- Runtimes are managed using Kubernetes CRI-O (all OCP deployments use CRI-O by default)

What are the Red Hat OpenShift Container Platform dependencies?

API Connect 10.0.9.0 can be deployed with the following version of OpenShift Container Platform (OCP):

- version 4.14 - 4.17: supported on Red Hat Enterprise Linux 8.6, 8.7, and 8.8; on-going certification for FIPS 140-2 and 140-3

For more information about OpenShift support for FIPS, see

- Current status on FIPS certification: Compliance Activities and Government Standards in the Red Hat Customer Portal

Install and configure OpenShift Container Platform

Configure settings for FIPS and IPSec, install the OpenShift cluster, and then configure the cluster to enable encryption and provide storage.

Procedure

1. Configure settings in the install-config.yaml file.
   Edit the install-config.yaml and make the following changes:
   - Set `fips: true`
   - Set the `networkType` to `OVNKubernetes`

   For example:

```
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork:
  - 172.30.0.0/16
fips: true
```

   For an example of the install-config.yaml file, see Sample install-config.yaml file for bare metal in the Red Hat OpenShift documentation.

2. Create the IPSec installation manifests to allow IPSec tunneling for node-to-node communication in the OpenShift cluster.
   a. Generate the manifests from `install-config.yaml` by running the following command:

```
openshift-install create manifests
```

   b. Create a cluster-network-03-config.yaml file with the following content, and save it in the `manifests` directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    type: OVNKubernetes
    ovnKubernetesConfig:
      ipsecConfig: {}
      mtu: 1400
```

3. Deploy the OpenShift cluster.
   Install the OpenShift cluster, and then install the OpenShift CLI.

a. Install the OpenShift cluster as explained in Chapter 2. Installing the system in FIPS mode in the Red Hat OpenShift "FIPS support" documentation.
b. Install the OpenShift CLI (oc) as explained in Installing the OpenShift CLI in the Red Hat OpenShift documentation.

4. Log in to the cluster as a user with `cluster-admin` privileges.

5. Validate the OpenShift cluster.
   a. Verify that FIPS is enabled on the OpenShift cluster.
      i. Run the following command to verify the `fips` setting:

```
oc get cm cluster-config-v1 -n kube-system -o json | jq -r '.data."install-config"' | grep -i "fips"
```

Review the results and verify that the `fips` setting is set to `true`:

```
fips: true
  name: fips-apic
  root@fips-apic
```

      ii. Run the following command to get the names of the machine configurations:

```
oc get mcp
```

In the result, the configuration name appears in the `CONFIG` column; for example:

```
NAME     CONFIG                                             UPDATED   UPDATING   DEGRADED   MACHINECOUNT
READYMACHINECOUNT   UPDATEDMACHINECOUNT   DEGRADEDMACHINECOUNT   AGE
master   rendered-master-41831cf684b6e570518728abd24b9006   True      False      False      3              3
3                   0                     15h
worker   rendered-worker-2a4937983238e94a74307abc3eed2080   True      False      False      7              7
7                   0                     15h
```

For each configuration listed in the result, run the following command to verify that `Fips` is set to `true`:

```
oc describe mc <CONFIG> | grep Fips
```

The previous example returned two configurations, so run the command on each configuration:

- `oc describe mc rendered-master-41831cf684b6e570518728abd24b9006 | grep Fips`
  `Fips:  true`
- `oc describe mc rendered-worker-2a4937983238e94a74307abc3eed2080 | grep Fips`
  `Fips:  true`

   b. Verify that IPSec is enabled on the OpenShift cluster.
      i. Check the `ovn-ipsec` daemonset that manages the daemons responsible for configuring IPSec:

```
oc get ds -n openshift-ovn-kubernetes ovn-ipsec
```

A successful result looks like the following example:

```
NAME        DESIRED   CURRENT   READY   UP-TO-DATE   AVAILABLE   NODE SELECTOR                 AGE
ovn-ipsec   66666           beta.kubernetes.io/os=linux   3d3h
```

      ii. Verify that IPSec pods are running in all of the nodes in your OpenShift cluster:

```
oc get pod -n openshift-ovn-kubernetes -o wide | grep ipsec
```

A successful result looks like the following example:

```
 ovn-ipsec-4qp86        1/1     Running   0          38m   192.168.7.23   master2.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-pk7vh        1/1     Running   0          38m   192.168.7.21   master0.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-q4mwj        1/1     Running   0          22m   192.168.7.11   worker0.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-trz5m        1/1     Running   0          22m   192.168.7.12   worker1.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-vjmw8        1/1     Running   0          38m   192.168.7.22   master1.ocp4.rober.lab   <none>
<none>
```

6. Enable `etcd` encryption with `aescbc` as explained in Encrypting etcd data in the Red Hat OpenShift documentation.

7. For local storage, choose either RHEL-provided disk encryption or Container Native Storage that uses RHEL-provided disk encryption.
   By storing all data in volumes that use RHEL-provided disk encryption and enabling FIPS mode for your cluster, both data at rest and data in motion (network data) are protected by FIPS-validated or Modules In Process encryption. You can configure your cluster to encrypt the root filesystem of each node, as described in Customizing nodes in the Red Hat OpenShift documentation.

Install API Connect

Install API Connect on the OpenShift cluster, and ensure that server connections support FIPS.

Procedure

1. Install API Connect.
   For instructions on installing API Connect with the top-level CR, see Installing with the top-level CR on OpenShift in this documentation. For instructions on installing API Connect with subsystem CRs, see Installing API Connect in a single namespace on OpenShift or Installing API Connect subsystems in different namespaces or environments on OpenShift in this documentation.

2. Ensure that all server connections support FIPS.

   Inbound connections: ensure that the Gateway API invocation endpoint supports FIPS
   The following list shows the inbound connections to an API Connect deployment:

```
$ oc get routes
NAME                          HOST/PORT                                                    PATH   SERVICES
PORT   TERMINATION            WILDCARD
apic-a7s-ai-endpoint          apic-a7s-ai-endpoint-apic.apps.fips-apic.cp.fyre.ibm.com             apic-a7s-mtls-gw
4443   passthrough            None
apic-gw-gateway               apic-gw-gateway-apic.apps.fips-apic.cp.fyre.ibm.com                  apic-gw-datapower
9443   passthrough            None
apic-gw-gateway-manager       apic-gw-gateway-manager-apic.apps.fips-apic.cp.fyre.ibm.com          apic-gw-datapower
3000   passthrough            None
apic-mgmt-admin               apic-mgmt-admin-apic.apps.fips-apic.cp.fyre.ibm.com                  apic-mgmt-juhu
2005   reencrypt/Redirect     None
apic-mgmt-api-manager         apic-mgmt-api-manager-apic.apps.fips-apic.cp.fyre.ibm.com            apic-mgmt-juhu
2006   reencrypt/Redirect     None
apic-mgmt-consumer-api        apic-mgmt-consumer-api-apic.apps.fips-apic.cp.fyre.ibm.com           apic-mgmt-juhu
2001   reencrypt/Redirect     None
apic-mgmt-platform-api        apic-mgmt-platform-api-apic.apps.fips-apic.cp.fyre.ibm.com            apic-mgmt-juhu
2000   reencrypt/Redirect     None
apic-ptl-portal-director      apic-ptl-portal-director-apic.apps.fips-apic.cp.fyre.ibm.com          apic-ptl-nginx
4443   passthrough            None
apic-ptl-portal-web           apic-ptl-portal-web-apic.apps.fips-apic.cp.fyre.ibm.com               apic-ptl-b1aab746-
www    4443    reencrypt/Redirect    None
```

All of the inbound connections support FIPS by default, except for the Gateway API invocation endpoint.

The TLS server profile used by the DataPower Gateway for API invocation is configured from the Cloud Manager when you create a gateway service. To be FIPS compliant, the TLS server profile used with a gateway service must be configured with FIPS-only ciphers to ensure that the server only accepts FIPS connections.

To configure the TLS server profile, use the Cloud Manager's Register Service > DataPower Gateway page, which you can access from the Topology menu. Locate the API invocation endpoint section and use the Server Name Indication (SNI) - TLS server profile setting to create the server profile. Use a TLS server profile that is FIPS-compliant (for example, do not use: **`TLS_CHACHA20_POLY1305_SHA256`**, which is not compliant). For information on configuring the TLS server profile, see Registering a gateway service in this documentation.

Outbound connections: Ensure that all of the outbound connections support FIPS

For outbound connections, it is your responsibility to ensure that the external servers configured with API Connect accept only FIPS connections. The following list shows the typical outbound connections for an API Connect deployment

- OIDC providers (Google, Facebook, Keycloak etc.)
- LDAP providers
- Authentication URLs
- External user registry
- Target URLs used in APIs
- Remote backups
- Auditing endpoints
- SMTP endpoints
- Analytics offloading
- Analytics backup to S3 storage
- Automated API behavior testing tool (ATM) - calls out to the APIs being tested
- Portal - Potential drupal extensions installed by customer
- Portal - SFTP and S3 backups
- 2-data-center deployments - Calls to other clusters

Preparing for installation

Set up your OpenShift environment in preparation for deploying API Connect.

About this task

Ensure that your environment meets all prerequisites, plan your deployment, and download files for installation.

Procedure

1. Ensure that your environment meets the following prerequisites:
   - IBM API Connect Version 10 software product compatibility requirements
   - Deployment requirements
   - If you want to use the OpenShift web console, Cluster admin access is required.
   - API Connect requires **`block storage`** as the storage class for all subsystems.
   - Set the default SCC (security context constraint) to **`restricted`**.
     API Connect supports only the **`restricted`** SCC on OpenShift.
   - If your OpenShift deployment uses a LimitRange and a CPU **`maxLimitRequestRatio`** is set, then its value must be at least 25; otherwise some API Connect pods might fail to start.
   - S3 object-store available for storing API Connect subsystem database backups.
2. Plan your deployment as explained in Planning your deployment.
3. Review Operator, CASE, and platform requirements to determine the operator, operand, and CASE versions that you need for your deployment.
4. Obtain the API Connect files..
   From the IBM Fix Central site, download the following files:

IBM® API Connect *<version>* for Containers
: Docker images for all API Connect subsystems. Filename is apiconnect-image-tool_*<version>*.

IBM® API Connect *<version>* Operator Release Files for Containers
: Kubernetes operators and API Connect Custom Resource (CR) templates. Filename is apiconnect-operator-release-files_*<version>*.

IBM API Connect *<version>* Security Signature Bundle File
: Signature files for verifying the integrity of your downloads.
Filename is signatures_*<version>*.

IBM API Connect *<version>* Toolkit for *<operating_system>*
: Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer:
  - IBM API Connect *<version>* Toolkit for *<operating_system>*
  - IBM API Connect *<version>* Toolkit Designer for *<operating_system>*

Filename is toolkit-...*<operating system>*_*<version>*.
Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI as explained in Installing the toolkit.

IBM API Connect *<version>* Local Test Environment
: Optional test environment for testing locally as explained in Testing an API with the Local Test Environment.
Filename is apic-lte-*<operating system>*_*<version>*.

5. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
6. Decide whether to install API Connect with a top-level CR, or with individual subsystem CRs, or using Cloud Pak for Integration.
   Installing with a top-level CR means you have a single `APIConnectCluster` CR which includes sections for all subsystem CRs: Management, Gateway, Analytics, and Portal. Installing with individual subsystem CRs means no `APIConnectCluster` CR, only subsystem CRs, for example `ManagementCluster`, `PortalCluster`.
7. Optional: Specify additional settings in each subsystem CR to define the deployment's configuration before beginning the installation.
   In particular, consider increasing the timeout value for Management endpoints as explained in Configuring timeouts for management endpoints.

   For information on other configuration settings, see API Connect configuration settings.

   Tip: If you choose not to specify configuration settings now, you can modify the installation CRs later and then re-apply them to update the deployment.

- **Operator, CASE, and platform requirements**
  Before you install API Connect on Red hat OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped installations), and OpenShift. version
- **API Connect configuration settings**
  Specify configuration settings for API Connect in the CR, or the Platform UI in Cloud Pak for Integration.
- **Configuring timeouts for management endpoints**
  Adjust the timeout settings for management endpoints by updating the CR.

Operator, CASE, and platform requirements

Before you install API Connect on Red hat OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped installations), and OpenShift. version

Table 1 lists the operator, operand, and CASE information that applies to API Connect.

Supported versions of operators for API Connect

Table 1 lists the operators that are used for the newest version of API Connect

Table 1. Operators for installing and upgrading API Connect

API Connect version	API Connect Operator channel	API Connect Operator version	Data Power version	DataPower Operator version	Foundational services CASE version
10.0.11.0	v6.2	6.2.0	10.6.5.0	1.16.0	4.6.18+

You can run the API Connect operator and subsystems at different versions. The following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
6.2.0	• 10.0.11.0
6.1.0	• 10.0.10.0
6.0.0	• 10.0.9.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

CASE versions required for air-gapped installation and upgrade

Note: There is no need to install a separate EDB case version during the deployment process as the EDB images are included within the API Connect case package.
Table 2 lists the required CASE file for each API Connect release:

Table 3. CASE versions for air-gapped deployments

API Connect version	API Connect CASE version	Foundational services CASE version
10.0.11.0	6.2.0	4.6.18+

Supported versions of Red Hat OpenShift Container Platform

Table 3 provides a quick reference of the supported OpenShift versions for each API Connect release:

Table 4. API Connect and OpenShift Container Platform (OCP) compatibility

API Connect version	OCP 4.10	OCP 4.12	OCP 4.14	OCP 4.16	OCP 4.17	OCP 4.18	OCP 4.19	OCP 4.20
10.0.11.0			✓	✓	✓	✓	✓	✓

API Connect configuration settings

Specify configuration settings for API Connect in the CR, or the Platform UI in Cloud Pak for Integration.

You can use the Platform UI on Cloud Pak for Integration, the OpenShift web console, or direct editing of the top-level or subsystem CR YAML files to specify advanced configuration options for API Connect. The following topics describe the available configuration options.

Attention: A mistake in a configuration update can result in an admission webhook error when `APIConnectCluster` is updated, or the `APIConnectCluster` can get stuck in a pending state with a webhook error message.

- Example of an admission webhook error when the `APIConnectCluster` update is rejected:
  In this example, the user attempted to change the deployment profile to `n12xc4.m12-incorrect` and the result looked like the following example:

```
oc edit apiconnectcluster

error: apiconnectclusters.apiconnect.ibm.com "production" could not be patched: admission webhook
"vapiconnectcluster.kb.io" denied the request: APIConnectCluster.apiconnect.ibm.com "production" is invalid: spec.Profile:
Invalid value: "n12xc4.m12-incorrect": invalid profile. Options are: [n3xc4.m16 n12xc4.m12]
```

- Example of when the `APIConnectCluster` update is allowed, but is the state changes pending due to an underlying webhook error:

```
oc get apiconnectcluster -n apic

NAME   READY  STATUS    VERSION             RECONCILED VERSION   AGE
m1     admission webhook "vmanagementcluster.kb.io" denied the request: ManagementCluster.management.apiconnect.ibm.com
"m1-mgmt" is invalid: [spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup protocol has changed
(from '' to 'objstore') and requires database restart. accept restartDB to restart database,
spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup configuration has changed and requires database
restart. accept restartDB to restart database]   Pending   10.0.1.5-3388-eus   10.0.1.5-3388-eus    2d6h
```

Basic configuration

- Basic configuration settings

Advanced configuration

To enable access to the advanced configuration settings with Platform UI, toggle the Advanced Options slider.

- Analytics subsystem settings
- Gateway subsystem settings
- Management subsystem settings
- Developer Portal subsystem settings
- Additional Kubernetes settings

Additional configuration

You must edit the yaml file to set additional properties.

- **Basic configuration settings**
  You can specify the API Connect basic configuration settings directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Management subsystem settings**
  You can specify advanced configuration settings for the Management subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Gateway subsystem settings**
  You can specify advanced configuration settings for the Gateway subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Developer Portal subsystem settings**
  You can specify advanced configuration options for the Developer Portal subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Analytics subsystem settings**
  Specify advanced configuration settings for the analytics subsystem directly in the analytics CR. If you are using Cloud Pak for Integration, you can configure many of the analytics settings in Platform UI.
- **Additional Kubernetes settings**
  For each API Connect subsystem, you can specify additional settings for annotations and pod management.

Basic configuration settings

You can specify the API Connect basic configuration settings directly in the CR or with the Platform UI in Cloud Pak for Integration.

Review the tables for information on configuration settings for the following areas:

- Details

- License
- Deployment profiles for installing with a single, top-level CR
- Product version
- Storage class

Details

Table 1. Details

Field	Type	Required	Description
Name	String	Yes	Name this instance using only lowercase alphanumeric characters plus the underscore "-". Maximum of 54 characters. Default: none

License

Table 2. License

Field	Type	Required	Description
License acceptance	Boolean	Yes	The license agreement https://ibm.biz/apictoolkitlic must be accepted before you can install the API Connect capability. Default value: **`false`** (off). In the UI, click the License acceptance toggle to enable it. In the CR, set the **`accept:`** field to **`true`** to accept the license.
License use	String	Yes	Select **`production`** or **`nonproduction`**, to match the license you purchased. Default: **`nonproduction`**
License metric	Enumerated	No	Enter the unit of measure that is used for your program license: OpenShift • PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program. Cloud Pak for Integration • VIRTUAL_PROCESSOR_CORE - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM Cloud Pak for Integration - API Calls add-on program. For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.
License ID	String	Yes	Select the license that you purchased for this instance of API Connect. Valid licenses are based on the selected value in the Product version field (see Table 4). When deploying the standalone IBM API Connect product, you must select the License ID for the API Connect program that you purchased. To view all License IDs, see API Connect licenses.

Deployment profiles for installing with a single, top-level CR

Select a deployment profile for the new installation. See API Connect deployment profiles for OpenShift and Cloud Pak for Integration for more information on the available profiles.

For information on switching to a different deployment profile after installation, see the following topics:

- Changing the deployment profile on Cloud Pak for Integration
- Changing deployment profiles on OpenShift top-level CR

Product version

Table 3. Product version

Field	Type	Required	Description
Product version	Enumerated	No	Select the product version to be installed in the system. Warning: Do not select a channel here instead of the API Connect version. Selecting a channel will result in any API Connect interim fix updates being applied automatically and without warning.

Storage class

Table 4. Storage class

Field	Type	Required	Description
Default Storage Class	Enumerated	No	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is optional, but is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel, select System Requirements > Storage. To review API Connect storage support, see Storage classes.

Management subsystem settings

You can specify advanced configuration settings for the Management subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Note: Optionally, you might want to increase the timeout settings for management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.

Database backups settings

Table 1. Database backup

Field	Type	Required	Description
Credentials	Drop down menu	Yes	The name of the Kubernetes secret containing your S3 access key and secret or your or SFTP username and password or SSH key. Default: (Generated Value) See Configuring management database backups.
Server hostname	String	Yes	Hostname of your remote SFTP backup server or object-store endpoint. If specifying an S3 object-store, use the format **<S3endpoint>/<S3region>**. For example: **s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard** Default: none See Configuring management database backups.
Path	String	Yes	The path to the location of for your backups on your remote server. If you are using a remote SFTP server, then this is a directory path. If you are using an object-store, then this is the name of your S3 bucket. For example, **bucket-name/folder**. The use of subdirectories in the bucket name is not supported. Ensure that **bucket-name/folder** is empty. Default: none See Configuring management database backups.
Port	Integer	No	If you are using a remote SFTP server, set this to the port the SFTP server listens on. Default is 22.
Protocol	String	Yes	Set according to your remote backup site as follows: • SFTP: Set **protocol=sftp**. • Object-store: Set **protocol=objstore**. • None: Set **local**. Backups are kept on local persistent storage.
Schedule	String	Yes	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * * • - - - - - - • | | | | | | • | | | | | +----- day of week (0 - 6) (Sunday=0) • | | | | +------- month (1 - 12) • | | | +--------- day of month (1 - 31) • | | +----------- hour (0 - 23) • | +------------- min (0 - 59) • +--------------- sec (0 - 59) The backup schedule defaults to **0 0 * * * *.** This means a backup is run every day at midnight and minute zero UTC. When you configure a host, if you do not specify a value for **schedule**, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed. See Configuring management database backups.
Backup certs	Drop down menu	Optional, if S3 object-store requires them.	Secret containing the CA certificate for your S3 object-store. Required for API Connect to trust the S3 object-store.
RepoRetentionFull	Integer	Yes	The number of days to retain backups for. For example, if **RepoRetentionFull** is set to 30, then any backups older than 30 days are deleted.
Backup S3 URI Style	Drop down menu	**host**	Indicates whether URIs to your S3 backup specify a host or a path value. Set to either **host** or **path**.

Database persistence

Table 2. Database persistence

Field	Type	Required	Description

Field	Type	Required	Description
Storage Class	Drop down menu	No. Optional	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel of the KC, select System Requirements > Storage. To review API Connect storage support, see Storage classes.
Volume size	Integer	No. Optional	Represents the size of the Database volume. Defaults to 120G for `n1xc4.m16` installation profile, 180G for `n3xc4.m16` installation profile.

Site name

Table 3. Site Name

Field	Type	Required	Description
Site name	string	No. Optional	Site name is the logical name of this failure domain. Typically site name is the name of your data center, such as Amazon AZ. Default: randomly generated name. This will be the site name of the management deployment. For example, given the site name of `test` your management deployment will look like `management-test-postgres`.

Test and Monitor

Table 4. Test and Monitor

Field	Type	Required	Description
Enable Test and Monitor	Boolean. Toggle off/on	No. Optional	Test and Monitor automatically generates API test assertions. It contains dashboards for monitoring API test assertions and getting alerts on the health of your APIs. Default: off See Installing the Automated API behavior testing application.

API Governance

Table 5. Governance

Field	Type	Required	Description
Enable Governance	Boolean. Toggle off/on	No. Optional	The API governance service is an optional add-on to API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. Default: off See Enabling governance on Kubernetes.

API Discovery

Table 6. Discovery

Field	Type	Required	Description
Enable Discovery	Boolean. Toggle off/on	No. Optional	The API discovery service is an optional add-on to API Connect that can be used to discover and add APIs to your API development process. Default: off See Enabling API discovery on Kubernetes.
Enable proxy collector	Boolean. Toggle off/on	No. Optional	The Proxy Collector is data source for API Discovery that allows you to discover APIs from analytics data within your provider organizations. The discovered OpenAPI documents can then be copied to draft APIs as required, to enable full lifecycle management in API Manager. Default: off See Configuring a DataPower API Gateway proxy collector for API discovery.

Billing

Table 7. Billing

Field	Type	Required	Description
Enable Billing	Boolean. Toggle off/on	No. Optional	To enable the monetization of your Product Plans, you must add a billing integration resource in your API Connect provider organization that defines the configuration data needed to synchronize with an external subscription billing system. Default: off See Adding a billing integration resource.

Gateway subsystem settings

You can specify advanced configuration settings for the Gateway subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

- v5 compatibility mode
- Operations Dashboard
- Token management service
- Autoscaling gateway pods

For annotations, labels, node selectors, and tolerances, see Additional Kubernetes settings

v5 compatibility mode

Table 1. v5 compatibility mode

Field	Type	Required	Description
V5 comparability mode	Toggle Switch off/on	No. Optional	Enabling this provides v5 compatibility (trading off some performance) with the IBM DataPower Gateway that was provided with IBM API Connect Version 5 and earlier releases. Consider using this DataPower Gateway (v5 compatible) if you are an existing DataPower user and want to utilize your DataPower resources and knowledge. Default: off To review v5 compatibility, see API Connect gateway types.

Operations Dashboard

Table 2. Operations Dashboard

Field	Type	Required	Description
Enable Operations Dashboard tracing	Toggle Switch off/on	No. Optional	Enable or disable cross-component transaction tracing to allow troubleshooting and investigating errors and latency issues. Default: disabled (off) To review the Operations Dashboard, see https://www.ibm.com/support/knowledgecenter/SSGT7J_20.3/tracing/operations_dashboard.html For information on configuring the Operations Dashboard, see https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta2/#odtracing.
Operations Dashboard namespace	string	No. Optional	Namespace where the IBM Cloud Pak for Integration Operations Dashboard has been deployed. Default: none
Replica count	string	No. Optional	Specify the number of instances of the Gateway that should be deployed. For high-availability, a minimum of 3 replicas (one per node) is recommended. Default: none

Token management service

Table 3. Token management service

Field	Type	Required	Description
Advanced: Enable TMS	Toggle Switch	No. Optional	Enable or disable token management service (TMS) to use the DataPower to manage the token lifecycle.. Default: disabled (off) The Token Management Service uses the DataPower distributed cache to manage the token lifecycle which includes when to revoke access rights. For more information, see Token management with DataPower API Gateway.
Advanced: Storage Class	string	No. Optional	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel of the KC, select System Requirements > Storage. To review DataPower storage configuration, see https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta2/#storage.
Advanced: Volume size	string	No. Optional	Resources represents the minimum resources the volume should have. For example, 10Gi.Default: none To review DataPower storage configuration, see `storage` API. in the DataPower documentation.

Autoscaling gateway pods

Autoscaling enables the gateway deployment to scale dynamically, either vertically or horizontally. It is not possible to use both horizontal and vertical pod scaling simultaneously. You must configure either **HPA** (for horizontal scaling) or **VPA** (for vertical scaling) as the scaling method.

Note: DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when pods are scaled down based on defined CPU or memory thresholds. Workloads with long-lived connections are more vulnerable to failed API transactions when auto-scaling is occurring.
To learn more about HPA and VPA autoscaling, see the following topics in the DataPower documentation:

- Autoscaling DataPower Pods
- `podAutoScaling` API

You can configure autoscaling for Gateway pods by inserting a new subsection in the **spec** **gateway** section of the top-level CR, or by filling in the corresponding fields in the OpenShift or IBM Cloud Pak Platform UI. Settings are described in Table 4.

The following example configures HPA autoscaling in the gateway section of the top-level API Connect CR:

```
spec:
  gateway:
    podAutoScaling:
      hpa:
        maxReplicas: 5
        minReplicas: 3
        targetCPUUtilizationPercentage: 90
        targetMemoryUtilizationPercentage: 80
      method: HPA
```

Table 4. Autoscaling configuration settings

UI Field name / CR Setting	Autoscaling method	Required	Description
• Scaling method • **method**	All	Yes	Select the autoscaling method to be used: either **HPA** (Horizontal Pod Autoscaling) or **VPA** (Vertical Pod Autoscaling). To disable autoscaling, leave **method** blank, or omit the **podAutoScaling:** section from the CR.
• Minimum pods • **minReplicas**	HPA	Yes	Minimum number of pods that can be scaled down to by the horizontal pod autoscaler.
• Maximum pods • **maxReplicas**	HPA	Yes	Maximum number of pods that can be scaled up to by the horizontal pod autoscaler. Must be a value greater than **minReplicas**.
• Target CPU Utilization Percentage • **targetCPUUtilizationPercentage:**	HPA	No	Percent threshold on average CPU usage by pods for triggering horizontal scaling.
• Target Memory Utilization Percentage • **targetMemoryUtilizationPercentage**	HPA	No	Percent threshold on average memory usage by pods for triggering horizontal scaling.
• Maximum CPU • **maxAllowedCPU**	VPA	No	Maximum value for CPU resource that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **DataPowerRequestsSpec.ResourceCPU**
• Maximum Memory • **maxAllowedMemory**	VPA	No	Maximum amount of memory that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **DataPowerRequestsSpec.ResourceMemory**

Developer Portal subsystem settings

You can specify advanced configuration options for the Developer Portal subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

- Database backups
- Site name

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Known limitation: When deployed on OpenShift or Cloud Pak for Integration, the API Connect Developer Portal subsystem does not support multiple hosts for the **portalUIEndpoint** endpoint, due to a limitation of Routes in OCP.

Database backups

Table 1. Database backup settings

Field	Type	Description
Credentials	String	For **objstore**, this is the name of your Kubernetes secret that was generated with your username and password for your backup database. For **sftp**, this is the secret that contains the credentials for your **sftp** username and password. Required if configuring backups. See also Configuring portal database backups.
Backup host	String	The S3 endpoint with the corresponding S3 region in the format **<S3endpoint>/<S3region>**. For example: **s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard** For sftp, this is the sftp server host name. Required if configuring backups. See also Configuring portal database backups.
Backup path	String	For **objstore**, the name of your S3 bucket to store backup data. For example: **test-bucket/restore-test**. For sftp, this is the path to the folder on the sftp server. Required if configuring backups. See also Configuring portal database backups.

Field	Type	Description
Backup port	Integer	This is the port for the protocol to connect to the host. There is no default. See also Configuring portal database backups.
Backup protocol	String	Choose the protocol (sftp or objstore) you wish to use to communicate with your remote backup endpoint. Objstore is recommended for most reliability. There is no default. This field must be set to either **`sftp`** or **`objstore`** to configure backups. See also Configuring portal database backups.
Backup schedule	String	This is the schedule in cron string format for how often automatic Developer Portal backups are run. For example: `0 /3 * * *` means at minute 0 past every 3rd hour. There is no default. Required if configuring backups. See also Configuring portal database backups.

Site name

Table 2. Site name

Field	Type	Description
Site name	string	Site name is the logical name of the failure domain of this portal subsystem. Typically site name is the name of your data center, such as Amazon AZ. The default is a randomly generated name.

Analytics subsystem settings

Specify advanced configuration settings for the analytics subsystem directly in the analytics CR. If you are using Cloud Pak for Integration, you can configure many of the analytics settings in Platform UI.

Review Analytics preinstallation planning to decide on the deployment options for your analytics subsystem. If you want to offload your analytics data and disable local storage, you must configure local storage disablement before installation because it cannot be changed after installation.

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Cloud Pak for Integration Platform UI

In the Cloud Pak for Integration Platform UI you can specify settings for:

- Analytics database backup
- Storage type, class, and size

All other analytics settings must be configured directly in the analytics section of the **`APIConnectCluster`** CR.

Table 1. Database backup

Field	Type	Required	Description
Backup chunk size in GB	Integer	No	**`chunkSize`** specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB. Default value is 1 GB. See Configuring analytics backups.
Credentials	String	No	The backup credential is the name of the Kubernetes secret that you created for accessing your S3-compatible storage. No default. See Configuring analytics backups.
Compress	Boolean: off or on	No	Determines whether metadata files are stored in compressed format. Default value is false (off). See Configuring analytics backups.
Enable server-side encryption	Boolean: off or on	No	Determines whether files are encrypted. When set to true (on), files are encrypted on the server side by using AES256. Default is false (off). See Configuring analytics backups.
Analytics server hostname	String	No	The URL to your S3 storage. No default. See Configuring analytics backups.
Backup Path	String	No	The path to your S3 storage at the URL specified by analytics server hostname.host. No default. See Configuring analytics backups.
Schedule cron expression	String	No	The schedule that determines how often backups are run automatically. The format for the schedule is any valid **`cron`** string. Default: "*/20 * * * *" See Configuring analytics backups.

Table 2. Storage type, class, and size settings

Field	Type	Required	Description
Master storage class	String	Yes	If you specified dedicated storage, the master storage class is the storage class that is used by your **`storage-os-master`** pods. Select from the drop down. Local-volume storage is recommended for best performance. If none selected, the default storage class of your cluster is used. See Analytics preinstallation planning.

Field	Type	Required	Description
Shared storage class	String	Yes	The storage class used by your analytics **storage** pods. Select from the drop down. Local-volume storage is recommended for best performance. If none selected, the default storage class of your cluster is used. See Analytics preinstallation planning.
Master volume size	Integer > 0	No	If you specified dedicated storage, then master volume size specifies the disk storage that is allocated to your **storage-os-master** pods. The **storage-os-master** pods do not store your analytics data, and if left unset the value defaults to 5Gi.
Shared volume size	Integer > 0	Yes	How much persistent disk storage is allocated for analytics data (in Gi). See Estimating storage requirements. If you do not have the information to estimate your usage, set this to 500Gi. For an installation where you expect to store little or no analytics data, you can set the storage to 50Gi.
Type	Boolean: dedicated or shared	Yes	OpenSearch storage type to use for your analytics data. For more information about storage types, see Analytics preinstallation planning. The default storage type is shared.

Additional Kubernetes settings

For each API Connect subsystem, you can specify additional settings for annotations and pod management.

The additional settings are generic Kubernetes configuration settings. The Platform UI advanced configuration option for API Connect enables you to set them specifically for each subsystem.

Annotations

The annotations field serves as a pass-through for all the resources managed by the CR. You can add any annotation to this field. The annotations here overwrite the default annotations.

See https://kubernetes.io/docs/concepts/overview/working-with-objects/annotations/.

Labels

The labels field serves as a pass-through for Pod labels. You can add any label to this field and have it apply to the pod. The labels here overwrite the default labels provided. For example, if the label 'mylabel=1' was provided, it would apply to all kubernetes resources managed by this CR.

See https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/.

Node Selector

This field allows you to specify a set of key value pair that must be matched against the node labels to decide which API Connect pods can be scheduled on that node. Only nodes matching all of these key value pairs in their labels will be selected for scheduling API Connect pods.

See https://kubernetes.io/docs/concepts/scheduling-eviction/assign-pod-node/.

Tolerations

This field allows you to select which nodes API Connect pods can be scheduled or not scheduled. By specifying a set of matching tolerations, you can control whether specific nodes can be used for scheduling API Connect Pods.

Effect (optional)
: Effect indicates the taint effect to match. Empty means match all taint effects. When specified, allowed values are NoSchedule, PreferNoSchedule and NoExecute.

Key (optional)
: Key is the taint key that the toleration applies to. Empty means match all taint keys. If the key is empty, operator must be Exists; this combination means to match all values and all keys.

  Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

Operator (optional)
: Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

Toleration seconds (optional)
: TolerationSeconds represents the period of time the toleration (which must be of effect NoExecute, otherwise this field is ignored) tolerates the taint. By default, it is not set, which means tolerate the taint forever (do not evict). Zero and negative values will be treated as 0 (evict immediately) by the system.

Value (optional)
: Value is the taint value the toleration matches to. If the operator is Exists, the value should be empty, otherwise just a regular string.

See https://kubernetes.io/docs/concepts/scheduling-eviction/taint-and-toleration/.

Configuring timeouts for management endpoints

Adjust the timeout settings for management endpoints by updating the CR.

About this task

On large deployments, or with large API usage, you might encounter timeout issues when deployed with the default timeout setting of 30 seconds. To avoid timeout issues, increase the setting for the management endpoints used in routing.

You do not have to set these values on initial installation. You can set them or change them after installation and reapply the CR YAML files.

Procedure

Edit the CR to set the timeout to 240 seconds.
The instructions for editing depend on whether you install API Connect using subsystem CRs or a single top-level CR:

- If you are installing API Connect using subsystem CRs, edit **`management_CR.yaml`**:

```
  cloudManagerEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: admin.example.com
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: manager.example.com
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: api.example.com
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: consumer.example.com
      secretName: consumer-endpoint
```

- If you are installing API Connect using a top-level CR, the management subsystem settings are embedded in the top-level APIConnectCluster CR. Edit the endpoint settings under **`spec:management:`** as follows:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: ${NAMESPACE}
spec:
...
  management:
    cloudManagerEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: admin.example.com
        secretName: cm-endpoint
    apiManagerEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: manager.example.com
        secretName: apim-endpoint
    platformAPIEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: api.example.com
        secretName: api-endpoint
    consumerAPIEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: consumer.example.com
        secretName: consumer-endpoint
...
```

Installation procedures with IBM Cloud Pak for Integration

The API Management capability of IBM Cloud Pak for Integration uses API Connect.

There are several methods for installing API Connect with Cloud Pak for Integration:

- Use the Cloud Pak for Integration Platform UI to install API Connect with a top-level CR. The steps are documented in the installation section of the Cloud Pak for Integration documentation: https://www.ibm.com/docs/en/cloud-paks/cp-integration.
- If API Connect is already installed with the top-level CR and you want to migrate it to Cloud Pak for Integration, see Migrating from OpenShift to Cloud Pak for Integration on the same cluster.

Installing API Connect in a single namespace on OpenShift

Use individual subsystem CRs to install API Connect subsystems in a shared namespace on OpenShift.

About this task

API Connect subsystems are installed by creating individual subsystem CRs in the same shared namespace. If you want to install your API Connect subsystems in different namespaces, for example Management server in a namespace that is called **`mgmt`**, and gateway in a namespace that is called **`gway`**, then see: Installing API Connect subsystems in different namespaces or environments on OpenShift.

Air-gapped installations: If you are installing API Connect in an offline environment, first follow the steps for configuring the catalog sources as described here: Air-gapped installation.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

1. Installing operators
   Install operators for API Connect, DataPower, and common services so that you can deploy the API Connect subsystems in a shared namespace on OpenShift.
2. Setting up a certificate issuer
   Create the cert-manager issuer for generating the certificates and secrets for use with API Connect.
3. Installing the management subsystem in a shared namespace
   Install the management subsystem by creating and applying the mgmt_cr.yaml file.
4. Installing the gateway subsystem in a shared namespace
   Install the gateway subsystem by creating and applying the apigateway_cr.yaml file.
5. Installing the portal subsystem in a shared namespace
   Install the portal subsystem by creating and applying the portal_cr.yaml file.
6. Installing the analytics subsystem in a shared namespace
   Install the analytics subsystem by creating and applying the analytics_cr.yaml file.

Installing operators

Install operators for API Connect, DataPower, and common services so that you can deploy the API Connect subsystems in a shared namespace on OpenShift.

Before you begin

The API Connect operator and operand must be at compatible release and fix pack levels. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.11.0	v6.2	6.2.0

If you want to run API Connect operator and subsystems at different versions, the following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
6.2.0	• 10.0.11.0
6.1.0	• 10.0.10.0
6.0.0	• 10.0.9.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

Note: There can be only one version of the API Connect operator in your OpenShift cluster. You cannot install different operator versions in different namespaces. If you install the API Connect operator in multiple namespaces, all installations must be at the same operator version.
The API Connect operator pods in your operator namespace must have network access to the namespace where your API Connect subsystems are installed. Do not configure OpenShift network policies that block communication between any of these namespaces:

- API Connect operator
- API Connect subsystems (operands)
- cert-manager
- openshift-operator-lifecycle-manager
- ibm-common-services

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.
3. Create the namespace where API Connect will be installed, either by selecting Home > Projects > Create Project in the UI, or with the following command:

   ```
   oc create ns <APIC-namespace>
   ```

   The namespace where you install API Connect must meet the following requirements:
   - Red Hat OpenShift: Only one top-level CR (**APIConnectCluster**) can be deployed in each namespace.
   - Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
   - Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:
     - **default**
     - **kube-system**
     - **kube-public**
     - **openshift-node**
     - **openshift-infra**
     - **openshift**
4. If you are installing the operator into a single namespace, create an OperatorGroup object specifying that namespace.
   Attention: If you are installing the operator into all namespaces, skip this step because the **openshift-operators** namespace already has an appropriate Operator group in place.
   a. Create the apiconnect-operator-group.yaml file with an OperatorGroup object that identifies the namespace in which RBAC permissions for the IBM API Connect Operator will be generated, and where the CSV will be available:

      ```
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: <operator-group-name>
        namespace: <APIC-namespace>
      spec:
        targetNamespaces:
        - <APIC-namespace>
      ```

   b. Apply the OperatorGroup object with the following command:

      ```
      oc apply -f apiconnect-operator-group.yaml
      ```

5. If you are installing the operator in all namespaces, then create the common services namespace:

   ```
   oc create ns ibm-common-services
   ```

6. Create a pull secret in the namespaces where you want to install API Connect.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
   b. Ensure that the Project is set to the namespace where you intend to install API Connect.
   c. Click Create and select Image pull secret.
   d. Set the following parameters for the secret:
      - Set Secret name to **ibm-entitlement-key**.
      - Set Authentication type to **Image registry credentials**.
      - Set Registry server address to **cp.icr.io**.
      - Set Username to **cp**.
      - Set Password to the entitlement key generated in Step 2.
      - Click Create to create the secret.

   Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with the following command: **ibmcloud oc worker reload**
   For information on using the **reload** command, see the Red Hat OpenShift on IBM Cloud documentation.

7. Add the API Connect catalog sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

   a. Generate the catalog source files:
      i. Log into your cluster using the **oc login** command and your user credentials:

         ```
         oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
         ```

      ii. Export the variables for the command line to use:
         API Connect:

         ```
         export CASE_NAME=ibm-apiconnect
         export CASE_VERSION=6.2.0
         export ARCH=amd64
         ```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

iii. Download the files for the operators required by API Connect:

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources for API Connect:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

b. Apply the catalog sources:

i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

8. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.

a. Generate the catalog source files:

i. Log into your cluster using the **oc login** command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

ii. Export the variables for the command line to use; substituting the appropriate CASE version:

```
export CASE_NAME=ibm-cp-common-services
export CASE_VERSION=<case version>
export ARCH=amd64
```

Set *<case version>* to the value specified for *Foundational services CASE version* in Operator, CASE, and platform requirements, for your deployment type.

iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

This command might not return anything if there are no architecture-specific catalog sources.

b. Apply the catalog sources:

i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

9. Add the DataPower operator sources to your cluster.
Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.

a. Generate the catalog source files:

i. Log into your cluster using the **oc login** command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

ii. Export the variables for the command line to use; substituting the appropriate CASE version:

```
export CASE_NAME=ibm-datapower-operator
export CASE_VERSION=<case version>
export ARCH=amd64
```

Set *<case version>* to the value specified for *DataPower operator version* in Operator, CASE, and platform requirements, for your deployment type.

iii. Download the files for the operators required by DataPower:

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

This command might not return anything if there are no architecture-specific catalog sources.

b. Apply the catalog sources:
   i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

   ii. Confirm that the catalog sources have been created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

10. Create the **apiconnect** subscription.
    a. Create the **apiconnect** subscription with the appropriate channel by creating a file called **apic-sub.yaml** and pasting in the following contents, updating the namespace as required:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
  namespace: <namespace>
spec:
  channel: v6.2
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

    Where ***<namespace>*** is one of the following values:
    - **openshift-operators** if you are installing the operator in all namespaces
    - The namespace created in step 3 if you are installing the operator in a single namespace

    b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

    c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
    If any operators such as **ibm-apiconnect** or **IBM DataPower Gateway** show the status of "Upgrade available", approve the upgrade by completing the following steps:

       i. Click Upgrade available.
       ii. Click Preview InstallPlan.
       iii. Click Approve.
       iv. Wait for the **IBM API Connect** and **IBM DataPower Gateway** operators to install.

    The **IBM DataPower Gateway** operator is a prerequisite to API Connect and must not be removed.

11. Install cert manager by completing the following steps:
    a. Log in to the OpenShift Container Platform web console.

    b. Navigate to Operators > OperatorHub.

    c. In the filter box, type: **cert-manager Operator for Red Hat OpenShift**.

    d. Select cert-manager Operator for Red Hat OpenShift and click Install.

    e. On the Install Operator page, complete the following steps:
       i. Update the Update channel if needed. The channel defaults to **stable-v1**, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

       ii. Select the Installed Namespace for the operator.
       The default operator namespace is **cert-manager-operator**; if that namespace doesn't exist, it is created for you.

       iii. Select an Update approval strategy:
          - Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
          - Manual: require a user with the appropriate credentials to approve all operator updates.

       iv. Click Install.

    f. Verify the cert-manager installation by completing the following steps:
       i. Click to Operators > Installed Operators.

       ii. Verify that **cert-manager Operator for Red Hat OpenShift** is listed with a Status of **Succeeded** in the **cert-manager-operator** namespace.

       iii. Verify that cert-manager pods are up and running by running the following command:

```
oc get pods -n cert-manager
```

       For a successful installation, the response looks like the following example:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
```

12. Create the **ibm-common-services-operator** subscription, if it does not already exist.
    a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: <namespace>
spec:
  channel: v4.6
  name: ibm-common-service-operator
```

```
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

Where: ***<namespace>*** is one of the following values:

- **openshift-operators** if you are installing the operator in all namespaces
- The namespace created in step 3 if you are installing the operator in a single namespace

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the **ibm-common-services** namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the **IBM Cloud Pak foundational services** and **Operand Deployment Lifecycle Manager** operators to install.

13. Create the **ibm-datapower-operator** subscription, if it does not already exist.
a. Create a file called datapower-operator-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: datapower-operator
  namespace: <namespace>
spec:
  channel: v1.15
  name: datapower-operator
  source: ibm-datapower-operator-catalog
  sourceNamespace: openshift-marketplace
```

Where: ***<namespace>*** is one of the following values:

- **openshift-operators** if you are installing the operator in all namespaces
- The namespace created in step 3 if you are installing the operator in a single namespace

b. Apply the subscription with the following command:

```
oc apply -f datapower-operator-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the **ibm-datapower-oprator** namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the **IBM Cloud Pak foundational services** and **Operand Deployment Lifecycle Manager** operators to install.

Next topic: Setting up a certificate issuer

Setting up a certificate issuer

Create the cert-manager issuer for generating the certificates and secrets for use with API Connect.

Before you begin

To deploy API Connect, you must first create the cert-manager issuers and certificates that API Connect uses. On OpenShift cert-manager is bundled as a foundational service, so you do not need to install cert-manager itself. For more information on cert-manager: Key Concepts: Cert-manager, Issuers, and Secrets

Procedure

1. Create a file that is called **ingress-issuer-v1.yaml** and paste in the following contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
```

```
#

   ```

Previous topic: Installing operators
Next topic: Installing the management subsystem in a shared namespace

Installing the management subsystem in a shared namespace

Install the management subsystem by creating and applying the mgmt_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Use the OpenShift® CLI to edit the custom resource template for the management subsystem then apply the resource. Verify that the pods are up and running, and validate that you can connect to the API Connect Cloud Manager.

Procedure

1. Create a file that is called mgmt_cr.yaml and paste in the following content:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: management
```

```
  annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  portal:
    admin:
      secretName: portal-admin-client
  analytics:
    ingestion:
      secretName: analytics-ingestion-client
  gateway:
    client:
      secretName: gateway-client-client
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.$STACK_HOST
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: manager.$STACK_HOST
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.$STACK_HOST
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer.$STACK_HOST
      secretName: consumer-endpoint
  consumerCatalogEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secretName: consumer-catalog-endpoint
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the YAML file and replace the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

version: <*version_number*>

Example version number: 10.0.11.0

$PROFILE
Specify your management subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress host names to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
cloudManagerEndpoint:
      < ... >
    hosts:
    - name: admin.myhost.subnet.example.com
      secretName: cm-endpoint

  apiManagerEndpoint:
      < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secretName: apim-endpoint

  platformAPIEndpoint:
      < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secretName: api-endpoint
```

```
consumerAPIEndpoint:
      < ... >
  hosts:
  - name: consumer.myhost.subnet.example.com
    secretName: consumer-endpoint

consumerCatalogEndpoint:
      < ... >
  hosts:
  - name: consumer-catalog.myhost.subnet.example.com
    secretName: consumer-catalog-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **cloudManagerEndpoint**, you can replace **admin.$STACK_HOST** with **my.cloudmgr.myhost.subnet.example.com**, where **my.cloudmgr** replaces **admin**, and **myhost.subnet.example.com** replaces **STACK_HOST**. For example:

  ```
  cloudManagerEndpoint:
        < ... >
    hosts:
    - name: my.cloudmgr.myhost.subnet.example.com
      secretName: cm-endpoint
  ```

  You can do this for some or all of the host names, depending on your customization requirements.

$STORAGE_CLASS
: The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

  ```
  storageClassName: local-storage
  ```

$LICENSE_ACCEPTANCE
: Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
: Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
: Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Install the management subsystem by applying the modified CR with the following command:

   ```
   oc apply -f mgmt_cr.yaml -n <management_namespace>
   ```

4. Verify that the management subsystem is fully installed by running the following command:

   ```
   oc get ManagementCluster -n <management_namespace>
   ```

   The installation is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online:

   ```
   NAME          READY   SUMMARY    VERSION     RECONCILED VERSION   AGE
   management    True    16/16       <version>    <version-build>       7m17s
   ```

5. Verify that you can log in to the API Connect Cloud Manager UI:
   a. Determine the URL for the Cloud Manager UI by running the following command to view the API Connect endpoints:

      ```
      oc get routes -n <management_namespace>
      ```

   b. Locate the **management-admin** endpoint, and note it down.
   c. Determine the Cloud Manager administrator password by running the following commands:

      ```
      oc get secret -n <management-namespace> | grep management-admin-secret

      oc get secret -n <management-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -
      d && echo ""
      ```

   d. Open a browser and go to the **management-admin-apic** endpoint.
   e. Log in to the Cloud Manager as **admin** with the administrator password.
6. Store all secrets and passwords in a safe place.
7. Backup your management subsystem database and infrastructure configuration: Backing up and restoring the management subsystem.
8. For more information about advanced configuration for Postgres components, see Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Setting up a certificate issuer
Next topic: Installing the gateway subsystem in a shared namespace

Installing the gateway subsystem in a shared namespace

Install the gateway subsystem by creating and applying the apigateway_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Important: When you install the gateway subsystem, you must configure the gateway subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Use the OpenShift® CLI to edit the custom resource template for the gateway, apply the resource, verify that the pods are up and running.

Procedure

1. Create the gateway admin secret with: `oc -n <gateway namespace> create secret generic admin-secret --from-literal=password=admin`
2. If you are installing the API Gateway (v6), create a yaml file that is called `apigateway_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

    use: $LICENSE_USE
    license: '$LICENSE_ID'
  adminUser:
    secretName: admin-secret
  mtlsValidateClient: true
  # syslogConfig:
  #   enabled: false # if true, provide below details
  #   remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
  #   remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
  #   secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

3. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.11.0

$PROFILE
Specify your gateway subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

  ```
  gatewayEndpoint:
        < ... >
      hosts:
      - name: rgw.myhost.subnet.example.com
        secret: gwv6-endpoint

    gatewayManagerEndpoint:
        < ... >
      hosts:
      - name: rgwd.myhost.subnet.example.com
        secret: gwv6-manager-endpoint
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
gatewayEndpoint:
       < ... >
    hosts:
    - name: my.gateway.endpoint.myhost.subnet.example.com
      secret: gwv6-endpoint
```

You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.
$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.
$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

syslogConfig
To enable this feature uncomment this section, set **enabled: true**, and set the properties:
$DATAPOWER_SYSLOG_TCP_REMOTE_HOST
remoteHost: <*remote.host*>
String. The hostname of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_REMOTE_PORT
remotePort: <*remote_port_number*>
Integer. The port number of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_TLS_SECRET
secretName: <*secret*>
String. The TLS secret name of the server for **syslogConfig**.

4. Optional: If applicable to your deployment, update the gateway CR file to configure **DataPowerService** APIs to customize your DataPower® deployment. See Customizing a DataPower deployment.
5. Configure Management-to-Gateway communication security. You must configure either mutual TLS (mTLS) or JWT for secure communication between the management subsystem and the gateway subsystem.
   a. To enable mutual TLS between the management client and the gateway service's manager endpoint, add **mtlsValidateClient** to the **spec** section:

   ```
   spec:
     mtlsValidateClient: true
   ```

   This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under **gatewayManagerEndpoint.hosts.secretName**. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under **gateway.client.secretName**.

   b. If you want to enable JWT security for communications between the management and gateway, add and set the property **jwksUrl**, and set **spec.mtlsValidateClient** to false.

   ```
   spec:
     ...
     jwksUrl: <JWKS URL>
     mtlsValidateClient: false
   ```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

   ```
   kubectl describe mgmt -n <namespace>
   ...
   status:
     - name: jwksUrl
       secretName: api-endpoint
       type: API
       uri: https://api.apic.acme.com/api/cloud/oauth2/certs
   ```

   For more information about JWT security, see Enable JWT security instead of mTLS.
6. Optional: Update the gateway CR file to enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
7. Install the gateway Custom Resource by applying the yaml file:
   For a DataPower API Gateway, run the following command:

   ```
   oc apply -f apigateway_cr.yaml -n <namespace>
   ```

   For a DataPower Gateway (v5 compatible), run the following command:

   ```
   oc apply -f v5cgateway_cr.yaml -n <namespace>
   ```

8. To verify that the gateway subsystem is fully installed, run the following command:

   ```
   oc get GatewayCluster -n <namespace>
   ```

The installation is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (**2/2**) for all the gateway subsystems that were installed. Example:

```
NAME    READY    SUMMARY    VERSION     RECONCILED VERSION    AGE
gwv6    True     2/2        <version>   <version-build>       7m32s
```

There is no need to wait for the **READY** status to be **True** before moving on to next Subsystem installation.

9. Verify that the gateway is ready to be registered with the Management subsystem by calling the **health** api on the **gatewayManagerEndpoint.hosts.name** defined in your yaml file: **https://gwd.$STACK_HOST/health**.

```
curl -k https://gwd.example.com/health
{"status":"ok"}
```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the management subsystem in a shared namespace
Next topic: Installing the portal subsystem in a shared namespace

Installing the portal subsystem in a shared namespace

Install the portal subsystem by creating and applying the portal_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Important: When you install the portal subsystem, you must configure the portal subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Use the OpenShift® CLI to edit the custom resource template for the portal subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called **portal_cr.yaml** and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#

    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the yaml file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.11.0

$PROFILE
Specify your portal subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **myhost.subnet.example.com**:

  ```
  portalAdminEndpoint:
      < ... >
      hosts:
      - name: api.portal.myhost.subnet.example.com
        secret: portal-admin

    portalUIEndpoint:
      < ... >
      hosts:
      - name: portal.myhost.subnet.example.com
        secret: portal-web
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **portalAdminEndpoint**, you can replace **api.portal.$STACK_HOST** with **my.api.portal.myhost.subnet.example.com**, where **my.api.portal** replaces **api.portal**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

  ```
  portalAdminEndpoint:
        < ... >
      hosts:
      - name: my.api.portal.myhost.subnet.example.com
        secret: cm-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**. For example, for local storage:

```
databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
```

```
    volumeSize: 12Gi
webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
backupVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 300Gi
adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
```

Note:

- The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation. For more information on planning your portal PV requirements, see Portal subsystem.
- The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
- The **certVolumeClaimTemplate** is used by the nginx pod and in 2DCDR mode it is also by the **tunnel**, **db-remote** and **www-remote** pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

$LICENSE_ACCEPTANCE
: Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
: Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
: Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

4. Install the portal subsystem by applying the modified CR with the following command:

```
oc apply -f portal_cr.yaml -n <namespace>
```

5. Verify that the portal subsystem is fully installed:

```
oc get PortalCluster -n <namespace>
```

The installation is complete when **STATUS** reports **Running**, **Ready** reports that all services are online (**3/3**), and **MESSAGE** reports "Ready for API Cloud Manager service registration", for example:

```
NAME           READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                      AGE
portal         3/3     Running   <version>  <version>            Ready for API Cloud Manager service registration   2h
```

You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.

6. Verify that you can access the portal web endpoint by browsing to the **portalUIEndpoint.hosts.name** as configured in your yaml file:

```
curl -k https://portal.$STACK_HOST
<!DOCTYPE html>
<html>
<head>
<title>Developer Portal is ready to create sites!</title>
<style>
    body {
        width: 35em;
        margin: 0 auto;
        font-family: Tahoma, Verdana, Arial, sans-serif;
    }
</style>
</head>
<body>Developer Portal is ready to create sites!</h1>
<p>If you see this page, the web server is successfully installed and
working. Further configuration is required.</p>
</body>
</html>
```

7. It is highly recommend that you retain the portal subsystem encryption secret in a safe location, in case you need to restore the portal subsystem during a disaster recovery scenario.
The encryption secret is created when the portal subsystem is initially deployed. You can obtain the name of the encryption secret from the portal subsystem custom resource after the installation is complete:

    a. Obtain the name of the encryptionSecret:

```
oc get ptl portal -o yaml -n <namespace> | grep encryptionSecret
encryptionSecret: portal-enc-key
```

The name of encryption secret is **portal-enc-key**.

b. Save the secret yaml in a safe location:

```
oc get secret portal-enc-key -o yaml -n <namespace> > portal-enc-key.yaml
```

8. Backup the portal installation. See Backing up and restoring the developer portal.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the gateway subsystem in a shared namespace
Next topic: Installing the analytics subsystem in a shared namespace

Installing the analytics subsystem in a shared namespace

Install the analytics subsystem by creating and applying the analytics_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Important: When you install the analytics subsystem, you must configure the analytics subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Use the OpenShift® CLI to edit the custom resource template for the analytics subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called **analytics_cr.yaml** and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsCluster
metadata:
  name: analytics
  labels:
    app.kubernetes.io/instance: analytics
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: analytics
annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  profile: $PROFILE
  mgmtPlatformEndpointCASecret:
    secretName: ingress-ca
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  ingestion:
    endpoint:
```

```
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ai.$STACK_HOST
      secretName: analytics-ai-endpoint
  clientSubjectDN: CN=analytics-ingestion-client,O=cert-manager
storage:
  type: $STORAGE_TYPE
  shared:
    volumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
      volumeSize: $DATA_VOLUME_SIZE
 #master: # uncomment this section if you set storage.type = dedicated.
 #  volumeClaimTemplate:
 #    storageClassName: $STORAGE_CLASS
```

2. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.11.0

$PROFILE
Specify your analytics subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.
Note: The profile that you select influences your storage type options. If you select an **n1** profile then you must select the **shared** storage type. For more information about storage types, see storage types.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
  ingestion:
    endpoint:
      < ... >
    hosts:
    - name: ai.myhost.subnet.example.com
      secret: analytics-ai-endpoint
     < .... >
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, you can replace **$STACK_HOST** with **my.analytics.ingestion.myhost.subnet.example.com**, where **my.analytics.ingestion** replaces **ai**, and **myhost.subnet.example.com** replaces **STACK_HOST**.

```
ingestion:
    endpoint:
      < ... >
    hosts:
    - name: my.analytics.ingestion.myhost.subnet.example.com
      secret: analytics-ai-endpoint
     < ... >
```

$STORAGE_TYPE
If you set **$PROFILE** to an **n1** (one replica) profile, then set this to **shared**. If you set **$PROFILE** to an **n3** (three replica) profile then set this to **dedicated** and uncomment the **storage.master** section, for example:

```
  storage:
    type: dedicated
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    master:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
```

For more information about storage types, see dedicated or shared storage.

$STORAGE_CLASS
The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: **oc get sc**. Example:

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
```

$DATA_VOLUME_SIZE
Size of storage allocated for data. To estimate the storage space you require, see Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
        volumeSize: 500Gi
```

`$LICENSE_ACCEPTANCE`
: Set `accept` to `true`. You must accept the license to successfully deploy API Connect.

`$LICENSE_USE`
: Set `use` to either `production` or `nonproduction` to match the license that you purchased.

$LICENSE_ID
: Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties `mtlsValidateClient` and `jwksUrl`.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.

4. Optional: If you plan to configure analytics database backups, then define the storage that is required for backups:
Define your backup PVC by adding the `backup.volumeClaimTemplate` property in `spec.storage`. For example:

```
spec:
  storage:
    backup:
      volumeClaimTemplate:
        storageClassName: <storage class>
        volumeSize: <size>
```

If you are not sure of the volume size that you need, then you can configure the `backup.volumeClaimTemplate` after installation.

5. Install the analytics subsystem by applying the modified CR with the following command:

```
oc apply -f analytics_cr.yaml -n <namespace>
```

6. Verify that the analytics subsystem is fully installed:

```
oc get AnalyticsCluster -n <namespace>
```

The installation is complete when `READY` shows all pods running (`n/n`), and the `STATUS` reports `Running`. Example:

```
NAME         READY   STATUS    VERSION          RECONCILED VERSION   AGE
analytics    n/n     Running   10.0.11.0   10.0.11.0-1281    86m
```

It is not necessary to wait for analytics installation to complete before you move on to the next subsystem installation.

7. Backup your analytics subsystem and configure scheduled analytics database backups: Backing up and restoring the analytics subsystem.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the portal subsystem in a shared namespace

Installing API Connect subsystems in different namespaces or environments on OpenShift

Install API Connect subsystems in different namespaces, for example Management subsystem in a namespace that is called `apicmgmt`, Gateway in a namespace called `apicgway`. These same steps can also be used for installing subsystems in different environments.

About this task

Install API Connect subsystems where you have separate namespaces for each subsystem.

Air-gapped installations: If you are installing API Connect in an offline environment, first follow the steps for configuring the catalog sources as described here: Air-gapped installation.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

1. Installing operators
   Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect subsystems across multiple namespaces on Red Hat OpenShift. If you deploy API Connect subsystems in different environments, then the corresponding operator must be installed in each environment; for example, install the DataPower operator in your Gateway environment, and the API Connect operator in your Portal environment.
2. Installing the management subsystem
   Install the managment subsystem by creating and applying the `ingress-issuer` and `mgmt_cr` YAML files.
3. Extracting the management ingress-ca certificates
   In order for the management subsystem to be able to communicate with subsystems in different namespaces, these subsystems need to have the same ingress-ca certificates as the management subsystem.
4. Installing the gateway subsystem
   Install the gateway subsystem by creating and applying the ingress-ca, common-issuer, gateway-certs and gateway_cr yaml files.
5. Installing the portal subsystem
   Install the portal subsystem by creating and applying the ingress-ca, common-issuer, and portal_cr yaml files.
6. Installing the analytics subsystem
   Install the analytics subsystem by creating and applying the ingress-ca, common-issuer, and analytics_cr yaml files.

Installing operators

Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect subsystems across multiple namespaces on Red Hat OpenShift. If you deploy API Connect subsystems in different environments, then the corresponding operator must be installed in each environment; for example, install the DataPower operator in your Gateway environment, and the API Connect operator in your Portal environment.

Before you begin

The API Connect operator and operand must be at compatible release and fix pack levels. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.11.0	v6.2	6.2.0

If you want to run API Connect operator and subsystems at different versions, the following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
6.2.0	• 10.0.11.0
6.1.0	• 10.0.10.0
6.0.0	• 10.0.9.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

Note: There can be only one version of the API Connect operator in your OpenShift cluster. You cannot install different operator versions in different namespaces. If you install the API Connect operator in multiple namespaces, all installations must be at the same operator version.
The API Connect operator pods in your operator namespace must have network access to the namespace where your API Connect subsystems are installed. Do not configure OpenShift network policies that block communication between any of these namespaces:

- API Connect operator
- API Connect subsystems (operands)
- cert-manager
- openshift-operator-lifecycle-manager
- ibm-common-services

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.

3. Create a pull secret in the namespaces where you want to install API Connect.
   a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
   b. Ensure that the Project is set to the namespace where you intend to install API Connect.
   c. Click Create and select Image pull secret.
   d. Set the following parameters for the secret:
      - Set Secret name to `ibm-entitlement-key`.
      - Set Authentication type to `Image registry credentials`.
      - Set Registry server address to `cp.icr.io`.
      - Set Username to `cp`.
      - Set Password to the entitlement key generated in Step 2.
      - Click Create to create the secret.

   Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with: `ibmcloud oc worker reload`. For information on using the `reload` command, see the Red Hat OpenShift on IBM Cloud documentation.
4. Add the API Connect catalog sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

   a. Generate the catalog source files:
      i. Log into your cluster using the `oc login` command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use:
      API Connect:

      ```
      export CASE_NAME=ibm-apiconnect
      export CASE_VERSION=6.2.0
      export ARCH=amd64
      ```

      For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

      iii. Download the files for the operators required by API Connect:

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources for API Connect:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

   b. Apply the catalog sources:
      i. Apply the catalog sources:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

      ```
      oc get catalogsource -n openshift-marketplace
      ```

5. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Generate the catalog source files:
      i. Log into your cluster using the `oc login` command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use; substituting the appropriate CASE version:

      ```
      export CASE_NAME=ibm-cp-common-services
      export CASE_VERSION=<case version>
      export ARCH=amd64
      ```

      Set *<case version>* to the value specified for *Foundational services CASE version* in Operator, CASE, and platform requirements, for your deployment type.

      iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      This command might not return anything if there are no architecture-specific catalog sources.

   b. Apply the catalog sources:
      i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

6. Add the DataPower operator sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Generate the catalog source files:
      i. Log into your cluster using the `oc login` command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

      ii. Export the variables for the command line to use; substituting the appropriate CASE version:

```
export CASE_NAME=ibm-datapower-operator
export CASE_VERSION=<case version>
export ARCH=amd64
```

      Set *<case version>* to the value specified for *DataPower operator version* in Operator, CASE, and platform requirements, for your deployment type.

      iii. Download the files for the operators required by DataPower:

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

      iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

      This command might not return anything if there are no architecture-specific catalog sources.

   b. Apply the catalog sources:
      i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

      ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

7. Create the `apiconnect` subscription.
   a. Create the `apiconnect` subscription with the appropriate channel by creating a file called `apic-sub.yaml` and pasting in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
  namespace: openshift-operators
spec:
  channel: v6.2
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

   b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

   c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
   If any operators such as `ibm-apiconnect` or `IBM DataPower Gateway` show the status of "Upgrade available", approve the upgrade by completing the following steps:

      i. Click Upgrade available.
      ii. Click Preview InstallPlan.
      iii. Click Approve.
      iv. Wait for the `IBM API Connect` and `IBM DataPower Gateway` operators to install.

   The `IBM DataPower Gateway` operator is a prerequisite to API Connect and must not be removed.

8. Install cert manager by completing the following steps:
   a. Log in to the OpenShift Container Platform web console.

   b. Navigate to Operators > OperatorHub.

   c. In the filter box, type: `cert-manager Operator for Red Hat OpenShift`.

   d. Select cert-manager Operator for Red Hat OpenShift and click Install.

   e. On the Install Operator page, complete the following steps:
      i. Update the Update channel if needed. The channel defaults to `stable-v1`, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

      ii. Select the Installed Namespace for the operator.
      The default operator namespace is `cert-manager-operator`; if that namespace doesn't exist, it is created for you.

      iii. Select an Update approval strategy:

- Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
- Manual: require a user with the appropriate credentials to approve all operator updates.

iv. Click Install.

f. Verify the cert-manager installation by completing the following steps:

i. Click to Operators > Installed Operators.

ii. Verify that `cert-manager Operator for Red Hat OpenShift` is listed with a Status of `Succeeded` in the `cert-manager-operator` namespace.

iii. Verify that cert-manager pods are up and running by running the following command:

```
oc get pods -n cert-manager
```

For a successful installation, the response looks like the following example:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
```

9. Create the `ibm-common-services-operator` subscription, if it does not already exist.

a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: openshift-operators
spec:
  channel: v4.6
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as `ibm-apiconnect`, `IBM Cloud Pak foundational services`, or `Operand Deployment Lifecycle Manager` show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the `ibm-common-services` namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the `IBM Cloud Pak foundational services` and `Operand Deployment Lifecycle Manager` operators to install.

10. Create the `ibm-datapower-operator` subscription, if it does not already exist.

a. Create a file called datapower-operator-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-datapower-operator
  namespace: openshift-operators
spec:
  channel: v1.15
  name: ibm-datapower-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

b. Apply the subscription with the following command:

```
oc apply -f datapower-operator-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as `ibm-apiconnect`, `IBM Cloud Pak foundational services`, or `Operand Deployment Lifecycle Manager` show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the `ibm-datapower-operator` namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the `IBM Cloud Pak foundational services` and `Operand Deployment Lifecycle Manager` operators to install.

11. Create the namespaces for your API Connect subsystems either by selecting Project > Create Project in the UI, or with the command:

```
oc create ns <APIC-namespace>
```

Note: Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:

- `default`
- `kube-system`
- `kube-public`
- `openshift-node`
- `openshift-infra`

- `openshift`

What to do next

Proceed to install the API Connect subsystems as explained in: Installing the management subsystem

Next topic: Installing the management subsystem

Installing the management subsystem

Install the managment subsystem by creating and applying the `ingress-issuer` and `mgmt_cr` YAML files.

Before you begin

When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Create a file called `ingress-issuer-management.yaml` and paste in the following:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: selfsigning-issuer

---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ingress-ca
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: ingress-ca
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: portal-admin-client
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
```

```
    app.kubernetes.io/name: portal-admin-client
spec:
  subject:
    organizations:
    - cert-manager
  commonName: portal-admin-client
  secretName: portal-admin-client
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: gateway-client-client
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: gateway-client-client
spec:
  subject:
    organizations:
    - cert-manager
  commonName: gateway-client-client
  secretName: gateway-client-client
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days

    rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: analytics-ingestion-client
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: analytics-ingestion-client
spec:
  subject:
    organizations:
    - cert-manager
  commonName: analytics-ingestion-client
  secretName: analytics-ingestion-client
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

2. Apply the YAML file with: `oc apply -f ingress-issuer-management.yaml -n <management namespace>`
3. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <management namespace>
NAME                 READY
ingress-issuer       True
selfsigning-issuer   True
```

Procedure

1. Create a file that is called mgmt_cr.yaml and paste in the following content:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
```

```
#

apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: management
  annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  portal:
    admin:
      secretName: portal-admin-client
  analytics:
    ingestion:
      secretName: analytics-ingestion-client
  gateway:
    client:
      secretName: gateway-client-client
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.$STACK_HOST
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: manager.$STACK_HOST
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.$STACK_HOST
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer.$STACK_HOST
      secretName: consumer-endpoint
  consumerCatalogEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secretName: consumer-catalog-endpoint
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the YAML file and replace the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.11.0

$PROFILE
Specify your management subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress host names to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
cloudManagerEndpoint:
      < ... >
    hosts:
    - name: admin.myhost.subnet.example.com
      secretName: cm-endpoint

  apiManagerEndpoint:
```

```
      < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secretName: apim-endpoint

  platformAPIEndpoint:
      < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secretName: api-endpoint

  consumerAPIEndpoint:
      < ... >
    hosts:
    - name: consumer.myhost.subnet.example.com
      secretName: consumer-endpoint

  consumerCatalogEndpoint:
      < ... >
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secretName: consumer-catalog-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **cloudManagerEndpoint**, you can replace **admin.$STACK_HOST** with **my.cloudmgr.myhost.subnet.example.com**, where **my.cloudmgr** replaces **admin**, and **myhost.subnet.example.com** replaces **STACK_HOST**. For example:

```
cloudManagerEndpoint:
      < ... >
    hosts:
    - name: my.cloudmgr.myhost.subnet.example.com
      secretName: cm-endpoint
```

  You can do this for some or all of the host names, depending on your customization requirements.

$STORAGE_CLASS
: The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
: Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
: Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
: Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Install the management subsystem by applying the modified CR with the following command:

```
oc apply -f mgmt_cr.yaml -n <management_namespace>
```

4. Verify that the management subsystem is fully installed by running the following command:

```
oc get ManagementCluster -n <management_namespace>
```

   The installation is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online:

```
NAME          READY   SUMMARY    VERSION    RECONCILED VERSION   AGE
management    True    16/16       <version>   <version-build>      7m17s
```

5. Verify that you can log in to the API Connect Cloud Manager UI:
   a. Determine the URL for the Cloud Manager UI by running the following command to view the API Connect endpoints:

```
oc get routes -n <management_namespace>
```

   b. Locate the **management-admin** endpoint, and note it down.
   c. Determine the Cloud Manager administrator password by running the following commands:

```
oc get secret -n <management-namespace> | grep management-admin-secret

oc get secret -n <management-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo ""
```

   d. Open a browser and go to the **management-admin-apic** endpoint.
   e. Log in to the Cloud Manager as **admin** with the administrator password.
6. Store all secrets and passwords in a safe place.
7. Backup your management subsystem database and infrastructure configuration: Backing up and restoring the management subsystem.
8. For more information about advanced configuration for Postgres components, see Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing operators
Next topic: Extracting the management ingress-ca certificates

Extracting the management ingress-ca certificates

In order for the management subsystem to be able to communicate with subsystems in different namespaces, these subsystems need to have the same ingress-ca certificates as the management subsystem.

About this task

This task describes how to extract the ingress-ca certificates to a yaml file, ready for applying to the subsystems that are in different namespaces.

Procedure

1. Export the ingress-ca secret to a yaml file with: `oc -n <management namespace> get secret ingress-ca -o yaml > ingress-ca.yaml`
2. Edit the ingress-ca.yaml file and remove the following properties: metadata.creationTimestamp, metadata.namespace,metadata.resourceVersion, metadata.uid, metadata.selfLink
3. Keep this file safe. You will need to apply it in the namespaces of your other subsystems so that they can communicate with the management subsystem.

Previous topic: Installing the management subsystem
Next topic: Installing the gateway subsystem

Installing the gateway subsystem

Install the gateway subsystem by creating and applying the ingress-ca, common-issuer, gateway-certs and gateway_cr yaml files.

Before you begin

Important: When you install the gateway subsystem, you must configure the gateway subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <gateway namespace>`
2. Create a file called `common-issuer-and-gateway-certs.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer

  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

3. Apply the above yaml file with: oc apply -f common-issuer-and-gateway-certs.yaml -n <gateway namespace>
4. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <gateway namespace>
NAME                READY
ingress-issuer      True
selfsigning-issuer  True
```

5. Confirm that the gateway secrets were created with `oc get secrets -n <gateway namespace>`:

```
oc get secrets -n <gateway namespace>
NAME                        TYPE                                  DATA   AGE
...
gateway-peering             kubernetes.io/tls                     3      2m
gateway-service             kubernetes.io/tls                     3      2m3s
...
```

About this task

Use the OpenShift CLI to edit the custom resource template for the gateway, apply the resource, verify that the pods are up and running.

Procedure

1. Create the gateway admin secret with: `oc -n <gateway namespace> create secret generic admin-secret --from-literal=password=admin`
2. If you are installing the API Gateway (v6), create a yaml file that is called `apigateway_cr.yaml` and paste in these contents:

```
#

  #   secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

3. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.11.0

$PROFILE
Specify your gateway subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
gatewayEndpoint:
      < ... >
    hosts:
    - name: rgw.myhost.subnet.example.com
      secret: gwv6-endpoint

  gatewayManagerEndpoint:
      < ... >
    hosts:
    - name: rgwd.myhost.subnet.example.com
      secret: gwv6-manager-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
gatewayEndpoint:
      < ... >
    hosts:
    - name: my.gateway.endpoint.myhost.subnet.example.com
      secret: gwv6-endpoint
```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.
$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.
$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

syslogConfig
To enable this feature uncomment this section, set **enabled: true**, and set the properties:
$DATAPOWER_SYSLOG_TCP_REMOTE_HOST
remoteHost: <*remote.host*>
String. The hostname of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_REMOTE_PORT
remotePort: <*remote_port_number*>
Integer. The port number of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_TLS_SECRET
secretName: <*secret*>
String. The TLS secret name of the server for **syslogConfig**.

4. Optional: If applicable to your deployment, update the gateway CR file to configure **DataPowerService** APIs to customize your DataPower® deployment. See Customizing a DataPower deployment.
5. Configure Management-to-Gateway communication security. You must configure either mutual TLS (mTLS) or JWT for secure communication between the management subsystem and the gateway subsystem.
   a. To enable mutual TLS between the management client and the gateway service's manager endpoint, add **mtlsValidateClient** to the **spec** section:

```
spec:
  mtlsValidateClient: true
```

This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under `gatewayManagerEndpoint.hosts.secretName`. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under `gateway.client.secretName`.

b. If you want to enable JWT security for communications between the management and gateway, add and set the property `jwksUrl`, and set `spec.mtlsValidateClient` to false.

```
spec:
  ...
  jwksUrl: <JWKS URL>
  mtlsValidateClient: false
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

6. Optional: Update the gateway CR file to enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
7. Install the gateway Custom Resource by applying the yaml file:
   For a DataPower API Gateway, run the following command:

   ```
   oc apply -f apigateway_cr.yaml -n <namespace>
   ```

   For a DataPower Gateway (v5 compatible), run the following command:

   ```
   oc apply -f v5cgateway_cr.yaml -n <namespace>
   ```

8. To verify that the gateway subsystem is fully installed, run the following command:

   ```
   oc get GatewayCluster -n <namespace>
   ```

   The installation is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online (`2/2`) for all the gateway subsystems that were installed. Example:

   ```
   NAME   READY   SUMMARY   VERSION     RECONCILED VERSION   AGE
   gwv6   True    2/2       <version>   <version-build>      7m32s
   ```

   There is no need to wait for the `READY` status to be `True` before moving on to next Subsystem installation.
9. Verify that the gateway is ready to be registered with the Management subsystem by calling the `health` api on the `gatewayManagerEndpoint.hosts.name` defined in your yaml file: `https://gwd.$STACK_HOST/health`.

   ```
   curl -k https://gwd.example.com/health
   {"status":"ok"}
   ```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Extracting the management ingress-ca certificates
Next topic: Installing the portal subsystem

Installing the portal subsystem

Install the portal subsystem by creating and applying the ingress-ca, common-issuer, and portal_cr yaml files.

Before you begin

Important: When you install the portal subsystem, you must configure the portal subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <portal namespace>`
2. Create a file called `common-issuer.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
```

```
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: selfsigning-issuer
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: ingress-issuer
spec:
  ca:
    secretName: ingress-ca
```

3. Apply the above yaml file with: `oc apply -f common-issuer.yaml -n <portal namespace>`
4. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <portal namespace>
NAME                 READY
ingress-issuer       True
selfsigning-issuer   True
```

About this task

Use the OpenShift CLI to edit the custom resource template for the portal subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called `portal_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalCluster
metadata:
  name: portal
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: portal
  annotations:
    apiconnect-operator/cp4i: "false"
spec:

    secretName: management-ca
  mgmtConsumerEndpointSvcCASecret:
    secretName: management-ca
  portalAdminEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.portal.$STACK_HOST
      secretName: portal-admin
  portalUIEndpoint:
```

```
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: portal.$STACK_HOST
      secretName: portal-web
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
  databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 12Gi
  webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
  backupVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 120Gi
  adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
  certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
  adminClientSubjectDN: CN=portal-admin-client,O=cert-manager
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the yaml file and set the variables:

`$APP_PRODUCT_VERSION`
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.11.0

`$PROFILE`
Specify your portal subsystem profile, where **`n`** indicates number of replicas, **`c`** number of cores, and **`m`** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

`$STACK_HOST`
The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **`STACK_HOST`** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **`myhost.subnet.example.com`**:

  ```
  portalAdminEndpoint:
      < ... >
      hosts:
      - name: api.portal.myhost.subnet.example.com
        secret: portal-admin

    portalUIEndpoint:
      < ... >
      hosts:
      - name: portal.myhost.subnet.example.com
        secret: portal-web
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **`$STACK_HOST`** subdomain to match your desired hostnames.

  For example, for **`portalAdminEndpoint`**, you can replace **`api.portal.$STACK_HOST`** with **`my.api.portal.myhost.subnet.example.com`**, where **`my.api.portal`** replaces **`api.portal`**, and **`myhost.subnet.example.com`** replaces **`$STACK_HOST`**:

  ```
  portalAdminEndpoint:
        < ... >
      hosts:
      - name: my.api.portal.myhost.subnet.example.com
        secret: cm-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

`$STORAGE_CLASS`
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **`oc get sc`**. For example, for local storage:

```
databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 12Gi
webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
backupVolumeClaimTemplate:
```

```
    storageClassName: $STORAGE_CLASS
    volumeSize: 300Gi
adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
```

Note:

- The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation. For more information on planning your portal PV requirements, see Portal subsystem.
- The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
- The **certVolumeClaimTemplate** is used by the nginx pod and in 2DCDR mode it is also by the **tunnel**, **db-remote** and **www-remote** pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

$LICENSE_ACCEPTANCE
: Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
: Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
: Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

4. Install the portal subsystem by applying the modified CR with the following command:

```
oc apply -f portal_cr.yaml -n <namespace>
```

5. Verify that the portal subsystem is fully installed:

```
oc get PortalCluster -n <namespace>
```

The installation is complete when **STATUS** reports **Running**, **Ready** reports that all services are online (**3/3**), and **MESSAGE** reports "Ready for API Cloud Manager service registration", for example:

```
NAME           READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                    AGE
portal         3/3     Running   <version>  <version>            Ready for API Cloud Manager service registration   2h
```

You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.

6. Verify that you can access the portal web endpoint by browsing to the **portalUIEndpoint.hosts.name** as configured in your yaml file:

```
curl -k https://portal.$STACK_HOST
<!DOCTYPE html>
<html>
<head>
<title>Developer Portal is ready to create sites!</title>
<style>
    body {
        width: 35em;
        margin: 0 auto;
        font-family: Tahoma, Verdana, Arial, sans-serif;
    }
</style>
</head>
<body>Developer Portal is ready to create sites!</h1>
<p>If you see this page, the web server is successfully installed and
working. Further configuration is required.</p>
</body>
</html>
```

7. It is highly recommend that you retain the portal subsystem encryption secret in a safe location, in case you need to restore the portal subsystem during a disaster recovery scenario.
The encryption secret is created when the portal subsystem is initially deployed. You can obtain the name of the encryption secret from the portal subsystem custom resource after the installation is complete:

   a. Obtain the name of the encryptionSecret:

   ```
   oc get ptl portal -o yaml -n <namespace> | grep encryptionSecret
   encryptionSecret: portal-enc-key
   ```

   The name of encryption secret is **portal-enc-key**.

b. Save the secret yaml in a safe location:

```
oc get secret portal-enc-key -o yaml -n <namespace> > portal-enc-key.yaml
```

8. Backup the portal installation. See Backing up and restoring the developer portal.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the gateway subsystem
Next topic: Installing the analytics subsystem

Installing the analytics subsystem

Install the analytics subsystem by creating and applying the ingress-ca, common-issuer, and analytics_cr yaml files.

Before you begin

Important: When you install the analytics subsystem, you must configure the analytics subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <analytics namespace>`
2. Create a file called `common-issuer.yaml` and paste in these contents:
   Note: If you have just done Installing the portal subsystem then you will already have this file.

```

   #master: # uncomment this section if you set storage.type = dedicated.
   #  volumeClaimTemplate:
   #    storageClassName: $STORAGE_CLASS
```

3. Apply the above yaml file with: `oc apply -f common-issuer.yaml -n <analytics namespace>`
4. Confirm that the issuers were created and are in ready state: `oc get issuers -n <analytics namespace>`

```
oc get issuers -n <analytics namespace>
NAME                READY
ingress-issuer      True
selfsigning-issuer  True
```

About this task

Use the OpenShift CLI to edit the custom resource template for the analytics subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called `analytics_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsCluster
metadata:
  name: analytics
  labels:
    app.kubernetes.io/instance: analytics
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: analytics
annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  profile: $PROFILE
  mgmtPlatformEndpointCASecret:
    secretName: ingress-ca
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  ingestion:
    endpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ai.$STACK_HOST
        secretName: analytics-ai-endpoint
    clientSubjectDN: CN=analytics-ingestion-client,O=cert-manager
  storage:
    type: $STORAGE_TYPE
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
   #master: # uncomment this section if you set storage.type = dedicated.
   #  volumeClaimTemplate:
   #    storageClassName: $STORAGE_CLASS
```

2. Edit the YAML file and set the variables:

`$APP_PRODUCT_VERSION`
: API Connect application version for the subsystems.

  `version: <version_number>`

  Example version number: 10.0.11.0

`$PROFILE`
: Specify your analytics subsystem profile, where `n` indicates number of replicas, `c` number of cores, and `m` is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.
  Note: The profile that you select influences your storage type options. If you select an `n1` profile then you must select the `shared` storage type. For more information about storage types, see storage types.

`$STACK_HOST`

The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
  ingestion:
    endpoint:
       < ... >
      hosts:
      - name: ai.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < .... >
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, you can replace **$STACK_HOST** with **my.analytics.ingestion.myhost.subnet.example.com**, where **my.analytics.ingestion** replaces **ai**, and **myhost.subnet.example.com** replaces **STACK_HOST**.

```
ingestion:
    endpoint:
      < ... >
      hosts:
      - name: my.analytics.ingestion.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < ... >
```

$STORAGE_TYPE
If you set **$PROFILE** to an **n1** (one replica) profile, then set this to **shared**. If you set **$PROFILE** to an **n3** (three replica) profile then set this to **dedicated** and uncomment the **storage.master** section, for example:

```
  storage:
    type: dedicated
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    master:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
```

For more information about storage types, see dedicated or shared storage.

$STORAGE_CLASS
The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: **oc get sc**. Example:

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
```

$DATA_VOLUME_SIZE
Size of storage allocated for data. To estimate the storage space you require, see Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
        volumeSize: 500Gi
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.
$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.
$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.

4. Optional: If you plan to configure analytics database backups, then define the storage that is required for backups:
   Define your backup PVC by adding the **backup.volumeClaimTemplate** property in **spec.storage**. For example:

```
spec:
  storage:
    backup:
      volumeClaimTemplate:
        storageClassName: <storage class>
        volumeSize: <size>
```

   If you are not sure of the volume size that you need, then you can configure the **backup.volumeClaimTemplate** after installation.

5. Install the analytics subsystem by applying the modified CR with the following command:

```
oc apply -f analytics_cr.yaml -n <namespace>
```

6. Verify that the analytics subsystem is fully installed:

```
oc get AnalyticsCluster -n <namespace>
```

   The installation is complete when **READY** shows all pods running (**n/n**), and the **STATUS** reports **Running**. Example:

```
NAME         READY   STATUS    VERSION          RECONCILED VERSION   AGE
analytics    n/n     Running   10.0.11.0   10.0.11.0-1281    86m
```

   It is not necessary to wait for analytics installation to complete before you move on to the next subsystem installation.

7. Backup your analytics subsystem and configure scheduled analytics database backups: Backing up and restoring the analytics subsystem.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the portal subsystem

Installing with the top-level CR on OpenShift

Use the single, top-level **APIConnectCluster** CR to deploy API Connect on OpenShift.

About this task

When you deploy API Connect with a top-level CR, all the API Connect subsystems are deployed in the same namespace. The CR contains a section for each subsystem; configure deployment settings in the appropriate section for each subsystem.
Note: The top-level CR installation creates and manages one instance of each subsystem. If you want multiple portal, gateway, or analytics subsystems in your API Connect deployment, then install the API Connect subsystems individually: Installing API Connect in a single namespace on OpenShift. For more information about API Connect installation options on OpenShift, see OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration.
If you want to install multiple API Connect instances, for example dev, uat, and prod, the recommended configuration is to have single API Connect and Datapower operators installed globally in the **openshift-operators** namespace and each API Connect instance installed in its own namespace using a top-level CR.

Attention:

- If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.
- Linking services from one topCR deployment to another is not recommended. If you attempt to link services from one topCR deployment to another, you will likely encounter errors with certificates along with limitations on the service names. In such a scenario, you should deploy the remote analytics service using an individual AnalyticsCluster CR. For more information, see Installing API Connect subsystems in different namespaces or environments on OpenShift.

- **Installing operators**
  Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect on Red Hat OpenShift.
- **Installing API Connect**
  Use the top-level **APIConnectCluster** CR to install all the API Connect subsystems into a shared namespace on OpenShift while connected to the internet.

Installing operators

Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect on Red Hat OpenShift.

Before you begin

The API Connect operator and operand must be at compatible release and fix pack levels. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version

API Connect (operand)	Operator channel version	Highest operator version
10.0.11.0	v6.2	6.2.0

If you want to run API Connect operator and subsystems at different versions, the following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
6.2.0	• 10.0.11.0
6.1.0	• 10.0.10.0
6.0.0	• 10.0.9.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

Note: There can be only one version of the API Connect operator in your OpenShift cluster. You cannot install different operator versions in different namespaces. If you install the API Connect operator in multiple namespaces, all installations must be at the same operator version.
The API Connect operator pods in your operator namespace must have network access to the namespace where your API Connect subsystems are installed. Do not configure OpenShift network policies that block communication between any of these namespaces:

- API Connect operator
- API Connect subsystems (operands)
- cert-manager
- openshift-operator-lifecycle-manager
- ibm-common-services

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.
3. Create the namespace where API Connect will be installed, either by selecting Home > Projects > Create Project in the UI, or with the following command:

   ```
   oc create ns <APIC-namespace>
   ```

   The namespace where you install API Connect must meet the following requirements:
   - Red Hat OpenShift: Only one top-level CR (**APIConnectCluster**) can be deployed in each namespace.
   - Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
   - Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:
     - **default**
     - **kube-system**
     - **kube-public**
     - **openshift-node**
     - **openshift-infra**
     - **openshift**
4. If you are installing the operator into a single namespace, create an OperatorGroup object specifying that namespace.
   Attention: If you are installing the operator into all namespaces, skip this step because the **openshift-operators** namespace already has an appropriate Operator group in place.
   a. Create the apiconnect-operator-group.yaml file with an OperatorGroup object that identifies the namespace in which RBAC permissions for the IBM API Connect Operator will be generated, and where the CSV will be available:

      ```
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: <operator-group-name>
        namespace: <APIC-namespace>
      spec:
        targetNamespaces:
        - <APIC-namespace>
      ```

   b. Apply the OperatorGroup object with the following command:

      ```
      oc apply -f apiconnect-operator-group.yaml
      ```

5. If you are installing the operator in all namespaces, then create the common services namespace:

   ```
   oc create ns ibm-common-services
   ```

6. Create a pull secret in the namespaces where you want to install API Connect.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.

a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
b. Ensure that the Project is set to the namespace where you intend to install API Connect.
c. Click Create and select Image pull secret.
d. Set the following parameters for the secret:
- Set Secret name to `ibm-entitlement-key`.
- Set Authentication type to `Image registry credentials`.
- Set Registry server address to `cp.icr.io`.
- Set Username to `cp`.
- Set Password to the entitlement key generated in Step 2.
- Click Create to create the secret.

Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with the following command: `ibmcloud oc worker reload`
For information on using the `reload` command, see the Red Hat OpenShift on IBM Cloud documentation.

7. Add the API Connect catalog sources to your cluster.
Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

a. Generate the catalog source files:
i. Log into your cluster using the `oc login` command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

ii. Export the variables for the command line to use:
API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

iii. Download the files for the operators required by API Connect:

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources for API Connect:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

b. Apply the catalog sources:
i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

8. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
a. Generate the catalog source files:
i. Log into your cluster using the `oc login` command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

ii. Export the variables for the command line to use; substituting the appropriate CASE version:

```
export CASE_NAME=ibm-cp-common-services
export CASE_VERSION=<case version>
export ARCH=amd64
```

Set *<case version>* to the value specified for *Foundational services CASE version* in Operator, CASE, and platform requirements, for your deployment type.

iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

This command might not return anything if there are no architecture-specific catalog sources.

b. Apply the catalog sources:
i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

9. Add the DataPower operator sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Generate the catalog source files:
      i. Log into your cluster using the `oc login` command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

      ii. Export the variables for the command line to use; substituting the appropriate CASE version:

```
export CASE_NAME=ibm-datapower-operator
export CASE_VERSION=<case version>
export ARCH=amd64
```

      Set *<case version>* to the value specified for *DataPower operator version* in Operator, CASE, and platform requirements, for your deployment type.

      iii. Download the files for the operators required by DataPower:

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

      iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

      This command might not return anything if there are no architecture-specific catalog sources.

   b. Apply the catalog sources:
      i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

      ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

10. Create the `apiconnect` subscription.
    a. Create the `apiconnect` subscription with the appropriate channel by creating a file called `apic-sub.yaml` and pasting in the following contents, updating the namespace as required:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
  namespace: <namespace>
spec:
  channel: v6.2
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

    Where `<namespace>` is one of the following values:
    - `openshift-operators` if you are installing the operator in all namespaces
    - The namespace created in step 3 if you are installing the operator in a single namespace

    b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

    c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
    If any operators such as `ibm-apiconnect` or `IBM DataPower Gateway` show the status of "Upgrade available", approve the upgrade by completing the following steps:

      i. Click Upgrade available.
      ii. Click Preview InstallPlan.
      iii. Click Approve.
      iv. Wait for the `IBM API Connect` and `IBM DataPower Gateway` operators to install.

    The `IBM DataPower Gateway` operator is a prerequisite to API Connect and must not be removed.

11. Install cert manager by completing the following steps:
    a. Log in to the OpenShift Container Platform web console.

    b. Navigate to Operators > OperatorHub.

    c. In the filter box, type: `cert-manager Operator for Red Hat OpenShift`.

    d. Select cert-manager Operator for Red Hat OpenShift and click Install.

    e. On the Install Operator page, complete the following steps:
      i. Update the Update channel if needed. The channel defaults to `stable-v1`, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

ii. Select the Installed Namespace for the operator.
The default operator namespace is **cert-manager-operator**; if that namespace doesn't exist, it is created for you.

iii. Select an Update approval strategy:
- Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
- Manual: require a user with the appropriate credentials to approve all operator updates.

iv. Click Install.

f. Verify the cert-manager installation by completing the following steps:

i. Click to Operators > Installed Operators.

ii. Verify that **cert-manager Operator for Red Hat OpenShift** is listed with a Status of **Succeeded** in the **cert-manager-operator** namespace.

iii. Verify that cert-manager pods are up and running by running the following command:

```
oc get pods -n cert-manager
```

For a successful installation, the response looks like the following example:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
```

12. Create the **ibm-common-services-operator** subscription, if it does not already exist.

a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: <namespace>
spec:
  channel: v4.6
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

Where: ***<namespace>*** is one of the following values:

- **openshift-operators** if you are installing the operator in all namespaces
- The namespace created in step 3 if you are installing the operator in a single namespace

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the **ibm-common-services** namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the **IBM Cloud Pak foundational services** and **Operand Deployment Lifecycle Manager** operators to install.

13. Create the **ibm-datapower-operator** subscription, if it does not already exist.

a. Create a file called datapower-operator-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: datapower-operator
  namespace: <namespace>
spec:
  channel: v1.15
  name: datapower-operator
  source: ibm-datapower-operator-catalog
  sourceNamespace: openshift-marketplace
```

Where: ***<namespace>*** is one of the following values:

- **openshift-operators** if you are installing the operator in all namespaces
- The namespace created in step 3 if you are installing the operator in a single namespace

b. Apply the subscription with the following command:

```
oc apply -f datapower-operator-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the **ibm-datapower-oprator** namespace and ensure that all operators with a status of "Upgrade available" are approved.

v. Wait for the **IBM Cloud Pak foundational services** and **Operand Deployment Lifecycle Manager** operators to install.

Installing API Connect

Use the top-level **APIConnectCluster** CR to install all the API Connect subsystems into a shared namespace on OpenShift while connected to the internet.

Before you begin

Review installation considerations and complete and prerequisite tasks as explained in:

1. Preparing for installation
2. Installing operators

About this task

Important: When you install API Connect, you must configure secure communication between subsystems. Use mTLS or JWT for management to portal and analytics subsystems. Use JWT for management to gateway communication. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.

Procedure

1. Install the subsystems using the OpenShift web console.
   API Connect uses a single top-level **APIConnectCluster** CR to quickly deploy all of the subsystems. With the **APIConnectCluster** CR, you provide values for a few properties, and then the installation logic chooses sensible defaults for the other properties during subsystem deployment.

   a. Click Operators->Installed Operators.
   b. Select the IBM API Connect operator.
   c. Click Create Instance on the API Connect cluster tile to install the top-level Custom Resource.
      Selecting API Connect cluster installs all the API Connect subsystems with the default configuration. The API Connect subsystems are Management, Developer Portal, Gateway, and Analytics.

   d. Provide values for the fields shown in Table 1.

Table 1. Properties for the API Connect top-level CR

Input	Value
Name	The name to be used when deploying the **APIConnectCluster** CR.
License acceptance	Required. Click to accept the license. You must accept the license to install API Connect.
License use	Required. Select production or nonproduction to match the type of license that you purchased.
License metric	Optional. Enter the unit of measurement that is used for your program license: • PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.
License ID	Required. Select the license ID for the API Connect program that you purchased. To view all license IDs, see API Connect licenses.
Deployment profile	The deployment profile defines the number of worker nodes, CPU, and memory that is available for API Connect. The available profiles are listed in API Connect deployment profiles for OpenShift and Cloud Pak for Integration.
Product version	Optional. The API Connect application version. Defaults to the latest version available.
Default storage class name	The name of the Storage class to be used. You can set a default to appear here with the command: **oc patch storageclass *<storage class name>* -p '{"metadata": {"annotations": {"storageclass.kubernetes.io/is-default-class":"true"}}}'**
Database Backup settings	
Backup Certs	The name of the Kubernetes secret containing your S3 access key and secret or your or SFTP username and password or SSH key. Default: (Generated Value) See Configuring management database backups.
Backup S3 URI style	Indicates whether URIs to your S3 backup specify a host or a path value. Set to either **host** or **path**.
Credentials	The name of the Kubernetes secret containing your S3 access key and secret or your or SFTP username and password or SSH key. Default: (Generated Value) See Configuring management database backups.
Server hostname	Hostname of your remote SFTP backup server or object-store endpoint. If specifying an S3 object-store, use the format **<S3endpoint>/<S3region>**. For example: **s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard** Default: none See Configuring management database backups.

Input	Value
Path	The path to the location of for your backups on your remote server. If you are using a remote SFTP server, then this is a directory path. If you are using an object-store, then this is the name of your S3 bucket. For example, **`bucket-name/folder`**. The use of subdirectories in the bucket name is not supported. Ensure that **`bucket-name/folder`** is empty. Default: none See Configuring management database backups.
Server port	Not used for S3 object-store backups.
RepoRetentionFull	The number of days to retain backups for. For example, if **`RepoRetentionFull`** is set to 30, then any backups older than 30 days are deleted.
Schedule	Cron like schedule for performing automatic backups. The format for the schedule is: • ****** • ------ • |||||| • ||||+----- day of week (0 - 6) (Sunday=0) • |||+------- month (1 - 12) • ||+--------- day of month (1 - 31) • |+----------- hour (0 - 23) • +------------- min (0 - 59) • ---------------- sec (0 - 59) The backup schedule defaults to **`0 0 * * * *`**. This means a backup is run every day at midnight and minute zero UTC. When you configure a host, if you do not specify a value for **`schedule`**, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed. See Configuring management database backups.

e. If you want to configure additional settings, click Advanced and see API Connect configuration settings for information on the advanced settings.
f. Optional: If Cloud Pak for Integration is installed, and you want your API Connect installation to be integrated with it, then click the **`YAML`** tab and set **`metadata.annotations.apiconnect-operator/cp4i`** to **`true`**.
This annotation enables integration with Cloud Pak for Integration.

2. Optional: If you are installing API Connect as a Cloud Pak for Integration component and you want to deploy with Cloud Pak endpoints, complete the following steps. This step is not applicable if you already disabled API Connect integration with Cloud Pak for Integration by setting **`metadata.annotations.apiconnect-operator/cp4i`** to false.
Beginning with version 10.0.7.0, API Connect no longer uses the Cloud Pak cpd routes for endpoints when deployed as a component of Cloud Pak for Integration. Instead, the API Management component uses the typical default API Connect routes (or the custom endpoints configured in the CR).

   a. Click the YAML tab to manually edit the CR.
   b. Insert the **`deprecatedCloudPakRoute`** object into the **`spec.management`** section as shown in the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: <APIC-namespace>
spec:
  license:
    accept: true
    license: L-MMBZ-295QZQ
    metric: PROCESSOR_VALUE_UNIT
    use: nonproduction
  profile: n1xc17.m48
  version: 10.0.8.0
  storageClassName: <default-storage-class>
  management:
    deprecatedCloudPakRoute:
      enabled: true
      cloudPakEndpoint:
        hosts:
        - name: cpd-apic.apps.admin-<domain>.com
```

   c. Optional: If you want to add a custom certificate for the Cloud Pak route, complete the following steps:
      i. Create a Cloud Pak certificate that was signed by a Cloud Pak CA as in the following example:

```
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
 name: custom-cpd-ca
 namespace: apic
spec:
 selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: custom-cpd
  namespace: apic
spec:
  commonName: small-mgmt-cpd
  dnsNames:
```

```
  - cpd-apic.apps.admin-apickeycloak.cp.fyre.ibm.com
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: custom-cpd-ca
  privateKey:
    algorithm: RSA
    rotationPolicy: Always
    size: 2048
  renewBefore: 720h0m0s
  secretName: custom-cpd
  usages:
  - key encipherment
  - digital signature
  - server auth
```

ii. In the CR, provide the secret name within the `cloudPakEndpoint` property of the new `deprecatedCloudPakRoute` object; for example:

```
spec:
  deprecatedCloudPakRoute:
    enabled: true
    cloudPakEndpoint:
      hosts:
      - name: cpd-apic.apps.admin-<domain>.com
        secretName: custom-cpd
```

3. Click Create to install API Connect.
4. To verify that your API Connect cluster is successfully installed, run `oc get apic -n <APIC-namespace>`.
5. Verify that you can log in to the API Connect Cloud Manager UI:
   a. To determine the location for logging in, view all the endpoints:

      ```
      oc get routes -n <APIC-namespace>
      ```

   b. Locate the `mgmt-admin-apic` endpoint, and access the Cloud Manager UI.
   c. Login as `admin`.
      When you install with the top-level CR, the password is auto-generated. To get the password, run the following commands:

      ```
      oc get secret -n <APIC-namespace> | grep mgmt-admin-pass

      oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d &&
      echo ""
      ```

6. Optional: Complete the following tasks:
   - Increase the timeout settings for management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.
   - Download the API Connect toolkit from the Cloud Manager UI or API Manager UI after installation is completed. See Installing the toolkit.
   - Install a test environment. See Testing an API with the Local Test Environment.

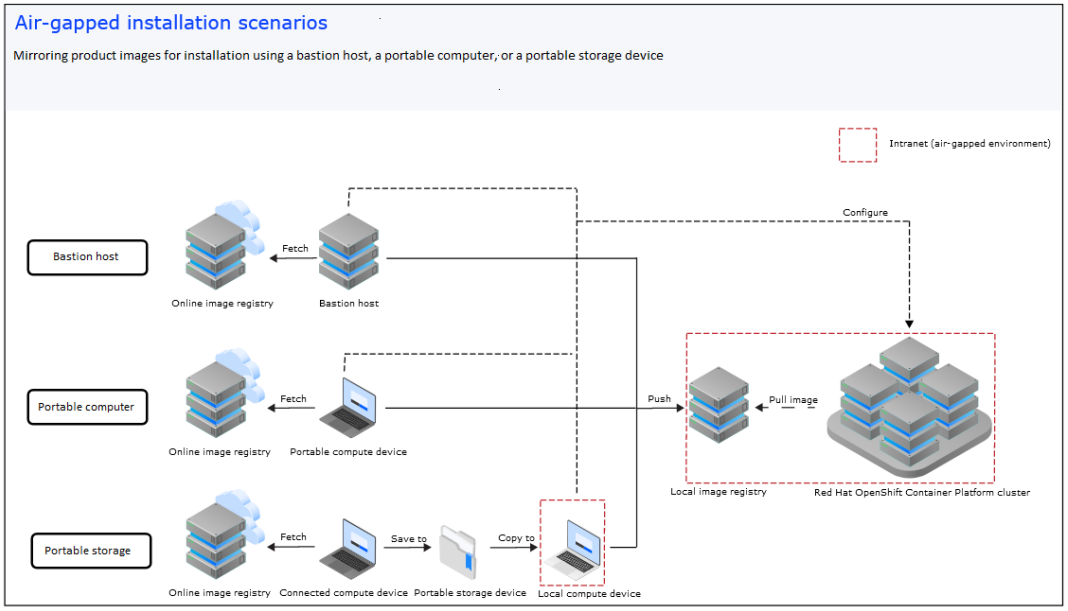
   Note: You can also install the Toolkit and Local Test Environment from IBM Fix Central. For a link to the latest files on Fix Central, see What's new in the latest release.
7. For more information about advanced configuration for Postgres components, see Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later.

What to do next

Configure backups for all your API Connect subsystems: Backing up, restoring, and disaster recovery.

Air-gapped installation

In a disconnected environment using Red Hat OpenShift Container Platform (OCP), install API Connect by mirroring product images to a bastion host or a portable device and then completing the installation.



Before you begin

- An air-gapped installation is not possible in the following environments:
  - Red Hat OpenShift Service on AWS (ROSA)
  - Red Hat OpenShift Service Kubernetes Service on IBM Cloud (ROKS)

About this task

If your cluster is not connected to the internet (it is network-restricted, or air-gapped), you can install API Connect in your cluster by using either a bastion host, a portable computer, or a portable storage device.

The following diagram illustrates how you can mirror product images for an air-gapped installation with a bastion host, a portable computer, or a portable storage device.

All of the scenarios use Container Application Software for Enterprises (CASE) files to mirror content from a source (on the internet) to an intermediary target (a bastion host, a portable computer, or a portable storage device) before pushing them to a local server or device.

Then, you can transfer the files to the local air-gapped network and run the installation.

- **Installing with a bastion host**
  You can use a bastion host to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.
- **Installing with a portable computer or storage device**
  You can use a portable device, such as a portal computer or a USB storage device to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Installing with a bastion host

You can use a bastion host to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Before you begin

This task must be performed by a Red Hat OpenShift administrator.

About this task

If your cluster is not connected to the internet, you can mirror product images to a registry in your network-restricted environment by using a bastion host. A bastion host has access to both the public internet and the network-restricted environment where the target clusters reside. You can fetch product images from the internet and push them to a local registry; then you can pull the images from the local registry to the target cluster for installation.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.
      - Configure storage on the cluster and make sure that it is available.
   b. Prepare the bastion host:
      You must be able to connect your bastion host to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry) at the same time. Your host must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).
      i. Ensure that the sites and ports listed in Table 1 can be reached from the bastion host:

      Table 1. Sites that must be reached from the bastion host

Site	Description
`icr.io:443`	IBM entitled registry
`quay.io:443`	Local API Connect image repository
`github.com`	CASE files and tools
`redhat.com`	Red Hat OpenShift Container Platform (OCP) upgrades

      ii. On the bastion host, install either Docker or Podman (not both).

Docker and Podman are used for managing containers; you only need to install one of these applications.

- To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

```
yum check-update
yum install docker
```

- To install Podman, see the Podman installation instructions.
  For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

```
yum install podman
```

iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

c. Set up a local image registry and credentials.
The local Docker registry stores the mirrored images in your network-restricted environment.

i. Install a registry, or get access to an existing registry.
You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:
- Supports multi-architecture images through Docker Manifest V2, Schema 2
  For details, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes
- Allows path separators in the image name

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:
- Supports auto-repository creation
- Has sufficient storage to hold all of the software that is to be transferred
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

When you modify the `ImageSetConfiguration`, include `openshift-cert-manager-operator` at channel `stable-v1` as one of the packages, as shown in the following example:

```
    packages:
    - name: openshift-cert-manager-operator
      channels:
      - name: stable-v1
```

3. Set environment variables and download CASE files.
Because you will use values from two different CASE files, you must create environment variables for both; notice that the variables for the foundational services (common services) CASE file are prefixed with "CS_" to differentiate them.

a. Create the following environment variables with the installer image name and the image inventory on your host:
- API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.18+
export CS_ARCH=amd64
```

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

- EDB:

```
export EDB_CASE_NAME=ibm-cloud-native-postgresql
export EDB_CASE_VERSION=1.25.1
```

- DataPower:

```
export DP_CASE_NAME=ibm-cp-common-services
export DP_CASE_VERSION=1.16.0
export DP_ARCH=amd64
```

b. Connect your host to the internet (it does not need to be connected to the network-restricted environment at this time).

c. Download the CASE files to your portable device:
- API Connect:

  ```
  oc ibm-pak get $CASE_NAME --version $CASE_VERSION
  ```

- Foundational services:

  ```
  oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
  ```

- EDB:

  ```
  oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
  ```

- DataPower

  ```
  oc ibm-pak get $DP_CASE_NAME --version $DP_CASE_VERSION
  ```

4. Mirror the images.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

a. Generate mirror manifests.
i. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace **<target-registry>** with the IP address (or host name) and port of the local registry; for example: **172.16.0.10:5000**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **172.16.0.10:5000/registry_ns**.

ii. Generate mirror manifests by running the following commands:
- API Connect:

  ```
  oc ibm-pak generate mirror-manifests $CASE_NAME --version $CASE_VERSION $TARGET_REGISTRY
  ```

- Foundational services:

  ```
  oc ibm-pak generate mirror-manifests $CS_CASE_NAME --version $CS_CASE_VERSION $TARGET_REGISTRY
  ```

- EDB:

  ```
  oc ibm-pak generate mirror-manifests $EDB_CASE_NAME --version $EDB_CASE_VERSION $TARGET_REGISTRY
  ```

- DataPower:

  ```
  oc ibm-pak generate mirror-manifests $DP_CASE_NAME file://integration --version $DP_CASE_VERSION --final-registry $TARGET_REGISTRY
  ```

If you need to filter for a specific image group, add the parameter **--filter** **<image_group>** to the command.

The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:
- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping.txt

The files are used when mirroring the images to the **TARGET_REGISTRY**.

b. Obtain an entitlement key for the entitled registry where the images are hosted:
i. Log in to the IBM Container Library.
ii. In the Container software library, select Get entitlement key.
iii. In the "Access your container software" section, click Copy key.
iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.

c. Authenticate with the entitled registry where the images are hosted.
The image pull secret allows you to authenticate with the entitled registry and access product images.

i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

```
podman login cp.icr.io
```

Use **cp** as the username and your entitlement key as the password.

d. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: **--tls-verify=false**.

e. Update the CASE manifest to correctly reference the DataPower Operator image.
Files for the DataPower Operator are now hosted on **icr.io**; however, the CASE manifest still refers to **docker.io** as the image host. To work around this issue, visit Airgap install failure due to 'unable to retrieve source image docker.io' in the DataPower documentation and update the manifest as instructed. After the manifest is updated, continue to the next step in this procedure.

f. Mirror the product images.

i. Connect the bastion host to both the internet and the restricted-network environment that contains the local registry.
ii. Run the following commands to copy the images to the local registry:
- API Connect:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

- Foundational services:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

- EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

- DataPower:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$DP_CASE_NAME/$DP_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

g. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

If the `insecureRegistries` field does not exist, you can add it.
iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:
- API Connect:

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
```

- Foundational services:

```
oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

- EDB:

```
oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
```

- DataPower:

```
oc apply -f ~/.ibm-pak/data/mirror/$DP_CASE_NAME/$DP_CASE_VERSION/image-content-source-policy.yaml
```

iv. Verify that the ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before proceeding to the next step.

5. Apply the catalog sources.

Now that you have mirrored images to the target cluster, apply the catalog sources for API Connect and Foundational services. There is no need to apply the catalog source for EDB because the API Connect operator will apply that catalog source in its own namespace when the API Connect operand is created.

In the following steps, replace **<*Architecture*>** with either **amd64**, **s390x** or **ppc64le** as appropriate for your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.18+
export CS_ARCH=amd64

export DP_CASE_NAME=ibm-datapower-operator
export DP_CASE_VERSION=1.16.0
export DP_ARCH=amd64
```

b. Generate the catalog sources and save them in another directory in case you need to replicate this installation in the future.

i. Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${DP_CASE_NAME}/${DP_CASE_VERSION}/catalog-sources.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.

i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${DP_CASE_NAME}/${DP_CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources were created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

What to do next

Install API Connect following the steps for your deployment type: Deploying on OpenShift and Cloud Pak for Integration.

Installing with a portable computer or storage device

You can use a portable device, such as a portal computer or a USB storage device to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Before you begin

This task must be performed by a Red Hat OpenShift administrator.

About this task

If your cluster is not connected to the internet, you can mirror product images to a registry in your network-restricted environment by using a portable device. Download images from the public registries on the internet to the portable device; then bring that portable device into the network-restricted environment (or transfer the files to a different device within the network-restricted environment) and mirror the images to the local registry. You can pull the images from the local registry to the target cluster for installation.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For more information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in Operator, CASE, and platform requirements.
      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the portable device:
      You must be able to connect your portable device to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry). The portable device must be on a Linux x86_64 or Mac platform with an operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Check that the portable device has sufficient storage to hold all the software that is to be transferred to the local registry.
      ii. On the portable device, install either Docker or Podman (not both).
      Docker and Podman are used for managing containers; you can install either of these applications.

         - To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

```
yum check-update
yum install docker
```

- To install Podman, see the Podman installation instructions.
  For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

  ```
  yum install podman
  ```

iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

c. Set up a local image registry and credentials.
The local Docker registry stores the mirrored images in your network-restricted environment.

i. Install a registry, or get access to an existing registry.
You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:
- Supports multi-architecture images through Docker Manifest V2, Schema 2.
  For more information, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes.
- Allows path separators in the image name.

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:
- Supports auto-repository creation.
- Has sufficient storage to hold all the software that is to be transferred.
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials).
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials).

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries at run time, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

When you modify the `ImageSetConfiguration`, include `openshift-cert-manager-operator` at channel `stable-v1` as one of the packages, as shown in the following example:

```
  packages:
  - name: openshift-cert-manager-operator
    channels:
    - name: stable-v1
```

3. Set environment variables and download CASE files.
Create environment variables to use while mirroring images, connect to the internet, and download the CASE files needed for installing API Connect.

a. Create the following environment variables with the installer image name and the image inventory on your portable device:
- API Connect:

  ```
  export CASE_NAME=ibm-apiconnect
  export CASE_VERSION=6.2.0
  export ARCH=amd64
  ```

  For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

- Foundational services:

  ```
  export CS_CASE_NAME=ibm-cp-common-services
  export CS_CASE_VERSION=4.6.18+
  export CS_ARCH=amd64
  ```

  For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

- EDB:

  ```
  export EDB_CASE_NAME=ibm-cloud-native-postgresql
  export EDB_CASE_VERSION=1.25.1
  ```

- DataPower:

  ```
  export DP_CASE_NAME=ibm-datapower-operator
  export DP_CASE_VERSION=1.16.0
  export DP_ARCH=amd64
  ```

b. Connect your portable device to the internet (it does not need to be connected to the network-restricted environment at this time).
c. Download the CASE files to your portable device:
- API Connect:

  ```
  oc ibm-pak get $CASE_NAME --version $CASE_VERSION
  ```

- Foundational services:

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

- EDB:

```
oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
```

- DataPower

```
oc ibm-pak get $DP_CASE_NAME --version $DP_CASE_VERSION
```

4. Mirror the images.
   The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

   a. Generate mirror manifests.
      i. Define the environment variable $TARGET_REGISTRY by running the following command:

      ```
      export TARGET_REGISTRY=<target-registry>
      ```

      Replace **<target-registry>** with the IP address (or host name) and port of the local registry; for example: **172.16.0.10:5000**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **172.16.0.10:5000/registry_ns**.
      ii. Generate mirror manifests by running the following commands:
      - API Connect:

      ```
      oc ibm-pak generate mirror-manifests $CASE_NAME file://integration --version $CASE_VERSION --final-registry $TARGET_REGISTRY
      ```

      - Foundational services:

      ```
      oc ibm-pak generate mirror-manifests $CS_CASE_NAME file://integration --version $CS_CASE_VERSION --final-registry $TARGET_REGISTRY
      ```

      - EDB:

      ```
      oc ibm-pak generate mirror-manifests $EDB_CASE_NAME file://integration --version $EDB_CASE_VERSION --final-registry $TARGET_REGISTRY
      ```

      - DataPower:

      ```
      oc ibm-pak generate mirror-manifests $DP_CASE_NAME file://integration --version $DP_CASE_VERSION --final-registry $TARGET_REGISTRY
      ```

      If you need to filter for a specific image group, add the parameter **--filter <image_group>** to the command.

   The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:
   - catalog-sources.yaml
   - catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
   - image-content-source-policy.yaml
   - images-mapping-to-filesystem.txt
   - images-mapping-from-filesystem.txt

   The files are used when mirroring the images to the **TARGET_REGISTRY**.

   b. Obtain an entitlement key for the entitled registry where the images are hosted:
      i. Log in to the IBM Container Library.
      ii. In the Container software library, select Get entitlement key.
      iii. In the "Access your container software" section, click Copy key.
      iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.

   c. Authenticate with the entitled registry where the images are hosted.
   The image pull secret allows you to authenticate with the entitled registry and access product images.

      i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

      ```
      export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
      ```

      The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

      ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

      ```
      podman login cp.icr.io
      ```

      Use **cp** as the username and your entitlement key as the password.

   d. Update the API Connect CASE manifest to correctly reference the DataPower Operator image.
   Files for the DataPower Operator are now hosted on **icr.io**; however, the CASE manifest still refers to **docker.io** as the image host. To work around this issue, visit Airgap install failure due to 'unable to retrieve source image docker.io' in the DataPower documentation and update the manifest as instructed.
   The manifest for API Connect (which uses the DataPower Operator) is stored in ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION.

   After the manifest is updated, continue to the next step in this procedure.

   e. Mirror the images from the internet to the portable device.
      i. Define the environment variable $IMAGE_PATH by running the following command:

      ```
      export IMAGE_PATH=<image-path>
      ```

      where **<image-path>** indicates where the files will be stored on the portable device's file system.
      ii. Mirror the images to the portable device:
      - API Connect:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

- Foundational services:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

- EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

- DataPower:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$DP_CASE_NAME/$DP_CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

There might be a slight delay before you see a response to the command.

f. Move the portable device to the restricted-network environment.
The procedure depends on the type of device that you are using:
If you are using a portable computer, disconnect the device from the internet and connect it to the restricted-network environment. The same environment variables can be used.

If you are using portable storage, complete the following steps:

i. Transfer the following files to a device in the restricted-network environment:
- The `~/.ibm-pak` directory.
- The contents of the ***<image-path>*** that you specified in the previous step.

ii. Create the same environment variables as on the original device; for example:
- API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64
```

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.18+
export CS_ARCH=amd64
```

- EDB:

```
export EDB_CASE_NAME=ibm-cp-common-services
export EDB_CASE_VERSION=1.25.1
export EDB_ARCH=amd64
```

- DataPower:

```
export DP_CASE_NAME=ibm-datapower-operator
export DP_CASE_VERSION=1.16.0
export DP_ARCH=amd64
```

- Registry:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

- Image path:

```
export IMAGE_PATH=<image-path>
```

g. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: `--tls-verify=false`.

h. Mirror the product images to the target registry.

i. If you are using a portable computer, connect it to the restricted-network environment that contains the local registry.
If you are using portable storage, you already transferred files to a device within the restricted-network environment.

ii. Run the following commands to copy the images to the local registry:

- API Connect:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

- Foundational services:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

- EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

- DataPower:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$DP_CASE_NAME/$DP_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

i. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

If the `insecureRegistries` field does not exist, you can add it.

iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:

- API Connect:

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
```

- Foundational services:

```
oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

- EDB:

```
oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
```

- DataPower:

```
oc apply -f ~/.ibm-pak/data/mirror/$DP_CASE_NAME/$DP_CASE_VERSION/image-content-source-policy.yaml
```

iv. Verify that each ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before proceeding to the next step.

5. Apply the catalog sources.
   Now that you have mirrored images to the target cluster, apply the catalog sources for API Connect and Foundational services. There is no need to apply the catalog source for EDB because the API Connect operator will apply that catalog source in its own namespace when the API Connect operand is created.

   In the following steps, replace **<*Architecture*>** with either **amd64**, **s390x** or **ppc64le** as appropriate for your environment.

   a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.18+
export CS_ARCH=amd64

export DP_CASE_NAME=ibm-datapower-operator
export DP_CASE_VERSION=1.16.0
export DP_ARCH=amd64
```

   b. Generate the catalog sources and save them in another directory in case you need to replicate this installation in the future.
      i. Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${DP_CASE_NAME}/${DP_CASE_VERSION}/catalog-sources.yaml
```

      You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

   c. Apply the catalog sources to the cluster.
      i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${DP_CASE_NAME}/${DP_CASE_VERSION}/catalog-sources.yaml
```

      ii. Confirm that the catalog sources were created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

What to do next

Install API Connect following the steps for your deployment type: Deploying on OpenShift and Cloud Pak for Integration.

Installing a two data center deployment with Cloud Pak for Integration

How to deploy a two data center disaster recovery (2DCDR) deployment on OpenShift with Cloud Pak for Integration.

Introduction

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Familiarize yourself with the Cloud Pak for Integration installation instructions linked from Deploying on OpenShift and Cloud Pak for Integration.
Note: During a 2DCDR installation, the management subsystem remains in a **Warning** state until the management subsystems in both data centers synchronize their databases. The management **Warning** status prevents the deployment and registration of the portal, gateway, and analytics subsystems. When the management subsystem databases are synchronized and both in **Ready** state, the deployment and registration of the other subsystems starts.

Prerequisites

The prerequisites for a 2DCDR deployment with Cloud Pak for Integration are as follows.

- The management and portal endpoints must be the same on both data centers.
- The network latency between data centers must be no more than 80 ms.
- The management cluster in each data center must use the same encryption secret.
- The portal cluster in each data center must use the same encryption secret.
- The ingress-ca certificate must be the same on both data centers.
- The API Connect namespace name must be the same in both clusters.
- The APIConnectCluster CR name must be identical on both clusters.

Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

Enabling 2DCDR environment on API Agent

To enable the 2DCDR environment on API Agent, you need to enable active node deployment first, wait until the management is ready, then enable the passive node deployment. If you have enabled the passive node instead of active, see Troubleshooting to resolve the issue.

- **Planning and initial preparation**
  Decide on endpoint, host, and namespace names. Prepare your Cloud Pak for Integration environments for 2DCDR API Connect.
- **Preparing your active data center**
  Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.
- **Preparing your warm-standby data center**
  Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.
- **Installing API Connect on the active data center**
  Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the `multiSiteHA` configuration to the API Connect YAML.
- **Installing API Connect on the warm-standby data center**
  Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the `multiSiteHA` configuration to the API Connect YAML.

Planning and initial preparation

Decide on endpoint, host, and namespace names. Prepare your Cloud Pak for Integration environments for 2DCDR API Connect.

Procedure

1. Decide on naming. Both data centers must use the same names for:
   - API Connect namespace.
   - API Connect Cluster CR name. Also known as the API Connect instance name, and referred to in this document as `<apic-instance-name>`.
   - Management subsystem endpoints
     - `cloudManagerEndpoint`
     - `apiManagerEndpoint`
     - `platformAPIEndpoint`
     - `consumerAPIEndpoint`
     - `consumerCatalogEndpoint`
   - Portal subsystem endpoints
     - `portalAdminEndpoint`
     - `portalUIEndpoint`

   Important: Each data center must use a different backup path for your management database backups. For portal database backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
2. Create a namespace for your API Connect deployment in both data centers.
   The API Connect namespace must be the same in both data centers, set it with:

   ```
   oc create ns <namespace>
   ```

3. Install the API Connect operators in both your data centers. See Installing operators. Return here when the operators are installed.
4. Decide which data center will start as the active and which will start as the warm-standby.
5. On the CLI of the active data center, where you run `oc` commands, create a directory called `2dcdr-active-yamls`. On the CLI of the warm-standby data center, create a directory called `2dcdr-ws-yamls`.

What to do next

Proceed to prepare the replication certificates, secrets, and issuers on your active data center Preparing your active data center.

Preparing your active data center

Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.

About this task

All operations are done on the CLI, in the `2dcdr-active-yamls` directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace `<apic-instance-name>` with the name you intend to use for your API Connect Cluster CR, and `<namespace>` with your API Connect namespace name (which will be the same for both Management and Portal subsystems). As decided in Planning and initial preparation.

Procedure

1. Create the encryption key secrets for the Management and Portal subsystems.
   a. Run the following command to create a file that contains a random string, which is used to create the management encryption key secret:

   ```
   cat /dev/urandom | head -c63 | base64 -w0 > mgmt-enc-key.txt
   ```

   b. Run the following command to create the management encryption key secret:

   ```
   oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
   namespace>
   ```

c. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key

mgmt-encryption-key        Opaque                                1      83s
```

d. Run the following command to create a file that contains a random string, which is used to create the portal encryption key secret:

```
cat /dev/urandom | head -c63 | base64 -w0 > ptl-enc-key.txt
```

e. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

f. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key         Opaque                                1      15s
```

2. Create a self-signed issuer.
   a. Create a file that is called **issuer.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: <apic-instance-name>-self-signed
spec:
  selfSigned: {}
```

   b. Apply this yaml file with:

```
oc apply -f issuer.yaml -n <namespace>
```

   c. Verify that the issuer was created with:

```
oc get issuer -n <namespace>

NAME                READY   AGE
apic-self-signed    True    25s
```

3. Create an ingress-ca certificate:
   a. Create a file that is called **self-signed-issuer-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ingress-ca
spec:
  commonName: ingress-ca
  duration: 87600h0m0s
  isCA: true
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-self-signed
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ingress-ca
```

   b. Apply this yaml file with:

```
oc apply -f self-signed-issuer-cert.yaml -n <namespace>
```

   c. Verify that the certificate was created with:

```
oc get cert -n <namespace>

NAME                          READY   SECRET                        AGE     EXPIRATION
apic-ingress-ca               True    apic-ingress-ca               11s     2032-08-15T13:01:47Z
```

4. Create the ingress issuer.
   a. Create a file **ingress-issuer.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: <apic-instance-name>-ingress-issuer
spec:
  ca:
    secretName: <apic-instance-name>-ingress-ca
```

   b. Apply this yaml file with:

```
oc apply -f ingress-issuer.yaml -n <namespace>
```

   c. Verify that the issuer was created with:

```
oc get issuer -n <namespace>

NAME                  READY   AGE
apic-ingress-issuer   True    20s
```

5. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-mgmt-replication-client
spec:
  commonName: <apic-instance-name>-mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>
```

```
NAME                                              READY   SECRET                                            AGE
EXPIRATION
...
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   16m     2024-
08-17T13:04:27Z
```

d. Create a file **ptl-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ptl-replication-client
spec:
  commonName: <apic-instance-name>-ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>
```

```
NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-ptl-replication-client   True    <apic-instance-name>-ptl-replication-client   16m     2024-08-
17T13:04:27Z
```

6. Export the ingress-ca issuer secret.
The ingress-ca issuer secret must be the same on the warm-standby data center. Export it from the active so that it can be imported on the warm-standby data center.

a. Run the following command to export the secret to a file called **ca-issuer-secret.yaml**:

```
oc get secret <apic-instance-name>-ingress-ca -o yaml -n <namespace>  > ca-issuer-secret.yaml
```

b. Edit the **ca-issuer-secret.yaml** file to remove the creationTimestamp, resourceVersion, uid, and managedFields. Remove the labels and annotations sections completely. The contents should look like this:

```
apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
metadata:
  name: <apic-instance-name>-ingress-ca
  namespace: <namespace>
type: kubernetes.io/tls
```

7. Copy the following files from your **2dcdr-active-yamls** directory to the **2dcdr-ws-yamls** directory in your warm-standby data center.

```
ca-issuer-secret.yaml
mgmt-enc-key.txt
ptl-enc-key.txt
```

These files are required to ensure that the ingress-ca and encryption secrets on both sites are the same.
Tip: To save time during the preparation of your warm-standby data center you can also copy these yaml files:

```
ptl-tls-client-cert.yaml
mgmt-tls-client-cert.yaml
ingress-issuer.yaml
```

What to do next

Create your secrets, certs, and issuers on your warm-standby data center: Preparing your warm-standby data center.

Preparing your warm-standby data center

Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.

About this task

All operations are done on the CLI, in the **2dcdr-ws-yamls** directory you created in Planning and initial preparation.

In the YAML files and commands that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR, and **<namespace>** with your API Connect namespace name (which will be the same for both Management and Portal subsystems). As decided in Planning and initial preparation.

Procedure

1. Import the ingress-ca issuer secret.
   This secret was created on your active data center here: Export the ingress-ca issuer secret
   a. Copy the **ca-issuer-secret.yaml** file to your warm-standby data center (if not done already).
   b. Create the secret with:

```
oc apply -f ca-issuer-secret.yaml -n <namespace>
```

   c. Verify that the secret was created with:

```
oc get secret -n <namespace>
```

```
NAME                                                  TYPE                                  DATA   AGE
<apic-instance-name>-ingress-ca                       kubernetes.io/tls                     3      19h
```

2. Create the ingress issuer.
   a. Create a file **ingress-issuer.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: <apic-instance-name>-ingress-issuer
spec:
  ca:
    secretName: <apic-instance-name>-ingress-ca
```

   b. Apply this yaml file with:

```
oc apply -f ingress-issuer.yaml -n <namespace>
```

   c. Verify that the issuer was created with:

```
oc get issuer -n <namespace>
```

```
NAME                   READY   AGE
apic-ingress-issuer    True    20s
```

3. Create the encryption key secrets for the Management and Portal subsystems, by using the random string generated on the active data center.
   Use the **mgmt-enc-key.txt** and **ptl-enc-key.txt** files that were copied to your warm-standby data center here: Copy keys to warm-standby.
   a. Run the following command to create the management encryption key secret:

```
oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
namespace>
```

   b. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key
```

```
mgmt-encryption-key         Opaque                                1      83s
```

   c. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

   d. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key
```

```
ptl-encryption-key          Opaque                                1      15s
```

4. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-mgmt-replication-client
spec:
  commonName: <apic-instance-name>-mgmt-replication-client
```

```
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>
```

```
NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   16m     2024-
08-17T13:04:27Z
```

d. Create a file `ptl-tls-client-cert.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ptl-replication-client
spec:
  commonName: <apic-instance-name>-ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>
```

```
NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-ptl-replication-client   True    <apic-instance-name>-ptl-replication-client   16m     2024-08-
17T13:04:27Z
```

What to do next

Install API Connect in your active data center: Installing API Connect on the active data center.

Installing API Connect on the active data center

Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **multiSiteHA** configuration to the API Connect YAML.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-ca              kubernetes.io/tls                     3      3d21h
<apic-instance-name>-mgmt-replication-client   kubernetes.io/tls                     3      3d21h
<apic-instance-name>-ptl-replication-client    kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-ca               True    <apic-instance-name>-ingress-ca               3d21h   2032-08-
15T13:01:47Z
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   3d21h   2024-08-
17T13:04:27Z
<apic-instance-name>-ptl-replication-client    True    <apic-instance-name>-ptl-replication-client    3d21h   2024-08-
17T13:04:26Z

oc get issuer -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-issuer   True    3d21h
<apic-instance-name>-self-signed      True    3d21h
```

Where **<apic-instance-name>** is the name you intend to use for your API Connect cluster CR, and **<namespace>** is the namespace you created for API Connect.

About this task

In the yaml files that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR. As decided in Planning and initial preparation. Set **<active data center ingress domain>** and **<warm-standby data center ingress domain>** to their appropriate values, which can be determined by running this command in each data center:

```
oc get ingresses.config/cluster -o jsonpath={.spec.domain}
```

Procedure

1. Follow the API Connect installation steps using the Platform UI, as described in the Cloud Pak for Integration documentation https://www.ibm.com/docs/en/cloud-paks/cp-integration. At the point where you specify the configuration properties of your API Connect instance, switch to the YAML tab so you can edit the YAML directly.
   Remember: Use the same **<apic-instance-name>** value when you specify the API Connect instance name in the Cloud Pak for Integration Platform UI.
2. Add the **management.encryptionSecret.secretName** property, and the **management.multiSiteHA** section to the YAML file inside the **spec** section.

   ```
   management:
     ...
     encryptionSecret:
       secretName: mgmt-encryption-key
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
         hosts:
         - name: mgmt-replication.<active data center ingress domain>
           secretName: <apic-instance-name>-mgmt-replication-server
       replicationPeerFQDN: mgmt-replication.<warm-standby data center ingress domain>
       tlsClient:
         secretName: <apic-instance-name>-mgmt-replication-client
   ```

   Also set the **management.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

3. Add the **portal.encryptionSecret.secretName** property, and the **portal.multiSiteHA** section to the YAML file inside the **spec** section.

   ```
   portal:
     ...
     encryptionSecret:
       secretName: ptl-encryption-key
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
         hosts:
         - name: ptl-replication.<active data center ingress domain>
           secretName: <apic-instance-name>-ptl-replication-server
       replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
       tlsClient:
         secretName: <apic-instance-name>-ptl-replication-client
   ```

   Also set the **portal.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

4. Continue the installation steps as described in Deploying on OpenShift and Cloud Pak for Integration.

Results

Confirm that the management subsystem is ready, but in **Warning** state with **oc get mgmt**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.11.0-0   10.0.11.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
oc get mgmt -n <namespace> -o yaml
```

```
...
status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

The management CR is expected to report the status of **Warning** until the warm-standby management subsystem is deployed, and both management subsystems complete data replication. When you see the status message "Management is ready. HA Status Warning - see HAStatus in CR for details", you can move on to Installing API Connect on the warm-standby data center.
Note: The portal, analytics, and gateway subsystems are not deployed until the management replication is complete and the management CRs in both data centers report the following:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
```

```
management   n/n     Running   10.0.11.0-0   10.0.11.0-0          Management is ready. HA status Ready - see HAStatus in CR
for details              8m59s

oc get mgmt -n <namespace> -o yaml

...
status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

What to do next

Extract the Cloud Pak for Integration credentials, and copy them to your warm-standby data center:

1. Identify the secret that contains the Cloud Pak for Integration credentials:

   ```
   oc -n <namespace> get secrets | grep cp4i-creds
   ```

2. Extract the credentials to a file:

   ```
   oc get secret <secret name>  -o json | jq
   'del(.metadata.creationTimestamp,.metadata.labels,.metadata.resourceVersion,.metadata.uid,.metadata.ownerReferences)' >
   cp4i-creds.json
   ```

   where *<secret name>* is the secret you identified in step 1.

3. Copy the cp4i-creds.json file to the warm-standby data center.

Install API Connect on your warm-standby data center: Installing API Connect on the warm-standby data center.

Installing API Connect on the warm-standby data center

Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **multiSiteHA** configuration to the API Connect YAML.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get certificate -n <namespace> | grep <apic-instance-name>
NAME                              READY   SECRET                            AGE     EXPIRATION
apic-mgmt-replication-client      True    apic-mgmt-replication-client      57s     2024-08-24T09:45:03Z
apic-ptl-replication-client       True    apic-ptl-replication-client       45s     2024-08-24T09:45:17Z

[root@api.iaincp4ilarge2.cp.fyre.ibm.com ~]# oc get secrets  -n <namespace> | grep <apic-instance-name>
NAME                              TYPE                                DATA   AGE
apic-ingress-ca                   kubernetes.io/tls                   3      4m6s
apic-mgmt-replication-client      kubernetes.io/tls                   3      2m40s
apic-ptl-replication-client       kubernetes.io/tls                   3      2m26s

[root@api.iaincp4ilarge2.cp.fyre.ibm.com ~]# oc get issuer -n <namespace> | grep <apic-instance-name>
NAME                  READY   AGE
apic-ingress-issuer   True    4m8s
```

Where **<apic-instance-name>** is the name you intend to use for your API Connect cluster CR, and **<namespace>** is the namespace you created for API Connect.

About this task

In the yaml files that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR. As decided in Planning and initial preparation. Set **<active data center ingress domain>** and **<warm-standby data center ingress domain>** to their appropriate values, which can be determined by running this command in each data center:

```
oc get ingresses.config/cluster -o jsonpath={.spec.domain}
```

Procedure

1. Apply the Cloud Pak for Integration credentials that you copied from your active data center (see Copy active credentials).

   ```
   oc -n <namespace> apply -f cp4i-creds.json
   ```

2. Follow the API Connect installation steps using the Platform UI, as described in the Cloud Pak for Integration documentation https://www.ibm.com/docs/en/cloud-paks/cp-integration. At the point where you specify the configuration properties of your API Connect instance, switch to the YAML tab so you can edit the YAML directly.
   Remember: Use the same **<apic-instance-name>** value when you specify the API Connect instance name in the Cloud Pak for Integration Platform UI.
3. Add the **management.encryptionSecret.secretName** property, and the **management.multiSiteHA** section to the YAML file inside the **spec** section.

   ```
   management:
     ...
     encryptionSecret:
   ```

```
      secretName: mgmt-encryption-key
    multiSiteHA:
      mode: passive
      replicationEndpoint:
        annotations:
          cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
        hosts:
        - name: mgmt-replication.<warm-standby data center ingress domain>
          secretName: <apic-instance-name>-mgmt-replication-server
      replicationPeerFQDN: mgmt-replication.<active data center ingress domain>
      tlsClient:
        secretName: <apic-instance-name>-mgmt-replication-client
```

Note: Warm-standby is referred to as 'passive' in the CR YAML.
Also set the **management.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

4. Add the **portal.encryptionSecret.secretName** property, and the **portal.multiSiteHA** section to the YAML file inside the **spec** section.

```
  portal:
    ...
    encryptionSecret:
      secretName: ptl-encryption-key
    multiSiteHA:
      mode: passive
      replicationEndpoint:
        annotations:
          cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
        hosts:
        - name: ptl-replication.<warm-standby data center ingress domain>
          secretName: <apic-instance-name>-ptl-replication-server
      replicationPeerFQDN: ptl-replication.<active data center ingress domain>
      tlsClient:
        secretName: <apic-instance-name>-ptl-replication-client
```

Also set the **portal.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

5. Continue the installation steps as described in Deploying on OpenShift and Cloud Pak for Integration.

Results

Installation can take around 1 hour to complete.

While the management subsystems on the warm-standby and active data centers are synchronizing, the management status reports **Warning**, and the **haStatus** reports **pending**:

```
oc get mgmt -n <namespace>

NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.11.0-0   10.0.11.0-0          Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
   }
```

When the management database replication between sites is complete, the management status reports **Running**, and **status.haStatus** reports **Ready**:

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.11.0-0   10.0.11.0-0          Management is ready. HA status Ready - see HAStatus in CR
for details             8m59s

status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

After the management subsystems in the active and warm-standby sites are synchronized, the other subsystems are deployed. Verify on both active and warm-standby sites that all subsystems reach **Running** state:

```
oc get all -n <namespace>
...
NAME                                                    READY   STATUS    VERSION    RECONCILED VERSION   AGE
analyticscluster.analytics.apiconnect.ibm.com/apis-minimum-a7s   n/n     Running   10.0.11.0   10.0.11.0-1281       27m

NAME                                                READY   STATUS   VERSION    RECONCILED VERSION   AGE
apiconnectcluster.apiconnect.ibm.com/apis-minimum   n/n     Ready    10.0.11.0   10.0.11.0-1281       2d20h

NAME                                                PHASE     READY   SUMMARY                          VERSION   AGE
datapowerservice.datapower.ibm.com/apis-minimum-gw   Running   True    StatefulSet replicas ready: 1/1   10.5.0.0   25m
```

```
NAME                                                PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
datapowermonitor.datapower.ibm.com/apis-minimum-gw  Running                false          false              25m

NAME                                                READY   STATUS    VERSION    RECONCILED VERSION   AGE
gatewaycluster.gateway.apiconnect.ibm.com/apis-minimum-gw   n/n     Running   10.0.11.0   10.0.11.0-1281        27m

NAME                                                READY   STATUS    VERSION    RECONCILED VERSION   AGE
managementcluster.management.apiconnect.ibm.com/apis-minimum-mgmt   8/8     Running   10.0.11.0   10.0.11.0-1281        2d20h

NAME                                                READY   STATUS    VERSION    RECONCILED VERSION   AGE
portalcluster.portal.apiconnect.ibm.com/apis-minimum-ptl   n/n     Running   10.0.11.0   10.0.11.0-1281        27m
```

Note: The warm-standby site has fewer `managementcluster` pods than the active site.
If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the `haStatus` output shows the reason, for example::

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.11.0-0   10.0.11.0-0          Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "PeerNotReachable"
   }
```

If the warning persists, see Troubleshooting a two data center deployment.

You can validate that your portal deployments are synchronizing by running `oc get pods` on both the active and warm-standby data centers. Confirm that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the `Ready` state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See Failing over to the warm-standby.

What to do next

Configure your deployment: Cloud Manager configuration checklist.
Important: It is strongly recommended to take complete backups of both sites, for disaster recovery in case the API Connect installation in both data centers is lost, or if a replication failure occurs. Complete backups consist of your infrastructure configuration backup and your subsystem database backups. See Backup and restore requirements for a 2DCDR deployment.

Installing a two data center deployment on OpenShift

How to deploy a two data center disaster recovery (2DCDR) deployment on OpenShift.

Introduction

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Familiarize yourself with the OpenShift installation instructions linked from Deploying on OpenShift and Cloud Pak for Integration.

Note: 2DCDR is not supported on OpenShift where the top-level CR is used. For 2DCDR on OpenShift, you must install API Connect as individual subsystems. See Installing API Connect in a single namespace on OpenShift and Installing API Connect subsystems in different namespaces or environments on OpenShift.

Prerequisites

The prerequisites for a 2DCDR deployment on OpenShift are as follows.

- The management and portal endpoints must be the same on both data centers.
- The network latency between data centers must be no more than 80 ms.
- The management cluster in each data center must use the same encryption secret.
- The portal cluster in each data center must use the same encryption secret.
- The ingress-ca certificate must be the same on both data centers.

Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

Enabling 2DCDR environment on API Agent

To enable the 2DCDR environment on API Agent, you need to enable active node deployment first, wait until the management node is ready, then enable the passive node deployment. If you have enabled the passive node instead of active, see Troubleshooting to resolve the issue.

- **Planning and initial preparation**
  Decide on endpoint names. Prepare your OpenShift environments for 2DCDR API Connect.
- **Preparing your active data center**
  Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.
- **Preparing your warm-standby data center**
  Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.
- **Installing API Connect on the active data center**
  Add the `multiSiteHA` configuration to the API Connect Management and Portal CR YAML files before they are applied.
- **Installing API Connect on the warm-standby data center**
  Add the `multiSiteHA` configuration to the API Connect Management and Portal YAML files before they are applied.

Planning and initial preparation

Decide on endpoint names. Prepare your OpenShift environments for 2DCDR API Connect.

Procedure

1. Decide on naming. Both data centers must use the same names for:
   - Management subsystem endpoints
     - `cloudManagerEndpoint`
     - `apiManagerEndpoint`
     - `platformAPIEndpoint`
     - `consumerAPIEndpoint`
     - `consumerCatalogEndpoint`
   - Portal subsystem endpoints
     - `portalAdminEndpoint`
     - `portalUIEndpoint`

   Each data center must have a different `siteName`. For example, `dallas` in data center 1, and `raleigh` in data center 2. The site name can contain only `a-z` and `0-9` characters. You set `siteName` in the `ManagementCluster` and `PortalCluster` CRs when the subsystems are first deployed. You cannot change the name after deployment. If you don't specify `siteName` at first deployment, a random `siteName` is created for you.

   Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
2. Install the API Connect operators in both your data centers. See Installing operators for a single namespace API Connect installation or Installing operators for a multi namespace API Connect installation, depending on whether all your API Connect subsystems are to be in the same namespace or not. Return here when the operators are installed.
3. If not already done, create namespaces for your API Connect subsystems in both data centers.

   ```
   oc create ns <namespace>
   ```

   the data centers do not have to use the same namespace name.
4. Decide which data center will start as the active and which will start as the warm-standby.
5. On the CLI of the active data center, where you run `oc` commands, create a directory called `2dcdr-active-yamls`. On the CLI of the warm-standby data center, create a directory called `2dcdr-ws-yamls`.

What to do next

Proceed to prepare the replication certificates, secrets, and issuers on your active data center Preparing your active data center.

Preparing your active data center

Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.

About this task

All operations are done on the CLI, in the `2dcdr-active-yamls` directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace `<namespace>` with the name of the corresponding subsystem namespace.

Procedure

1. Create the encryption key secrets for the Management and Portal subsystems.
   a. Run the following command to create a file that contains a random string, which is used to create the management encryption key secret:

   ```
   cat /dev/urandom | head -c63 | base64 -w0 > mgmt-enc-key.txt
   ```

   b. Run the following command to create the management encryption key secret:

   ```
   oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
   namespace>
   ```

   c. Confirm that the secret was created successfully by running:

   ```
   oc get secrets -n <management namespace> | grep mgmt-encryption-key
   ```

```
mgmt-encryption-key         Opaque                                1      83s
```

d. Run the following command to create a file that contains a random string, which is used to create the portal encryption key secret:

```
cat /dev/urandom | head -c63 | base64 -w0 > ptl-enc-key.txt
```

e. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

f. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key
```

```
ptl-encryption-key          Opaque                                1      15s
```

2. If all your API Connect subsystems are to be installed in the same namespace, then create your certificates, issuers, and secrets as described here: Setting up a certificate issuer. Return here when complete, do not proceed to install the subsystems.
3. If your API Connect subsystems are to be installed in different namespaces, then create your certificates, issuers, and secrets for your Management subsystem as described here Create Management subsystem issuers and secrets. For your Portal subsystem, follow the steps here Create Portal subsystem issuers and secretes. Return here when complete, do not proceed to install either subsystem.
4. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: mgmt-replication-client
spec:
  commonName: mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: mgmt-replication-client
```

   b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

   c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>
```

```
NAME                        READY   SECRET                      AGE     EXPIRATION
...
mgmt-replication-client     True    mgmt-replication-client     16m     2024-08-17T13:04:27Z
```

   d. Create a file **ptl-tls-client-cert.yaml** and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ptl-replication-client
spec:
  commonName: ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: ptl-replication-client
```

   e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

   f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>
```

```
NAME                        READY   SECRET                      AGE     EXPIRATION
...
ptl-replication-client      True    ptl-replication-client      16m     2024-08-17T13:04:27Z
```

5. Export the ingress-ca issuer secret.
   The ingress-ca issuer secret must be the same on the warm-standby data center. Export it from the active so that it can be imported on the warm-standby data center.
   Note: If you are deploying API Connect subsystems in different namespaces, then you export the Management subsystem ingress-ca secret.
   a. Run the following command to export the secret to a file called **ca-issuer-secret.yaml**:

```
oc get secret ingress-ca -o yaml -n <management namespace>  > ca-issuer-secret.yaml
```

   b. Edit the **ca-issuer-secret.yaml** file to remove the creationTimestamp, resourceVersion, uid, namespace, and managedFields. Remove the labels and annotations sections completely. The resulting contents should look like this:

```
apiVersion: v1
data:
  ca.crt: <long cert string>
```

```
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
metadata:
  name: ingress-ca
type: kubernetes.io/tls
```

6. Copy the following files from your **2dcdr-active-yamls** directory to the **2dcdr-ws-yamls** directory in your warm-standby data center.

   ca-issuer-secret.yaml
   mgmt-enc-key.txt
   ptl-enc-key.txt

   These files are required to ensure that the ingress-ca and encryption secrets on both sites are the same.
   Tip: To save time during the preparation of your warm-standby data center you can also copy these yaml files:

   ptl-tls-client-cert.yaml
   mgmt-tls-client-cert.yaml

7. If you are installing the Portal subsystem in a different namespace to the Management subsystem on the active data center, use the **ca-issuer-secret.yaml** file to create the issuer in your portal namespace. Follow the 'Before you begin steps here: Create issuer. Do not proceed to install the Portal subsystem after creating the issuer.

What to do next

Prepare your warm-standby data center Preparing your warm-standby data center.

Preparing your warm-standby data center

Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.

About this task

All operations are done on the CLI, in the **2dcdr-ws-yamls** directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace **<namespace>** with the name of the corresponding subsystem namespace.

Procedure

1. Import the ingress-ca issuer secret.
   This secret was created on your active data center here: Preparing your active data center
   a. If you did not do it as part of Preparing your active data center, copy the **ca-issuer-secret.yaml** file to your warm-standby data center.
   b. Create the secret with:

      ```
      oc apply -f ca-issuer-secret.yaml -n <namespace>
      ```

   c. Verify that the secret was created with:

      ```
      oc get secret -n <namespace>
      ```

      ```
      NAME                          TYPE                                DATA   AGE
      ingress-ca                    kubernetes.io/tls                   3      19h
      ```

   d. If your Portal subsystem is in a different namespace in your warm-standby data center, then repeat the **oc apply** operation against the portal namespace.
2. Create a file that is called **warm-standby-certs.yaml** and paste in:

```

      app.kubernetes.io/managed-by: "ibm-apiconnect"
      app.kubernetes.io/name: "gateway-peering"
```

3. Apply this file by running against your Management subsystem namespace:

```
oc apply -f warm-standby-certs.yaml -n <namespace>
```

4. Verify that the certificates, secrets, and issuers were created with:

```
oc get secrets -n <namespace>
NAME                          TYPE                                  DATA   AGE
analytics-ingestion-client    kubernetes.io/tls                     3      12s
gateway-client-client         kubernetes.io/tls                     3      21s
gateway-peering               kubernetes.io/tls                     3      11s
gateway-service               kubernetes.io/tls                     3      21s
ingress-ca                    kubernetes.io/tls                     3      18m
portal-admin-client           kubernetes.io/tls                     3      17s

oc get certificates -n <namespace>
NAME                          READY   SECRET                        AGE     EXPIRATION
analytics-ingestion-client    True    analytics-ingestion-client    2m18s   2024-09-04T12:27:38Z
gateway-client-client         True    gateway-client-client         2m19s   2024-09-04T12:27:28Z
gateway-peering               True    gateway-peering               2m17s   2024-09-04T12:27:39Z
gateway-service               True    gateway-service               2m18s   2024-09-04T12:27:28Z
portal-admin-client           True    portal-admin-client           2m19s   2024-09-04T12:27:33Z

oc get issuers -n <namespace>
```

```
NAME                 READY   AGE
ingress-issuer       True    18m
selfsigning-issuer   True    2m42s
```

5. If your Portal subsystem is in a different namespace in your warm-standby data center, then to create your certificates, issuers, and secrets in the Portal subsystem namespace:
   a. Create a file that is called **warm-standby-ptl-certs.yaml** and paste in:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "selfsigning-issuer"
  }
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-issuer"
  }
spec:
  ca:
    secretName: ingress-ca
```

   b. Apply this file to your Portal subsystem namespace:

```
oc apply -f warm-standby-certs.yaml -n <namespace>
```

   c. Verify that your issuers and secrets were created successfully:

```
oc get issuers -n <portal namespace>
NAME                 READY   AGE
ingress-issuer       True    43s
selfsigning-issuer   True    43s

oc get secrets -n <portal namespace>
NAME                         TYPE                                  DATA   AGE
ingress-ca                   kubernetes.io/tls                     3      4m18s
```

6. Create the encryption key secrets for the Management and Portal subsystems, by using the random string generated on the active data center.
   Use the **mgmt-enc-key.txt** and **ptl-enc-key.txt** files that were copied to your warm-standby data center when you followed Preparing your active data center.
   a. Run the following command to create the management encryption key secret:

```
oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
namespace>
```

   b. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key

mgmt-encryption-key          Opaque                                1      83s
```

   c. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

   d. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key           Opaque                                1      15s
```

7. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
```

```
  name: mgmt-replication-client
spec:
  commonName: mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>

NAME                        READY   SECRET                      AGE     EXPIRATION
...
mgmt-replication-client     True    mgmt-replication-client     16m     2024-08-17T13:04:27Z
```

d. Create a file **ptl-tls-client-cert.yaml** and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ptl-replication-client
spec:
  commonName: ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>

NAME                        READY   SECRET                      AGE     EXPIRATION
...
ptl-replication-client      True    ptl-replication-client      16m     2024-08-17T13:04:27Z
```

What to do next

Install API Connect on your active data center Installing API Connect on the active data center.

Installing API Connect on the active data center

Add the **multiSiteHA** configuration to the API Connect Management and Portal CR YAML files before they are applied.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace>
ingress-ca                kubernetes.io/tls                     3      3d21h
mgmt-replication-client   kubernetes.io/tls                     3      3d21h
ptl-replication-client    kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace>
ingress-ca                True    ingress-ca                 3d21h   2032-08-15T13:01:47Z
mgmt-replication-client   True    mgmt-replication-client    3d21h   2024-08-17T13:04:27Z
ptl-replication-client    True    ptl-replication-client     3d21h   2024-08-17T13:04:26Z

oc get issuer -n <namespace>
ingress-issuer   True    3d21h
self-signed      True    3d21h
```

Where **<namespace>** are the namespaces you created for API Connect.
Note: If you have separate namespaces for Management and Portal subsystems, then run the check in both namespaces. You should not see the **mgmt-replication-client** in the portal namespace, nor the **ptl-replication-client** in the management namespace.

Procedure

1. Follow these steps for installing the Management subsystem on OpenShift Installing the management subsystem in a shared namespace, but add the **encryptionSecret**

and **multiSiteHA** section to the **mgmt_cr.yaml** file:

```
  siteName: <dc1 site name>
  encryptionSecret:
    secretName: mgmt-encryption-key
  multiSiteHA:
    mode: active
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: mgmt-replication.<active data center ingress domain>
        secretName: mgmt-replication-server
    replicationPeerFQDN: mgmt-replication.<warm-standby data center ingress domain>
    tlsClient:
      secretName: mgmt-replication-client
```

where

- **<dc1 site name>** is the site name for this data center, as decided in Planning and initial preparation.
- **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

Note: If you are installing the Management subsystem in a separate namespace, these same steps apply.

2. Apply the update **mgmt_cr.yaml** file as directed in Installing the management subsystem in a shared namespace. You can monitor the deployment with:

```
oc get ManagementCluster -n <management namespace>
NAME          READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE AGE
management    n/n     Running   10.0.11.0  10.0.11.0-1281       Management is ready. HA status Warning - see HAStatus in CR
for details 74m
```

3. Follow these steps for installing the Portal subsystem on OpenShift Installing the portal subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **portal_cr.yaml** file.

```
  siteName: <dc1 site name>
  encryptionSecret:
    secretName: ptl-encryption-key
  multiSiteHA:
    mode: active
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ptl-replication.<active data center ingress domain>
        secretName: ptl-replication-server
    replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
    tlsClient:
      secretName: ptl-replication-client
```

where

- **<dc1 site name>** is the site name for this data center, as decided in Planning and initial preparation.
- **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

Note: If you are installing the Portal subsystem in a separate namespace, these same steps apply.

4. Apply the updated **portal_cr.yaml** file as directed in Installing the portal subsystem in a shared namespace.

```
oc get PortalCluster -n <portal namespace>
NAME      READY   STATUS    VERSION    RECONCILED VERSION   AGE
portal    6/6     Running   10.0.11.0  10.0.11.0-1281        49m
```

Results

Confirm that the management subsystem is ready, but in **Warning** state with **oc get mgmt**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.11.0-0  10.0.11.0-0          Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
oc get mgmt -n <namespace> -o yaml
```

```
...
status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

The management CR is expected to report the status of **Warning** until the warm-standby management subsystem is deployed, and both management subsystems complete data replication. When you see the status message "Management is ready. HA Status Warning - see HAStatus in CR for details", you can move on to Installing API Connect on the warm-standby data center.

What to do next

Install API Connect in your warm-standby data center Installing API Connect on the warm-standby data center.

Deploy your Gateway and Analytics subsystems in your active data center. For shared namespace: Installing API Connect in a single namespace on OpenShift or multiple namespaces: Installing API Connect subsystems in different namespaces or environments on OpenShift.

Installing API Connect on the warm-standby data center

Add the **multiSiteHA** configuration to the API Connect Management and Portal YAML files before they are applied.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace>
ingress-ca                kubernetes.io/tls                     3      3d21h
mgmt-replication-client   kubernetes.io/tls                     3      3d21h
ptl-replication-client    kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace>
mgmt-replication-client   True    mgmt-replication-client   3d21h   2024-08-17T13:04:27Z
ptl-replication-client    True    ptl-replication-client    3d21h   2024-08-17T13:04:26Z

oc get issuer -n <namespace>
ingress-issuer   True    3d21h
self-signed      True    3d21h
```

Where **<namespace>** are the namespaces you created for API Connect.
Note: If you have separate namespaces for Management and Portal subsystems, then run the check in both namespaces. You should not see the **mgmt-replication-client** in the portal namespace, nor the **ptl-replication-client** in the management namespace.

Procedure

1. Follow these steps for installing the Management subsystem on OpenShift Installing the management subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **mgmt_cr.yaml** file:

   ```
   siteName: <dc2 site name>
   encryptionSecret:
     secretName: mgmt-encryption-key
   multiSiteHA:
     mode: passive
     replicationEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: mgmt-replication.<warm-standby data center ingress domain>
         secretName: mgmt-replication-server
     replicationPeerFQDN: mgmt-replication.<active data center ingress domain>
     tlsClient:
       secretName: mgmt-replication-client
   ```

   where
   - **<dc2 site name>** is the site name for this data center, as decided in Planning and initial preparation.
   - **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

   Note: If you are installing the Management subsystem in a separate namespace, these same steps apply.
   Remember: Make sure that the management endpoints are set the same as for your active data center deployment.
2. Apply the update **mgmt_cr.yaml** file as directed in Installing the management subsystem in a shared namespace. Monitor the deployment, but note that on the warm-standby there are fewer pods than on the active:

   ```
   oc get ManagementCluster -n <namespace>

   NAME         READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE      AGE
   management   n/n     Running   10.0.11.0   10.0.11.0-1281        Management is ready. HA Status Warning - see HAStatus in
   CR for details      62m
   ```

3. Follow these steps for installing the Portal subsystem on OpenShift Installing the portal subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **portal_cr.yaml** file.

   ```
   siteName: <dc2 site name>
   encryptionSecret:
     secretName: ptl-encryption-key
   multiSiteHA:
     mode: passive
     replicationEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: ptl-replication.<warm-standby data center ingress domain>
         secretName: ptl-replication-server
     replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
     tlsClient:
       secretName: ptl-replication-client
   ```

   where

- **<dc2 site name>** is the site name for this data center, as decided in Planning and initial preparation.
- **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

Remember: Make sure that the portal endpoints are set the same as for your active data center deployment.

4. Apply the updated **portal_cr.yaml** file as directed in Installing the portal subsystem in a shared namespace.

```
oc get PortalCluster -n <namespace>
NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
portal   6/6     Running   10.0.11.0   10.0.11.0-1281        47m
```

Results

While the management subsystems on the warm-standby and active data centers are synchronizing their databases, the management status reports **Warning**, and the **haStatus** reports **pending**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management   n/n     Warning   10.0.11.0-0   10.0.11.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
oc get mgmt -n <namespace> -o yaml
```

```
...
status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
   }
```

When the management database replication between sites is complete, the management status reports **Running**, and **status.haStatus** reports **Ready**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management   n/n     Running   10.0.11.0-0   10.0.11.0-0           Management is ready. HA status Ready - see HAStatus in CR
for details              8m59s
```

```
oc get mgmt -n <namespace> -o yaml
```

```
...
status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the **haStatus** output shows the reason, for example::

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management   n/n     Warning   10.0.11.0-0   10.0.11.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "PeerNotReachable"
   }
```

If the warning persists, see Troubleshooting a two data center deployment.
You can validate that your portal deployments are synchronizing by running **oc get pods** on both the active and warm-standby data centers. Confirm that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the **Ready** state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See Failing over to the warm-standby.

What to do next

Deploy your Gateway and Analytics subsystems for shared namespace: Installing API Connect in a single namespace on OpenShift or multiple namespaces: Installing API Connect subsystems in different namespaces or environments on OpenShift

Configure your deployment: Cloud Manager configuration checklist, and complete a test failover to verify that your data replicated to the warm-standby. See Failing over to the warm-standby for details.

Important: It is strongly recommended to take complete backups of both sites, for disaster recovery in case the API Connect installation in both data centers is lost, or if a replication failure occurs. Complete backups consist of your infrastructure configuration backup and your subsystem database backups. See Backup and restore requirements for a 2DCDR deployment.

Enable additional features post-install

After installing API Connect, you can enable additional features that are related to inter-subsystem communication.

- **Enable management CA verification on REST API calls**
  Enable the portal and gateway to validate the management subsystem's REST API server certificates.
- **Enable JWT security and disable mTLS between subsystems**
  Postinstallation steps to enable JWT security and disable mTLS between subsystems.

Enable management CA verification on REST API calls

Enable the portal and gateway to validate the management subsystem's REST API server certificates.

About this task

After you install API Connect, you can enable the portal and gateway to verify the REST API server certificate when they make calls to the REST API. The gateway and portal subsystems make calls to the management subsystem REST API during their normal operations. The gateway makes calls to the platform REST API, and the portal makes calls to the platform REST API and the consumer REST API. To verify the CA certificates of the REST API endpoints, enter the secret names of the CA certificates into the portal and gateway CRs.
Note:
If you are not sure of the secret names, follow these steps to determine their names:

1. Check the management subsystem CR with `oc describe mgmt`, and identify the issuer of the platform and consumer API endpoints:

```
oc describe mgmt

...
Platform API Endpoint:
    Annotations:
      cert-manager.io/issuer:               <instance name>-ingress-issuer
...
  Consumer API Endpoint:
    Annotations:
      cert-manager.io/issuer:               <instance name>-ingress-issuer
```

2. Describe the issuer with `oc describe issuer`, and identify the secret name:

```
oc describe issuer <instance name>-ingress-issuer
...
Spec:
  Ca:
    Secret Name:  <instance name>-ingress-ca
...
```

Note: If you are using `in-cluster` communication (see In-cluster service communication between subsystems), then the portal and gateway make REST calls on the service endpoints, instead of the `external` endpoints. In the steps documented in this topic, replace `mgmtPlatformEndpointCASecret` with `mgmtPlatformEndpointSvcCASecret`, and `mgmtConsumerEndpointCASecret` with `mgmtConsumerEndpointSvcCASecret`. For `secretName`, the default for the service endpoints is `mgmt-ca` or `<apic instance name>-mgmt-ca`.

Procedure

1. Update the portal CR.
   a. Edit the portal CR

```
oc edit ptl
```

   Note: If you are using the OpenShift® top-level CR deployment, edit your `APIConnectCluster` CR instead. Updates should be made in the `spec.portal` section.
   b. Set `spec.mgmtPlatformEndpointCASecret.secretName` and `spec.mgmtConsumerEndpointCASecret.secretName` to the name of the CA secret.

```
spec:
...
  mgmtPlatformEndpointCASecret:
    secretName: <instance name>-ingress-ca
  mgmtConsumerEndpointCASecret:
    secretName: <instance name>-ingress-ca
```

2. Update the gateway CR.
   a. Edit the gateway CR

```
oc edit gw
```

Note: If you are using the OpenShift top-level CR deployment, edit your `APIConnectCluster` CR instead. Updates should be made in the `spec.portal` section.

b. Set `spec.mgmtPlatformEndpointCASecret.secretName` to the name of the CA secret.

```
spec:
...
  mgmtPlatformEndpointCASecret:
    secretName: <instance name>-ingress-ca
```

Enable JWT security and disable mTLS between subsystems

Postinstallation steps to enable JWT security and disable mTLS between subsystems.

About this task

JWT security is an alternative to using mTLS to secure inter-subsystem communication. For more information on JWT security and when to use it, see: Enable JWT security instead of mTLS.

If you disable mTLS then you must enable JWT.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow. This flow is secured by mTLS, which cannot be disabled.

Procedure

1. Describe the management CR to get the JWKS URL:

```
oc describe mgmt

Status:
  Endpoints:
    - name: jwksUrl
      secretName: api-endpoint
      type: API
      uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

2. For each portal, gateway, and analytics subsystem where you want to use JWT security, update the CR corresponding to that subsystem, and set `spec.mtlsValidateClient` to `false`, and `spec.jwksUrl` to the JWKS URL you identified in step 1.

```
spec:
...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

Note: If you are using the OpenShift® top-level CR deployment, edit your `APIConnectCluster` CR instead. Updates should be made in appropriate the `spec.<subsystem name>` section.

3. Enable JWT on the gateway to analytics communications flow. Enable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Troubleshooting installation on OpenShift

Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Failed `integration-ibm-cloud-native-postgresql` `CatalogSource` on ROKS 4.14 and OpenShift Container Platform 4.15

The API Connect operator creates the EDB catalog source in the same namespace as the API Connect operator.

The EDB catalog source reports a failed state and shows the following status message:

```
Status:
  Message:  couldn't ensure registry server - error ensuring pod: : error creating new pod: integration-ibm-cloud-native-
postgresql-: pods "integration-  ibm-cloud-native-postgresql-hnjbn" is forbidden: violates PodSecurity "restricted:v1.24":
allowPrivilegeEscalation != false (container "registry-server"   must set securityContext.allowPrivilegeEscalation=false),
unrestricted capabilities (container "registry-server" must set   securityContext.capabilities.drop=["ALL"]), runAsNonRoot !=
true (pod or container "registry-server" must set securityContext.runAsNonRoot=true),   seccompProfile (pod or container
"registry-server" must set securityContext.seccompProfile.type to "RuntimeDefault" or "Localhost")
  Reason:   RegistryServerError
```

The problem occurs when the namespace is set to enforce the restricted pod security admission policy with the `pod-security.kubernetes.io/enforce: restricted` label.

ROKS 4.14 and some OpenShift Container Platform versions such as 4.15 have `enforce` set to `restricted`.

To workaround this problem, update the `integration-ibm-cloud-native-postgresql` `CatalogSource` to use the restricted security context constraint:

```
oc patch CatalogSource integration-ibm-cloud-native-postgresql --type merge --patch '{"spec":{"grpcPodConfig":
{"securityContextConfig":"restricted"}}}'
```

One or more pods in `CrashLoopBackoff` or `Error` state, and report a certificate error in the logs

In rare cases, cert-manager might detect a certificate in a bad state right after it has been issued, and then re-issues the certificate. If a CA certificate has been issued twice, the certificate that was signed by the previously issued CA will be left stale and can't be validated by the newly issued CA. In this scenario, one of the following messages displays in the log:

- `javax.net.ssl.SSLHandshakeException: Received fatal alert: certificate_unknown`
- `Error: unable to verify the first certificate`
- `ERROR: openssl verify failed to verify the Portal CA tls.crt, ca.crt chain signed the Portal Server tls.crt cert`

Resolve the problem by completing the following steps:

1. Use `apicops` (v10 version 0.10.57+ required) to validate the certificates in the system:

   ```
   apicops upgrade:stale-certs -n <namespace>
   ```

2. If any certificate that is managed by cert-manager fails the validation, delete the stale certificate secret:

   ```
   oc delete secret <stale-secret> -n <namespace>
   ```

   Cert-manager automatically generates a new certificate to replace the one you deleted.

3. Use `apicops` to make sure all certificates can be verified successfully:

   ```
   apicops upgrade:stale-certs -n <namespace>
   ```

You see the `denied: insufficient scope` error during an air-gapped deployment

Problem: You encounter the `denied: insufficient scope` message while mirroring images during an air-gapped installation or upgrade.

Reason: This error occurs when a problem is encountered with the entitlement key that is used for obtaining images.

Solution: Obtain a new entitlement key by completing the following steps:

1. Log in to the IBM Container Library.
2. In the Container software library, select Get entitlement key.
3. After the Access your container software heading, click Copy key.
4. Copy the key to a safe location.

Apiconnect operator pod fails

Problem: During installation (or upgrade), the `apiconnect` operator fails with the following message:

```
panic: unable to build API support: unable to get Group and Resources: unable to retrieve the complete list of server APIs:
packages.operators.coreos.com/v1: the server is currently unable to handle the request

goroutine 1 [running]:
github.ibm.com/velox/apiconnect-operator/operator-utils/v2/apiversions.GetAPISupport(0x0)
        operator-utils/v2/apiversions/api-versions.go:89 +0x1e5
main.main()
        ibm-apiconnect/cmd/manager/main.go:188 +0x4ee
```

Additional symptoms:

- Apiconnect operator is in crash loopback status
- Kube `apiserver` pods log the following information:

  ```
  E1122 18:02:07.853093 18 available_controller.go:437] v1.packages.operators.coreos.com failed with:
   failing or missing response from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1:
   bad status from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1: 401
  ```

- The IP logged here belongs to the *package server* pod present in the `openshift-operator-lifecycle-manager` namespace
- Package server pods log the following error message: `/apis/packages.operators.coreos.com/v1 API call is being rejected with 401 issue`.

  ```
  E1122 18:10:25.614179 1 authentication.go:53] Unable to authenticate the request due to an error: x509:
  certificate signed by unknown authority I1122 18:10:25.614224 1 httplog.go:90]
  verb="GET" URI="/apis/packages.operators.coreos.com/v1" latency=161.243µs resp=401
  UserAgent="Go-http-client/2.0" srcIP="10.128.0.1:41370":
  ```

- The problem is intermittent

Solution:

- If you find the exact symptoms as described, the solution is to delete package server pods in the `openshift-operator-lifecycle-manager` namespace.
- New package server pods log the `200 Success` message for the same API call.

Disabling the Portal web endpoint check

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the **portal-www** pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete the following update:

On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration

Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

Enabling 2DCDR in API Agent

The issue arises from enabling API Agent on the passive node before the active node. This causes the passive node to attempt to create the database, which fails because the database does not exist.

If you have enabled the passive mode first, complete the following steps:

1. Disable API Agent on the passive node.
2. Remove both **api-agent** jobs.
3. Enable API Agent on the active node, and wait for the active node's management to be ready.
4. Enable API Agent on the passive node.

Upgrading API Connect

Upgrade API Connect on Kubernetes and OpenShift platforms to a newer version.

Upgrading your API Connect deployment consists of three phases:

1. Upgrade planning. Decide on your upgrade path based on your platform and current version. It might be necessary to upgrade your container environment before you can upgrade API Connect.

   Review any feature changes in the new API Connect version that might impact how you use API Connect and plan for such changes.

   Upgrade planning should be started as early as possible to identify any issues that might influence when you are able to upgrade, and any actions to take before upgrade.

2. Upgrade preparation. Run pre-upgrade checks on your current deployment, download the new version of API Connect from Fix Central, backup your current deployment. Upgrade your container platform if required.

   Upgrade preparation can be done at any time, and it is worth doing early to identify and fix any potential problems before your upgrade window. If you do complete the upgrade preparation early, repeat the pre-upgrade checks just before your upgrade window to check for any new problems.

3. Upgrade procedure. Updating your API Connect operator and operands to the new version. Upgrading cert-manager might also be necessary.

   The upgrade process should be started only when all upgrade planning and preparation are completed. Interrupting and rolling back API Connect upgrades is not possible. Disaster recovery procedures must be followed to restore API Connect to the old version if problems are encountered during upgrade.

The upgrade planning, preparation, and execution steps are different for each deployment type. Select from the following sections:

- **Upgrading on Kubernetes**
  Upgrade API Connect on Kubernetes distributions.
- **Upgrading on OpenShift and Cloud Pak for Integration**
  You can upgrade API Connect in an OpenShift environment and as part of IBM Cloud Pak for Integration.
- **Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9**
  How to upgrade a two data center disaster recovery deployment to V10.0.10 from V10.0.8 and V10.0.9 on Kubernetes and OpenShift.
- **Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.9**
  How to upgrade from an API Connect V10.0.9 two data center disaster recovery (DR) deployment on Cloud Pak for Integration.

Upgrading on Kubernetes

Upgrade API Connect on Kubernetes distributions.

- **Planning your API Connect upgrade on Kubernetes**
  Review the supported versions, requirements, and limitations for upgrading API Connect on Kubernetes.
- **Pre-upgrade preparation and checks on Kubernetes**
  Prepare your Kubernetes environment and API Connect deployment for upgrade.
- **Upgrading DataPower Operator and Operand independently of the APIC**
  API Connect and DataPower each have their own Operator, which manages their respective products. The Operand is the actual product that users interact with.

Before you deploy an Operand, its corresponding Operator must be installed at a specific version. While Operators and Operands can have different versions, each Operator supports a specific range of Operand versions. This separation allows customers to upgrade the Operator and Operand independently, reducing upgrade times. The primary use case is that customers want the flexibility to upgrade API Connect (management plane) and DataPower (data plane) separately. This flexibility allows them to either minimize the upgrade window or apply fixes to one component without affecting the other. When DataPower is deployed through API Connect in Kubernetes, API Connect strictly controls the versions of both the DataPower Operator and Operand, ensuring that the management and data plane upgrades occur simultaneously. In OpenShift Container Platform and Cloud Pak for Integration, API Connect still handles Operator installation, but customers can change the Operator version without relying on Helm. The Operand upgrade process remains the same across Kubernetes, OpenShift Container Platform, and Cloud Pak for Integration.

- **Upgrading API Connect on Kubernetes**
  Upgrade your API Connect subsystems to a newer version on Kubernetes.
- **Troubleshooting upgrades on Kubernetes**
  Review the following troubleshooting guidance if you encounter a problem during an API Connect on Kubernetes.

Planning your API Connect upgrade on Kubernetes

Review the supported versions, requirements, and limitations for upgrading API Connect on Kubernetes.

Supported upgrade paths

Table 1 lists the supported upgrade paths for API Connect and explains whether a direct upgrade is supported or an interim upgrade is required.

Table 1. Supported upgrade paths on Kubernetes

Upgrade from:	How to upgrade to 10.0.11.0
• 10.0.10.0 • 10.0.8.4	Complete the procedure in Upgrading API Connect on Kubernetes.
• 10.0.9.0 • 10.0.8.2-ifix2 • 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0	• Upgrade to 10.0.10.0 or 10.0.8.4 as explained in Upgrading on Kubernetes. • Upgrade to 10.0.11.0 on API Connect
• 10.0.8.0 • 10.0.8.1	• Upgrade to 10.0.9.0 as explained in Upgrading on Kubernetes on API Connect 10.0.9.0 documentation. • Upgrade to 10.0.8.2-ifix1 as explained in Upgrading on Kubernetes on API Connect 10.0.8.2-ifix1 documentation.
• 10.0.5.8 • 10.0.7.0 • 10.0.5.7 • 10.0.5.6 • 10.0.5.5 • 10.0.5.4	Upgrade to 10.0.8.0 as explained in Upgrading on Kubernetes on API Connect 10.0.8.0 documentation.
10.0.6.0	Complete two upgrades, making sure to perform the additional steps to preserve and re-create your SFTP backup configuration: 1. Upgrade to version 10.0.7.0 as explained in Upgrading on Kubernetes in the API Connect 10.0.7.0 documentation. If you used SFTP backups for the Management subsystem in 10.0.6.0, you must temporarily remove the SFTP backup configuration before running the upgrade to 10.0.7.0: a. Edit the Management subsystem CR, delete the `databaseBackup` section, and save it so you can restore it later. b. Add the following annotation into the Management CR: `apiconnect-operator/backups-not-configured: "true"` 2. Upgrade to the current release by completing the procedures in Upgrading API Connect on Kubernetes. 3. Restore your SFTP backup configuration in the new version of API Connect: a. Edit the Management subsystem CR, and add the preserved `databaseBackup` section. b. Delete the `apiconnect-operator/backups-not-configured: "true"` annotation.
10.0.5.3 or earlier	Complete two upgrades: 1. Upgrade to version 10.0.5.4 or later as explained in Upgrading on Kubernetes in the API Connect 10.0.5.x documentation. 2. Upgrade to the current release by completing the procedures in Upgrading API Connect on Kubernetes.

Supported DataPower Gateway versions

You can use API Connect 10.0.11.0 with DataPower 10.6.5.0.

Before you upgrade, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. When you find the information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Supported versions of Kubernetes

Table 2 provides a quick reference of the supported Kubernetes versions for each API Connect release:

Table 2. API Connect and Kubernetes (K8S) compatibility matrix

API Connect version	K8S 1.24	K8S 1.25	K8S 1.26	K8S 1.27	K8S 1.28	K8S 1.29	K8S 1.30	K8S 1.31	K8S 1.32	K8S 1.33	K8S 1.34
10.0.5.4	✓	✓	✓	✓							
10.0.5.5			✓	✓	✓						
10.0.5.6				✓	✓	✓					
10.0.5.7				✓	✓	✓					
10.0.5.8					✓	✓	✓				
10.0.6.0	✓	✓	✓	✓							
10.0.7.0			✓	✓	✓						
10.0.8.0					✓	✓	✓				
10.0.8.1						✓	✓	✓			
10.0.9.0						✓	✓	✓			
10.0.10.0							✓	✓	✓	✓	
10.0.11.0									✓	✓	✓

When you upgrade API Connect, both your current deployment and your target release must support the same version of Kubernetes. After the API Connect upgrade, you can update Kubernetes to the highest version supported by the new release of API Connect.

It is possible that you must upgrade both Kubernetes and API Connect more than once to complete the process. For example, suppose that your current deployment is running API Connect 10.0.5.4 on Kubernetes v1.24 and you want to upgrade to API Connect 10.0.10.0. The highest version of Kubernetes that API Connect 10.0.5.4 supports is v1.27, and v1.30 is the lowest version of Kubernetes that API Connect10.0.10.0 supports.

In this scenario, you must make multiple upgrades of both Kubernetes and API Connect to reach the target versions; for example:

1. On your API Connect 10.0.5.4 deployment, upgrade Kubernetes from v1.24 to v1.25 to v1.26 and then to v1.27. (all interim upgrades are required).
2. Upgrade API Connect to 10.0.7.0 on Kubernetes v1.27.
3. Upgrade Kubernetes from v1.27 to v1.28.
4. Upgrade API Connect to 10.0.8.0 on Kubernetes v1.28.
5. Upgrade Kubernetes from v1.28 to v1.29 and then to v1.30.
6. Upgrade API Connect to 10.0.10.0 on Kubernetes v1.30.
7. Upgrade Kubernetes from v1.30 to v31 and then to v1.32
8. Upgrade API Connect to 10.0.11.0 on Kubernetes v1.32.
9. Upgrade Kubernetes from v1.32 to v1.34 to reach the highest supported version of Kubernetes in API Connect 10.0.11.0.(all interim upgrades are required).

Important upgrade considerations

Important:
Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema.

- Customers upgrading from 10.0.10.0 will lose all previous scan history.
- To preserve critical information, archive or export important scan results before starting the upgrade.

Carefully review the following items, to plan and prepare for your upgrade.

Analytics backup changes

In V10.0.8, the analytics database backup functions moved from the API Connect operator to the analytics subsystem pods. This change has two implications:

- It is not possible to restore pre-V10.0.8 analytics database backups to a V10.0.8 or later analytics subsystem.
- During the upgrade procedure, after the API Connect operator is upgraded but before the analytics subsystems are upgraded, the analytics subsystem CR status reports

```
The backup and restore functionality for the API Analytics subsystem has been moved from the IBM API Connect operator
into the API Analytics microservices.
This means that the v5.2-sc2 operator cannot support backup and restore on versions before 10.0.8.
Update to 10.0.8 for scheduled backups to continue.
```

Extra persistent storage required for analytics local backups

If analytics database backups are configured, then beginning with 10.0.8.0, an extra PV is required to store local backups and prepare them for transmission to your remote SFTP server or object-store.

Before you upgrade, verify that you have an extra PV available for your analytics subsystem local backups, and decide how much space to allocate to it. To estimate storage requirements for your local backups, see Estimating storage requirements.

The default size of the new PVC is 150Gi. You can override the size to increase it during the upgrade procedure.

Analytics `n3xc4.m16` component profile is deprecated

The analytics `n3xc4.m16` profile is deprecated in 10.0.8.0. If you use this profile, then it is recommended to switch to the `n3xc4.m32` profile. You can switch profile either before or after upgrade to V10.0.8. For information about switching profile, see Changing deployment profiles on Kubernetes and OpenShift.

API transaction failure during the upgrade of gateway

The gateway subsystem remains available and continues processing API calls during the upgrade of the management, portal, and analytics subsystems. However, a few API transactions might fail during the upgrade of the gateway.

When you upgrade a cluster of gateway pods, a few API transactions might fail. During the upgrade, Kubernetes removes the pod from the load balancer configuration, deletes the pod, and then starts a new pod. The steps are repeated for each pod. Socket hang-ups occur on transactions that are in process at the time the pod is terminated.

The number of transactions that fail depends on the rate of incoming transactions, and the length of time that is needed to complete each transaction. Typically the number of failures is a small percentage. This behavior is expected during an upgrade. If the failure level is not acceptable, schedule the upgrade during an off-hours maintenance window.

DataPower Gateway supports long-lived connections such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when you upgrade. Workloads with long-lived connections are more vulnerable to failed API transactions during upgrading.

You can limit the number of failed API transactions during the upgrade by using the DataPower Operator's **`lifecycle`** property to configure the **`preStop`** container lifecycle hook on the gateway pods. This approach mitigates the risk of API failures during the rolling update of the gateway StatefulSet by sleeping the pod for a span of time, allowing in-flight transactions to complete before the SIGTERM is delivered to the container. While this feature does not guarantee no in-flight API call failures, it does provide some mitigation for in-flight transactions that can complete successfully within the configured time window. For more information, see Delaying SIGTERM with preStop in the DataPower documentation.

FIPS support
: API Connect is not supported in a FIPS-enabled environment on Kubernetes.

OAuth provider resources with **`api.securityDefintions`**
: If you have native OAuth providers that are configured with the **`api.securityDefintions`** field assigned, then upgrade fails. Before upgrade, remove all **`api.securityDefintions`** from all native OAuth providers that you configured in the Cloud Manager and API Manager UIs:

  - Configuring a native OAuth provider in the Cloud Manager UI
  - Configuring a native OAuth provider in the API Manager UI

  Switch to the source view and delete any **`securityDefintions`** sections that are present.

Extra backup folder appended to management database backup path
: When you upgrade to V10.0.7.0 or later with S3 backups configured, an extra backup path folder /edb is appended to your backup path. The /edb path distinguishes new EDB backups from your previous management backups.

Extra persistent storage requirement for management subsystem
: Upgrading to V10.0.7.0 or later requires extra persistent storage space for the management subsystem. Verify that your environment has at least as much extra capacity as the capacity assigned to your existing Postgres PVC:

  ```
  kubectl get pvc -n <namespace>
  ```

  ```
  NAME                                    STATUS   VOLUME              CAPACITY   ACCESS MODES   STORAGECLASS    AGE
  def-management-site1-postgres           Bound    local-pv-7b528204   244Gi      RWO            local-storage   125d
  def-management-site1-postgres-pgbr-repo Bound    local-pv-8d425510   244Gi      RWO            local-storage   125d
  def-management-site1-postgres-wal       Bound    local-pv-ee8feb38   244Gi      RWO            local-storage   125d
  ```

Analytics persistent queue enablement requires extra PV. Upgrades from V10.0.8
: The analytics persistent queue feature is enabled during the upgrade (if it was not already enabled). This feature requires an extra Physical Volume (PV). Before you upgrade from V10.0.8.x, ensure that your environment has an available PV.

Pre-upgrade preparation and checks on Kubernetes

Prepare your Kubernetes environment and API Connect deployment for upgrade.

This topic covers all the preparation steps you must complete before you can start the upgrade process.

Before completing the steps in this topic, review Planning your API Connect upgrade on Kubernetes to ensure that you are following a supported upgrade path and that you are aware of any API Connect feature changes that might affect your deployment.

Run the pre-upgrade health checks during your upgrade planning stage to identify any problems as early as possible. Run the checks again just before upgrade to confirm API Connect is still ready for upgrade.
Important:
Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema.

- Customers upgrading from 10.0.10.0 will lose all previous scan history.
- To preserve critical information, archive or export important scan results before starting the upgrade.

Gathering and preparing upgrade files

1. Obtain the API Connect files from IBM Fix Central.
   From the IBM Fix Central site, download the following files:

   IBM API Connect *<version>* for Containers
   : Docker images for all API Connect subsystems. Filename is apiconnect-image-tool_*<version>*.

   IBM API Connect *<version>* Operator Release Files for Containers
   : Kubernetes operators and API Connect Custom Resource (CR) templates. Filename is apiconnect-operator-release-files_*<version>*.

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files for verifying the integrity of your downloads.
   Filename is signatures_*<version>*.

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer:
     - IBM® API Connect *<version>* Toolkit for *<operating_system>*
     - IBM® API Connect *<version>* Toolkit Designer for *<operating_system>*

   Filename is toolkit-...*<operating system>*_*<version>*.
   Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI as explained in Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment for testing locally as explained in Testing an API with the Local Test Environment.
   Filename is apic-lte-*<operating system>*_*<version>*.

2. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
3. Upload the image files to your docker registry.
   a. Load the image-tool image for the new API Connect version into your local Docker registry:

      ```
      docker load < apiconnect-image-tool-<version>.tar.gz
      ```

      Ensure that the registry has sufficient disk space for the files.

   b. If your Docker registry requires repositories to be created before images can be pushed, create the repositories for each of the images that the image tool lists. If your Docker registry does not require creation of repositories, skip to step 3.c.
      i. Run the following command to get a list of the images from image-tool:

         ```
         docker run --rm apiconnect-image-tool-<version> version --images
         ```

      ii. From the output of each entry of the form **<image-name>:<image-tag>**, use your Docker registry repository create command to create a repository for **<image-name>**.
      For example, in AWS ECR the command for each **<image-name>** is:

         ```
         aws ecr create-repository --repository-name <image-name>
         ```

   c. Upload the image:
      - If you do not need to authenticate with the docker registry, use:

        ```
        docker run --rm apiconnect-image-tool-<version> upload <registry-url>
        ```

      - If you need to authenticate and your docker registry accepts the username and password arguments, use:

        ```
        docker run --rm apiconnect-image-tool-<version> upload <registry-url> --username <username> --password <password>
        ```

      - Otherwise, if you need the image-tool to use your local Docker credentials (for example, with IBM Container Registry), first authenticate with your Docker registry, and then upload images with the command:

        ```
        docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
        ```

        Review the following installation notes for your environment:

        - Alternative Docker command for macOS if Docker is configured to use osxkeychain
        - Docker authentication notes
        - Providing a certificate for verification, or disabling TLS verification

   If necessary, you can populate a remote container registry with repositories. Then you can push the images from the local registry to the remote registry.

4. Extract the **IBM API Connect <version> Operator Release Files for Containers** that you downloaded in step 1.
   Create a directory called **helper_files** and extract the contents of **helper_files.zip** from the release_files.zip into the **helper_files** directory.

Pre-upgrade health-checks

1. Check that the API Connect operator and subsystems are all running.
   To verify the health of each subsystem, run the following commands:

   ```
   kubectl get ManagementCluster -n <management namespace>
   kubectl get GatewayCluster -n <gateway namespace>
   kubectl get PortalCluster -n <portal namespace>
   kubectl get AnalyticsCluster -n <analyticsnamespace>
   ```

   Confirm that all pods are **READY**, for example:

   ```
   kubectl get PortalCluster -n apic
   NAME      READY   STATUS    VERSION    RECONCILED VERSION   AGE
   portal    3/3     Running   version    version-95    57m
   ```

2. Run the pre-upgrade health check:
   Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.
   a. Verify that the **apicops** utility is installed and that you have the latest version by running the following command:

      ```
      apicops --version
      ```

      For more information about the **apicops** utility, see The API Connect operations tool: apicops.

   b. Run the following command to set the KUBECONFIG environment variable.

      ```
      export KUBECONFIG=</path/to/kubeconfig>
      ```

   c. Run the **apicops pre-upgrade-check** check for the management, portal, and analytics subsystems:
      - Management subsystem:

        ```
        apicops system:pre-upgrade-check management -n <namespace>
        ```

      - Portal subsystem:

        ```
        apicops system:pre-upgrade-check portal -n <namespace>
        ```

      - Analytics subsystem:

        ```
        apicops system:pre-upgrade-check analytics -n <namespace>
        ```

      If your API Connect deployment is working correctly, the output shows no error messages.

      If the pre-upgrade check returns any errors, then collect the output and open a support case.

Additional pre-upgrade checks and operations

Extra checks and operations to review and complete before you start the upgrade.

1. If analytics database backups are configured, or you want to enable them in future, then ensure that you have an extra Physical Volume available for the local backup storage. The default size is 150Gi. You can override the size during the upgrade procedure.

2. If you used any microservice image overrides in any of your API Connect subsystem CRs, remove the image overrides before upgrade.
3. If your Developer Portal includes any custom themes or modules, the upgrade might fail. API Connect does not support any upgrade issues caused by custom themes or modules as these issues are outside the scope of IBM technical support. To avoid any upgrade issues, review the following considerations before upgrading your API Connect deployment:
   - Test the upgrade in a staging environment. Use the same set of custom modules and themes, and upgrade between the same versions planned for the production deployment to validate compatibility and functionality.
   - Remove problematic custom modules or themes. You can re-apply the custom themes or modules after the upgrade, if needed.
   - Take a portal backup.
   - If there are any issues related custom modules or themes, contact the developer who added the modules and themes to the Developer Portal.

Backup your API Connect deployment

If upgrade fails, rollback is not possible. Before upgrade complete the disaster recovery preparation for all your subsystems.

For instructions on backing up and disaster recovery preparation for v10.0.9.0, see Backing up, restoring, and disaster recovery

Upgrading DataPower Operator and Operand independently of the APIC

API Connect and DataPower each have their own Operator, which manages their respective products. The Operand is the actual product that users interact with. Before you deploy an Operand, its corresponding Operator must be installed at a specific version. While Operators and Operands can have different versions, each Operator supports a specific range of Operand versions. This separation allows customers to upgrade the Operator and Operand independently, reducing upgrade times. The primary use case is that customers want the flexibility to upgrade API Connect (management plane) and DataPower (data plane) separately. This flexibility allows them to either minimize the upgrade window or apply fixes to one component without affecting the other. When DataPower is deployed through API Connect in Kubernetes, API Connect strictly controls the versions of both the DataPower Operator and Operand, ensuring that the management and data plane upgrades occur simultaneously. In OpenShift Container Platform and Cloud Pak for Integration, API Connect still handles Operator installation, but customers can change the Operator version without relying on Helm. The Operand upgrade process remains the same across Kubernetes, OpenShift Container Platform, and Cloud Pak for Integration.

Operand upgrade

You can upgrade the DP operand while APIC controls the DP operator version, see Overriding the default DataPower image, version, and license. The operand version that you specify must be compatible with the installed DataPower Operator version. For compatibility information, see DP Operator and Operand Compatibility matrix. If operand is not compatible, you must update the DataPower Operator.

You can update the GatewayCluster CR to override the image, version, and license information for the Gateway subsystem.

The DataPower operand images are pushed to the IBM Entitled Registry. If the image is to be pulled from the IBM Entitled Registry, an Entitlement Key must be used as an Image Pull Secret. You can obtain an Entitlement Key from My IBM, see Entitlement keys.

1. Create the Secret using your own Entitlement Key in the same namespace as the GatewayCluster subsystem.

```
oc create secret docker-registry \
  ibm-entitlement-key \
  --docker-username=cp \
  --docker-password=<entitlement-key> \
  --docker-server=cp.icr.io
```

2. Specify your secret in GatewayCluster CR under `imagePullSecrets` property to pull the operand images from the registry.

```
apiVersion: gateway.apiconnect.ibm.com/v1beta1
kind: GatewayCluster
metadata:
  name: api-gateway
spec:
  dataPowerOverride:
     version: 10.5.0.3
     license: X-XXXX-XXXXXX
  imagePullSecrets:
  - ibm-entitlement-key
```

3. When a custom registry is used, or if you want to a specific image (for urgent/hot fixes), it is important to specify the image field in the override. This scenario is not typical.

```
apiVersion: gateway.apiconnect.ibm.com/v1beta1
kind: GatewayCluster
metadata:
  name: api-gateway
spec:
  dataPowerOverride:
     image: customregistry.com/custom-image-datapower:10.5.0.3
     version: 10.5.0.3
     license: X-XXXX-XXXXXX
  imagePullSecrets:
  - ibm-entitlement-key
```

Operator upgrade

If you want greater flexibility in what DP operand version is installed, as well as plan to install DP operator/operand at different times than APIC, it is recommended to do the following steps so that you can control version of operator rather than APIC deciding operator version. The following allows you to install DP operator at different times compared to APIC operator.

Make sure that the version of the DataPower Operator you're installing is compatible with the APIC version. You can find the compatibility information in the following matrix:

API Connect Operator version	API Connect Operand version	DataPower minimum Operator version	DataPower supported Operand version
6.2.0	10.0.11.0	1.16.0	DP Operator and Operand Compatibility matrix

If you previously used the Helm Chart to install the DataPower Operator, then to upgrade Operator, see Upgrading with Helm.

If you want to install the DataPower by using Helm chart after the Operator installation was done through the APIC shipped yaml files, uninstall the DataPower operator by running the following command:

```
kubectl delete -f ibm-datapower.yaml -n <namespace>
```

Install the DataPower Operator by using the Helm chart, see Installation with Helm.

Use new CRD during upgrade

If you use Helm chart to upgrade DP operator, use different file to apply new APIC CRDs during APIC upgrades instead of using file to apply combined APIC and DP operator CRDs. See Upgrading API Connect on Kubernetes.

If you upgraded the DataPower Operator by using the Helm Chart independently of the APIC, run the following command to apply the new CRDs from the extracted version (contains only APIC CRDs):

```
kubectl apply -f ibm-apiconnect-only-crds.yaml
```

Otherwise, run the following command to apply the new CRDs from the extracted version (contains both APIC and DP CRDs):

```
kubectl apply -f ibm-apiconnect-crds.yaml
```

Upgrading API Connect on Kubernetes

Upgrade your API Connect subsystems to a newer version on Kubernetes.

Before you begin

Review Planning your API Connect upgrade on Kubernetes and complete the Pre-upgrade preparation and checks on Kubernetes.

About this task

- To ensure operator compatibility, upgrade the API Connect management subsystem first and the gateway subsystem second. This requirement applies to all upgrade scenarios.
- The gateway subsystem remains available during the upgrade of the management, portal, and analytics subsystems.

Notes:

- If any subsystem database backups are running or are scheduled to run within a few hours, do not start the upgrade process.
- Do not perform maintenance tasks such as updating certificates, restoring subsystem databases from backup, or triggering subsystem database backups at any time while you are upgrading API Connect.
- Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema. As a result, customers upgrading from 10.0.10.0 will lose all previous scan history. To preserve critical information, archive or export important scan results before starting the upgrade.

Procedure

1. If you did not run the pre-upgrade health checks recently, run them now.
2. If you have a two data center disaster recovery deployment, then upgrade the warm-standby data center first.
   See the special steps for 2DCDR upgrades: Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9
3. Apply the API Connect CRDs that you downloaded and extracted in the pre-upgrade steps:

   ```
   kubectl apply --server-side --force-conflicts -f ibm-apiconnect-crds.yaml
   ```

4. Apply the new DataPower Operator YAML into the namespace where the DataPower operator is running.
   a. Edit the `ibm-datapower.yaml` file and set the following properties:the `namespace` property to the namespace where you deployed the operator.
      - Set all instances of the `namespace` property to the namespace where you deployed the operator.
      - Set the `containers.image` property to the location of the `datapower-operator` image, either uploaded to your own registry or pulled from a public registry.

   b. Run the following command:

      ```
      kubectl -n <namespace> apply -f ibm-datapower.yaml
      ```

      The gateway CR goes to `Pending` state when the operator is updated, and then changes to `Running` after installation of the API Connect operator in the next step.

      Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting upgrade.

5. Upgrade cert-manager to version 1.18.2.
   a. Run the following command to back up the existing certificates and issuers to a file called backup.yaml:

      ```
      kubectl get --all-namespaces -oyaml issuer,clusterissuer,cert,secret > backup.yaml
      ```

   b. Run the following command to verify the version of cert-manager that you are upgrading:
      - API Connect 10.0.5.4: verify that you are upgrading cert-manager 1.9.1:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.9.1
        ```

      - API Connect 10.0.5.5 or 10.0.7.0: verify that you are upgrading cert-manager 1.11.5:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.11.5
        ```

      - API Connect 10.0.5.6: verify that you are upgrading cert-manager 1.12.7:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.12.7
        ```

      - API Connect 10.0.5.7: verify that you are upgrading cert-manager 1.12.9:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.12.9
        ```

      - API Connect 10.0.5.8: no upgrade needed.
      - API Connect 10.0.8.0: verify that you are upgrading cert-manager 1.12.10:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.12.10
        ```

      - API Connect 10.0.9.0: verify that you are upgrading cert-manager 1.12.13:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.12.13
        ```

      - API Connect 10.0.10.0: verify that you are upgrading cert-manager 1.17.2:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.17.2
        ```

   c. Run the following command to upgrade cert-manager to version 1.18.2:

      ```
      kubectl apply -f helper_files/cert-manager-1.18.2.yaml
      ```

6. If you generated your internal certificates with the custom-certs-internal.yaml file when you installed API Connect (following these steps Generating custom certificates using cert-manager), then apply the new custom-certs-internal.yaml file from your target release files and renew **db-server-certificate**.
   Note: If you are not sure if API Connect was installed with custom-certs-internal.yaml, then check the follow these steps to confirm:
   a. Check whether the management CR has a **customCertificates** section:

      ```
      kubectl -n <management namespace> get mgmt -o yaml | grep customCertificates
      ```

      If the management CR does not have this section, then custom-certs-internal.yaml was not used. If it does have this section, then continue to the next check.

   b. Check the issuer of the **management-server** certificate:

      ```
      kubectl -n <management namespace> describe secret management-server | grep issuer-name
      ```

      If the command returns:

      ```
       cert-manager.io/issuer-name: ingress-issuer
      ```

      then custom-certs-internal.yaml was used.
   a. Edit the new custom-certs-internal.yaml file. Replace all instances of **<namespace>** and **<site_name>** with the values from the original custom-certs-internal.yaml file that you used during installation.
   b. Apply the new custom-certs-internal.yaml file.

      ```
      kubectl apply -f helper_files/custom-certs-internal.yaml
      ```

   c. Renew **db-server-certificate**.

      ```
      kubectl -n <management namespace> delete secret db-server-certificate
      ```

7. Apply the new API Connect operator YAML into the namespace where the API Connect operator is running.
   - For a single-namespace deployment:
     - For a single-namespace deployment, update the configuration file by replacing each occurrence of **namespace: default** with **namespace: <namespace>**. Replace **<namespace>** with the actual name of the namespace where you deployed API Connect.
       Note: If you are using Operator Lifecycle Manager (OLM), then skip this step.
     - Edit the **ibm-apiconnect.yaml** file and replace each occurrence of **REPLACE-DOCKER-REGISTRY** with the location of the **apiconnect** operator images, either uploaded to your own registry or pulled from a public registry. This includes replacing the **REPLACE-DOCKER-REGISTRY** placeholder in the following locations:
       - **image** properties for containers.
       - Any other instances of **REPLACE-DOCKER-REGISTRY** in the file, regardless of whether they are part of an **image** key.
     - Run the following command:

       ```
       kubectl -n <namespace> apply -f ibm-apiconnect.yaml
       ```

   - For a multi-namespace deployment:

- Edit the `ibm-apiconnect-distributed.yaml` file and replace each occurrence of `$OPERATOR_NAMESPACE` with the namespace for the deployment.
- Also in `ibm-apiconnect-distributed.yaml`, set the values of the `containers.image` properties. Replace the placeholder values `REPLACE-DOCKER-REGISTRY` with the docker registry host location of the API Connect operator image (either uploaded to own registry or pulled from public registry).
- Install `ibm-apiconnect-distributed.yaml` with the following command:

  ```
  kubectl apply -f ibm-apiconnect-distributed.yaml
  ```

8. Verify that the `ibm-datapower-operator` and the `ibm-apiconnect` operators are restarted.
9. Ensure that the `apiconnect` operator re-created the necessary microservices:

   ```
   kubectl get apic -n <namespace>
   ```

   Do not proceed to upgrade the API Connect subsytems until the operator upgrade is complete.

   Note: If analytics backups are configured, then after the API Connect operator is upgraded, the analytics CR reports a status of `Blocked` until the analytics subsystem is upgraded to V10.0.8. With top-level CR deployments, the `apiconnectcluster` CR reports `Pending` until the analytics CR is no longer `Blocked`. For more information, see Analytics backup changes.
10. Upgrade the API Connect subsystems:
    a. Upgrading the management subsystem on Kubernetes
    b. Upgrading the gateway subsystem on Kubernetes
    c. Upgrading the portal subsystem on Kubernetes
    d. Upgrading the analytics subsystem on Kubernetes
11. Verify that the upgraded subsystems report as `Running` and the `RECONCILED VERSION` displays the new version of API Connect.
    Run the following command:

    ```
    kubectl get apic --all-namespaces
    ```

    Example response:

    ```
    NAME                                                READY   STATUS    VERSION          RECONCILED VERSION      AGE
    analyticscluster.analytics.apiconnect.ibm.com/analytics      8/8     Running   10.0.11.0   10.0.11.0-1074   121m

    NAME                                    PHASE     READY   SUMMARY                          VERSION    AGE
    datapowerservice.datapower.ibm.com/gw1   Running   True    StatefulSet replicas ready: 1/1   10.0.11.0   100m

    NAME                                    PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
    datapowermonitor.datapower.ibm.com/gw1   Running                false          false              100m

    NAME                                          READY   STATUS    VERSION          RECONCILED VERSION      AGE
    gatewaycluster.gateway.apiconnect.ibm.com/gw1   2/2     Running   10.0.11.0   10.0.11.0-1074  100m

    NAME                                               READY   STATUS    VERSION          RECONCILED VERSION      AGE
    managementcluster.management.apiconnect.ibm.com/m1   16/16   Running   10.0.11.0  10.0.11.0-1074   162m

    NAME                                          READY   STATUS    VERSION          RECONCILED VERSION      AGE
    portalcluster.portal.apiconnect.ibm.com/portal   3/3     Running   10.0.11.0   10.0.11.0-1074   139m
    ```

    Important: If you need to restart the deployment, wait until all portal sites complete the upgrade.
    After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the `MESSAGE` column in the `oc get ptl` output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the `oc get ptl` output shows how many sites the portal is serving:

    ```
    NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
    portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
    ```

    On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

12. Optional: **If upgrading from 10.0.5.x or 10.0.7.0:** Provide a custom endpoint for the Consumer Catalog.
    Skip this step if you are upgrading from 10.0.8.0 or later.

    Beginning with version 10.0.8.0, API Connect includes the Consumer Catalog feature. If your deployment uses cert-manager, then during the upgrade from 10.0.5.x or 10.0.7.0, a new endpoint is added to the management CR for the Custom Catalog.

    The following definition is generated and automatically added to the management CR during the upgrade, using a certificate from cert-manager:

    ```
    consumerCatalogEndpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: consumer-catalog.<domain>
        secretName: <name>-consumer-catalog-endpoint
    ```

    a. Make the following optional changes to the endpoint definition in the CR:
       - Change the `name` to a host name of your own choosing.
       - Specify a custom cert-manager certificate.
    b. Run the following command to save and apply the CR: `wq`
13. Optional: For the optional components API Connect Toolkit and API Connect Local Test Environment, install the latest version of each after you complete the upgrade of the subsystems.

- **Upgrading the management subsystem on Kubernetes**
  Upgrade the management subsystem to a newer version of API Connect on Kubernetes.
- **Upgrading the portal subsystem on Kubernetes**
  Upgrade the portal subsystem to a newer version of API Connect on Kubernetes.
- **Upgrading the analytics subsystem on Kubernetes**
  Upgrade the analytics subsystem to a newer version of API Connect on Kubernetes.

- **Upgrading the gateway subsystem on Kubernetes**
  Upgrade the gateway subsystem to a newer version of API Connect on Kubernetes.

Upgrading the management subsystem on Kubernetes

Upgrade the management subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes
- Upgrading API Connect on Kubernetes

About this task

Upgrade the management subsystem by updating the version property in your management CR. The API Connect operator detects this change and starts the upgrade.

Procedure

1. Update the management CR for the new version of API Connect.
   a. Run the following command to edit the management CR:

      ```
      kubectl -n <namespace> edit mgmt
      ```

   b. Update `spec.version` in the management CR to your target version:
      For example:

      ```
      version: 10.0.11.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update `spec.license`.
      For example:

      ```
      license: L-KYAL-S3RCBM
      ```

      For the list of licenses, see API Connect licenses.

   d. If you have a two data center disaster recovery installation, and are upgrading the warm-standby, then add the annotation:

      ```
      apiconnect-operator/dr-warm-standby-upgrade-data-deletion-confirmation: "true"
      ```

      For more information about two data center disaster recovery upgrade, see Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9.
   e. If you are upgrading from V10.0.5 and you generated your internal certificates with the custom-certs-internal.yaml file when you installed API Connect (following these steps Generating custom certificates using cert-manager), then add the new `db-client-replication` certificate in the `customCertificates` section:

      ```
      customCertificates:
         ...
         - name: dbClientReplicator
           secretName: db-client-replication
      ```

   f. Run the following command to save and apply the CR: `wq`
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the Troubleshooting upgrades on Kubernetes.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl -n <namespace> get apic
   ```

   Example output after management subsystem upgrade:

   ```
   NAME                                                READY   STATUS    VERSION              RECONCILED VERSION      AGE
   managementcluster.management.apiconnect.ibm.com/m1   16/16   Running   <version>   <version-build>   162m

   NAME                                                                STATUS    MESSAGE                                                                
   ```

Upgrading the portal subsystem on Kubernetes

Upgrade the portal subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes
- Upgrading API Connect on Kubernetes
- Upgrading the management subsystem on Kubernetes

About this task

Upgrade the portal subsystem by updating the version property in your portal CR. The API Connect operator detects this change and starts the upgrade.

Procedure

1. Update the portal CR for the new version of API Connect.
   a. Run the following command to edit your portal CR:

      ```
      kubectl -n <namespace> edit ptl
      ```

   b. Set the `spec.version` property in the portal CR to your target version:
      For example:

      ```
      version: 10.0.11.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update `spec.license`.
      For example:

      ```
      license: L-KYAL-S3RCBM
      ```

      For the list of licenses, see API Connect licenses.

   d. Run the following command to save and apply the CR: `wq`
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl -n <namespace> get apic
   ```

   Example output after portal subsystem upgrade:

   ```
   NAME                                                READY   STATUS    VERSION     RECONCILED VERSION   MESSAGE
   AGE
   portalcluster.portal.apiconnect.ibm.com/portal      3/3     Running   <version>   <version>            Site Upgrades
   Executing:(1) Queued(5) Failed(0) Success(0)   22h
   ```

   Note: After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the `MESSAGE` column in the `kubectl get apic` output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the `kubectl get apic` output shows how many sites the portal is serving:

   ```
   NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
   portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
   ```

   On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

   If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the portal CR status for errors:

   ```
   kubectl -n <namespace> get ptl -o yaml
   ```

   Refer to Troubleshooting upgrades on Kubernetes, for known issues.

Upgrading the analytics subsystem on Kubernetes

Upgrade the analytics subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes

- Upgrading API Connect on Kubernetes
- Upgrading the management subsystem on Kubernetes

About this task

Upgrade the analytics subsystem by updating the version property in your analytics CR. The API Connect operator detects this change and starts the upgrade.

Procedure

1. Update the analytics CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n <namespace> edit a7s
      ```

   b. Set the `spec.version` property in the analytics CR to your target version:
      For example:

      ```
      version: 10.0.11.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update `spec.license`.
      For example:

      ```
      license: L-KYAL-S3RCBM
      ```

      For the list of licenses, see API Connect licenses.

   d. Optional: Set the size of local database backup storage.
      Upgrades to V10.0.8.0: By default the new PVC that is created for the analytics subsystem's local database backups is set to 150Gi. If you want to specify a larger size, then add the following to the CR `spec` section:

      ```
        storage:
          backup:
            volumeClaimTemplate:
              storageClassName: <storage class>
              volumeSize: <size>
      ```

      where:
      - *<storage class>* is the same as used by your other analytics PVCs.
      - *<size>* is the size. For example: `500Gi`. See Estimating storage requirements.

   e. Attention: This step applies only when upgrading to API Connect version 10.0.10 or later.
      `$PLATFORM_CA_SECRET` `Set to ingress-ca`. The $PLATFORM_CA_SECRET contains the CA certificate for the platform ingress endpoint of the management subsystem. The analytics makes calls to the platform REST API and this property must be set so that the analytics can verify the server certificate.

      ```
      mgmtPlatformEndpointCASecret:
                    secretName: $PLATFORM_CA_SECRET
      ```

      Note: The value of `secretName` must match the name of the `Kubernetes Secret` containing the CA certificate for the platform ingress endpoint.
      Optional: In-cluster subsystem communication (mgmtPlatformEndpointSvcCASecret)

      If you plan to enable In-cluster intersubsystem communication (internal Kubernetes service-based communication instead of ingress) you can optionally configure the `mgmtPlatformEndpointSvcCASecret` field.

      ```
      mgmtPlatformEndpointSvcCASecret:
              secretName: management-ca  # Usually 'management-ca
      ```

      The `management-ca` secret contains the certificate authority (CA) certificate that the internal Kubernetes service uses to sign its TLS certificates. This secret is typically generated automatically during the management subsystem installation. Copy the `management-ca` secret to the Analytics namespace.

   f. Save your changes to the CR.
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after an analytics subsystem upgrade:

   ```
   NAME                                                  READY   STATUS    VERSION              RECONCILED VERSION
   AGE
   analyticscluster.analytics.apiconnect.ibm.com/analytics   5/5     Running   <version>   <version-build>   121m
   ```

   If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the analytics CR status for errors:

   ```
   kubectl -n <namespace> get a7s -o yaml
   ```

   Refer to Troubleshooting upgrades on Kubernetes, for known issues.

3. Update analytics profile.
   If your analytics subsystem uses the `n3xc4.m16` profile, then update the profile in your analytics CR to `n3xc4.m32`. For information about switching profiles, see Changing deployment profiles on Kubernetes and OpenShift

Upgrading the gateway subsystem on Kubernetes

Upgrade the gateway subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes
- Upgrading API Connect on Kubernetes
- Upgrading the management subsystem on Kubernetes

Note: To upgrade a high-availability cluster, ensure that you meet the following requirements:

- Gateways must be updated one at a time.
- Before you start the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
- To upgrade multiple gateways, upgrade the primary gateway last.
  Ensure that the pod with a name like `gwv6-0` or `gwv5-0` is the primary because it is the last node to be upgraded.

  To determine which gateway is running as primary, use either
  - The **show gateway-peering-status** command in the DataPower CLI. Access the CLI with:

    ```
    kubectl attach -it <gateway pod name>
    ```

  - The Gateway Peering Status display in the WebGUI (in the API Connect application domain).

  To move the primary to the DataPower on which you are working, you can issue the following command:

  ```
  gateway-peering-switch-primary <peering-object-name>
  ```

About this task

Upgrade the analytics subsystem by updating the version property in your analytics CR. The API Connect operator detects this change and starts the upgrade.

Gateway upgrade can result in failure of some in-flight transactions, for more information see: API transactions might fail during the upgrade of gateway pods.

Procedure

1. Update the gateway CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n <namespace> edit gw <gateway CR name>
      ```

      where *<gateway CR name>* is the name of your gateway CR. The names of your gateway CRs are shown in the output of: **kubectl get gw**.

   b. Set the **spec.version** property in the gateway CR to your target version:
      For example:

      ```
      version: 10.0.11.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update **spec.license**.
      For example:

      ```
      license: L-KYAL-S3RCBM
      ```

      For the list of licenses, see API Connect licenses.

   d. Delete any **template** or **dataPowerOverride** override sections.
      If the CR contains an override, an upgrade is not possible.

   e. Run the following command to save and apply the CR: **wq**
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after a gateway subsystem upgrade:

   ```
   NAME                                          READY   STATUS    VERSION              RECONCILED VERSION      AGE
   gatewaycluster.gateway.apiconnect.ibm.com/gw1   2/2     Running   <version>  <version-build>  100m
   ```

Troubleshooting upgrades on Kubernetes

Review the following troubleshooting guidance if you encounter a problem during an API Connect on Kubernetes.

Subsystem is stuck in `Pending` state with a reason of `PreUpgradeCheckInProgress`

Before the subsystem microservices are upgraded, the operator triggers a set of pre-upgrade checks that must pass for the upgrade to proceed. If one or more of the checks fail, the subsystem status remains in `Pending` state with a reason of `PreUpgradeCheckInProgress`. Check the status condition of the subsystem CR to confirm the pre-upgrade check failed. The `status.PreUpgradeCheck` property contains a summary of the failed checks. Full logs for the checks that are carried out can be viewed in the `ConfigMap` referenced in the `status.PreUpgradeCheck` property. The pre-upgrade checks automatically retry until they successfully pass. If you are unable to rectify the problem that causes a check to fail, then open an IBM support case.

License webhook error

If you did not update the license ID in the CR, then when you save your changes, the following webhook error might display:

```
admission webhook "vmanagementcluster.kb.io" denied the request:
ManagementCluster.management.apiconnect.ibm.com "management" is invalid:
spec.license.license: Invalid value: "L-RJON-BYGHM4":
License L-RJON-BYGHM4 is invalid for the chosen version 10.0.11.0.
Please refer license document https://ibm.biz/apiclicenses
```

To resolve the error, see API Connect licenses for the list of the available license IDs and select the appropriate license IDs for your deployment. Update the CR with the new license value as in the following example, and then save and apply your changes again.

Taskmanager error syncing management and gateway

If the gateways are not in sync with management after upgrade, check if the management subsystem `taskmanager` pods log the following error message. It starts 15 minutes after upgrade and repeats every 15 minutes for any stuck task.

```
TASK: Stale claimed task set to errored state:
```

If these errors are reported, restart all the `management-natscluster` pods, for example: `management-natscluster-1`.

```
kubectl -n <namespace> delete pod management-natscluster-1 management-natscluster-2 management-natscluster-3
```

After upgrading to API Connect v10.0.11.0, all existing scan records are removed

Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema. As a result, Customers upgrading from 10.0.10.0 will lose all previous scan history. To avoid losing critical governance or validation information, it is recommended to archive or export important scan results before initiating the upgrade.

DataPower operator fails to start

There is a known issue on Kubernetes that can cause the DataPower operator to fail to start. In this case, the DataPower operator pods can fail to schedule, and display the status message: `no nodes match pod topology spread constraints (missing required label)`. For example:

```
0/15 nodes are available: 12 node(s) didn't match pod topology spread constraints (missing required label),
3 node(s) had taint {node-role.kubernetes.io/master: }, that the pod didn't tolerate.
```

You can workaround the issue by editing the DataPower operator deployment and reapplying it, as follows:

1. Delete the DataPower operator deployment, if deployed already:

   ```
   kubectl delete -f ibm-datapower.yaml -n <namespace>
   ```

2. Open `ibm-datapower.yaml`, and locate the `topologySpreadConstraints:` section. For example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: zone
     whenUnsatisfiable: DoNotSchedule
   ```

3. Replace the values for `topologyKey:` and `whenUnsatisfiable:` with the corrected values that are shown in the following example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: topology.kubernetes.io/zone
     whenUnsatisfiable: ScheduleAnyway
   ```

4. Save `ibm-datapower.yaml` and deploy the file to the cluster:

   ```
   kubectl apply -f ibm-datapower.yaml -n <namespace>
   ```

Unexpected behavior in Cloud Manager and API Manager UIs after upgrade

Stale browser cache issues can cause problems after an upgrade. To remedy this problem, clear your browser cache, and open a new browser window.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Portal sites failed to be upgraded successfully

If one or more of the Portal sites failed to be upgraded successfully, check the portal-www admin container logs to see what prevented the site upgrade from completing successfully.

To trigger the site upgrade again, exec into the portal-www pod admin container and run the following command:

`upgrade_devportal -s <site_uuid> -p <platform>`

where:

- *<site_uuid>* can be obtained by running the command: `list_sites`
- *<platform>* can be obtained by running the command: `list_platforms`

- **Enabling gateway peering and verifying cluster status**
  Scale the replicas to 0 and back up to reset gateway-peering.

Enabling gateway peering and verifying cluster status

Scale the replicas to 0 and back up to reset gateway-peering.

Before you begin

This task is only needed under certain scenarios, such as when you rotate the root CA, and is not automatically required for an upgrade.

About this task

Follow these steps to fix gateway peering. When the ingress issuer changes, the gateway pods must be scaled down and back up. This process causes 5 to 10 minutes of API downtime.

Procedure

1. Verify that the management, portal, and analytics subsystems report `Running` status.
2. Scale down the gateway firmware containers by editing the gateway CR and setting `replicaCount` to 0:

   ```
   kubectl edit gw <gw-cr-name>
   ```

   For example:

   ```
   ...
   spec:
     replicaCount: 0
   ...
   ```

3. Wait for the gateway firmware pods to scale down and terminate. Ensure that the gateway firmware pods are terminated before you move to next step.
4. Scale up the gateway firmware containers back to their original value, or remove the `replicaCount` field if none was there before.

   ```
   kubectl edit gw <gw-cr-name>
   ```

5. Wait for the cluster status to become `Running`. If you performed an upgrade, verify that the `RECONCILED VERSION` displays the new version number.
   For example:

   ```
   kubectl get apic -n <namespace>
   ```

   ```
   NAME                                                    READY   STATUS    VERSION              RECONCILED VERSION
   AGE
   analyticscluster.analytics.apiconnect.example.com/analytics   8/8     Running   10.0.11.0   10.0.11.00-1074   121m

   NAME                                    PHASE     READY   SUMMARY                          VERSION    AGE
   datapowerservice.datapower.example.com/gw1   Running   True    StatefulSet replicas ready: 1/1   10.0.11.0   100m

   NAME                                    PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
   datapowermonitor.datapower.example.com/gw1   Running                false          false              100m

   NAME                                          READY   STATUS    VERSION             RECONCILED VERSION      AGE
   gatewaycluster.gateway.apiconnect.example.com/gw1   2/2     Running   10.0.11.0   10.0.11.0-1074  100m

   NAME                                             READY   STATUS    VERSION             RECONCILED VERSION      AGE
   managementcluster.management.apiconnect.example.com/m1   16/16   Running   10.0.11.0   10.0.11.0-1074   162m

   NAME                                          READY   STATUS    VERSION             RECONCILED VERSION      AGE
   portalcluster.portal.apiconnect.example.com/portal   3/3     Running   10.0.11.0   10.0.11.0-1074   139m
   ```

   Troubleshooting: If you find your gateways do not sync with your management service, see known upgrade issues.

Upgrading on OpenShift and Cloud Pak for Integration

You can upgrade API Connect in an OpenShift environment and as part of IBM Cloud Pak for Integration.

- **Planning your API Connect upgrade on OpenShift**
  Review the supported upgrade paths and other upgrade considerations on OpenShift or Cloud Pak for Integration.
- **Pre-upgrade preparation and checks on OpenShift**
  Prepare your API Connect deployment on OpenShift or Cloud Pak for Integration for upgrade.
- **Upgrading API Connect on OpenShift**
  Upgrade your API Connect installation to a newer version on OpenShift in an online (connected to the internet) environment.

- **Troubleshooting upgrade on OpenShift**
  Review the following troubleshooting tips if you encounter a problem during API Connect upgrade on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Planning your API Connect upgrade on OpenShift

Review the supported upgrade paths and other upgrade considerations on OpenShift or Cloud Pak for Integration.

Supported upgrade paths for API Connect

Table 1 lists the supported upgrade paths for API Connect and explains whether you can upgrade directly or an interim upgrade is required.

Table 1. Supported upgrade paths on OpenShift

Upgrade from:	How to upgrade to 10.0.11.0
• 10.0.10.0 • 10.0.8.4	Complete the procedure in Upgrading on OpenShift and Cloud Pak for Integration
• 10.0.9.0 • 10.0.8.2-ifix2 • 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0	• Upgrade to 10.0.10.0 or 10.0.8.4 as explained in Upgrading on OpenShift and Cloud Pak for Integration. • Upgrade to 10.0.11.0 on API Connect
• 10.0.8.1 • 10.0.8.0	• Upgrade to 10.0.9.0 as explained in Upgrading on Kubernetes on API Connect 10.0.9.0 documentation. • Upgrade to 10.0.8.2-ifix1 as explained in Upgrading on Kubernetes on API Connect 10.0.8.2-ifix1 documentation.
10.0.7.0	Upgrade to 10.0.8.0 first.
10.0.6.0	Complete two upgrades, making sure to perform the additional steps to preserve and re-create your SFTP backup configuration: 1. Upgrade to version 10.0.7.0 as explained in Upgrading on OpenShift and Cloud Pak for Integration in the API Connect 10.0.7.0 documentation. If you used SFTP backups for the Management subsystem in 10.0.6.0, you must temporarily remove the SFTP backup configuration before running the upgrade to 10.0.7.0: a. Edit the Management subsystem CR (or the `spec.management` section of your top-level `apiconnectcluster` CR), delete the `databaseBackup` section, and save it so you can restore it later. b. Add the following annotation into that CR: `apiconnect-operator/backups-not-configured: "true"` 2. Upgrade to the current release by completing the procedures in Upgrading on OpenShift and Cloud Pak for Integration. 3. Restore your SFTP backup configuration in the new version of API Connect: a. Edit the Management subsystem CR (or the `spec.management` section of your top-level `apiconnectcluster` CR), and add the preserved `databaseBackup` section. b. Delete the `apiconnect-operator/backups-not-configured: "true"` annotation.
10.0.5.3 or earlier	Complete three upgrades: 1. Upgrade to version 10.0.5.4 or later as explained in Upgrading on OpenShift and Cloud Pak for Integration in the API Connect 10.0.5.x documentation. 2. Upgrade to 10.0.8.0 3. Upgrade to the current release by completing the procedures in Upgrading on OpenShift and Cloud Pak for Integration.

Supported DataPower Gateway versions

You can use API Connect 10.0.11.0 with DataPower 10.6.5.0.

Before you upgrade, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. When you find the information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Version and platform compatibility

Be sure to review Operator, CASE, and platform requirements for upgrading for the latest information on OpenShift and API Connect requirements.

Important upgrade considerations

Important:
Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema.

- Customers upgrading from 10.0.10.0 will lose all previous scan history.
- To preserve critical information, archive or export important scan results before starting the upgrade.

Carefully review the following items, to plan and prepare for your upgrade.

Analytics backup changes

In V10.0.8, the analytics database backup functions moved from the API Connect operator to the analytics subsystem pods. This change has two implications:

- It is not possible to restore pre-V10.0.8 analytics database backups to a V10.0.8 or later analytics subsystem.
- During the upgrade procedure, after the API Connect operator is upgraded but before the analytics subsystems are upgraded, the analytics subsystem CR status reports

  ```
  The backup and restore functionality for the API Analytics subsystem has been moved from the IBM API Connect operator into the API Analytics microservices.
  This means that the v5.2-sc2 operator cannot support backup and restore on versions before 10.0.8.
  Update to 10.0.8 for scheduled backups to continue.
  ```

If you are using the top-level CR, then the **`APIConnectCluster`** CR reports a status of **`Pending`** until the analytics subsystems are upgraded to V10.0.8.

Upgrading multiple instances of API Connect

- If a single operator manages multiple instances, all of those instances must be upgraded, one at a time, as soon as possible.
  The operator should not be managing an operand based on an older version any longer than necessary.
- Ensure that each instance is fully upgraded before you start the upgrade on the next instance.

Top-level CR deployment profiles n3xc16.m48 and n3xc12.m40 deprecated

The top-level CR deployment profiles **`n3xc16.m48`** and **`n3xc12.m40`** are deprecated, and replaced with the profiles **`n3xc16.m64`** and **`n3xc12.m56`**. It is recommended to switch to one of these new profiles after upgrade to V10.0.8 is completed. For information about switching profile, see Changing deployment profiles on OpenShift top-level CR.

Analytics **`n3xc4.m16`** component profile is deprecated

The analytics **`n3xc4.m16`** profile is deprecated in 10.0.8.0. If you use this profile, then it is recommended to switch to the **`n3xc4.m32`** profile. You can switch profile either before or after upgrade to V10.0.8. For information about switching profile, see Changing deployment profiles on Kubernetes and OpenShift.

Extra persistent storage required for analytics local backups

If analytics database backups are configured, then beginning with 10.0.8.0, an extra PV is required to store local backups and prepare them for transmission to your remote SFTP server or object-store.

Before you upgrade, verify that you have an extra PV available for your analytics subsystem local backups, and decide how much space to allocate to it. To estimate storage requirements for your local backups, see Estimating storage requirements.

The default size of the new PVC is 150Gi. You can override the size to increase it during the upgrade procedure.

API transaction failure during the upgrade of gateway

The gateway subsystem remains available and continues processing API calls during the upgrade of the management, portal, and analytics subsystems. However, a few API transactions might fail during the upgrade of the gateway.

When you upgrade a cluster of gateway pods, a few API transactions might fail. During the upgrade, Kubernetes removes the pod from the load balancer configuration, deletes the pod, and then starts a new pod. The steps are repeated for each pod. Socket hang-ups occur on transactions that are in process at the time the pod is terminated.

The number of transactions that fail depends on the rate of incoming transactions, and the length of time that is needed to complete each transaction. Typically the number of failures is a small percentage. This behavior is expected during an upgrade. If the failure level is not acceptable, schedule the upgrade during an off-hours maintenance window.

DataPower Gateway supports long-lived connections such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when you upgrade. Workloads with long-lived connections are more vulnerable to failed API transactions during upgrading.

You can limit the number of failed API transactions during the upgrade by using the DataPower Operator's **`lifecycle`** property to configure the **`preStop`** container lifecycle hook on the gateway pods. This approach mitigates the risk of API failures during the rolling update of the gateway StatefulSet by sleeping the pod for a span of time, allowing in-flight transactions to complete before the SIGTERM is delivered to the container. While this feature does not guarantee no in-flight API call failures, it does provide some mitigation for in-flight transactions that can complete successfully within the configured time window. For more information, see Delaying SIGTERM with preStop in the DataPower documentation.

OAuth provider resources with **`api.securityDefintions`**

If you have native OAuth providers that are configured with the **`api.securityDefintions`** field assigned, then upgrade fails. Before upgrade, remove all **`api.securityDefintions`** from all native OAuth providers that you configured in the Cloud Manager and API Manager UIs:

- Configuring a native OAuth provider in the Cloud Manager UI
- Configuring a native OAuth provider in the API Manager UI

Switch to the source view and delete any **`securityDefintions`** sections that are present.

Extra backup folder appended to management database backup path

When you upgrade to V10.0.7.0 or later with S3 backups configured, an extra backup path folder /edb is appended to your backup path. The /edb path distinguishes new EDB backups from your previous management backups.

Extra persistent storage requirement for management subsystem

Upgrading to V10.0.7.0 or later requires extra persistent storage space for the management subsystem. Verify that your environment has at least as much extra capacity as the capacity assigned to your existing Postgres PVC:

```
kubectl get pvc -n <namespace>
```

```
NAME                                    STATUS   VOLUME              CAPACITY   ACCESS MODES   STORAGECLASS    AGE
def-management-site1-postgres           Bound    local-pv-7b528204   244Gi      RWO            local-storage   125d
def-management-site1-postgres-pgbr-repo Bound    local-pv-8d425510   244Gi      RWO            local-storage   125d
def-management-site1-postgres-wal       Bound    local-pv-ee8feb38   244Gi      RWO            local-storage   125d
```

Analytics persistent queue enablement requires extra PV. Upgrades from V10.0.8

The analytics persistent queue feature is enabled during the upgrade (if it was not already enabled). This feature requires an extra Physical Volume (PV). Before you upgrade from V10.0.8.x, ensure that your environment has an available PV.

- **Operator, CASE, and platform requirements for upgrading**
  Before you upgrade API Connect on OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped upgrades), and OpenShift version.

Operator, CASE, and platform requirements for upgrading

Before you upgrade API Connect on OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped upgrades), and OpenShift version.

Supported versions of operators for API Connect

Table 1 lists the operators that are used for the newest version of API Connect

Table 1. Operators for installing and upgrading API Connect

API Connect version	API Connect Operator channel	API Connect Operator version	Data Power version	DataPower Operator version	Foundational services CASE version
10.0.11.0	v6.2	6.2.0	10.6.5.0	1.16.0	4.6.18+

You can run the API Connect operator and subsystems at different versions. The following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
6.2.0	• 10.0.11.0
6.1.0	• 10.0.10.0
6.0.0	• 10.0.9.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

CASE versions required for air-gapped installation and upgrade

Note: There is no need to install a separate EDB case version during the deployment process as the EDB images are included within the API Connect case package.
Table 2 lists the required CASE file for each API Connect release:

Table 3. CASE versions for air-gapped deployments

API Connect version	API Connect CASE version	Foundational services CASE version
10.0.11.0	6.2.0	4.6.18+

Supported versions of Red Hat OpenShift Container Platform

Table 3 provides a quick reference of the supported OpenShift versions for API Connect:

Table 4. API Connect and OpenShift Container Platform (OCP) compatibility

API Connect version	OCP 4.10	OCP 4.12	OCP 4.14	OCP 4.15	OCP 4.16	OCP 4.17	OCP 4.18	OCP 4.19	OCP 4.20
10.0.5.4	✓	✓							
10.0.5.5	✓	✓	✓						
10.0.5.6		✓	✓						
10.0.5.7		✓	✓						
10.0.5.8		✓	✓		✓				
10.0.6.0	✓	✓							
10.0.7.0		✓	✓						
10.0.8.0		✓	✓	✓	✓				
10.0.8.1		✓	✓	✓	✓	✓			
10.0.9.0			✓	✓	✓	✓			
10.0.10.0			✓	✓	✓	✓	✓		
10.0.11.0			✓	✓	✓	✓	✓	✓	✓

Upgrading OpenShift to support a newer version of API Connect

When you upgrade API Connect, both your current deployment and your target release must support the same version of OpenShift. After the API Connect upgrade, you can optionally update OpenShift to the highest version supported by the new release of API Connect.

During the upgrade process, it is possible that API Connect is temporarily running on an unsupported version of OpenShift because you must upgrade API Connect before you upgrade OpenShift.

For example, suppose that your current deployment is running API Connect 10.0.8.0 on OpenShift 4.12 and you want to upgrade to API Connect 10.0.10.0 on OpenShift 4.16. Both versions of API Connect support OpenShift 4.14, so on the API Connect 10.0.8.0 deployment, you must upgrade OpenShift to 4.14 before you can upgrade to

API Connect 10.0.10.0. After you complete the API Connect upgrade to 10.0.10.0, you can optionally upgrade to the highest supported version of OpenShift.

In this scenario, the upgrade path is as follows:

1. On the API Connect 10.0.8.0 deployment, upgrade OpenShift to 4.14 and then 4.16 (interim upgrades are required).
2. Upgrade API Connect 10.0.8.0 to API Connect 10.0.11.0.
3. Upgrade OpenShift from 4.16 to 4.17, 4.18, 4.19 and then 4.20.

For OpenShift upgrade instructions, see the Red Hat OpenShift documentation.

Pre-upgrade preparation and checks on OpenShift

Prepare your API Connect deployment on OpenShift or Cloud Pak for Integration for upgrade.

This topic covers all the preparation steps you must complete before you can start the upgrade process.

Before following the steps in this topic, review the Planning your API Connect upgrade on OpenShift to ensure that you are following a supported upgrade path and that you understand important changes that might affect your deployment.

Run the Pre-upgrade health-checks during your upgrade planning stage to identify any problems as early as possible. Run the checks again just before upgrade to confirm API Connect is still ready for upgrade.

Obtaining upgrade files

1. Obtain the API Connect files from IBM Fix Central.
   From the IBM Fix Central site, download the following files:

   IBM® API Connect *<version>* for Containers
   : Docker images for all API Connect subsystems. Filename is apiconnect-image-tool_*<version>*.

   IBM® API Connect *<version>* Operator Release Files for Containers
   : Kubernetes operators and API Connect Custom Resource (CR) templates. Filename is apiconnect-operator-release-files_*<version>*.

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files for verifying the integrity of your downloads.
   Filename is signatures_*<version>*.

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer:
   - IBM API Connect *<version>* Toolkit for *<operating_system>*
   - IBM API Connect *<version>* Toolkit Designer for *<operating_system>*

   Filename is toolkit-...*<operating system>*_*<version>*.
   Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI as explained in Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment for testing locally as explained in Testing an API with the Local Test Environment.
   Filename is apic-lte-*<operating system>*_*<version>*.

2. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
3. Extract the **`IBM API Connect <version> Operator Release Files for Containers`** that you downloaded in step 1.
   Create a directory called **`helper_files`** and extract the contents of **`helper_files.zip`** from the release_files.zip into the **`helper_files`** directory.

Pre-upgrade health-checks

1. Verify that the API Connect operator and subsystems are all running.
   To verify the health of each subsystem, run the following commands:

   ```
   oc get ManagementCluster -n <management namespace>
   oc get GatewayCluster -n <gateway namespace>
   oc get PortalCluster -n <portal namespace>
   oc get AnalyticsCluster -n <analyticsnamespace>
   ```

   Confirm that all pods are **`READY`**, for example:

   ```
   oc get PortalCluster -n apic
   NAME      READY   STATUS    VERSION     RECONCILED VERSION   AGE
   portal    3/3     Running   10.0.11.0   10.0.11.0-95     57m
   ```

2. **Upgrading from V10.0.5.x:** Verify that the management subsystem's **`pgcluster`** is working correctly:
   a. Get the name of the **`pgcluster`**:

      ```
      oc get pgcluster -n <management namespace>
      ```

      The response displays the name of the postgres cluster that is running in the specified namespace.

   b. Check the status of the **`pgcluster`**:

      ```
      oc get pgcluster <pgcluster_name> -n <APIC_namespace> -o yaml | grep status -A 2 | tail -n3
      ```

      A successful response looks like the following example, where the state is **`Initialized`**:

```
status:
    message: Cluster has been initialized
    state: pgcluster Initialized
```

Important: If the `pgcluster` returns any other state, then do not proceed with the upgrade.

- If backup or restore jobs are running, wait until they complete and then check the status again. Do not proceed with the upgrade until the status is `Initialized`.
- If all background jobs are complete but the `pgcluster` does not return `state: pgcluster Initialized`, then contact IBM Support for assistance.

3. Run the pre-upgrade health check:
   Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.
   a. Verify that the `apicops` utility is installed and that you have the latest version by running the following command:

   ```
   apicops --version
   ```

   For more information about the **apicops** utility, see The API Connect operations tool: apicops.

   b. Run the following command to set the KUBECONFIG environment variable.

   ```
   export KUBECONFIG=</path/to/kubeconfig>
   ```

   c. Run the **apicops pre-upgrade** check:
      i. If using the top-level CR, the check can be run against all subsystems with a single command:

      ```
      apicops system:pre-upgrade-check apiccluster -n <namespace> [--iscp4i]
      ```

      Note: Before upgrading, run the following command to check for encryption issues and invalid gateway extensions:
      For a full check (requires admin password to verify topology)

      ```
      apicops preupgrade -n <namespace>
      ```

      To skip topology verification (no admin password needed)

      ```
      apicops preupgrade --no-topology -n <namespace>
      ```

      ii. If using individual subsystem CRs:

      Run the check separately for each subsystem:

      - Management subsystem:

        ```
        apicops system:pre-upgrade-check management -n <namespace> [--iscp4i]
        ```

        Note: Before upgrading, run the following command to check for encryption issues and invalid gateway extensions:
        For a full check (requires admin password to verify topology)

        ```
        apicops preupgrade -n <namespace>
        ```

        To skip topology verification (no admin password needed)

        ```
        apicops preupgrade --no-topology -n <namespace>
        ```

      - Portal subsystem:

        ```
        apicops system:pre-upgrade-check portal -n <namespace> [--iscp4i]
        ```

      - Analytics subsystem:

        ```
        apicops system:pre-upgrade-check analytics -n <namespace> [--iscp4i]
        ```

   If your API Connect installation is part of Cloud Pak for Integration, then include the argument `--iscp4i` when you run the command.

   If your API Connect deployment is working correctly, the output shows no error messages.

   If the pre-upgrade check returns any errors, then collect the output and open a support case.

   Note: Cloud Pak for Integration: If you are upgrading API Connect in Cloud Pak for Integration and the pre-upgrade check indicates duplicate user accounts in the registry, resolve them now as explained in Resolving duplicate users before upgrade on Cloud Pak for Integration.

Additional pre-upgrade operations

Extra operations to review and complete before you start the upgrade.

1. If analytics database backups are configured, or you want to enable them in future, then ensure that you have an extra Physical Volume available for the local backup storage. The default size is 150Gi. You can override the size during the upgrade procedure.
2. If you used any microservice image overrides in any of your API Connect subsystem CRs, remove the image overrides before upgrade.
3. If you are upgrading an air-gapped (disconnected from the internet) installation, configure the catalog sources for the target API Connect version on your bastion host or portable storage device:
   - Pre-upgrade preparation for air-gapped environment using a bastion host.
   - Pre-upgrade preparation for air-gapped environment using a portable storage device.
4. If your Developer Portal includes custom themes or modules, the upgrade might fail. API Connect does not support any upgrade issues caused by custom themes or modules as these issues are outside the scope of IBM technical support. To avoid any upgrade issues, review the following considerations before upgrading your API Connect deployment:
   - Test the upgrade in a staging environment. Use the same set of custom modules and themes, and upgrade between the same versions planned for the production deployment to validate compatibility and functionality.
   - Remove problematic custom modules or themes. You can re-apply the custom themes or modules after the upgrade, if needed.
   - Take a portal backup.
   - If there are any issues related custom modules or themes, contact the developer who added the modules and themes to the Developer Portal.

Backup your API Connect deployment

If upgrade fails, rollback is not possible. Before upgrade complete the disaster recovery preparation for all your subsystems.

For instructions on backing up and disaster recovery preparation, see the following topics:

- V10.0.8: Backing up, restoring, and disaster recovery.
- v10.0.7.0: Backing up, restoring, and disaster recovery
- v10.0.5.4 or later: Backups on OpenShift and Cloud Pak for Integration, Disaster recovery on OpenShift and Cloud Pak for Integration.

- **Resolving duplicate users before upgrade on Cloud Pak for Integration**
  If you are upgrading API Connect in Cloud Pak for Integration and the API Connect pre-upgrade check indicates duplicate user accounts in the registry, resolve them before you proceed with the upgrade.
- **Pre-upgrade preparation for air-gapped environment using a bastion host**
  In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your bastion host.
- **Pre-upgrade preparation for air-gapped environment using a portable storage device**
  In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your portable storage device.

Resolving duplicate users before upgrade on Cloud Pak for Integration

If you are upgrading API Connect in Cloud Pak for Integration and the API Connect pre-upgrade check indicates duplicate user accounts in the registry, resolve them before you proceed with the upgrade.

Before you begin

This task applies only when you are upgrading API Connect in Cloud Pak for Integration from 2023.2 (or earlier) to 16.1 (or later). Be sure to run the pre-upgrade check as explained in Pre-upgrade preparation and checks on OpenShift to determine whether duplicate user records exist in your deployment.

About this task

Cloud Pak for Integration uses Keycloak as an OIDC provider to authenticate users instead of IAM (Identity and Access Management). Due to differences in how Keycloak and IAM treat usernames, you might need to manually delete duplicate user accounts to ensure that users can log in after the upgrade. Review the following scenarios to determine whether you need to manually delete any user accounts.

In a user registry, each user is uniquely identified by their username. If a registry allows for case-sensitive usernames, then two user records with matching usernames that use different cases (for example, **Alice** and **ALICE**) can exist and they point to two different users. If the registry is case-insensitive, then **Alice** and **ALICE** point to the same user.

If the user registry that is backing IAM supports case-sensitive usernames, then IAM uses the case of the username from that registry. For example, if IAM is backed by an LDAP directory that contains **ALICE** as the username, then IAM also uses **ALICE** as the username.

Keycloak supports only lowercase letters for usernames, so **ALICE** from the LDAP directory is stored with the **preferred_name** **alice** in Keycloak.

Assuming **ALICE** is the username in the LDAP directory and was used by IAM before the API Connect upgrade, then API Connect might contain either **alice** or **ALICE** in its database after the upgrade, depending on how that user logged in to API Connect after the upgrade:

- If the user logged in using the Automation UI in Cloud Pak for Integration, then API Connect created a lowercase username (**alice**).
- If the user logged in using the API Connect toolkit, or an invitation from API Connect, then API Connect created a username that matches the case that was used in the underlying registry (**ALICE**).

It is possible that two user records now exist for the same user because one might be in lowercase letters and the other might be in uppercase or mixed-case letters. To determine whether duplicate user records exist and then resolve them, complete the following steps.

Procedure

1. Review the results of the pre-upgrade check to determine whether your deployment includes duplicate users.
   If duplicate user records are detected, the script returns a response similar to the following example (note the duplicated **username** setting):

```
** Checking for duplicate users in the common-services user registry **
Command: apicops-v10 duplicate-users
****************************
getDuplicateUsers::getDuplicateUsers Entering
Found duplicate user entries: [
    {
        "username": "alice",
        "id": "291339db-acd9-493d-98c2-cfd47185588e",

    }
]
================================================
 WARNING:
================================================
 Duplicate user records have been detected in the common-services user registry.
 Duplicate records will NOT be fixed by the system and might cause unexpected behavior.
 Please refer to product documentation on steps to clean up the duplicate entries.
================================================
*****************************

************************************************
** Finished: apicops-v10 version:pre-upgrade **
************************************************
```

In this example, duplicate records were detected, with the username "alice" and "ALICE".

If your results do not indicate any duplicate users, skip the rest of this task. If the results indicate any duplicates, continue with the remaining steps to resolve the user records.

2. Decide which user account you want to preserve; the other account is considered to be the duplicate.
   You can retain either account. The choice is a matter of convenience. For example, if one of the accounts functions as the owner of organizations, you might find it simpler to retain that account to avoid having to transfer ownership to the other account. You do not have to rename the account because you delete the duplicate account; the username of the preserved account is converted to lowercase during the upgrade. For example, if you choose to preserve user "ALICE" and you delete the record for "alice" then the **username** for "ALICE" will be converted to "alice" the first time the user logs in after the upgrade.

3. If needed, transfer ownership of assets to the account that you want to preserve:
   a. Transfer ownership of catalogs.
      For instructions, see Transfer Catalog Owner on GitHub.

   b. Transfer ownership of spaces within catalogs.
      For instructions, see Transfer Space Owner on GitHub.

   c. Transfer ownership of a provider organization.
      For instructions, see Transfer Org Owner on GitHub.

4. Add any missing roles to the account that you want to preserve.
   Check the roles that are assigned to the duplicate account. If the account that you want to preserve does not include those roles, assign them now. For instructions, see Assigning roles to members in this documentation.

5. Delete the duplicate user account.
   For instructions, see Removing a user from a user registry in this documentation.

Pre-upgrade preparation for air-gapped environment using a bastion host

In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your bastion host.

Before you begin

- Review and complete all steps that are documented in Planning your API Connect upgrade on OpenShift and Pre-upgrade preparation and checks on OpenShift.
- The upgrade procedure requires you to use Red Hat Skopeo for moving container images. Skopeo is not available for Microsoft Windows, so you cannot perform this task with a Windows host.

Attention: Some steps in this task use tilde character: ~. Do not use this character within double quotation marks in any command because the tilde doesn't expand and the command might fail.

About this task

If you previously deployed or upgraded API Connect in an air-gapped environment, you can use the same bastion host as before.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.

      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the bastion host:

You must be able to connect your bastion host to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry) at the same time. Your host must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

i. Ensure that the sites and ports listed in Table 1 can be reached from the bastion host:

Table 1. Sites that must be reached from the bastion host

Site	Description
`icr.io:443`	IBM entitled registry
`quay.io:443`	Local API Connect image repository
`github.com`	CASE files and tools
`redhat.com`	Red Hat OpenShift Container Platform (OCP) upgrades

ii. On the bastion host, install either Docker or Podman (not both).
Docker and Podman are used for managing containers; you only need to install one of these applications.

- To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

```
yum check-update
yum install docker
```

- To install Podman, see the Podman installation instructions.
For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

```
yum install podman
```

iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

c. Set up a local image registry and credentials.
The local Docker registry stores the mirrored images in your network-restricted environment.

i. Install a registry, or get access to an existing registry.
You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:

- Supports multi-architecture images through Docker Manifest V2, Schema 2
For details, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes
- Allows path separators in the image name

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:

- Supports auto-repository creation
- Has sufficient storage to hold all of the software that is to be transferred
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

When you modify the `ImageSetConfiguration`, include `openshift-cert-manager-operator` at channel `stable-v1` as one of the packages, as shown in the following example:

```
  packages:
  - name: openshift-cert-manager-operator
    channels:
    - name: stable-v1
```

3. Set environment variables and download the CASE files.
Create environment variables to use while mirroring images, connect to the internet, and download the CASE files needed for installing API Connect.

a. Create the following environment variables with the installer image name and the image inventory on your host:

- API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64
```

For information about API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.18+
export CS_ARCH=amd64
```

For information about IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

- EDB:

```
export EDB_CASE_NAME=ibm-cloud-native-postgresql
export EDB_CASE_VERSION=1.25.1
```

b. Connect your host to the internet (it does not need to be connected to the network-restricted environment yet).
c. Download the CASE files to your host:
- API Connect:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

- Foundational services:

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

- EDB:

```
oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
```

4. Generate mirror manifests.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before you install API Connect.

a. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace **<target-registry>** with the IP address (or hostname) and port of the local registry; for example: **172.16.0.10:5000**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **172.16.0.10:5000/registry_ns**.
b. Generate mirror manifests by running the following commands:
- API Connect:

```
oc ibm-pak generate mirror-manifests $CASE_NAME --version $CASE_VERSION $TARGET_REGISTRY
```

- Foundational services:

```
oc ibm-pak generate mirror-manifests $CS_CASE_NAME --version $CS_CASE_VERSION $TARGET_REGISTRY
```

- EDB:

```
oc ibm-pak generate mirror-manifests $EDB_CASE_NAME --version $EDB_CASE_VERSION $TARGET_REGISTRY
```

If you need to filter for a specific image group, add the parameter **--filter <image_group>** to the command.

The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:
- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping.txt

The files are used when mirroring the images to the **TARGET_REGISTRY**.

5. Authenticate with the entitled registry where the images are hosted.
a. Obtain an entitlement key for the registry where the images are hosted:
i. Log in to the IBM Container Library.
ii. In the Container software library, select Get entitlement key.
iii. In the "Access your container software" section, click Copy key.
iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.
b. Login to **cp.icr.io** registry:
The image pull secret is used to authenticate with the registry and access product images.

i. Run the following command to export the path to the file that stores the authentication credentials that are generated on a Podman or Docker login:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

The authentication file is typically located in $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

```
podman login cp.icr.io
```

Use **cp** as the username and your entitlement key as the password.

6. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: **--tls-verify=false**.

7. Mirror the product images.
a. Connect the bastion host to both the internet and the restricted-network environment that contains the local registry.
b. Run the following commands to copy the images to the local registry:
- API Connect:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

- Foundational services:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

- EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

Note: If the local registry does not use TLS, or your device does not trust the certificate that the local registry presents, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

8. Configure the target cluster.
Now that images are mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

   a. Log in to your Red Hat OpenShift Container Platform cluster:

   ```
   oc login <openshift_url> -u <username> -p <password> -n <namespace>
   ```

   b. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
   Updating the image pull secret provides the cluster with the credentials that are needed for pulling images from your local registry.

   Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

   ```
   oc edit image.config.openshift.io/cluster -o yaml
   ```

   and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

   ```
   spec:
     registrySources:
       insecureRegistries:
       - insecure0.svc:5001
       - <TARGET_REGISTRY>
   ```

   If the `insecureRegistries` field does not exist, you can add it.

   c. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:

   - API Connect:

   ```
   oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
   ```

   - Foundational services:

   ```
   oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
   ```

   - EDB:

   ```
   oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
   ```

   d. Verify that each ImageContentSourcePolicy resource was created:

   ```
   oc get imageContentSourcePolicy
   ```

   e. Verify your cluster node status:

   ```
   oc get MachineConfigPool -w
   ```

   Wait for all nodes to be updated before you proceed to the next step.

9. Apply the catalog sources.
Now that the images are mirrored to the target cluster, apply the catalog sources for API Connect and Foundational services. You do not need to apply the catalog source for EDB because the API Connect operator applies that catalog source in its own namespace when the API Connect operand is created.

   In the following steps, replace `<Architecture>` with either `amd64`, `s390x` or `ppc64le` according to your environment.

   a. Export the variables for the command line to use:

   ```
   export CASE_NAME=ibm-apiconnect
   export CASE_VERSION=6.2.0
   export ARCH=amd64

   export CS_CASE_NAME=ibm-cp-common-services
   export CS_CASE_VERSION=4.6.18+
   export CS_ARCH=amd64
   ```

   b. Generate the catalog source and save it in another directory in case you need to replicate this installation in the future.

Get the catalog source:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

```
cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.
   i. Apply the universal catalog sources:

   ```
   oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
   ```

   ```
   oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
   ```

   ii. Confirm that the catalog source was created in the `openshift-marketplace` namespace:

   ```
   oc get catalogsource -n openshift-marketplace
   ```

What to do next

Upgrade your API Connect deployment, following the procedure documented in Upgrading API Connect on OpenShift.

Pre-upgrade preparation for air-gapped environment using a portable storage device

In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your portable storage device.

Before you begin

- Review and complete all steps that are documented in Planning your API Connect upgrade on OpenShift and Pre-upgrade preparation and checks on OpenShift.
- The upgrade procedure requires you to use Red Hat Skopeo for moving container images. Skopeo is not available for Microsoft Windows, so you cannot perform this task with a Windows host.

Attention: Some steps in this task use tilde character: ~. Do not use this character within double quotation marks in any command because the tilde doesn't expand and the command might fail.

About this task

If you previously deployed or upgraded API Connect in an air-gapped environment, you can use the same portable storage device as before.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For more information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in Operator, CASE, and platform requirements.
      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the portable device:
   You must be able to connect your portable device to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry). The portable device must be on a Linux x86_64 or Mac platform with an operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Check that the portable device has sufficient storage to hold all the software that is to be transferred to the local registry.
      ii. On the portable device, install either Docker or Podman (not both).
      Docker and Podman are used for managing containers; you can install either of these applications.

         - To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

           ```
           yum check-update
           yum install docker
           ```

         - To install Podman, see the Podman installation instructions.
           For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

           ```
           yum install podman
           ```

      iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
      The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

      iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
      The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

      ```
      oc ibm-pak --help
      ```

   c. Set up a local image registry and credentials.
   The local Docker registry stores the mirrored images in your network-restricted environment.

      i. Install a registry, or get access to an existing registry.

You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:

- Supports multi-architecture images through Docker Manifest V2, Schema 2.
  For more information, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes.
- Allows path separators in the image name.

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:

- Supports auto-repository creation.
- Has sufficient storage to hold all the software that is to be transferred.
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials).
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials).

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries at run time, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
   Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

   When you modify the **`ImageSetConfiguration`**, include **`openshift-cert-manager-operator`** at channel **`stable-v1`** as one of the packages, as shown in the following example:

```
packages:
- name: openshift-cert-manager-operator
  channels:
  - name: stable-v1
```

3. Set environment variables and download the CASE files.
   Create environment variables to use while mirroring images, connect to the internet, and download the CASE files needed for installing API Connect.

   a. Create the following environment variables with the installer image name and the image inventory on your portable device:

   - API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64
```

     For information about API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

   - Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.18+
export CS_ARCH=amd64
```

     For information about IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

   - EDB:

```
export EDB_CASE_NAME=ibm-cloud-native-postgresql
export EDB_CASE_VERSION=1.25.1
```

   b. Connect your portable device to the internet (it does not need to be connected to the network-restricted environment yet).
   c. Download the CASE files to your portable device:

   - API Connect:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

   - Foundational services:

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

   - EDB:

```
oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
```

4. Generate mirror manifests.
   The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before you install API Connect.

   a. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

   Replace ***`<target-registry>`*** with the IP address (or hostname) and port of the local registry; for example: **`172.16.0.10:5000`**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **`172.16.0.10:5000/registry_ns`**.
   b. Generate mirror manifests by running the following commands:

   - API Connect:

```
oc ibm-pak generate mirror-manifests $CASE_NAME --version $CASE_VERSION $TARGET_REGISTRY
```

   - Foundational services:

```
oc ibm-pak generate mirror-manifests $CS_CASE_NAME --version $CS_CASE_VERSION $TARGET_REGISTRY
```

   - EDB:

```
oc ibm-pak generate mirror-manifests $EDB_CASE_NAME --version $EDB_CASE_VERSION $TARGET_REGISTRY
```

If you need to filter for a specific image group, add the parameter **--filter** ***<image_group>*** to the command.

The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:

- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping-to-filesystem.txt
- images-mapping-from-filesystem.txt

The files are used when mirroring the images to the **TARGET_REGISTRY**.

5. Authenticate with the entitled registry where the images are hosted.
   a. Obtain an entitlement key for the registry where the images are hosted:
      i. Log in to the IBM Container Library.
      ii. In the Container software library, select Get entitlement key.
      iii. In the "Access your container software" section, click Copy key.
      iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.
   b. Login to **cp.icr.io** registry:
   The image pull secret is used to authenticate with the registry and access product images.

      i. Run the following command to export the path to the file that stores the authentication credentials that are generated on a Podman or Docker login:

      ```
      export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
      ```

      The authentication file is typically located in $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

      ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

      ```
      podman login cp.icr.io
      ```

      Use **cp** as the username and your entitlement key as the password.

6. Mirror the images from the internet to the portable device.
   a. Define the environment variable $IMAGE_PATH by running the following command:

   ```
   export IMAGE_PATH=<image-path>
   ```

   where ***<image-path>*** indicates where the files are stored on the portable device's file system.
   b. Mirror the images to the portable device:
   - API Connect:

   ```
   oc image mirror \
     -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-to-filesystem.txt \
     --filter-by-os '.*' \
     -a $REGISTRY_AUTH_FILE \
     --skip-multiple-scopes \
     --max-per-registry=1 \
     --dir "$IMAGE_PATH"
   ```

   - Foundational services:

   ```
   oc image mirror \
     -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-to-filesystem.txt \
     --filter-by-os '.*' \
     -a $REGISTRY_AUTH_FILE \
     --skip-multiple-scopes \
     --max-per-registry=1 \
     --dir "$IMAGE_PATH"
   ```

   - EDB:

   ```
   oc image mirror \
     -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-to-filesystem.txt \
     --filter-by-os '.*' \
     -a $REGISTRY_AUTH_FILE \
     --skip-multiple-scopes \
     --max-per-registry=1 \
     --dir "$IMAGE_PATH"
   ```

   There might be a slight delay before you see a response to the command.

7. Move the portable device to the restricted-network environment.
   The procedure depends on the type of device that you are using:
   If you are using a portable computer, disconnect the device from the internet and connect it to the restricted-network environment. The same environment variables can be used.

   If you are using portable storage, complete the following steps:

   a. Transfer the following files to a device in the restricted-network environment:
   - The **~/.ibm-pak** directory.
   - The contents of the ***<image-path>*** that you specified in the previous step.

   b. Create the same environment variables as on the original device; for example:
   - API Connect:

   ```
   export CASE_NAME=ibm-apiconnect
   export CASE_VERSION=6.2.0
   export ARCH=amd64
   ```

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

- EDB:

```
export EDB_CASE_NAME=ibm-cp-common-services
export EDB_CASE_VERSION=1.15.10
export EDB_ARCH=amd64
```

- Registry:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

- Image path:

```
export IMAGE_PATH=<image-path>
```

8. Authenticate with the local registry.
   Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

   If the registry is insecure, add the following flag to the command: `--tls-verify=false`.

9. Mirror the product images to the target registry.
   a. Mirror the product images to the target registry.
      i. If you are using a portable computer, connect it to the restricted-network environment that contains the local registry.
      If you are using portable storage, you already transferred files to a device within the restricted-network environment.

      ii. Run the following commands to copy the images to the local registry:
      - API Connect:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

      - Foundational services:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

      - EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

      Note: If the local registry does not use TLS, or your device does not trust the certificate that the local registry presents, add the `--insecure` option to the command.
      There might be a slight delay before you see a response to the command.

10. Configure the target cluster.
    Now that images are mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

    a. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

    b. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
    Updating the image pull secret provides the cluster with the credentials that are needed for pulling images from your local registry.

    Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

    and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

    If the `insecureRegistries` field does not exist, you can add it.
    c. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:
    - API Connect:

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
```

- Foundational services:

```
oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

- EDB:

```
oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
```

d. Verify that each ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

e. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before you proceed to the next step.

11. Apply the catalog sources.
Now that the images are mirrored to the target cluster, apply the catalog sources for API Connect and Foundational services. You do not need to apply the catalog source for EDB because the API Connect operator applies that catalog source in its own namespace when the API Connect operand is created.

In the following steps, replace ***<Architecture>*** with either **amd64**, **s390x** or **ppc64le** according to your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=6.2.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.18+
export CS_ARCH=amd64
```

b. Generate the catalog source and save it in another directory in case you need to replicate this installation in the future.
Get the catalog source:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.
   i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

   ii. Confirm that the catalog source was created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

What to do next

Upgrade your API Connect deployment, following the procedure documented in Upgrading API Connect on OpenShift.

Upgrading API Connect on OpenShift

Upgrade your API Connect installation to a newer version on OpenShift in an online (connected to the internet) environment.

Before you begin

Review and complete all steps that are documented in Planning your API Connect upgrade on OpenShift and Pre-upgrade preparation and checks on OpenShift.

- If any subsystem database backups are running or are scheduled to run within a few hours, do not start the upgrade process.
- Do not perform maintenance tasks such as updating certificates, restoring subsystem databases from backup, or triggering subsystem database backups at any time while you are upgrading API Connect.
- Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema. As a result, customers upgrading from 10.0.10.0 will lose all previous scan history. To preserve critical information, archive or export important scan results before starting the upgrade.

Procedure

1. If you did not run the Pre-upgrade health-checks recently, run them now.
2. If you have a two data center disaster recovery deployment, then upgrade the warm-standby data center first.
See the special steps for 2DCDR upgrades: Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9
3. Update the operators for the API Connect deployment.
API Connect uses three operators; which you update by selecting a newer version for the operator channel. Update the channels in the following sequence:
   a. DataPower: set the channel to v1.15
   b. API Connect: set the channel to v6.2
   c. Foundational services: set the channel to v4.6

Be sure to update the Foundational services operator channel in all namespaces.

Complete the following steps to update a channel:

a. Click Operators > Installed Operators.
b. Select the operator to be upgraded.
c. Select the Subscription tab.
d. In the Update channel list, select the new channel version.

If you previously chose automatic subscriptions, the operator version upgrades automatically when you update the operator channel. If you previously chose manual subscriptions, OpenShift OLM notifies you that an upgrade is available and then you must manually approve the upgrade before proceeding.

Wait for the operators to update, for the pods to restart, and for the instances to display the **Ready** status. Both the API Connect and DataPower channels must be changed before either operator upgrades. The upgrade of both operators begins when the channel is changed for both operators.

Troubleshooting: See Troubleshooting upgrade on OpenShift.

Note: If analytics backups are configured, then after the API Connect operator is upgraded, the analytics CR reports a status of **Blocked** until the analytics subsystem is upgraded to V10.0.8. With top-level CR deployments, the **apiconnectcluster** CR reports **Pending** until the analytics CR is no longer **Blocked**. For more information, see Analytics backup changes.

4. Ensure that the operators and operands are working correctly before proceeding.
5. If you are using the top-level CR (includes Cloud Pak for Integration), then update the top-level **apiconnectcluster** CR:
   The **spec** section of the **apiconnectcluster** looks like the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-production
  name: prod
  namespace: <APIC_namespace>
spec:
  license:
    accept: true
    use: production
    license: L-KYAL-S3RCBM
  profile: n12xc4.m12
  version: 10.0.11.0
  storageClassName: rook-ceph-block
```

   a. Edit the **apiconnectcluster** CR by running the following command:

```
oc -n <APIC_namespace> edit apiconnectcluster
```

   b. Update the **spec.version** property to the version you are upgrading to.
   c. If you are upgrading to a version of API Connect that requires a new license, update the **spec.license** property accordingly.
   For the list of licenses, see API Connect licenses.

   d. Attention: This step applies only when upgrading to API Connect version 10.0.10 or later.
   $PLATFORM_CA_SECRET Set to ingress-ca. The $PLATFORM_CA_SECRET contains the CA certificate for the platform ingress endpoint of the management subsystem. The analytics makes calls to the platform REST API and this property must be set so that the analytics can verify the server certificate.

```
mgmtPlatformEndpointCASecret:
               secretName: $PLATFORM_CA_SECRET
```

   Note: The value of **secretName** must match the name of the **Kubernetes Secret** containing the CA certificate for the platform ingress endpoint.
   Optional: In-cluster subsystem communication (mgmtPlatformEndpointSvcCASecret)

   If you plan to enable In-cluster intersubsystem communication (internal Kubernetes service-based communication instead of ingress) you can optionally configure the **mgmtPlatformEndpointSvcCASecret** field.

```
mgmtPlatformEndpointSvcCASecret:
        secretName: management-ca  # Usually 'management-ca
```

   The **management-ca** secret contains the certificate authority (CA) certificate that the internal Kubernetes service uses to sign its TLS certificates. This secret is typically generated automatically during the management subsystem installation. Copy the **management-ca** secret to the Analytics namespace.

   e. Optional: Set local analytics backups PVC size.
   By default the new PVC that is created for the analytics subsystem's local database backups is set to 150Gi. If you want to specify a larger size, then add the following to the CR **spec.analytics** section:

```
  storage:
    backup:
      volumeClaimTemplate:
        storageClass: <storage class>
        volumeSize: <size>
```

   where:
   - *<storage class>* is the same as used by your other analytics PVCs.
   - *<size>* is the size. For example: **500Gi**. See Estimating storage requirements.

   f. Optional: If you had preserved the Cloud Pak CPD endpoints during a previous upgrade from 10.0.5.x to 10.0.8.0, and now want to add a custom certificate for the Cloud Pak route, complete the following steps:
      i. Create a Cloud Pak certificate that is signed by a Cloud Pak CA, as in the following example:

```
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
 name: custom-cpd-ca
 namespace: apic
spec:
 selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: custom-cpd
  namespace: apic
spec:
  commonName: small-mgmt-cpd
  dnsNames:
  - cpd-apic.apps.admin-apickeycloak.cp.fyre.ibm.com
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: custom-cpd-ca
  privateKey:
    algorithm: RSA
    rotationPolicy: Always
    size: 2048
  renewBefore: 720h0m0s
  secretName: custom-cpd
  usages:
  - key encipherment
  - digital signature
  - server auth
```

ii. In the CR, provide the secret name within the **cloudPakEndpoint** property of the new **deprecatedCloudPakRoute** object; for example:

```
spec:
  deprecatedCloudPakRoute:
    enabled: true
    cloudPakEndpoint:
      hosts:
      - name: cpd-apic.apps.admin-<domain>.com
        secretName: custom-cpd
```

g. In the **spec.gateway** section, delete any **template** or **dataPowerOverride** override sections.
If the CR contains an override, then you cannot complete the upgrade.

h. If you have a two data center disaster recovery installation, and are upgrading the warm-standby, then add the annotation:

```
apiconnect-operator/dr-warm-standby-upgrade-data-deletion-confirmation: "true"
```

For more information about two data center disaster recovery upgrade, see Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9.

i. Save and close the CR to apply your changes.
The response looks like the following example:

```
apiconnectcluster.apiconnect.ibm.com/prod configured
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

j. Run the following command to verify that the upgrade is completed and the status of the top-level CR is **READY**:

```
oc get apiconnectcluster -n <APIC_namespace>
```

Important: If you need to restart the deployment, wait until all portal sites complete the upgrade.
After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the **MESSAGE** column in the **oc get ptl** output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the **oc get ptl** output shows how many sites the portal is serving:

```
NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
```

On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

Troubleshooting: If the upgrade appears to be stuck, showing the status of **Pending** for a long time, then check the management CR status for errors:

```
oc -n <namespace> get mgmt -o yaml
```

Refer to Troubleshooting upgrade on OpenShift, for known issues.

6. If you are using individual subsystem CRs: Start with the management subsystem, and update the management CR as follows:
   a. Edit the **ManagementCluster** CR:

```
oc edit ManagementCluster -n <mgmt_namespace>
```

   b. Update the **spec.version** property to the version you are upgrading to.
   c. If you are upgrading to a version of API Connect that requires a new license, update the **spec.license** property accordingly.
   For the list of licenses, see API Connect licenses.

   d. If you have a two data center disaster recovery installation, and are upgrading the warm-standby, then add the annotation:

```
apiconnect-operator/dr-warm-standby-upgrade-data-deletion-confirmation: "true"
```

For more information about two data center disaster recovery upgrade, see Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9.

e. Save and close the CR to apply your changes.
The response looks like the following example:

```
managementcluster.management.apiconnect.ibm.com/management edited
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

f. Wait until the management subsystem upgrade is complete before you proceed to the next subsystem. Check the status of the upgrade with: `oc get ManagementCluster -n <mgmt_namespace>`, and wait until all pods are running at the new version. For example:

```
oc -n <mgmt_namespace> get ManagementCluster
NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
management    18/18   Running   10.0.11.0   10.0.11.0-1281        97m
```

Troubleshooting: If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the management CR status for errors:

```
oc -n <namespace> get mgmt -o yaml
```

Refer to Troubleshooting upgrade on OpenShift, for known issues.

g. Repeat the process for the remaining subsystem CRs in your preferred order: `GatewayCluster`, `PortalCluster`, `AnalyticsCluster`.
Important: In the `GatewayCluster` CR, delete any `template` or `dataPowerOverride` override sections. If the CR contains an override, then you cannot complete the upgrade.
Note:
Upgrades to V10.0.8.0: By default the new PVC that is created for the analytics subsystem's local database backups is set to 150Gi. If you want to specify a larger size, then add the following to the CR `spec` section:

```
  storage:
    backup:
      volumeClaimTemplate:
        storageClassName: <storage class>
        volumeSize: <size>
```

where:
- *<storage class>* is the same as used by your other analytics PVCs.
- *<size>* is the size. For example: `500Gi`. See Estimating storage requirements.

Important: If you need to restart the deployment, wait until all portal sites complete the upgrade.
After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the `MESSAGE` column in the `oc get ptl` output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the `oc get ptl` output shows how many sites the portal is serving:

```
NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
```

On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

Troubleshooting: If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the subsystem CR status for errors:

```
oc -n <namespace> get <subsystem cr> -o yaml
```

Refer to Troubleshooting upgrade on OpenShift, for known issues.

7. Upgrade your deployment to the latest version of OpenShift that your current release of API Connect supports.
For more information, see Supported versions of OpenShift.

8. Switch from deprecated deployment profiles.
If you have a top-level CR installation, and were using the `n3xc16.m48` or `n3xc12.m40` deployment profiles, then switch to the new replacement profiles `n3xc16.m64` or `n3xc12.m56`. For information about switching profiles, see Changing deployment profiles on OpenShift top-level CR.

   If you are using individual subsystem CRs, and your analytics subsystem uses the `n3xc4.m16` profile, then update the profile in your analytics CR to `n3xc4.m32`. For information about switching profiles, see Changing deployment profiles on Kubernetes and OpenShift

What to do next

Update your toolkit CLI by downloading it from Fix Central or from the Cloud Manager UI. For more information, see Installing the toolkit.

Troubleshooting upgrade on OpenShift

Review the following troubleshooting tips if you encounter a problem during API Connect upgrade on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Subsystem is stuck in `Pending` state with a reason of `PreUpgradeCheckInProgress`

Before the subsystem microservices are upgraded, the operator triggers a set of pre-upgrade checks that must pass for the upgrade to proceed. If one or more of the checks fail, the subsystem status remains in `Pending` state with a reason of `PreUpgradeCheckInProgress`. Check the status condition of the subsystem CR to confirm the pre-upgrade check failed. The `status.PreUpgradeCheck` property contains a summary of the failed checks. Full logs for the checks that are carried out can be viewed in the `ConfigMap` referenced in the `status.PreUpgradeCheck` property. The pre-upgrade checks automatically retry until they successfully pass. If you are unable to rectify the problem that causes a check to fail, then open an IBM support case.

Incorrect `productVersion` of gateway pods after upgrade

When you upgrade on OpenShift, the rolling update might fail to start on gateway operand pods due to a gateway peering issue, so that the **productVersion** of the gateway pods is incorrect even though the reconciled version on the gateway CR displays correctly. This problem happens when there are multiple primary pods for gateway peering, and some of the peering pods are assigned to each primary. There can be only one primary pod for gateway-peering; the existence of multiple primaries prevents the upgrade from completing.

Verify that you have a gateway-peering issue with multiple primaries, and then resolve the issue by assigning a single primary for all gateway-peering pods. Complete the following steps:

1. Determine whether multiple primary pods are causing the problem:
   a. Run one of the following commands to check the **productVersion** of each gateway pod.

      ```
      oc get pods -n apic_namespace <gateway_pods> -o yaml | yq .metadata.annotations.productVersion
      ```

      or

      ```
      oc get pods -n apic_namespace <gateway_pods> -o custom-columns="productVersion:.metadata.annotations.productVersion"
      ```

      where:
      - ***apic_namespace*** is the namespace where API Connect is installed
      - ***<gateway_pods>*** is a space-delimited list of the names of your gateway peering pods

   b. Verify that the target version of API Connect supports the **productVersion**.
      For information about supported versions of DataPower Gateway, see
      tapic_upgrade_OpenShift_consider.html#tapic_upgrade_OpenShift_consider__gwy_versions.

   c. If any pod returns an incorrect value for the **productVersion**, check the DataPower operator logs for peering issues; look for messages similar to the following example:

      ```
      "level":"error","ts":"2023-10-20T16:31:47.824751077Z","logger":"controllers.DataPowerRollout","msg":"Unable to check

      ```

   If you confirmed that gateway-peering (multiple primaries) is the issue, complete the following steps to resolve the issue.

2. Attach to a gateway pod:
   a. Run the following command to get a list of gateway pods:

      ```
      oc get pods -l app.kubernetes.io/managed-by=datapower-operator
      ```

      The response looks like the following example:

      ```
      NAME                                                  READY   STATUS    RESTARTS   AGE
      datapower-operator-conversion-webhook-585d95cf87-mktrv   1/1     Running   0          2d22h
      datapower-operator-f4d8fbd85-5xt47                    1/1     Running   0          2d22h
      production-gw-0                                       1/1     Running   0          2d22h
      production-gw-1                                       1/1     Running   0          2d22h
      production-gw-2                                       1/1     Running   0          2d22h
      ```

   b. Select a pod from the list and run the following command to attach to it using the NAME:

      ```
      oc -n ns attach -it <pod_NAME> -c datapower
      ```

3. Select the new primary:
   a. Run the following commands to switch to the API Connect configuration:

```
config; switch apiconnect
```

b. Run the following command to show the current peering status:

```
show gateway-peering-status
```

Example response:

```
Address      Name              Pending Offset     Link Primary Service port Monitor port Priority
------------ ----------------- ------- ---------- ---- ------- ------------ ------------ --------
10.254.12.45 api-probe         0       19114431   ok   no      16382        26382        2

10.254.36.32 api-probe         0       19114739   ok   yes     16382        26382        3
10.254.36.32 gwd               0       1589848370 ok   no      16380        26380        3
10.254.36.32 rate-limit        0       19148496   ok   no      16383        26383        3
10.254.36.32 ratelimit-module  0       19117538   ok   no      16386        26386        3
10.254.36.32 subs              0       26840742   ok   no      16384        26384        3
10.254.36.32 tms               0       19115634   ok   no      16381        26381        3
10.254.36.32 tms-external      0       19116159   ok   no      16385        26385        3
```

c. Take note of the IP address that has the most primary **yes** options; this IP address will be the new primary for all **functions** involved in gateway peering. In this example, **10.254.28.61** is the primary for the largest number of **functions**; however **api-probe** is not primary on this pod. In the following steps, set **api-probe** as primary on this pod.

4. For every function that needs the primary changed, attach to the primary pod and set the function to primary:
   a. Log out of the current pod by pressing Ctrl+P, and then pressing Ctrl+Q.
   b. Run the following command to attach to a pod that needs its primary updated:

```
oc -n ns attach -it <IP_of_pod> -c datapower
```

   c. Run the following command to switch to the API Connect configuration:

```
config; switch apiconnect
```

   d. Run the following command to show the current peering status:

```
show gateway-peering-status
```

   Verify that the function is set to the wrong primary IP and requires updating (in the example, **api-probe** requires updating).

   e. Run the following command to change the primary for the function:

```
gateway-peering-switch-primary <function>
```

   For example:

```
gateway-peering-switch-primary api-probe
```

   f. Repeat this process for every function that needs its primary updated.
5. Verify that all functions are now primary on the same IP address by running the following command:

```
show gateway-peering-status
```

6. Log out of the gateway pod (Ctrl+P, then Ctrl+Q).

Upgrade fails with an error message about a missing cert-manager

Beginning in API Connect V10.0.7.0, it is recommended to use the cert-manager operator for Red Hat OpenShift. If you did not install Red Hat OpenShift cert-manager operator during the upgrade, the upgrade fails with the following error message from the **ibm-apiconnect** pod:

```
cert-manager is required but not installed. Please install a cert-manager operator such as [cert-manager Operator for Red Hat OpenShift]. APIC instance being upgraded
```

Resolve the issue by completing the following steps:

1. Install the cert-manager operator for Red Hat OpenShift:
   a. Log in to the OpenShift Container Platform web console.

   b. Click Operators > OperatorHub.

   c. In the filter box, type: **cert-manager Operator for Red Hat OpenShift**.

   d. Select cert-manager Operator for Red Hat OpenShift and click Install.

   e. On the Install Operator page, complete the following steps:
      i. Update the Update channel if needed. The channel defaults to **stable-v1**, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

ii. Select the Installed Namespace for the operator.
The default operator namespace is `cert-manager-operator`; if that namespace doesn't exist, it is created for you.

iii. Select an Update approval strategy:
- Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
- Manual: require a user with the appropriate credentials to approve all operator updates.

iv. Click Install.

2. Verify the new cert-manager installation by completing the following steps:
   a. Click Operators > Installed Operators.

   b. Verify that `cert-manager Operator for Red Hat OpenShift` is listed with a Status of `Succeeded` in the `cert-manager-operator` namespace.

   c. Verify that cert-manager pods are up and running with the following command:

   ```
   oc get pods -n cert-manager
   ```

   For a successful installation, the response looks like the following example:

   ```
   NAME                                       READY   STATUS    RESTARTS   AGE
   cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
   cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
   cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
   ```

3. Remove the obsolete IBM cert-manager operator by running the following command:

   ```
   oc delete certmanagers.operator.ibm.com default
   ```

DataPower operator pod stuck waiting for lock removal

If you see messages in the `datapower-operator` pod log that indicate that the pod is waiting for a lock to be removed:

```
{"level":"info","ts":"2021-03-08T19:29:53.432Z","logger":"leader","msg":"Not the leader. Waiting."}
{"level":"info","ts":"2021-03-08T19:29:57.971Z","logger":"leader","msg":"Leader pod has been deleted, waiting for garbage collection to remove the lock."}
```

The DataPower operator cannot be upgraded until this problem is resolved, see: DataPower operator documentation.

You see the `denied: insufficient scope` error during an air-gapped deployment

Problem: You encounter the `denied: insufficient scope` message while mirroring images during an air-gapped installation or upgrade.

Reason: This error occurs when a problem is encountered with the entitlement key that is used for obtaining images.

Solution: Obtain a new entitlement key by completing the following steps:

1. Log in to the IBM Container Library.
2. In the Container software library, select Get entitlement key.
3. After the Access your container software heading, click Copy key.
4. Copy the key to a safe location.

Apiconnect operator pod fails

Problem: During installation (or upgrade), the `apiconnect` operator fails with the following message:

```
panic: unable to build API support: unable to get Group and Resources: unable to retrieve the complete list of server APIs:
packages.operators.coreos.com/v1: the server is currently unable to handle the request

goroutine 1 [running]:
github.ibm.com/velox/apiconnect-operator/operator-utils/v2/apiversions.GetAPISupport(0x0)
        operator-utils/v2/apiversions/api-versions.go:89 +0x1e5
main.main()
        ibm-apiconnect/cmd/manager/main.go:188 +0x4ee
```

Additional symptoms:

- Apiconnect operator is in crash loopback status
- Kube `apiserver` pods log the following information:

  ```
  E1122 18:02:07.853093 18 available_controller.go:437] v1.packages.operators.coreos.com failed with:
   failing or missing response from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1:
   bad status from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1: 401
  ```

- The IP logged here belongs to the *package server* pod present in the `openshift-operator-lifecycle-manager` namespace
- Package server pods log the following error message: `/apis/packages.operators.coreos.com/v1 API call is being rejected with 401 issue`.

  ```
  E1122 18:10:25.614179 1 authentication.go:53] Unable to authenticate the request due to an error: x509:
  certificate signed by unknown authority I1122 18:10:25.614224 1 httplog.go:90]
  verb="GET" URI="/apis/packages.operators.coreos.com/v1" latency=161.243µs resp=401
  UserAgent="Go-http-client/2.0" srcIP="10.128.0.1:41370":
  ```

- The problem is intermittent

Solution:

- If you find the exact symptoms as described, the solution is to delete package server pods in the `openshift-operator-lifecycle-manager` namespace.
- New package server pods log the `200 Success` message for the same API call.

Unexpected behavior in Cloud Manager and API Manager UIs after upgrade

Stale browser cache issues can cause problems after an upgrade. To remedy this problem, clear your browser cache, and open a new browser window.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.9

How to upgrade a two data center disaster recovery deployment to V10.0.10 from V10.0.8 and V10.0.9 on Kubernetes and OpenShift.

To upgrade API Connect in a 2DCDR deployment, use the upgrade instructions for your platform, but with the extra considerations and steps documented in this topic.

- Upgrading on Kubernetes.
- Upgrading on OpenShift and Cloud Pak for Integration.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Before you begin

- Verify that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Check that you have recent backups of management and portal subsystems: Backup and restore requirements for a 2DCDR deployment.
- If you have a top-level CR deployment, and your portal and management warm-standby subsystems are not in the same data center, then complete an operational failover of either the management or portal subsystems so that they are both warm-standby in the same data center. See Failing over to the warm-standby.

Important:
Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema.

- Customers upgrading from 10.0.10.0 will lose all previous scan history.
- To preserve critical information, archive or export important scan results before starting the upgrade.

Key points applicable to both management and portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.
- Both data centers must be upgraded in the same maintenance window.
- Upgrade steps might result in an update to the `ingress-ca` X.509 certificate. Extra steps must be taken at various points in the upgrade process to ensure that the `ingress-ca` secret in both data centers contains the same `ingress-ca` X.509 certificate.

Note: If you are not using cert-manager and you customized your certificates, the `ingress-ca` certificate might have a different name. Ensure that the CA certificate that is used by both data centers is the same during all stages of the upgrade.

Upgrading to V10.0.10: Steps for management upgrades

1. Upgrade the warm-standby data center first.
   Follow the upgrade steps for your platform:
   - Upgrading API Connect on Kubernetes.
   - Upgrading API Connect on OpenShift.
   When the warm-standby upgrade is complete, the warm-standby management CR reports an HA status error:

   ```
   kubectl get mgmt -A
   ```

   returns:

   ```
   NAMESPACE   NAME   READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
   AGE
   ns1         m2     2/19    Blocked   10.0.10.0   10.0.9.0-6227        HA status Error - see HAStatus in CR for details
   83m
   ```

   Confirm the blocked status with the following command:

   ```
   kubectl get mgmt <management CR name> -o json| jq -r '.status.conditions[] | select(.status=="True")
   ```

   returns:

   ```
   {
     "lastTransitionTime": "2024-05-21T16:05:34Z",
     "message": "HA status Error - see HAStatus in CR for details",
     "reason": "na",
     "status": "True",
     "type": "Blocked"
   }
   ```

   Check the HA status with the following command:

   ```
   kubectl get mgmt <management CR name> -o json | jq -r '.status.haStatus[] | select(.status=="True")'
   ```

   returns:

   ```
   {
     "lastTransitionTime": "2024-05-21T16:05:34Z",
   ```

```
  "message": "Remote HAMode is Empty (Not received from peer). Expected it to be in either active or setup complete
phase",
  "reason": "na",
  "status": "True",
  "type": "Error"
}
```

Do not proceed until the warm-standby reports this status.

2. Verify that both data centers have the same **ingress-ca** X.509 certificate in their **ingress-ca** secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" |
   awk '{print $2}' | base64 -d)
   ```

   if you do not have the **openssl** command available, you can instead run only the **kubectl** part, which produces a larger output:

   ```
   kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.
3. Upgrade the active data center, following the steps for your platform:
   - Upgrading API Connect on Kubernetes.
   - Upgrading API Connect on OpenShift.

Steps for portal upgrade

1. Verify that both data centers have the same **ingress-ca** X.509 certificate in their **ingress-ca** secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" |
   awk '{print $2}' | base64 -d)
   ```

   if you do not have the **openssl** command available, you can instead run only the **kubectl** part, which produces a larger output:

   ```
   kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.
2. Start the upgrade of your warm-standby data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
3. Verify that both data centers still have the same **ingress-ca** X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing the ingress-ca X.509 certificate across data centers.
4. Complete the upgrade of your warm-standby data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform. Do not wait for the warm-standby to reach READY state before starting the upgrade on the active data center (in certain circumstances the warm-standby portal does not reach READY state until the active data center is upgraded).
5. Start the upgrade of your active data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
6. Verify that both data centers still have the same **ingress-ca** X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing the ingress-ca X.509 certificate across data centers.
7. Upgrade the portal subsystem in your active data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform.

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center by following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the **multiSiteHA** section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that **HA Mode** reports "passive".
3. Remove the **multiSiteHA** section from failed data center, and verify that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following operations:
   - Upgrade API Connect on the failed data center to the same version as the active.
   - Add the **multiSiteHA** sections to both data centers, setting the failed data center to be warm-standby.
     Important: Do not set the failed data center to be active in the **multiSiteHA** section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.9

How to upgrade from an API Connect V10.0.9 two data center disaster recovery (DR) deployment on Cloud Pak for Integration.

To upgrade a Cloud Pak for Integration deployment of API Connect in a 2DCDR deployment, use the Cloud Pak for Integration upgrade instructions Upgrading on OpenShift and Cloud Pak for Integration, but with the extra considerations and steps documented in this topic.

Before you begin

- Verify that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Check that you have recent backups of management and portal subsystems: Backup and restore requirements for a 2DCDR deployment.
- If you have a top-level CR deployment, and your portal and management warm-standby subsystems are not in the same data center, then complete an operational failover of either the management or portal subsystems so that they are both warm-standby in the same data center. See Failing over to the warm-standby.

Important:
Upgrading to v10.0.11.0 removes all existing scan records to align with the updated database schema.

- Customers upgrading from 10.0.10.0 will lose all previous scan history.
- To preserve critical information, archive or export important scan results before starting the upgrade.

Key points applicable to both management and portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.
- Both data centers must be upgraded in the same maintenance window.
- Upgrade steps might result in an update to the **ingress-ca** X.509 certificate. Extra steps must be taken at various points in the upgrade process to ensure that the **ingress-ca** secret in both data centers contains the same **ingress-ca** X.509 certificate.

V10.0.9 to V10.0.10 2DCDR upgrade steps for Cloud Pak for Integration

In Cloud Pak for Integration, the **apiconnectcluster** CR (also known as the top-level CR) manages the management and portal subsystems. When the **apiconnectcluster** CR is updated with the new API Connect version, all the subsystems are updated automatically. Follow the upgrade process for Cloud Pak for Integration, review Upgrading on OpenShift and Cloud Pak for Integration, along with the following steps.

1. Verify that both data centers have the same 2DCDR mode for both management and portal subsystems. For example, in DC1, both management and portal subsystems are active, and in DC2, both are warm-standby. If necessary, complete a failover of one of the subsystems so that management and portal have the same mode in the same data centers: Failing over to the warm-standby.
2. Verify that both data centers have the same **ingress-ca** X.509 certificate in their ***<apic instance-name>*-ingress-ca** secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
   ```

   if you do not have the **openssl** command available, you can instead run only the **oc** part, which produces a larger output:

   ```
   oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.
3. Start the upgrade of your warm-standby data center.
   Follow the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
4. Repeat step 2 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
5. Complete the upgrade of your warm-standby data center, updating the operands as described in the Cloud Pak for Integration documentation.
6. Check the state of your APIConnectCluster CR:
   a. Check the cluster status:

      ```
      oc get apiconnectcluster <apic CR name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
      ```

      returns:

      ```
      {
        "lastTransitionTime": "2024-05-17T21:05:15Z",
        "message": "APIC instance being upgraded. Not all services are ready, pending services: management",
        "reason": "Upgrading",
        "status": "True",
        "type": "Pending"
      }
      ```

   b. Check the management subsystem status:

      ```
      oc get mgmt <mgmt CR name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
      ```

      returns:

      ```
      {
        "lastTransitionTime": "2024-05-21T16:05:34Z",
        "message": "HA status Error - see HAStatus in CR for details",
        "reason": "na",
        "status": "True",
        "type": "Blocked"
      }
      ```

   c. Check the management subsystem 2DCDR status:

      ```
      oc get mgmt <mgmt CR name> -o json | jq -r '.status.haStatus[] | select(.status=="True")'
      ```

      returns:

```
{
  "lastTransitionTime": "2024-05-21T16:05:34Z",
  "message": "Remote HAMode is Empty (Not received from peer). Expected it to be in either active or setup complete
phase",
  "reason": "na",
  "status": "True",
  "type": "Error"
}
```

7. Repeat step 2 to verify that the `ingress-ca` X.509 certificates are still the same in both data centers.
8. Start the upgrade of your active data center by following the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
9. Repeat step 2 to verify that the `ingress-ca` X.509 certificates are still the same in both data centers.
10. Complete the upgrade of the active data center, updating the operands as described in the Cloud Pak for Integration documentation.
11. If the management CR has successfully reconciled to the new version:

```
NAME               READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE
AGE
production-mgmt    6/6     Running   10.0.10.0-1087   10.0.10.0-1087       Management is ready. HA status Ready - see
HAStatus in CR for details 46h
```

    but the portal CR spec has not been updated to the new version:

```
NAME              READY   STATUS    VERSION         RECONCILED VERSION   MESSAGE                              AGE
production-ptl    7/7     Warning   10.0.8.0        10.0.8.0-300         Full file synchronization running    46h
```

    Then you must manually set the `spec.version` property in the portal CR to the new version to proceed with the upgrade. This issue can occur due to incompatibilities in the file synchronization specification between the old and new portal web (www) pods.
12. 2DCDR installations on Cloud Pak for Integration before V10.0.7 required the creation of a custom endpoint for the management subsystem user-facing certificates. The custom endpoint is not required from V10.0.7 and later, so you can update your management subsystem endpoints.
    In both data centers, edit your top-level CR:

```
oc edit apiconnectcluster
```

    Add the following endpoint sections:
    - `spec.management.cloudManagerEndpoint`
    - `spec.management.apiManagerEndpoint`
    - `spec.management.platformAPIEndpoint`
    - `spec.management.consumerAPIEndpoint`

    For example:

```
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: <APIConnectCluster CR name>-ingress-issuer
    hosts:
    - name: <cloudManagerEndpoint>
      secretName: <secret name>
```

    where:
    - *<APIConnectCluster CR name>* is the name of your APIConnectCluster CR. Run `oc get apiconnectcluster` to see this name.
    - *<cloudManagerEndpoint>* is the new endpoint that you want to use for the Cloud Manager UI.
    - *<secret name>* name for the secret that stores the TLS certificate for the endpoint. Set this value as follows according to the endpoint:
        - `platformAPIEndpoint`: *<APIConnectCluster CR name>*-mgmt-platform-api
        - `consumerAPIEndpoint`: *<APIConnectCluster CR name>*-mgmt-consumer-api
        - `cloudManagerEndpoint`: *<APIConnectCluster CR name>*-mgmt-admin
        - `apiManagerEndpoint`: *<APIConnectCluster CR name>*-mgmt-api-manager

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center by following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the `multiSiteHA` section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that `HA Mode` reports "passive".
3. Remove the `multiSiteHA` section from failed data center, and verify that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following operations:
    - Upgrade API Connect on the failed data center to the same version as the active.
    - Add the `multiSiteHA` sections to both data centers, setting the failed data center to be warm-standby.
      Important: Do not set the failed data center to be active in the `multiSiteHA` section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.

Note: When maintaining API Connect, do not use `kubectl exec` or `oc exec` commands to access API Connect pods unless advised by IBM.

- **Advanced configuration**
  You can optionally install and configure advanced features.
- **Backing up, restoring, and disaster recovery**
  Backup your API Connect subsystems, configure scheduled database backups, and recover from a disaster.
- **Maintaining a two data center deployment**
  How to maintain a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift, including information about normal operation, failure handling, and recovery.
- **Renewing TLS certificates**
  Renew TLS certificates in your API Connect deployment.
- **Monitoring and health checks**
  Monitor your deployment and complete health checks on subsystems.
- **Logging**
  Configure logging for your deployment on Kubernetes.
- **Troubleshooting**
  Troubleshooting problems with your API Connect subsystems.

Advanced configuration

You can optionally install and configure advanced features.

See:

- **Installing License Service**
  License Service helps you assess whether your IBM® API Connect deployment in a Kubernetes environment is compliant with licensing requirements.
- **Installing the Automated API behavior testing application**
  Update the custom resource for installing IBM API Connect to deploy the Automated API behavior testing application on Kubernetes.
- **Installing the toolkit**
- **Customizing user-facing certificates**
  Convert a user-facing certificate that was generated by cert-manager to a custom certificate for an existing IBM API Connect deployment.
- **Changing deployment profiles on Kubernetes and OpenShift**
  You can change an API Connect installation to use different deployment profiles.
- **Changing deployment profiles on OpenShift top-level CR**
  You can change an API Connect top-level CR installation to use different profiles.
- **Changing the deployment profile on Cloud Pak for Integration**
  You can change an API Connect installation to use a different profile.
- **Replica override for microservices**
  Modify the replica count for microservices by using template overrides for Custom Resources.
- **Enabling Developer Portal feature flags on Kubernetes**
  Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- **Enabling Developer Portal feature flags on OpenShift and Cloud Pak for Integration**
  Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- **Enabling UI feature flags on Kubernetes**
  Use a template override to update the installation CR with settings that control UI features.
- **Enabling UI feature flags on OpenShift and Cloud Pak for Integration**
  Use a template override to update the installation CR with settings that control UI features.
- **Advanced configuration for the management subsystem**
  Specify advanced configuration for the management subsystem.
- **Advanced configuration for the analytics subsystem**
  Specify advanced configuration for the analytics subsystem on Kubernetes, OpenShift, or Cloud Pak for Integration.
- **Advanced configuration for the gateway subsystem**
  Specify advanced configuration for the gateway subsystem.
- **Advanced configuration for the portal subsystem**

Installing License Service

License Service helps you assess whether your IBM® API Connect deployment in a Kubernetes environment is compliant with licensing requirements.

About this task

License Service provides useful features for managing virtualized environments and measuring license utilization. License Service discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure, for example the computer groups, software installations, and the content of your software catalog.

By default, every License Service audit report presents data from the previous 90 days. You can customize the type and amount of information that is displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or pdf format, and schedule report emails so that specified recipients are notified when important events occur.

When you install API Connect, the **`license-use`** setting that is configured in the ibm-apiconnect operator CR (custom resource) for a particular subsystem is reflected in the Pod annotations. For the Analytics, Portal, and Management subsystems the **`license-use`** value can be "production" or "nonproduction". For the Gateway subsystem, the **`license-use`** value can be "production", "nonproduction", or "developer". The subsystem pod annotations are scanned by the ibm-licensing-operator, which reports license and CPU usage for each subsystem.

For more information, see License Service in the IBM Cloud Pak foundational services documentation.

Procedure

Install License Service as explained in the installation instructions in License Service in the IBM Cloud Pak foundational services documentation.
The instructions describe the appropriate License Service installation procedure for API Connect deployments, and apply to the Analytics, Portal, Management, and Gateway subsystems.

Installing the Automated API behavior testing application

Update the custom resource for installing IBM® API Connect to deploy the Automated API behavior testing application on Kubernetes.

About this task

You can install the Automated API behavior testing application as part of a new IBM API Connect deployment, or you can add it to an existing deployment. After you install the application, enable the Autotest Assist feature as explained later in this topic.
Note: It is not possible to use the Automated API behavior testing application with a two data center disaster recovery configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

Adding the Automated API behavior testing application to an existing deployment

Before you begin

Make sure that the following requirements are met before attempting to deploy the Automated API behavior testing application:

- The IBM API Connect subsystems are installed.
- The cert-manager is installed for use with IBM API Connect and you are using the default certificates that it generates.
  The Automated API behavior testing application requires that the IBM API Connect deployment use the cert-manager and the default certificates. Custom certificates are not supported and if used, the Automated API behavior testing application will not install correctly.

About this task

Edit the deployed CR (custom resource) for the management subsystem and add the settings for the Automated API behavior testing application.

Procedure

1. Retrieve the name of the deployed management subsystem's deployed CR by running the following command:

   ```
   kubectl get managementcluster -n <management_namespace>
   ```

2. Edit the deployed CR by running the following command:

   ```
   kubectl edit managementcluster <management-cr-name> -n <management_namespace>
   ```

3. Append the new `testAndMonitor` definition at the end of the `spec` section, making sure to adhere to the spacing used in the file.
   Attention: The `testAndMonitor` host must not conflict with any of the management hosts.

   ```
   testAndMonitor:
     enabled: true
     hubEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: hub.$STACK_HOST
         secretName: hub-endpoint
   ```

   `$STACK_HOST` is the ingress subdomain for the API Connect stack, as documented in Installing the management subsystem.

4. Apply the updated CR by running the following command:

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   where *<management_namespace>* is the name of the target installation namespace in the Kubernetes cluster.

   The Automated API behavior testing application will be installed into the existing Management subsystem.

5. Check the `atm-api` and `atm-ui` pods periodically until the "READY" value is "1/1" and the "STATUS" is "Running".
   Verify that the pods are running by executing the following command:

   ```
   kubectl get pods -n <management_namespace>
   ```

6. Verify that the application deployed properly by completing the following steps:
   a. Log in to API Manager.
   b. On the home page, click the Test APIs tile.
   c. Verify that the Automated API behavior testing opens.

Including the Automated API behavior testing application in a new deployment

Before you begin

Make sure that the cert-manager is installed for use with IBM API Connect and you are using the default certificates that it generates. The Automated API behavior testing application requires that the IBM API Connect deployment use the cert-manager and the default certificates. Custom certificates are not supported and if used, the Automated API behavior testing application will not install correctly.

About this task

Edit the CR (custom resource) for the Management subsystem and add the settings for the Automated API behavior testing application.

Procedure

1. Edit the `ManagementCluster` custom resource (CR) and add the following definition for the Automated API behavior testing application.
   Append the new definition at the end of the `spec` section, making sure to adhere to the spacing used in the file.

   ```
   testAndMonitor:
     enabled: true
     hubEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: hub.$STACK_HOST
         secretName: hub-endpoint
   ```

   `$STACK_HOST` is the ingress subdomain for the API Connect stack, as documented in Installing the management subsystem.

   Attention: The `testAndMonitor` host must not conflict with any of the management hosts.
2. Apply the updated CR by running the following command:

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   where *<management_namespace>* is the name of the target installation namespace in the Kubernetes cluster.

   The Automated API behavior testing application will be installed with the management subsystem.
3. Check the `atm-api` and `atm-ui` pods periodically until the "READY" value is "1/1" and the "STATUS" is "Running".
   Verify that the pods are running by executing the following command:

   ```
   kubectl get pods -n <management_namespace>
   ```
4. Verify that the application deployed properly by completing the following steps:
   a. Log in to API Manager.
   b. On the home page, click the Test APIs tile.
   c. Verify that the Automated API behavior testing opens.

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + Designer: provides a command line environment for working with IBM API Connect, including API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Clients tile. The two toolkit options are listed under the Toolkit tab.
     - Click your platform alongside either the CLI option or the CLI + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.

- To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 4.

2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:

   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.

3. Run the CLI.
   - For the macOS or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       ```
       chmod +x download_name
       ```

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - If you are using macOS, remove the quarantine attribute by running the following command:

       ```
       sudo xattr -dr com.apple.quarantine apic-slim
       ```

     - Run CLI commands as follows:

       ```
       ./apic command_name_and_parameters
       ```

       or

       ```
       ./apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see the toolkit CLI reference documentation.
   - For the Windows platform, complete the following steps:
     - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Run CLI commands as follows:

       ```
       apic command_name_and_parameters
       ```

       or

       ```
       apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see the toolkit CLI reference documentation.

   Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

4. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   ```
   apic client-creds:set toolkit_credentials_file_path/credentials.json
   ```

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   ```
   apic client-creds:clear
   ```

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:
   a. Log in to the management server as an administrator; see Logging in to a management server.
   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

5. Install the API Designer credentials.
   If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **APIC_DESIGNER_CREDENTIALS** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **APIC_DESIGNER_CREDENTIALS** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:
     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:
       - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
       - On the Advanced tab of the System Properties dialog box, click Environment Variables.
       - In the "User variables" section, click New and create an environment variables with the following settings:
         - Variable: **APIC_DESIGNER_CREDENTIALS**
         - Value: <*designer_credentials_file_path*>\designer_credentials.json where **<*designer_credentials_file_path*>** is the location where you stored the designer_credentials.json file.
       - Click OK to save the new environment variable, and then exit the dialog box.

- If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
  - Open the Windows command prompt.
  - Run the following command to set the temporary environment variable:

    ```
    set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
    ```

    where *<designer_credentials_file_path>* is the location where you stored the designer_credentials.json file.

    Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
  - Now run the following command to start API Designer:

    ```
    C:\"Program Files\API Designer\API Designer.exe"
    ```

    By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

- Mac:
  If you are using macOS, create an environment variable using one of the following methods:

  - Run the following command to set the global environment variable:

    ```
    launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
    ```

    where *<designer_credentials_file_path>* is the location where you stored the API Designer credentials JSON file.
  - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

    ```
    APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
    <designer_application_file_path>/'API Designer.app'
    ```

    where:
    - *<designer_credentials_file_path>* is the location to which you downloaded the API Designer credentials JSON file.
    - *<designer_application_file_path>* is the location to which you downloaded and uncompressed the API Designer application.

6. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Customizing user-facing certificates

Convert a user-facing certificate that was generated by cert-manager to a custom certificate for an existing IBM® API Connect deployment.

The API Connect user-facing certificates are the server certificates that are presented to users of API Connect's external interfaces.

The server certificates are:

- The certificate the user's browser receives when it makes a connection to the:
  - Cloud Manager UI.
  - API Manager UI.
  - Developer portal sites.
- The certificate that is presented to callers of the API Connect platform and consumer REST APIs. The toolkit CLI uses the same REST APIs, and so is presented with the same certificates.
- The API invocation certificate. The certificate presented to callers of your published APIs. This certificate can be different on each gateway.

Remember: As per the DNS specification, wildcard certificates apply only to one level of subdomain and not more than that. For example, a certificate for `*.example.com` is not valid for `foo.bar.example.com`.
See the full list of user-facing certificates in User-facing certificates.

Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.
To replace the certificates for your management and portal UIs and for your management REST API endpoints, follow these steps:

1. Create the secrets that you want to use for each user-facing endpoint with the `kubectl create secret` command.
2. Edit the subsystem CR, and make the following changes for the endpoint secret you want to change:
   - In the `annotations` section, remove the following line:

     ```
     cert-manager.io/issuer: ingress-issuer
     ```

- In the **hosts** section, update the **secretName** to the new secret that you created in step 1.

The following example shows where to make the updates:

```
spec:
  <endpoint>
    annotations:
      cert-manager.io/issuer: ingress-issuer REMOVE THIS LINE
    hosts:
    - name: <api endpoint hostname>
      secretName: REPLACE WITH YOUR SECRET
```

Note: By default, the secret name is identical to the cert-name. Do not create replacement custom secrets with the same name as the default secrets.

Changing deployment profiles on Kubernetes and OpenShift

You can change an API Connect installation to use different deployment profiles.

About this task

After you complete initial installation of the API Connect subsystems, you can change to another of the profiles that are supported for the subsystem. For more information on the available profiles, see: Deployment and component profiles.

Important considerations:

- If you are changing from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (at least 3 worker nodes).
- Based on the resources configured for each microservice in the profile, there might be downtime during the profile change.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Management subsystem:
   a. Verify that subsystem is in **Running** state.

      ```
      kubectl get ManagementCluster
      ```

   b. Edit the CR:

      ```
      kubectl edit ManagementCluster
      ```

      Change **spec.profile** value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in **Running** state.

      ```
      kubectl get ManagementCluster
      ```

2. Developer Portal subsystem:
   a. Verify that subsystem is in **Running** state.

      ```
      kubectl get PortalCluster
      ```

   b. Edit the CR:

      ```
      kubectl edit PortalCluster
      ```

      Change **spec.profile** value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in **Running** state.

      ```
      kubectl get PortalCluster
      ```

3. Analytics subsystem:
   Note: If you have a three replica profile, and want to change to one replica, you must first change your analytics configuration to shared storage. Dedicated storage is not supported on the one replica profile.
   a. Verify that subsystem is in **Running** state.

      ```
      kubectl get AnalyticsCluster
      ```

   b. Edit the Analytics CR:

      ```
      kubectl edit AnalyticsCluster
      ```

      Change **spec.profile** value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in **Running** state.

      ```
      kubctl get AnalyticsCluster
      ```

4. Gateway subsystem

a. Verify that subsystem is in **Running** state.

```
kubectl get GatewayCluster
```

b. Edit the CR:

```
kubectl edit GatewayCluster
```

Change **spec.profile** value to the new profile you want to use.

c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.

d. Verify that subsystem is in **Running** state.

```
kubectl get GatewayCluster
```

Changing deployment profiles on OpenShift top-level CR

You can change an API Connect top-level CR installation to use different profiles.

Before you begin

This task assumes that you have already deployed an API Connect cluster as explained in Deploying on OpenShift and Cloud Pak for Integration. If you are changing from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (3 worker nodes) available. For more information on the available profiles, see: Deployment and component profiles.

Note: If you have a three replica profile, and want to change to one replica, you must first change your analytics configuration to shared storage. Dedicated storage is not supported on the one replica profile.

Procedure

1. Verify that the API Connect cluster is in the **Ready** state by running the following command:

   ```
   oc get apiconnectcluster
   ```

2. Update the API Connect Cluster CR:
   a. Open the API Connect Cluster CR in edit mode by running the following command:

      ```
      oc edit apiconnectcluster <APIC-instance-name>
      ```

   b. In the CR, change the **spec.profile** value to the profile that you want to use.
   c. Save the change by running the following command: **:wq**
3. Wait for microservice to scale up, or scale down, as needed.
4. Verify that the API Connect cluster is in the **Ready** state by running the following command:

   ```
   oc get apiconnectcluster
   ```

Changing the deployment profile on Cloud Pak for Integration

You can change an API Connect installation to use a different profile.

Before you begin

This task assumes that you have already deployed an API Connect cluster as explained in Deploying on OpenShift and Cloud Pak for Integration. If you are switching from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (3 worker nodes) available. For more information on the available profiles, see: Deployment and component profiles.

Note: If you have a three replica profile, and want to change to one replica, you must first change your analytics configuration to shared storage. Dedicated storage is not supported on the one replica profile.

Procedure

1. Verify that the API Connect cluster is in the **Ready** state.
   Open the IBM Cloud Pak Platform UI, locate the API Management capability on the Integration instances tab, and verify that the state displays as **Ready**. Leave the page open for the next step.

2. Update the API Management instance:
   a. In the Platform UI, click the overflow menu next to the instance and select Edit.
   b. In the Details section of the deployment pages, navigate to the Deployment profile field.
   c. Click the field and select the new deployment profile.
3. Click Update to save the change.
4. Wait for microservice to scale up, or scale down, as needed.
5. Verify that the status for the API Management instance displays as **Ready**.

Replica override for microservices

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For one replica profiles, specified by `n1x....`, the replica count is 1. For three replica profiles, specified by `n3x...`, replica count is 3. Note, however, that for Cloud Pak for Integration the API Connect Cluster profile `n3xc4.m16` replica count is 1.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the `template:` element should be under the main `spec:` element of a CR. The rest of the CR is not shown.
- Specification of microservice overrides in CP4I requires prefixing the microservice name with a designator for the subsystem type, as follows:
  - Management subsystem: `mgmt-`
  - Gateway: `gw-`
  - Analytics: `a7s-`

  For example, for the `apim` Management microservice, use `apim` when defining the override for OpenShift (or Kubernetes), but use `mgmt-apim` for a CP4I override.

Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the `apim` deployment:

```
spec:
  template:
  - name: apim
    replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- `juhu`
- `ldap`
- `lur`

The same override for CP4I:

```
spec:
  template:
  - name: mgmt-apim
    replicaCount: 5
```

On CP4I, you can also configure replicate count through a similar template override for:

- `mgmt-juhu`
- `mgmt-ldap`
- `mgmt-lur`

Gateway subsystem

The following override is supported for a Gateway CR in Kuberneter or OpenShift:

```
spec:
 template:
  - name: datapower
    replicaCount: 5
```

The same override for CP4I:

```
spec:
  template:
  - name: gw-datapower
    replicaCount: 5
```

Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- `director`
- `ingestion`
- `mtls-gw`
- `storage`
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

On CP4I, you can also configure replica count through a similar template override for:

- `a7s-directory`
- `a7s-ingestion`
- `a7s-mtls-gw`
- `a7s-storage`
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

Enabling Developer Portal feature flags on Kubernetes

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description

`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible.
				
				Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs:
				
				`An error occurred contacting the provided portal web endpoint: example.com`
				`The provided Portal web endpoint example.com returned HTTP status code 504`
				
				You can disable the check by setting this flag to `false`.

`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list.
				
				If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`.
				
				The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy.
				
				To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller configmap` with the following information:
				
				`data:`
				`  compute-full-forwarded-for: "true"`
				`  use-forwarded-headers: "true"`
				
				Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. If API Connect is already deployed, retrieve the name of the deployed CR for the Developer Portal subsystem by running the following command:

   ```
   kubectl get portalcluster -n <portal_namespace>
   ```

   If API Connect yet is not yet deployed, skip this step.

2. Edit the `portal` CR by running the following command:

   ```
   kubectl edit portalcluster <portal-cr-name> -n <portal_namespace>
   ```

3. In the editor, append the feature flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the `trusted_reverse_proxy` feature.

   ```
   spec:
   ...
     template:
     - containers:
       - env:
           - name: ENABLE_TRUSTED_REVERSE_PROXY
             value: true
         name: container
       name: pod
   ```

   Where:
   - *container* is the name of the portal container.
   - *pod* is the name of the portal pod.

   Note: You can add multiple feature flags to the CR.
4. Save the update.

The Developer Portal subsystem is updated to enable or disable features as specified.

Enabling Developer Portal feature flags on OpenShift and Cloud Pak for Integration

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description

`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible.
				
				Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs:
				
				`An error occurred contacting the provided portal web endpoint: example.com`
				`The provided Portal web endpoint example.com returned HTTP status code 504`
				
				You can disable the check by setting this flag to `false`.

`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list.
				
				If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`.
				
				The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy.
				
				To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information:
				
				`data:`
				`  compute-full-forwarded-for: "true"`
				`  use-forwarded-headers: "true"`
				
				Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. If API Connect is already deployed, retrieve the name of the deployed CR by running the following command:

   ```
   oc get apiconnectcluster -n <APIC_namespace>
   ```

   If API Connect yet is not yet deployed, skip this step.

2. Edit the `apiconnectcluster` CR by running the following command:

   ```
   oc edit apiconnectcluster <APIC_instance_name> -n <APIC_namespace>
   ```

3. In the CR, append the feature flag definition to the end of the `spec.portal` section, making sure to adhere to the spacing used in the file.
   You can add multiple feature flags as follows:

   ```
   spec:
     template
     - containers:
         - env:
             - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
               value: 'true'
           name: admin
       name: ptl-www
   ```

   ```
   spec:
     template
     - containers:
         - env:
   ```

```
          - name: ENABLE_TRUSTED_REVERSE_PROXY
            value: 'true'
        name: admin
    name: ptl-www
```

4. Close and save the file with the following command:

   ```
   :wq
   ```

   The Developer Portal subsystem is updated to enable or disable features as specified.

Enabling UI feature flags on Kubernetes

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. If you already deployed API Connect, retrieve the name of the deployed CR for the Management subsystem by running the following command:

   ```
   kubectl get managementcluster -n <management_namespace>
   ```

   If you did not deploy API Connect yet, skip this step.

2. Edit the `management` CR by running the following command:

   ```
   kubectl edit managementcluster <management-cr-name> -n <management_namespace>
   ```

3. In the editor, append the feature-flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

   ```
   spec:
     template:
       - name: ui
         containers:
         - name: ui
           env:
             - name: APIC_UI_FEATURES
               value: allOmniSearch=always
   ```

   `APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

   Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

   - `true` - On by default, but can be overridden by the user, for their browser alone
   - `false` - Off by default, but can be overridden by the user, for their browser alone
   - `never` - Off regardless of browser setting, disabled in feature flag page
   - `always` - On regardless of browser setting, disabled in feature flag page

4. Save the update.
   The cluster is updated to enable or disable features as specified.

Enabling UI feature flags on OpenShift and Cloud Pak for Integration

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. If you already deployed API Connect, retrieve the name of the deployed CR by running the following command:

   ```
   oc get apiconnectcluster -n <APIC_namespace>
   ```

   If you did not deploy API Connect yet, skip this step.

2. Edit the `apiconnectcluster` CR by running the following command:

   ```
   oc edit apiconnectcluster <APIC_instance_name> -n <APIC_namespace>
   ```

3. In the CR, append the feature-flag definition to the end of the `spec.management` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

   ```
   spec:
     management:
       template:
         - name: ui
           containers:
           - name: ui
             env:
               - name: APIC_UI_FEATURES
                 value: allOmniSearch=always
   ```

   `APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

   Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

   - `true` - On by default, but can be overridden by the user, for their browser alone
   - `false` - Off by default, but can be overridden by the user, for their browser alone
   - `never` - Off regardless of browser setting, disabled in feature flag page
   - `always` - On regardless of browser setting, disabled in feature flag page

4. Close and save the file with the following command:

   ```
   :wq
   ```

   The cluster is updated to enable or disable features as specified.

Advanced configuration for the management subsystem

Specify advanced configuration for the management subsystem.

See:

- **Updating management subsystem password, keys, and secrets**
  Update the cloud administrator password, the key for encrypted database fields, and the `client_ID` and `client_secret` values for the management subsystem in an API Connect deployment.
- **Configuring maximum size of client requests to the Management subsystem**
  You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- **Setting rate limits for public APIs on the management service for a Kubernetes environment**
  Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- **Enabling API discovery on Kubernetes**
  You can optionally configure API discovery in IBM® API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the API discovery service.

- **Enabling governance on Kubernetes**
  You can optionally configure governance in IBM API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the governance service.
- **Enabling API Agent for the management subsystem**
  API Agent is an optional add-on for API Connect that simplifies and automates complex API management workflows. By intelligently converting user queries into actions, it streamlines API discovery, creation, governance, and testing. You can configure API Agent in IBM API Connect deployments on Kubernetes, Red Hat OpenShift, or IBM Cloud Pak for integration deployment by enabling the API Agent services. API Agent is not supported on VMware deployments.
- **Configuring monetization on Kubernetes**
  You can optionally configure monetization in API Connect on a Kubernetes deployment by enabling the billing microservice.
- **Restarting the Management subsystem pods**
  How to restart Management subsystem pods in your API Connect deployment.
- **Disabling the PodDisruptionBudget (PDB) for the management EDB database**
  Disable PDB for single replica management subsystems.
- **Postgres database shutdown**
  This document provides detailed guidance to shut down and start the Postgres database to prevent any changes during the migration process.
- **Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later**
  This section describes the default affinity, nodeSelector, and toleration settings of EDB Postgres and Operator pods and examples of how to customize them.
- **Disabling the status feedback on products page**
  You can view the state of the products on the Products page inside a catalog. Administrators have the flexibility to show or hide this status feedback on the Products page. Regardless of this setting, the state of the product lifecycle events remains visible on the Gateway processing status pages so that the critical deployment information remains accessible to administrators.

Updating management subsystem password, keys, and secrets

Update the cloud administrator password, the key for encrypted database fields, and the **`client_ID`** and **`client_secret`** values for the management subsystem in an API Connect deployment.

- **Changing the cloud administrator password**
  Update the cloud administrator password for the management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.
- **Changing the database encryption key**
  Replace the value of the secret that is used for encrypting database fields in the management subsystem.
- **Changing the registration client_id and client_secret for applications**
  Change the registration credentials (the **`client_id`** and **`client_secret`**) for applications provided by the management subsystem.

Changing the cloud administrator password

Update the cloud administrator password for the management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.

About this task

In the management subsystem for an API Connect on-premises deployment, the administrator is called the *cloud administrator* and works with the management server to configure the deployment of the local server cloud. Updating the cloud administrator password for the management subsystem requires no service interruption because the change takes place immediately.

You can change the cloud administrator's password using any of the following methods.

Note: Passwords must contain eight or more characters, with at least one character from three of the following categories: lowercase letters, uppercase letters, numerals, and punctuation (for example: ! $ # %). The same character cannot be used more than twice consecutively.

Cloud Manager UI

1. Log in to the Cloud Manager UI.
2. Change your Cloud Manager password.

Toolkit CLI

1. Run the **`apic login`** command to log in to a management server.
2. Run the **`apic me:change-password`** command to change your password.

API call

1. Run the **`apic login`** command to log in to a management server.
   You must log in to a management server with the toolkit CLI before you can call the API Connect APIs.
2. Execute the **`/api/me/change-password`** API call. as explained in the "Resource: Me" section of the IBM API Connect Platform - Cloud Management API.

The next time that you log in as the cloud administrator, you must use the new password.

Changing the database encryption key

Replace the value of the secret that is used for encrypting database fields in the management subsystem.

Before you begin

Take a backup of your existing management database encryption key. If you need to restore a management database backup, you must have the encryption key that was in use at the time the database backup was created.

To take backup of your encryption key:

1. Identify the name of the management database encryption secret:

   ```
   kubectl get mgmt <mangement CR name> -o=jsonpath='{.status.encryptionSecret}'
   ```

   where *<mangement CR name>* can be determined by running:

   ```
   kubectl get mgmt
   ```

2. Copy the secret to a YAML file:

   ```
   kubectl get secret <management enc secret> -o yaml > management_enc_key_backup_<date>.yaml
   ```

The key is backed up to the file management_enc_key_backup_*<date>*.yaml. Set *<date>* to the current date, for example management_enc_key_backup_20240101.yaml, so that you can identify when this backup was taken.
Keep your backed up encryption secret with your management infrastructure configuration backup: Taking a management infrastructure configuration backup. If you want to restore a database backup that was taken when a previous encryption key was in use, then see restore backup.

About this task

This update does not require an outage; however some operations might take longer than usual due to database locking.

Procedure

1. Create a file called rotate_mgmt_enc_secret.yaml, and paste in the following contents:

   ```
   apiVersion: management.apiconnect.ibm.com/v1beta1
   kind: ManagementSecretRotation
   metadata:
     name: rotate-secret
   spec:
     managementCluster: <mangement CR name>
     rotateEncryptionSecret:
       rotate: true
   ```

   Note: If your deployment was originally installed at V2018.4.1, then the database encryption key is called `managementUpgradeName-encryption-secret`.
2. Run the following command to apply the `rotate-secret` CR:

   ```
   kubectl create -f rotate_mgmt_enc_secret.yaml
   ```

   The update can take a few minutes. You can monitor the progress with:

   ```
   kubectl get managementsecretrotation
   ```

   The update is complete when the status shows `Completed`:

   ```
   NAME            READY   STATUS      AGE
   rotate-secret   1/1     Completed   13m
   ```

What to do next

If you need to restore a management database backup that was taken before you updated the encryption key, then you must restore your previous encryption key from your backup.

1. Edit your secret backup file: management_enc_key_backup_*<date>*.yaml and change `metadata.name` to a unique name for your backup secret. Delete all other `metadata` contents. Your updated YAML file should look like this:

   ```
   apiVersion: v1
   data:
     encryption_secret.bin:
   If7HlVzZeAgrYrwvcEhv1Ub0LVXNQsN0mGISy1GvYXKA4d1tSWLB80hB89sn+VvN0/vAVTU90AP6jPOsi5LpOaddfoqT85ugvjEwHLnEtSI6CbEr05NtMUwJGA
   r5/KWfjj6mwCn+EMp4VBsEDppU54yvycyb7iBLRtGyrPktTaw=
   kind: Secret
   metadata:
     name: backup_mgmt_encryption_secret
   type: Opaque
   ```

2. Restore the encryption secret from your updated backup file:

   ```
   kubectl create -f management_enc_key_backup_<date>.yaml
   ```

3. Verify that the backup secret was created:

   ```
   kubectl get secrets
   ```

   You should see your restored backup secret in the output:

   ```
   NAME                                TYPE            DATA   AGE
   ...
   backup_mgmt_encryption_secret       Opaque          3      10s
   ...
   ```

4. In your mgmtrestore_cr.yaml file, add the property `spec.mgmtEncKeyName` and set it to your newly created backup secret name:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
  generateName: management- # this the prefix for the name of the restore CR that is created
spec:
  backupName: <backup CR name>
  subsystemName: <management CR name>
  mgmtEncKeyName: backup_mgmt_encryption_secret
```

The encryption key that is contained in **backup_mgmt_encryption_secret** is copied to your active encryption secret. After you restore the backup, you might want to update the encryption key again (for the same reason that you previously updated the secret).

For more information about management database backup restore, see Restoring from a management database backup.

If you have a two data center disaster recovery deployment, you must copy the updated encryption secret to your warm-standby data center. Follow these steps:

1. Extract the management database encryption secret from the active data center:

   ```
   kubectl get secret <mgmt encryption secret> --template='{{ index .data "encryption_secret.bin" }}' > mgmt-enc-secret.txt
   ```

2. Verify that the mgmt-enc-secret.txt file contains your secret:

   ```
   cat mgmt-enc-secret.txt
   ```

   Expected output should be a long string, for example:

   ```
   YSXft4YoApS+UJHpaXjdu8OUovFGhLT9YsBaWeRCI5sUigPdchY/cq18Z5UKaW5afZDXxQDWUcY6tx9xTXVGzEm9oZCDV1hmq4mu7qM015rBjZIJ7FPrA3gNgx
   flxim9SORSybnhW2JT6S41ZH9QJwfUtIUUpe981h8sraSEtOQ=
   ```

3. In your warm-standby data center, identify the name of the management database encryption secret:

   ```
   kubectl get mgmt <mangement CR name> -o=jsonpath='{.status.encryptionSecret}'
   ```

4. Update the warm-standby secret with the secret from the active that you obtained in step 1:

   ```
   kubectl patch secret <warm-standby enc secret name> -p "{\"data\": {\"encryption_secret.bin\":\"$(<mgmt-enc-
   secret.txt)\"}}"
   ```

Changing the registration `client_id` and `client_secret` for applications

Change the registration credentials (the **client_id** and **client_secret**) for applications provided by the management subsystem.

About this task

Update the application registration **client_id** and **client_secret** by changing the Kubernetes secret containing them. The **apim** file-watcher detects the change and automatically updates the following secrets in the database:

- toolkit: **management-cli-cred** (Customer facing)
  When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in Installing the toolkit.
- consumer-toolkit: **management-ccli-cred** (Customer facing)
  When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in Installing the toolkit.
- designer: **management-dsgr-cred** (Customer facing)
  When you update the secret for API Designer, users must download and install new credentials as explained in Installing the toolkit.
- atm: **management-atm-cred** (Internal)
- governance: **management-governance-cred** (Internal)
- consumer-ui: **management-cui-cred** (Internal)
- juhu: **management-juhu-cred** (Internal)
- ai: **management-ai-cred** (Internal)
  The API Manager and Cloud Manager read the credentials from the back-end on start-up.

When you update the registration credentials for the default registrations, the registration name associated with the updated secret remains unchanged. Table 1 lists the registration secrets with the default registration name for each secret.

Table 1. Secret names and the corresponding default registration names for each secret

Secret	Default registration name
management-cli-cred	toolkit-default
management-ccli-cred	consumer-toolkit-default
management-dsgr-cred	designer-default
management-atm-cred	atm-default
management-governance-cred	compliance-default
management-cui-cred	consumer-ui-default
management-juhu-cred	juhu-default
management-ui-cred	ui-default
management-ai-cred	ai-default

Procedure

1. To renew an internal certificate, complete the following steps:

a. Create a ManagementSecretRotation CR (for example, operationcr.yaml) with contents similar to the following example, and list the secrets that you want to update:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: rotate-credentials
spec:
  managementCluster: management
  rotateClientIDandSecret:
    secrets:
    - management-ui-cred
    - management-cui-cred
    - management-juhu-cred
    - management-atm-cred
```

b. Apply the CR by running the following command:

```
kubectl create -f operationcr.yaml -n namespace
```

where:

- ***namespace*** is the namespace where you installed the management subsystem
- operationcr.yaml is the file the contains the CR

Applying the resource updates the credential for the specified secrets with new values.

2. To update customer-facing credentials, complete the following steps:
   a. For each of the credential secrets, run the following command to update the **client_id** and **client_secret**:

```
kubectledit secret credential_secret_name -n namespace
```

where:

- ***namespace*** is the namespace where the management subsystem is installed.
- ***credential_secret_name*** is the name of the secret that you want to update.

The response opens the secret in a text editor as shown in the following example:

```
apiVersion: v1
data:
  credential.json:
eyAiaWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MWYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=
```

In the secret, the value of **credential.json** is a base64 encoded string of the following JSON format. Decode it first, modify the values of **id** and **secret**, and encode back as base64 and paste it in the secret. (Note that either **id** or **secret** or both can be updated, but if the credentials have been compromised then its recommended to update both id and secret). For example:

   b. Decode the value of **credential.json**.
   To decode the value, copy it from the secret in step 2a, and paste it between the quotation marks as the ***encoded_value*** in the following command:

```
echo "encoded_value" | base64 --decode
```

Using the value returned in step 1, the command looks like the following example:

```
echo
"eyAiaWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MWYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=" | base64 --decode
```

The response displays decoded values of the **id** and **secret**, as in the following example:

```
{ "id": "56716266-d14f-486f-b41f-e1736de87614", "secret": "fb5907a7-326c-48ef-b44d-a129ffd33b11" }
```

   c. Update the values of **id** and **secret**.
   You can use any string that meets the following requirements:
   - The **id** (it becomes **client_id**) must be unique across all credentials in your entire deployment.
   - The values must be enclosed in straight quotation marks. To make sure you use the correct character, create the values in a plain text editor.

   d. Encode the updated **id** and **secret** as base64 by running the following command:

```
echo -n '{ "id": "new_id", "secret": "new_secret" }' | base64
```

Replace ***new_id*** and ***new_secret*** with your updated values. For example:

```
echo -n '{ "id": "21034840-b439-a393-4482-a948bcb39603", "secret": "43450ab9-4038-acf0-0498-793b29ade396" }' | base64
```

Returns the following base640-encoded value:

```
aWQ6IDIxMDM0ODQwLWI0MzktYTM5My00NDgyLWE5NDhiY2IzOTYwMywgc2VjcmV0OiA0MzQ1MGFiOS00MDM4LWFjZjAtMDQ5OC03OTNiMjlhZGUzOTY=
```

   e. Paste the newly coded value for **credential.json** into the secret.
   f. Save the secret.
   When you save the secret, the logs in the **apim** pods indicate that a new registration was created. For example, if the **client_id** changed, the display looks similar to the following messages

```
2020-09-14T09:55:58.331Z bhendi:audit [ce64fd50-e4de-4cfb-baa7-7379a892b2c9] Created internal resource "Registration"

2020-09-14T11:00:52.377Z audit [866bb70b-3bb5-4ac3-9a59-0b60ade7feb2] Creating a new registration for type, ui, with
client_id: ui-client-id.
```

g. If the response shows any errors, you must correct the errors.
When the logs show no errors, the saved values are updated in the management subsystem's database.

h. Confirm that the new registration exists in the registrations list by running the following toolkit CLI command:

```
apic --server server registrations:list
```

where ***server*** is the management server endpoint URL.

i. Verify that the updated registration is now in effect by running the following toolkit CLI command:

```
apic --server server registrations:get new_registration_name --output -
```

where:

- ***server*** is the management server endpoint URL
- ***new_registration_name*** is the new registration name (including any numeric suffix) following the patterns in Table 1.

j. Save the old registration (refer to Table 1 to determine the previous registration's file name) in case you need it when restoring an older backup.
Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created.

k. If you updated the registration credentials for API Designer or the toolkit, inform users so they can download new credentials.
Users can download and set up new credentials as explained in Installing the toolkit. Other credentials are updated automatically and require no actions from the user.

Configuring maximum size of client requests to the Management subsystem

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Procedure

1. Edit the Management CR. Refer to the Management CR templates:

```
spec:
  ...
  ...
  template:
  - name: juhu
    containers:
    - name: juhu
      env:
      - name: CLIENT_MAX_BODY_SIZE
        value: "12m"
```

Note that the default value is `"8m"`. The `template:` entry must be indented two spaces, and be located within the `spec:` element.

2. Apply the changes:

```
kubectl -n <namespace> apply -f management_cr.yaml
```

Setting rate limits for public APIs on the management service for a Kubernetes environment

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

Before you begin

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

These instructions assume you have a working Kubernetes environment with the kubectl command-line tool installed, and that you understand how to manage Kubernetes. For more information, see https://kubernetes.io.

About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **`429 Too Many Requests`**.

Procedure

- Configure the ingress-nginx-ingress-controller to pass the real client IP address:
  1. Set the **`use-proxy-protocol`** parameter to **`true`** by entering the following command:

     ```
     kubectl edit ConfigMap -n kube-system ingress-nginx-ingress-controller
     ```

  2. In the ConfigMap, set the following: **`use-proxy-protocol: "true"`**
- Set a rate limit:
  1. You can add a **`template:`** value in your subsystem CR to provide an override.
     For example, the Management CR template value can be:

     ```
     spec:
       ...
       template:
       - name: juhu
         containers:
         - name: juhu
           env:
           - name: RATE_LIMIT_PER_CLIENT
             value: "10"
           - name: LIMIT_REQUEST_OPTION
             value: "burst=10 nodelay"
     ```

     Note that the **`template:`** entry must be indented two spaces, and must be located in the **`spec:`** element.

     In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

     The **`rateLimitPerClient`** property sets **`rate`**, and **`limitRequestOption`** sets **`[burst=number] [nodelay | delay=number]`** in the following nginx configuration:

     ```
     limit_req_zone key zone=name:size rate=rate;
     limit_req zone=name [burst=number] [nodelay | delay=number];
     ```

     Note that **`zone`** has been pre-defined and can't be configured. For more details, see the nginx doc http://nginx.org/en/docs/http/ngx_http_limit_req_module.html.

  2. Apply the changes:

     ```
     kubectl -n <namespace> apply -f management_cr.yaml
     ```

  3. Validate that the juhu pod has restarted by listing the pods:

     ```
     kubectl get pods -n <namespace> | grep juhu
     ```

  4. Check the AGE column to ensure a new juhu pod has started.
  5. If the older juhu pod is still running, delete it with the following command:

     ```
     kubectl delete pods -n <namespace> <old-juhu-pod>
     ```

- Disable a rate limit:

1. Validate that the juhu pod has restarted by listing the pods:

   ```
   kubectl get pods -n <namespace> | grep juhu
   ```

2. Check the AGE column to ensure a new juhu pod has started.
3. If the older juhu pod is still running, delete it with the following command:

   ```
   kubectl delete pods -n <namespace> <old-juhu-pod>
   ```

Enabling API discovery on Kubernetes

You can optionally configure API discovery in IBM® API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the API discovery service.

About this task

The API discovery service is an optional add-on to API Connect that can be used to discover and add APIs to your API development process.

Note:

- These instructions apply only to Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations.
- APIs cannot be discovered and added to your deployment until the API discovery service is enabled.
- If you're using a two data center disaster recovery (2DCDR) deployment, the API discovery service must be enabled on both the active and warm-standby centers. Enable the service on the warm-standby data center first, and then the active center.
- If you enable the API discovery service, the backups that you take can be restored only onto a management subsystem that also has the API discovery service enabled.

To enable or disable the API discovery service, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the API discovery service as part of a new deployment**
- **Enabling the API discovery service as part of an existing deployment**
- **Disabling the API discovery service**

After the API discovery service is enabled, API discovery resources can be created. For more information, see API discovery.

Procedure

- **Enabling the API discovery service as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the API discovery service.

  1. Edit the `ManagementCluster` CR and add the following definition for the API discovery service. Append the API discovery definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       discovery:
         enabled: true
         proxyCollectorEnabled: true
     ```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the management subsystem for details):

     ```
     kubectl apply -f management_cr.yaml -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
     The API discovery service will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `api-discovery` pods are shown in the list of returned values, and the `ManagementCluster` has completed with a `READY` status of `True`, and the `SUMMARY` reports that the services are online, for example `1/1`.
- **Enabling the API discovery service as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the API discovery service.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the API discovery definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       discovery:
     ```

```
    enabled: true
    proxyCollectorEnabled: true
```

4. Save the update.
   The API discovery service is enabled in the Management subsystem.

5. You can monitor your Kubernetes deployments by running the following command:

   ```
   kubectl get deployments -n <management_namespace>
   ```

   The installation is complete when the `api-discovery` pods are shown in the list of returned values, and the `ManagementCluster` has completed with a `READY` status of `True`, and the `SUMMARY` reports that the services are online, for example `1/1`.

- **Disabling the API discovery service**
  Edit the deployed CR for the Management subsystem and update the settings for the API discovery service.

1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

   ```
   kubectl get managementcluster -n <management_namespace>
   ```

   Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
2. Edit the deployed CR by running the following command:

   ```
   kubectl edit managementcluster <management-cr-name> -n <management_namespace>
   ```

   Where:
   - *management-cr-name* is the name of the deployed CR for the Management subsystem.
   - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
3. In the editor, change the API discovery definition to `enabled: false`.

   ```
   spec:
     ...
     discovery:
       enabled: false
       proxyCollectorEnabled: false
   ```

4. Save the update.
   The API discovery service is disabled in the Management subsystem.

Results

Note that when the API discovery service is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes API discovery resources have names that contain `api-discovery`. For example:

```
kubectl get pods -n apic | grep discovery
management-api-discovery-gw-proxy-collector-8d8bdfbdf51fbj   1/1     Running     0             88m
management-api-discovery-gw-proxy-collector-8d8bdfbdf67qqz   1/1     Running     0             88m
management-api-discovery-gw-proxy-collector-8d8bdfbdfzrhkv   1/1     Running     0             88m
management-api-discovery-service-f7dc497d8-gc7dn             1/1     Running     0             89m
management-api-discovery-service-f7dc497d8-pd877             1/1     Running     0             89m
management-api-discovery-service-f7dc497d8-shzm9             1/1     Running     0             89m
management-api-discovery-ui-5549df59d9-b4fks                 1/1     Running     0             88m
management-api-discovery-ui-5549df59d9-gjqmx                 1/1     Running     0             88m
management-api-discovery-ui-5549df59d9-pjvsx                 1/1     Running     0             88m
management-up-api-discovery-service-data-populate-0-tvxbvs   0/1     Completed   0             90m
management-up-api-discovery-service-schema-0-to-2-mrs8d      0/1     Completed   0             90m
```

Enabling governance on Kubernetes

You can optionally configure governance in IBM® API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the governance service.

About this task

The governance service is an optional add-on to API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process.

Note:

- These instructions apply only to Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations.
- Governance rulesets cannot be added to your deployment until the governance service is enabled.
- If you're using a two data center disaster recovery (2DCDR) deployment, the governance service must be enabled on both the active and warm-standby centers. Enable the service on the warm-standby data center first, and then the active center.

To enable or disable the governance service, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the governance service as part of a new deployment**
- **Enabling the governance service as part of an existing deployment**
- **Disabling the governance service**

After the governance service is enabled, governance resources can be created. For more information, see Configuring governance in the Cloud Manager, and Configuring governance in the API Manager.

Procedure

- **Enabling the governance service as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the governance service.

  1. Edit the `ManagementCluster` CR and add the following definition for the governance service. Append the governance definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       governance:
         enabled: true
     ```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the management subsystem for details):

     ```
     kubectl apply -f management_cr.yaml -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
     The governance service will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-compliance` pods are shown in the list of returned values.

- **Enabling the governance service as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the governance service.
  Note: When you enable governance in the existing deployment, the UI requires approximately 15 minutes to restart the pod and display the new feature. There will be an outage in the UI during this period.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the governance definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       governance:
         enabled: true
     ```

  4. Save the update.
     The governance service is enabled in the Management subsystem.

  5. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-compliance` pods are shown in the list of returned values.

- **Disabling the governance service**
  Edit the deployed CR for the Management subsystem and update the settings for the governance service.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, change the governance definition to `enabled: false`.

     ```
     spec:
       ...
       governance:
         enabled: false
     ```

  4. Save the update.
     The governance service is disabled in the Management subsystem.

Results

Note that when the governance service is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes governance resources have names containing either `compliance-service` or `compliance-ui`. For example:

```
kubectl get pods -n apic | grep compliance
management-compliance-service-f6cdf95fc-t4qkx                     1/1     Running     0          127m
management-compliance-ui-59897fcc4-zm25v                          1/1     Running     0          126m
```

```
management-up-compliance-service-data-populate-0-to-1-t2f4d       0/1     Completed   1          132m
management-up-compliance-service-schema-0-to-1-21kqq              0/1     Completed   0
```

Enabling API Agent for the management subsystem

API Agent is an optional add-on for API Connect that simplifies and automates complex API management workflows. By intelligently converting user queries into actions, it streamlines API discovery, creation, governance, and testing. You can configure API Agent in IBM® API Connect deployments on Kubernetes, Red Hat OpenShift, or IBM Cloud Pak for integration deployment by enabling the API Agent services. API Agent is not supported on VMware deployments.

Before you begin

Ensure that your system meets the following requirements:

- A Milvus database instance is required to enable the API Agent and its details must be added to the **`ManagementCluster`** CR.
- The base profile for management in API Connect is not dependent on API Agent, but you might require extra CPU or memory. For more information about memory or CPU requirements, see Management subsystem deployment profile limits.

About this task

By default, API Agent is disabled and remains inactive unless it is explicitly enabled in the **`ManagementCluster`** CR (henceforth referred to as just management CR). You can also enable API Agent during the initial deployment of a new management CR or later. The enablement experience is the same whether you're deploying a new system on 10.0.10.0, or upgrading to 10.0.10.0 from version 10.0.8.x or 10.0.9.0.

To enable API Agent, complete the following tasks:

Procedure

1. Create a Milvus secret as shown in the example below:

   ```
   kubectl create secret generic milvus-creds --from-literal=username=$MILVUS_USER_NAME --from-literal=password=$MILVUS_API_KEY
   ```

2. Edit the **`ManagementCluster`** CR and add the following definition for the API Agent service. Append the API Agent definition to the end of the **`spec:`** section, making sure to adhere to the spacing used in the file.

   ```
   spec:
     ai:
       enabled: true
       apiAgent:
         enabled: true
         vectorDatabaseSource: remote
         remoteVectorDatabase:
           type: milvus
           host: milvus.host
           port: 30279
           databaseName: default
           collectionName: apic_agent
           credentials: milvus-creds
   ```

   The following are the details of each field:
   - **`ai`**: enables AI features.
   - **`enabled: true`**: enables AI.
   - **`apiAgent`**:
     - **`enabled: true`**: enables the API Agent tab.
     - **`vectorDatabaseSource: remote`**: specifies that the vector database is remote.
     - **`remoteVectorDatabase`**: configures the remote vector database.
     - **`type: milvus`**: specifies the type of vector database (milvus).
     - **`host: milvus.host`**: specifies the host of the milvus database.
     - **`port: 30279`**: specifies the port of the milvus database.
     - **`databaseName: default`**: specifies the name of the milvus database.
     - **`collectionName: apic_agent`**: specifies the name of the collection in the milvus database.
     - **`credentials: milvus-creds`**: specifies the credentials for the milvus database.

   Note:
   - Both **`ai`** and **`ai.apiAgent`** must be set to either true or false.
   - If **`apiAgent`** is enabled, then **`remoteVectorDatabase`** is required and is validated when CR is created or updated. During validation, the system also checks connectivity to the database.
   - For collection name, specify a new collection to be created by API Agent. The name can include letters, numbers, and underscores. If the specified collection already exists, API Agent attempts to use it. If the existing schema differs from what API Agent requires, it will drop the existing collection and create a new a collection with required schema.
3. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the management subsystem for details):

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
   The API Agent service will be enabled with the Management subsystem. Alternatively, use the form view or apply the **`APIConnectCluster CR`** directly in Red Hat OpenShift. The settings are under Advanced configuration > Management subsystem > Advanced configuration > AI, and its children fields. For more information about Open Shift settings, see API Connect configuration settings.

Configuring monetization on Kubernetes

You can optionally configure monetization in API Connect on a Kubernetes deployment by enabling the billing microservice.

About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to Kubernetes installations. .
- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.
- After provider organizations have added billing integrations, the billing microservice must not be disabled.

To enable or disable the billing microservice, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the billing microservice as part of a new deployment**
- **Enabling the billing microservice as part of an existing deployment**
- **Disabling the billing microservice**

Procedure

- **Enabling the billing microservice as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the billing microservice.

  1. Edit the `ManagementCluster` CR and add the following definition for the billing microservice. Append the billing definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       billing:
         enabled: true
     ```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the management subsystem for details):

     ```
     kubectl apply -f management_cr.yaml -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
     The billing microservice will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-billing` pod is shown in the list of returned values.

  After the billing microservice is enabled, provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Enabling the billing microservice as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the billing microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the billing definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       billing:
         enabled: true
     ```

  4. Save the update.
     The billing microservice is enabled in the Management subsystem.

  5. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

The installation is complete when the `management-billing` pod is shown in the list of returned values.

After the billing microservice is enabled, provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Disabling the billing microservice**

  Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.

  Edit the deployed CR for the Management subsystem and update the settings for the billing microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, change the billing definition to `enabled: false`.

     ```
     spec:
       ...
       billing:
         enabled: false
     ```

  4. Save the update.

     The billing microservice is disabled in the Management subsystem.

Restarting the Management subsystem pods

How to restart Management subsystem pods in your API Connect deployment.

Procedure

1. Determine your deployment name by running the following command:

   ```
   kubectl -n <namespace> get deployment | grep <management CR>
   ```

   where
   - *<namespace>* is the namespace where the management subsystem is installed.
   - *<management CR>* is the name your management subsystem CR.
2. Restart pods by running the `kubectl` commands shown in Table 1.

   Use the deployment name that you obtained in step 1.

Table 1. Management pods and the commands to restart them

Pod	Restart command
`management-analytics-proxy`	`kubectl rollout restart deployment/deployment_name -n <namespace>`
`management-apim`	`kubectl rollout restart deployment/deployment_name -n <namespace>` A manual restart is not needed when the certificate is updated.
`management-client-downloads-server`	`kubectl rollout restart deployment/deployment_name -n <namespace>` A manual restart is not needed when the certificate is updated.
`management-atm-api`	`kubectl rollout restart deployment/deployment_name -n <namespace>`
`management-atm-ui`	`kubectl rollout restart deployment/deployment_name -n <namespace>`
`management-juhu`	`kubectl rollout restart deployment/deployment_name -n <namespace>`
`management-ldap`	`kubectl rollout restart deployment/deployment_name -n <namespace>` A manual restart is not needed when the certificate is updated.
`management-lur`	`kubectl rollout restart deployment/deployment_name -n <namespace>` A manual restart is not needed when the certificate is updated.
`management-natscluster`	Run for each `natscluster` pod, one at a time: `kubectl exec management-natscluster-n -- bash -c "kill -HUP 1"` A manual restart is not needed when the certificate is updated.
`edb-operator`	`kubectl rollout restart deployment edb-operator -n <namespace>`

Pod	Restart command
`management-portal-proxy`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-taskmanager`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-tunnel`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-ui`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-analytics-ui`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-`*`remote-sitename`*`-postgres`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`

3. Verify that all management pods are ready by running the following command:

   ```
   kubectl -n <namespace> get pods
   ```

   where *<namespace>* is the namespace where the management subsystem is installed.

   The restart is complete when all pods are **`Running`** and **`Ready`**.

Disabling the PodDisruptionBudget (PDB) for the management EDB database

Disable PDB for single replica management subsystems.

About this task

Some maintenance scenarios require that Postgres is shutdown, and on one replica deployments the PDB prevents this. You can disable the **`PodDisruptionBudget`** by setting the **`nodeMaintenanceWindow`** to **`inProgress: true`** and **`reusePVC: true`**.

Procedure

1. Identify the name of your Postgres cluster:

   ```
   kubectl -n <management namespace> get cluster
   ```

   Example:

   ```
   NAME                        AGE   INSTANCES   READY   STATUS                     PRIMARY
   apic-management-site1-db    95d   1           1       Cluster in healthy state   apic-management-site1-db-1
   ```

2. Edit the Postgres cluster:

   ```
   kubectl -n <management namespace> edit cluster <cluster name>
   ```

3. Add the following to the **`spec:`** section

   ```
   spec:
     nodeMaintenanceWindow:
       inProgress: true
       reusePVC: true
   ```

4. Verify that the PDB is no longer present.

   ```
   kubectl -n <management namespace> get pdb
   ```

   should return empty.

What to do next

Complete whatever task required PDB disablement, then edit the Postgres cluster and remove the **`spec.nodeMaintenanceWindow`** section to enable PDB.

Postgres database shutdown

This document provides detailed guidance to shut down and start the Postgres database to prevent any changes during the migration process.

- **Shutting down the Postgres database in the Management subsystem on different environments**
  Shut down or fence the Postgres database in the Management subsystem to prevent data corruption, ensure safe failover, or perform maintenance tasks across development, staging, and production environments.
- **Starting the Postgres database in the Management subsystem on different environments**
  Restart or unfence the Postgres database in the Management subsystem to restore connectivity, resume normal operations after maintenance or failover, and ensure system availability across development, staging, and production environments.

Shutting down the Postgres database in the Management subsystem on different environments

Shut down or fence the Postgres database in the Management subsystem to prevent data corruption, ensure safe failover, or perform maintenance tasks across development, staging, and production environments.

Before you begin

- Make sure that the EDB cluster is healthy and running.
- If the EDB cluster shuts down due to an issue in any environment, such as full disks, resolve the issue and then restart the cluster.

About this task

The shutdown of the Postgres database is controlled using the **`k8s.enterprisedb.io/fencedInstances`** annotation, which accepts a JSON-formatted list of instance names. If the annotation is set to **`["*"]`**, a singleton list with a wildcard, the entire cluster is shut down. To shut down only one EDB instance, replace the **`"*"`** in the command with the instance name.

Note: The OVA package includes API Connect with the CNP plug-in preinstalled. To install the CNP plug-in for other environments, see https://github.com/EnterpriseDB/kubectl-cnp. For non-OVA environments, you must manually install the CNP plug-in version **`v1.22.4`** to ensure compatibility with the Cloud Native PostgreSQL operator used by API Connect.

Procedure

1. If you are on an appliance (VMware), to run the **`kubectl`** commands, connect to the Management node and log in as root user (**`sudo -i`**).
2. Shut down the cluster using the preinstalled CNP plug-in.
   a. To get the cluster name, run the following command.

      ```
      kubectl get clusters.postgresql.k8s.enterprisedb.io
      ```

   b. To shut down the cluster, run the following command.

      ```
      kubectl cnp fencing on <cluster_name_from_above_command> "*"
      ```

   Tip: You can also shut down the cluster if CNP plug-in is not preinstalled.
   a. To get the cluster name, run the following command.

      ```
      kubectl get clusters.postgresql.k8s.enterprisedb.io
      ```

   b. To shut down all the instances of the database, run the following command.

      ```
      kubectl annotate cluster <cluster_name_from_above_command> k8s.enterprisedb.io/fencedInstances='["*"]' -n <namespace>
      ```

   c. To shut down one instance of the database by passing the instance name, run the following command.

      ```
      kubectl annotate cluster <cluster_name_from_above_command> k8s.enterprisedb.io/fencedInstances='["<instance-name-db-1>"]' -n <namespace>
      ```

Results

The Postgres database in Management subsystem is now shut down.

Starting the Postgres database in the Management subsystem on different environments

Restart or unfence the Postgres database in the Management subsystem to restore connectivity, resume normal operations after maintenance or failover, and ensure system availability across development, staging, and production environments.

About this task

Important:
The procedure that is provided in this document is intended to restart a shut down database. Use the steps provided in this document only when the database is in a stable state and is ready to be restarted. For more information about shutting down the database, see Shutting down the Postgres database in the Management subsystem on different environments.

A database is shut down for various reasons as mentioned below.

- At times, the system automatically shuts down the database to prevent corruption when a critical error occurs.
- Sometimes, an administrator manually shuts down the database before performing maintenance, such as a server restart.

Restart the database manually only in the following circumstances.

- The underlying issue that caused the database to be shut down is resolved.
- You are certain that restarting the database will not reintroduce risk to the system.

To start the Postgres database:

Note: The OVA package includes API Connect with the CNP plug-in preinstalled. For other environments, install the CNP plug-in from https://github.com/EnterpriseDB/kubectl-cnp. For non-OVA environments, you must manually install the CNP plug-in version `v1.22.4` to ensure compatibility with the Cloud Native PostgreSQL operator used by API Connect.

Procedure

If you have the CNP plug-in preinstalled, to start the Postgres database:

a. Get the cluster name by running the following command.

```
kubectl get clusters.postgresql.k8s.enterprisedb.io
```

b. Start the cluster by running the following command.

```
kubectl cnp fencing off <cluster_name_from_above_command> "*"
```

Tip: You can start the Postgres database even if you don't have the CNP plug-in preinstalled.

a. Get the cluster name by running the following command.

```
kubectl get clusters.postgresql.k8s.enterprisedb.io
```

b. Start the cluster by running the following command.

```
kubectl annotate cluster <cluster_name_from_above_command> k8s.enterprisedb.io/fencedInstances- -n <namespace>
```

Remember: Remember to replace `<cluster_name_from_above_command>` and `<namespace>`, as required.

Results

The Postgres database in the Management subsystem is successfully started.

Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later

This section describes the default affinity, nodeSelector, and toleration settings of EDB Postgres and Operator pods and examples of how to customize them.

EDB Postgres pods

Defaults for EDB Postgres pods

The following are the Postgres pods default:
Note: The following are examples only and it can vary from your pod name.
The following are the rules for Affinity:

- Required: Repels its own pods within the same hostname.
- Preferred: Repels edb-operator pods within the same hostname.

```
spec:
  affinity:
    podAntiAffinity:
      preferredDuringSchedulingIgnoredDuringExecution:
      - podAffinityTerm:
          labelSelector:
            matchExpressions:
            - key: app.kubernetes.io/name
              operator: In
              values:
              - cloud-native-postgresql
          namespaceSelector: {}
          topologyKey: kubernetes.io/hostname
        weight: 100
      requiredDuringSchedulingIgnoredDuringExecution:
      - labelSelector:
          matchExpressions:
          - key: k8s.enterprisedb.io/cluster
            operator: In
            values:
            - management-b6d7a59d-db
        topologyKey: kubernetes.io/hostname
```

Tolerations:

```
tolerations:
  - effect: NoExecute
    key: node.kubernetes.io/not-ready
    operator: Exists
    tolerationSeconds: 300
  - effect: NoExecute
    key: node.kubernetes.io/unreachable
    operator: Exists
    tolerationSeconds: 300
```

NodeSelector: None

Customization

To customize affinity (which can be nodeAffinity, podAffinity, podAntiAffinity),nodeSelector, or toleration, you need to add a template in the spec section of the ManagementCluster. This template will help you set the desired rules for pod placement in your Kubernetes cluster.

```
spec:
  template:
  - name: edb-cluster
    affinity:
      nodeAffinity:
         <your settings>
      podAffinity:
         <your settings>
      podAntiAffinity:
         <your settings>
    nodeSelector:
      <your settings>
    tolerations:
      <your settings>
```

To customize a deployment using API ConnectCluster CR for OpenShift or CP4i deployments, you can use the following template:

```
spec:
  template:
# management services must be specified with prefix "mgmt-"
  - name: mgmt-edb-cluster
    affinity:
      nodeAffinity:
         <your settings>
      podAffinity:
         <your settings>
      podAntiAffinity:
         <your settings>
    nodeSelector:
      <your settings>
    tolerations:
      <your settings>
```

EDB operator pods

Defaults for EDB operator pods

The following are the rules for Affinity:

- Preferred: Repels its own pods within the same hostname.
- Preferred: Repels Postgres pods with podRole=instance (all Postgres master and replica pods) within the same hostname.

```
spec:
  affinity:
    podAntiAffinity:
      preferredDuringSchedulingIgnoredDuringExecution:
      - podAffinityTerm:
          labelSelector:
            matchExpressions:
            - key: app.kubernetes.io/instance
              operator: In
              values:
              - management
            - key: app.kubernetes.io/managed-by
              operator: In
              values:
              - ibm-apiconnect
            - key: app.kubernetes.io/name
              operator: In
              values:
              - cloud-native-postgresql
          topologyKey: kubernetes.io/hostname
        weight: 100
      - podAffinityTerm:
          labelSelector:
            matchExpressions:
            - key: app.kubernetes.io/instance
              operator: In
              values:
              - management
            - key: app.kubernetes.io/managed-by
              operator: In
              values:
              - ibm-apiconnect
            - key: k8s.enterprisedb.io/podRole
              operator: In
              values:
              - instance
          namespaceSelector: {}
          topologyKey: kubernetes.io/hostname
        weight: 100
```

Tolerations:

```
tolerations:
  - effect: NoExecute
```

```
    key: node.kubernetes.io/not-ready
    operator: Exists
    tolerationSeconds: 300
  - effect: NoExecute
    key: node.kubernetes.io/unreachable
    operator: Exists
    tolerationSeconds: 300
```

NodeSelector: None

- **Configuring zone affinity in the management subsystem**
  After installing IBM® API Connect, you can configure zone affinity in the management subsystem to improve high availability and resilience. You can update either the top-level change request (CR) or the Management CR to confirm that each PostgresSQL database pod is scheduled in a separate availability zone.

Configuring zone affinity in the management subsystem

After installing IBM® API Connect, you can configure zone affinity in the management subsystem to improve high availability and resilience. You can update either the top-level change request (CR) or the Management CR to confirm that each PostgresSQL database pod is scheduled in a separate availability zone.

Procedure

1. Add a template to the available change request by running the appropriate command.
   Note: If the top-level CR is available, add the template to it. If the top-level CR is not available, add the template to the Management CR.

Change Request	Command

Top-level CR	`spec:`
	`  template:`
	`  - affinity:`
	`  podAntiAffinity:`
	`  preferredDuringSchedulingIgnoredDuringExecution:`
	`  - podAffinityTerm:`
	`  labelSelector:`
	`  matchExpressions:`
	`  - key: k8s.enterprisedb.io/podRole`
	`  operator: In`
	`  values:`
	`  - instance`
	`  topologyKey: topology.kubernetes.io/zone`
	`  weight: 100`
	`  name: mgmt-edb-cluster`

Management CR	`spec:`
	`  template:`
	`  - affinity:`
	`  podAntiAffinity:`
	`  preferredDuringSchedulingIgnoredDuringExecution:`
	`  - podAffinityTerm:`
	`  labelSelector:`
	`  matchExpressions:`
	`  - key: k8s.enterprisedb.io/podRole`
	`  operator: In`
	`  values:`
	`  - instance`
	`  topologyKey: topology.kubernetes.io/zone`
	`  weight: 100`
	`  name: edb-cluster`

   After the template is added, some pods restart. However, you need to make further updates to the EDB cluster.

   Tip: You can check whether the top-level CR is present by running the following command.

   ```
   oc get apiconnectcluster
   ```

2. To display the name and node for the primary Postgres pod, run the following command for your management system.

   ```
   kubectl -n <namespace> get po -l role=primary -o wide
   ```

   Or

   ```
   oc get po -l role=primary -o wide
   ```

   Note the name of the pod and the zone that it is running in.

3. To display the name and node for the replica postgres pods, run the following command for your management system.

   ```
   kubectl -n <namespace> get po -l role=replica -o wide
   ```

   Or

   ```
   oc get po -l role=replica -o wide
   ```

   Note the name of the pods and the zones that they are running in.

   Note: Identify the replicas that are in the same zone as the primary or as each other. Each pod must be located in a different zone. Remove any pod and related PersistentVolumeClaims (PVCs) that are in the same zone as the primary or another replica.
4. To list the PVC and PersistentVolumes (PV) that are to be deleted, run the following command.

```
kubectl get pod <pod-name> -n <namespace> -o json | jq -r '
  .spec.volumes[]
  | select(.persistentVolumeClaim)
  | .persistentVolumeClaim.claimName
' | while read pvc; do
  pv=$(kubectl get pvc "$pvc" -n <namespace> -o jsonpath='{.spec.volumeName}')
  echo "$pvc -> $pv"
done
```

Or

```
oc get pod <pod-name> -o json | jq -r '
  .spec.volumes[]
  | select(.persistentVolumeClaim)
  | .persistentVolumeClaim.claimName
' | while read pvc; do
  pv=$(oc get pvc "$pvc" -n <namespace> -o jsonpath='{.spec.volumeName}')
  echo "$pvc -> $pv"
done
```

5. To delete the listed PVC, PV, and the associated pod, run the following command.

```
kubectl n <namespace> delete pvc <pvc-name>
kubectl n <namespace> delete pv <pv-name>
kubectl n <namespace> delete pod <pod-name>
```

Or

```
oc delete pvc <pvc-name>
oc delete pv <pv-name>
oc delete pod <pod-name>
```

6. To verify that the new pods are displayed in the correct zone to replace the deleted replica, run the following command.

```
kubectl -n <namespace> get po -l role -o wide
```

Or

```
oc get po -l role-o wide
```

Postgres database shutdown

This document provides detailed guidance to shut down and start the Postgres database to prevent any changes during the migration process.

- **Shutting down the Postgres database in the Management subsystem on different environments**
  Shut down or fence the Postgres database in the Management subsystem to prevent data corruption, ensure safe failover, or perform maintenance tasks across development, staging, and production environments.
- **Starting the Postgres database in the Management subsystem on different environments**
  Restart or unfence the Postgres database in the Management subsystem to restore connectivity, resume normal operations after maintenance or failover, and ensure system availability across development, staging, and production environments.

Shutting down the Postgres database in the Management subsystem on different environments

Shut down or fence the Postgres database in the Management subsystem to prevent data corruption, ensure safe failover, or perform maintenance tasks across development, staging, and production environments.

Before you begin

- Make sure that the EDB cluster is healthy and running.
- If the EDB cluster shuts down due to an issue in any environment, such as full disks, resolve the issue and then restart the cluster.

About this task

The shutdown of the Postgres database is controlled using the `k8s.enterprisedb.io/fencedInstances` annotation, which accepts a JSON-formatted list of instance names. If the annotation is set to `["*"]`, a singleton list with a wildcard, the entire cluster is shut down. To shut down only one EDB instance, replace the `"*"` in the command with the instance name.

Note: The OVA package includes API Connect with the CNP plug-in preinstalled. To install the CNP plug-in for other environments, see https://github.com/EnterpriseDB/kubectl-cnp. For non-OVA environments, you must manually install the CNP plug-in version `v1.22.4` to ensure compatibility with the Cloud Native PostgreSQL operator used by API Connect.

Procedure

1. If you are on an appliance (VMware), to run the `kubectl` commands, connect to the Management node and log in as root user (`sudo -i`).

2. Shut down the cluster using the preinstalled CNP plug-in.
   a. To get the cluster name, run the following command.

      ```
      kubectl get clusters.postgresql.k8s.enterprisedb.io
      ```

   b. To shut down the cluster, run the following command.

      ```
      kubectl cnp fencing on <cluster_name_from_above_command> "*"
      ```

   Tip: You can also shut down the cluster if CNP plug-in is not preinstalled.
   a. To get the cluster name, run the following command.

      ```
      kubectl get clusters.postgresql.k8s.enterprisedb.io
      ```

   b. To shut down all the instances of the database, run the following command.

      ```
      kubectl annotate cluster <cluster_name_from_above_command> k8s.enterprisedb.io/fencedInstances='["*"]' -n <namespace>
      ```

   c. To shut down one instance of the database by passing the instance name, run the following command.

      ```
      kubectl annotate cluster <cluster_name_from_above_command> k8s.enterprisedb.io/fencedInstances='["<instance-name-db-1>"]' -n <namespace>
      ```

Results

The Postgres database in Management subsystem is now shut down.

Starting the Postgres database in the Management subsystem on different environments

Restart or unfence the Postgres database in the Management subsystem to restore connectivity, resume normal operations after maintenance or failover, and ensure system availability across development, staging, and production environments.

About this task

Important:
The procedure that is provided in this document is intended to restart a shut down database. Use the steps provided in this document only when the database is in a stable state and is ready to be restarted. For more information about shutting down the database, see Shutting down the Postgres database in the Management subsystem on different environments.

A database is shut down for various reasons as mentioned below.

- At times, the system automatically shuts down the database to prevent corruption when a critical error occurs.
- Sometimes, an administrator manually shuts down the database before performing maintenance, such as a server restart.

Restart the database manually only in the following circumstances.

- The underlying issue that caused the database to be shut down is resolved.
- You are certain that restarting the database will not reintroduce risk to the system.

To start the Postgres database:
Note: The OVA package includes API Connect with the CNP plug-in preinstalled. For other environments, install the CNP plug-in from https://github.com/EnterpriseDB/kubectl-cnp. For non-OVA environments, you must manually install the CNP plug-in version `v1.22.4` to ensure compatibility with the Cloud Native PostgreSQL operator used by API Connect.

Procedure

If you have the CNP plug-in preinstalled, to start the Postgres database:

a. Get the cluster name by running the following command.

   ```
   kubectl get clusters.postgresql.k8s.enterprisedb.io
   ```

b. Start the cluster by running the following command.

   ```
   kubectl cnp fencing off <cluster_name_from_above_command> "*"
   ```

Tip: You can start the Postgres database even if you don't have the CNP plug-in preinstalled.

a. Get the cluster name by running the following command.

   ```
   kubectl get clusters.postgresql.k8s.enterprisedb.io
   ```

b. Start the cluster by running the following command.

   ```
   kubectl annotate cluster <cluster_name_from_above_command> k8s.enterprisedb.io/fencedInstances- -n <namespace>
   ```

   Remember: Remember to replace `<cluster_name_from_above_command>` and `<namespace>`, as required.

Results

The Postgres database in the Management subsystem is successfully started.

Disabling the status feedback on products page

You can view the state of the products on the Products page inside a catalog. Administrators have the flexibility to show or hide this status feedback on the Products page. Regardless of this setting, the state of the product lifecycle events remains visible on the Gateway processing status pages so that the critical deployment information remains accessible to administrators.

About this task

You can show or hide the state of the product on the Products page in a catalog. To hide the state of the product on the Products page in a catalog, you add the DISABLE_RESOURCE_STATUS variable to the deployment configuration. When set to true, the state is hidden. When set to false, the state is displayed on the Products page.

Procedure

1. Locate the API Manager deployment.

   ```
   kubectl --kubeconfig <kubeconfig_file> -n <namespace> get deploy
   ```

2. Edit the API Manager deployment.

   ```
   kubectl --kubeconfig <kubeconfig_file> -n <namespace> edit deploy <deployment_name>
   ```

3. In the environment section of the deployment configuration, add a variable:

   ```
   - name: DISABLE_RESOURCE_STATUS
     value: "true"
   ```

4. Save the updated configuration.

Advanced configuration for the analytics subsystem

Specify advanced configuration for the analytics subsystem on Kubernetes, OpenShift, or Cloud Pak for Integration.

To manage advanced analytics features, see: Advanced configuration for the analytics subsystem.

Advanced configuration for the gateway subsystem

Specify advanced configuration for the gateway subsystem.

See:

- **Customizing a DataPower deployment**
  Update the `GatewayCluster` CR to configure `DataPowerService` APIs to customize your DataPower deployment.
- **Updating the gateway password, secrets, and certificates**
  How to update the gateway administrator password, the client_secret, the peering secret, and the invocation endpoint certificate.
- **Overriding the default DataPower image, version, and license**
  Update the `GatewayCluster` CR to override the image, version, and license information for the Gateway subsystem.
- **Overriding pod CPU and memory settings**
  Use template overrides to set a higher CPU and memory for your gateway pod.
- **Enabling autoscaling of gateway pods**
  Enable autoscaling of gateway pods to ensure high availability of DataPower pods.
- **Configuring rate limits on the gateway nodes**
  Create an env.yaml file on each Gateway node to configure the default rate limit.
- **Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment**
  In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.
- **Overriding DataPowerService spec properties**
  Use the `dataPowerServiceSpecOverride` to configure `DataPowerService` spec-level properties.

Customizing a DataPower deployment

Update the `GatewayCluster` CR to configure `DataPowerService` APIs to customize your DataPower deployment.

You can set the following properties in the CR. Note that each `GatewayCluster` CR property has a corresponding `DataPowerService` API. Refer to the DataPower Operator documentation link for each property:
Note: If you are using a top-level CR (`APIConnectCluster`), ensure that the `spec.gateway` section is included. If it is missing, add the `spec.gateway` section first before adding the required property within it.

Table 1. Mapping of `GatewayCluster` properties to `DataPowerService` properties

GatewayCluster property	DataPowerService property	DataPowerService API Docs
`additionalDomainConfig`	`domains`	domains For domain configuration, see also: • Guides: Domain Configuration • Features: Configuration Management
`additionalExtraExe`	`extraExe`	extraExe
`additionalInitCmds`	`initCmds`	initCmds
`lifecycle`	`lifecycle`	lifecycle
`healthcheck`	`healthcheck`	healthcheck
`readinessTimeoutSeconds`	`readinessTimeoutSeconds`	readinessTimeoutSeconds
`hostAliases`	`hostAliases`	hostAliases

Examples of how to add the DataPower service properties to a `GatewayCluster` CR, in an API Connect deployment on native Kubernetes:

- Adding `additionalDomainConfig`:

```
spec:
  additionalDomainConfig:
  - name: "default"
    certs:
    - certType: "usrcerts"
      secret: "default-cert"
    - certType: "sharedcerts"
      secret: "shared-cert"
    dpApp:
      config:
      - "default-config"
      local:
      - "default-local"
```

- Extending the `apiconnect` domain:

```
spec:
  additionalDomainConfig:
  - name: "apiconnect"
    dpApp:
      config:
      - "custom-apiconnect-config"
      local:
      - "custom-apiconnect-local"
```

Updating the gateway password, secrets, and certificates

How to update the gateway administrator password, the client_secret, the peering secret, and the invocation endpoint certificate.

- **Changing the gateway administrator password**
  Change the gateway administrator password by updating the CR and reinstalling the subsystem.
- **Changing the gateway client secret**
  The gateway subsystem receives its `client_secret` from the management subsystem.
- **Updating the gateway peering certificate**
  Update the certificate that secures communication between gateways in your API Connect deployment.
- **Updating the gateway director and invocation endpoint profiles**
  Update the TLS profile that secures communications with the gateway subsystem in your API Connect deployment.

Changing the gateway administrator password

Change the gateway administrator password by updating the CR and reinstalling the subsystem.

About this task

Updating the administrator password for the gateway subsystem requires no measurable reduction in API enforcement performance (gateways remain "up"); however, services such as SNMP will experience a disconnect until the password is updated on all pods.

Procedure

1. Get the name of the secret that is used in the gateway CR.
   a. Run the following command to get the gateway's `secretName`:

      ```
      kubectl -n <namespace> get gatewaycluster <gw-cluster-name> -o yaml
      ```

      where *`<namespace>`* is the namespace where you installed the gateway subsystem, and *`<gw-cluster-name>`* is the name of the gateway cluster.

      In the CR, the gateway's `secretName` is in the `adminUser` section.

   b. Note down the secret name for use in a later step.
2. Scale the *`<gw-cluster-name>`* to 0 pods.
   a. Using the following example as a guide, set `replicaCount=0` for the *`<gw-cluster-name>`*.

```
kubectl -n <namespace> patch gatewaycluster <gw-cluster-name> --type json -p='[{"op": "add", "path":
"/spec/replicaCount", "value": 0 }]'
```

b. Validate that `statefulset READY = 0/0`.
Run the following command:

```
kubectl  -n <namespace> get statefulset <gw-cluster-name>
```

A successful response looks like the following example:

```
NAME   READY   AGE
gwv6   0/0     18h
```

3. Update the gateway's secret.
   a. Run the following command to edit the gateway's `secretName`:

```
kubectl -n <namespace> edit secret secretName
```

   b. Change the value of `.data.password` to be the base64-encoded value of a new password. The new password can be any string you want but you must encode it to base64.
4. Scale the gateway back up to the correct number of pods.
   a. Using the following example as a guide, set `replicaCount=3` for *<gw-cluster-name>*.

```
kubectl -n <namespace> patch gatewaycluster <gw-cluster-name> --type json -p='[{"op": "add", "path":
"/spec/replicaCount", "value": 3 }]'
```

   b. Validate that `statefulset READY = 3/3` (this step might take few minutes to complete).
   Run the following command:

```
kubectl  -n <namespace> get statefulset <gw-cluster-name>
```

   A successful response looks like the following example:

```
NAME   READY   AGE
gwv6   3/3     18h
```

5. Verify that the gateway subsystem is fully updated.
   Run the following command, replacing *<namespace>* with the appropriate namespace.

```
kubectl -n namespace get GatewayCluster
```

   The update is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online (`2/2`) for all the Gateway subsystems that were updated. Example:

```
NAME   READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
gwv5   True    2/2       10.0.8.0   10.0.8.0-1219        7m31s
gwv6   True    2/2       10.0.8.0   10.0.8.0-1219        7m32s
```

Changing the gateway client secret

The gateway subsystem receives its `client_secret` from the management subsystem.

About this task

If you changed the `client_secret` on the management subsystem, force a dynamic reconfiguration and reregistration (DRR) as explained in How can I force re-population of the configuration data?. On completion, the gateway subsystem uses the new `client_secret` in its communications with the management subsystem.

Updating the gateway peering certificate

Update the certificate that secures communication between gateways in your API Connect deployment.

About this task

This task covers updating the gateway peering certificate, which is used to secure communication between gateway cluster members, on Kubernetes and OpenShift deployments.
Note: For gateway appliance deployments, you must manually update the Gateway Peering Identification Credential and Validation Credential objects.
The gateway peering certificate is stored in a Kubernetes secret. To update the certificate, delete this secret so that the cert-manager creates a new secret that contains a new peering certificate.

Important: If you are updating the peering certificate because you updated the ingress-ca certificate, then the update causes a gateway outage and the gateway pods must be manually restarted.

Procedure

1. Determine the name of your gateway cluster CR:

```
kubectl get GatewayCluster
```

2. Determine the name of the gateway peering secret:

```
kubectl get -o yaml gatewayCluster <gateway cluster>
```

where *<gateway cluster>* is the name that you obtained in step 1.

The name of the secret is defined in `spec.apicGatewayPeeringTLS.secretName`, for example:

```
spec:
  ...
  apicGatewayPeeringTLS:
    secretName: apic-ocp-gw-peer
```

3. Delete the gateway peering secret:

```
kubectl delete secret <gateway peering secret>
```

where *<gateway peering secret>* is the name that you identified in step 2.
A new gateway peering secret is created and a rollout restart of the gateway statefulset is triggered.

4. If the `ingress-ca` certificate was also updated, then the rollout restart does not complete, and you must restart the gateway pods manually:

```
kubectl delete pod <gw pod1> <gw pod2> <gw pod3>
```

5. To verify the update, check the age of the gateway peering secret to confirm a new secret was created:

```
kubectl get secret <gateway peering secret>
```

```
NAME                        TYPE                DATA   AGE
<gateway peering secret>    kubernetes.io/tls   3      30s
```

Updating the gateway director and invocation endpoint profiles

Update the TLS profile that secures communications with the gateway subsystem in your API Connect deployment.

Update the gateway API invocation certificate and the gateway director client certificate in the TLS profiles that are configured for your gateway service in the Cloud Manager UI. See Registering a gateway service and TLS profiles overview.

To update the gateway director server certificate on Kubernetes deployments, update the Kubernetes secret: `gwv6-manager-endpoint/gw-gateway-manager`.

Overriding the default DataPower image, version, and license

Update the `GatewayCluster` CR to override the image, version, and license information for the Gateway subsystem.

Procedure

To override these settings in the CR, add a `spec.dataPowerOverride` section as shown in the following example:

- If you deployed the gateway subsystem on Kubernetes, or if you deployed the individual gateway subsystem on OpenShift, add the override to the `spec` section of the Gateway CR:

```
spec:
   dataPowerOverride:
     image: customregistry.com/custom-image-datapower:10.6.5.0
     version: 10.6.5.0
     license: X-XXXX-XXXXXX
```

- If you deployed all API Connect subsystems at once on OpenShift using the top-level `apiconnectcluster` CR, add the override to the `spec.gateway` section:

```
spec:
  gateway:
    dataPowerOverride:
      image: customregistry.com/custom-image-datapower:10.6.5.0
      version: 10.6.5.0
      license: X-XXXX-XXXXXX
```

For information about the minimum DataPower Operator version and licenses by version, see:

- Operand Version Matrix
- Licenses

Overriding pod CPU and memory settings

Use template overrides to set a higher CPU and memory for your gateway pod.

About this task

Important: The recommended method to increase the resources for your API Connect deployment is to change deployment profile:

- Changing deployment profiles on Kubernetes and OpenShift

- Changing deployment profiles on OpenShift top-level CR
- Changing the deployment profile on Cloud Pak for Integration

Increasing the number of CPUs impacts API Connect licensing. See Deployment and component profiles.

Note: For OpenShift® users - The example steps in this document use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR (`APIConnectCluster`), make sure that the `spec.gateway` section is included. If it is not included already, you must add the `spec.gateway` section before adding the required property within it.

Procedure

1. Edit the gateway CR:

   ```
   kubectl edit gw
   ```

2. Add a `spec.template` section with the new memory and CPU settings. For example:

   ```
   template:
   - name: datapower
     containers:
     - name: gateway
       resources:
         limits:
           cpu: 4
           memory:  12Gi
         requests:
           cpu: 2
           memory: 10Gi
   ```

   Note:
   The default memory limit and request is 8Gi. The memory limit must always be greater than or equal to the memory request.

   For information about overriding other properties, see Overriding the default DataPower image, version, and license.

   The template override mechanism is specific only to the CPU and memory values, and cannot be used for other resource requests in the DataPower Gateway CR.

Enabling autoscaling of gateway pods

Enable autoscaling of gateway pods to ensure high availability of DataPower pods.

Autoscaling enables the gateway deployment to scale dynamically, either vertically or horizontally.

It is not possible to use both horizontal and vertical pod scaling simultaneously. You must configure either `HPA` (for horizontal scaling) or `VPA` (for vertical scaling) as scaling method.

- To enable HPA, add the following fields to the CR:
  In OpenShift or Cloud Pak for Integration, add the fields to the `spec.gateway` section of the API Connect Cluster CR.

  ```
  podAutoScaling:
    hpa:
      maxReplicas: 5
      minReplicas: 3
      targetCPUUtilizationPercentage: 90
      targetMemoryUtilizationPercentage: 80
    method: HPA
  ```

- To enable VPA, add the following fields to the CR:
  In OpenShift or Cloud Pak for Integration, add the fields to the `spec.gateway` section of the API Connect Cluster CR.

  ```
  podAutoScaling:
    method: VPA
    vpa:
      maxAllowedCPU: 4
      maxAllowedMemory: 16G
  ```

Note that the values shown in the CR entries are just examples.

Table 1. Autoscaling configuration settings

Setting	Description
`method`	Specifies either Horizontal Pod Autoscaling or Vertical Pod Autoscaling Value must be either `HPA` or `VPA`. To disable autoscaling, leave `method` blank or omit the `podAutoScaling:` section from the CR.
`maxReplicas`	HPA. Maximum pods that can be scaled up to by the horizontal pod autoscaler. Must be a value greater than `minReplicas`.
`minReplicas`	HPA. Minimum pods that can be scaled down to by the horizontal pod autoscaler.
`targetCPUUtilizationPercentage:`	HPA. Percent threshold on average CPU usage by pods for triggering horizontal scaling.
`targetMemoryUtilizationPercentage`	HPA. Percent threshold on average memory usage by pods for triggering horizontal scaling.
`maxAllowedCPU`	VPA. Maximum value for CPU resource that can be assigned to a DataPower container when scaling vertically. Minimum value is set from `DataPowerRequestsSpec.ResourceCPU`
`maxAllowedMemory`	VPA. Maximum amount of memory that can be assigned to a DataPower container when scaling vertically. Minimum value is set from `DataPowerRequestsSpec.ResourceMemory`

Note:

DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when pods are scaled down based on defined CPU or memory thresholds. Workloads with long-lived connections are more vulnerable to failed API transactions when auto-scaling is occurring.

To learn more about HPA and VPA autoscaling, see

- https://ibm.github.io/datapower-operator-doc/features/pod-auto-scaling/
- https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta3#podautoscaling

Configuring rate limits on the gateway nodes

Create an env.yaml file on each Gateway node to configure the default rate limit.

The Gateway uses scale limits (instead of strict limits) by default to enforce rate limits. This improves the gateway's performance by providing the ability to handle large amounts of rate-limited traffic.

1. To configure the rate limit, create a file called env.yaml with the settings provided in Table 1:

Table 1. Rate limit settings

Setting	Type	Default	Optoins	Comments
`USE_RATE_LIMIT_DEFINITION`	boolean	`true`	• `true` Use scale limits • `false` Use strict limits	Determines the type of rate limiting to use on the Gateway node.
`RATE_LIMIT_UPDATE_MODE`	enumerated	`prior`	• `none`No limits in a plan are incremented after a limit is reached. • `all` All limits in a plan are incremented after a limit is reached. • `prior` Retains the behavior from pre-V10 releases: When the plan rate limit is reached, all limits in the plan that are sorted before that plan limit will be incremented.	Determines how the counts within a plan are incremented when a rate limit is hit. Applies only to scale limits.
`RATE_LIMIT_SORT_BY_DURATION`	boolean	`true`	• `true` Sort the rate limits by duration. • `false` Revert to the previous sort order.	Determines the sort order for rate limits in a plan, which in turn determines the sequence in which they are applied.
`RATE_LIMIT_USE_OFFSET`	boolean	`false`	• `true` Prevent all rate limit counts for an interval from being reset at the same time. • `false` Allow all rate limit counts for an interval to be reset at the same time.	Allow or prevent all of the rate limit counts for an interval from being reset at the same time. Preventing the simultaneous reset protects backends from being saturated with requests by resetting the counts for different subscribers of a plan at different points with in the interval. Applies only to scale limits.
`RATE_LIMIT_DEFINITION_RESPONSE_HEADERS`	boolean	`true`	• `true` Show the `x-rate-limit` headers. • `false` Hide the `x-rate-limit` headers.	Show or hide the `x-rate-limit` headers in an API response. Applies only to scale limits.

2. Save the file in the local:/ directory on the Gateway node so that the file persists on reboots of both physical and virtual machines. The settings apply only to the node where the file is stored, so each node in the Gateway cluster requires its own copy of the file.

Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

Preventing the loss of configuration data

For high availability in production environments, use a minimum of three gateways in the Gateway service.

Forcing re-population of the configuration data

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the **apic-gw-service**. This task can only be performed with CLI, and requires the default admin ID for running the **diag** command.

1. Access the gateway service:
   - For a virtual gateway, run the following command to access the DataPower CLI:

     ```
     kubectl attach -it <pod_name>
     ```

   - For a physical gateway, use **ssh** to connect to the gateway service.
2. Switch to the API Connect application:

   ```
   switch <APIC_APP_DOMAIN>
   ```

3. Show the current gateway-peering-status:

   ```
   show gateway-peering-status
   ```

4. If the server that you connected to is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

   ```
   config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
   ```

5. Flush the apic-gw-service gateway-peering object:

   ```
   diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
   ```

   When prompted, confirm the operation.

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

   ```
   config; apic-gw-service; admin-state disabled; exit
   apic-gw-service; admin-state enabled; exit; exit
   ```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:
   Look in the debug log target for the apic-gw-service, located in logtemp:/// and check for a message similar to the following example:

   ```
   20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
   apic-gw-service(default): tid(2653): Waiting for gateway service registration.
   ```

   The DRR will be triggered by the next arrival of a webhook event. The Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In addition, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. If you attached to a virtual gateway, you can detach by pressing Ctrl+P and then pressing Ctrl+Q.
9. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:
   If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

   a. Open the API Manager.
   b. Open the Catalog.
   c. Click Settings > Edit.
   d. Update the Summary field with some text so that it is modified.
   e. Click Save.

When the event is received, the DRR is initiated.

Confirm that DRR is complete by testing your APIs. You can also use the health check API.

Overriding `DataPowerService` spec properties

Use the **dataPowerServiceSpecOverride** to configure **DataPowerService** spec-level properties.

Configure the **spec.dataPowerServiceSpecOverride** section in your gateway CR to set **DataPowerService** properties.

1. Edit your gateway CR:

   ```
   kubectl edit GatewayCluster
   ```

2. Add the **dataPowerServiceSpecOverride** section to the **spec** section (if it does not exist), and configure the properties as required.

Sample configurations:

- Specify a new environment:

```
spec:
  dataPowerServiceSpecOverride:
    env:
    - name: TEST_ENV
      value: "true"
```

- Add new `initCmds`:

```
spec:
  dataPowerServiceSpecOverride:
    initCmds:
    - ls -al /opt/ibm/datapower/drouter/config
```

If you are using the OpenShift top-level CR, then add the `dataPowerServiceSpecOverride` section to `spec.gateway`.

Advanced configuration for the portal subsystem

- **Updating portal keys and secrets**
  Update the database passwords, keys, and the `client_secret` values for your portal subsystem.

Updating portal keys and secrets

Update the database passwords, keys, and the `client_secret` values for your portal subsystem.

- **Changing the secret for portal data and system tools**
  Replace the encryption key that generates the secret used for securing the database and system tools that are used by the portal subsystem.
- **Changing the portal client_secret**
  Change the `client_secret` for the portal subsystem to keep it in sync with the management subsystem.

Changing the secret for portal data and system tools

Replace the encryption key that generates the secret used for securing the database and system tools that are used by the portal subsystem.

Before you begin

If you are using a stand-alone, single data center deployment, you can update the encryption key with the PortalSecretRotation CR, as explained in Renewing the portal-ca with the PortalSecretRotation CR. The PortalSecretRotation CR is not supported for a two data center configuration or a Cloud Pak for Integration deployment, so you must update the key manually as explained in the following steps.

About this task

The portal subsystem uses a database plus several system tools to manage storage, hot backups, and cluster synchronization. The following services are all secured with the secret that is generated by the portal CR during installation:

- MySQL root account for each portal site
- Csync2 cluster synchronization service

Updating the portal-encryption-secret will make the following changes to your deployment:

- Change the root MySQL password
- Generate a new, site-specific MySQL password for each site
- Generate a new csync2 cluster key
- Re-encrypt all client_ids and client_secrets in the portal database

If you need to change the secret, the update is applied to all of the listed services. You can change the secret by generating a new value and restarting pods to pick up the new value. In a two data center deployment, you must manually copy the new secret to the other site.

Procedure

Generate a new secret and apply it to the deployment using the appropriate steps for your environment:

- Single data center
  Run the following command to generate a new secret and apply it to the deployment:

  ```
  kubectl -n <namespace> patch secret portal-enc-key -p "{\"data\": {\"encryption_secret\":\"$(head -c74 /dev/urandom | base64 -w0 | tr '+/=' 'abc' | base64 -w0)\"}}"
  ```

  where *namespace* is the namespace where you installed the portal subsystem.

  The `portal-enc-key` was generated during installation and added to the CR as the `encryptionSecret` setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the Portal installation as recommended, be sure to update that file now.

- Two data centers

a. Generate the new secret on DC1 by running the following command:

```
head -c74 /dev/urandom | base64 -w0 | tr '+/=' 'abc' | base64 -w0 > secret.txt
```

The **portal-enc-key** was generated during installation and added to the CR as the **encryptionSecret** setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the Portal installation as recommended, be sure to update that file now.

b. Open a terminal to each DC in the same working directory where you saved **secret.txt** (or, copy the file to somewhere you can open a terminal to each DC).

c. In each terminal, verity that you can access **secret.txt** by typing the following command:

```
echo $(<secret.txt)
```

d. In each terminal, type the following command -- but do not press Enter yet:

```
kubectl -n <namespace> patch secret portal-enc-key -p "{\"data\": {\"encryption_secret\":\"$(<secret.txt)\"}}"
```

where ***namespace*** is the namespace where you installed the portal subsystem.

e. Press Enter in both terminals at the same time (or as close in time as possible).
There is a 5-minute time-out that starts as soon as any of the pods has the new secret mounted by Kubernetes. All pods will get the secret at slightly different times, but within about a minute of each other. If the 5-minute time-out expires before all pods across both DCs have the new secret, then the pods will rotate the new secret in at different times, resulting in errors in the logs and some down time for various pods, until they manage to rotate the new secret into use and recover.

Results

When pods restart, the new secret is used to secure the services. The **portal-www** admin logs display messages as the new secret is used to re-encrypt the database. The following example shows sample log messages when the updated secret is applied to the database:

```
[   upgrade stdout]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: NEW k8s encryption key detected on this system!
Reencrypting portal data
[   upgrade stderr]  2954 888ec0:73add2:7fce1b 2020-08-06 13:16:21: refresh_encryption_key: Command Started:
/opt/ibm/bin/refresh_encryption_key
FEgX8F5MXtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zhl1rVNFZTlzRnVfkGheLr9Le/Pb9jq
[   upgrade stdout]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: No portal service exists! Simply overriding the key
[   upgrade stdout]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: New key installed
(FEgX8F5MXtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zhl1rVNFZTlzRnVfkGheLr9Le/Pb9jq)
[   upgrade stderr]  2954 888ec0:73add2:7fce1b 2020-08-06 13:16:21: refresh_encryption_key: Command Finished:
/opt/ibm/bin/refresh_encryption_key
FEgX8F5MXtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zhl1rVNFZTlzRnVfkGheLr9Le/Pb9jq with RC 0
[   upgrade stderr]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: Command Finished: /opt/ibm/bin/sysupgrade with RC 0
```

If there is a portal service registered and developer portal sites installed, then this task re-encrypts that data as well. When the site encryption is complete, the log displays a "Command Finished" message for the **refresh_encryption_key** command, as shown in the following example:

```
Command Finished: /opt/ibm/bin/refresh_encryption_key <KEY> with RC 0
```

Changing the portal client_secret

Change the **client_secret** for the portal subsystem to keep it in sync with the management subsystem.

About this task

The portal subsystem uses the same **client_secret** as the management subsystem. If you change the **client_secret** on the management subsystem, update the portal subsystem by pulling the credential from the management subsystem.

Note: If you did not deploy the portal subsystem, skip this task.

Procedure

1. On a portal pod, run the following command to pull the portal service's **client_secret** from the management subsystem:

   ```
   kubectl -n namespace exec -t portal-mydc-www-0 -- bash -ic refresh_cloud_credentials
   ```

   where ***namespace*** is the namespace where you installed the portal subsystem.

2. Then, run the following command to update the credential for the portal sites:
   Note: If you did not deploy any portal sites, skip this step.

   ```
   kubectl -n namespace exec -t portal-mydc-www-0 -- bash -ic "refresh_site_credentials -a"
   ```

   where ***namespace*** is the namespace where you installed the portal subsystem.

Backing up, restoring, and disaster recovery

Backup your API Connect subsystems, configure scheduled database backups, and recover from a disaster.

Backups for the management, portal, and analytics subsystems consist of an infrastructure configuration backup and a database backup.
Note: The gateway receives all its configuration from the management subsystem, and does not require a backup.

Note: If you installed API Connect with Cloud Pak for Integration, you can use Red Hat OpenShift API for Data Protection (OADP) to backup your infrastructure configuration and subsystem databases. For more information about OADP, see Administering backup and restore in Cloud Pak for Integration.

Infrastructure configuration backup
: Your infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:

  - Subsystem YAML files (or top-level CR YAML file).
  - Custom certificates. Such as certificates used to secure communication with remote systems like analytics offload targets.
  - Encryption secrets.
  - Backup secrets.

  The infrastructure configuration backup is also referred to as the "config backup".

  If you have a disaster, your config backup is essential for restoring your API Connect subsystems.

  Config backups must be taken manually, by exporting your API Connect Kubernetes artifacts to YAML files. If you make a configuration change, you must update your config backup.

Subsystem database backups
: Your subsystem database backups contain everything that API Connect users configure in the API Connect UIs, the toolkit CLI, and the REST API. Subsystem database backups for portal contain all site customizations. The analytics database backup contains all your analytics data.

  Subsystem database backups can be configured to run automatically, and can also be taken on-demand.

  Important points:

  - Subsystem database backups are for recovery in the same environment that the backups were taken, or in a different environment that has the same network configuration and form factor. If you want to move your API Connect deployment to a different environment and change the form factor, or modify your API Connect endpoints, then see Migrating from v10 to v10 on a different form factor.
  - The management and portal subsystems databases must be kept in sync with each other, so take management and portal database backups at the same time. When you perform a management or portal database restore, complete the restoration of the management database first, and then restore the developer portal.

Two data center disaster recovery deployments

Two data center disaster recovery deployments have additional backup, restore, and disaster recovery considerations. Review the Backup and restore requirements for a 2DCDR deployment before you follow the topics in this section.

- **Backing up and restoring the management subsystem**
  How to backup and restore the infrastructure configuration and database of your management subsystem.
- **Backing up and restoring the developer portal**
  How to backup and restore the infrastructure configuration and database of your portal subsystem.
- **Backing up and restoring the analytics subsystem**
  How to configure analytics backups and recover from a disaster.
- **Backing up and restoring on OpenShift top-level CR**
  How to backup and restore your top-level CR deployment of API Connect
- **Backing up and restoring on Cloud Pak for Integration and OpenShift top-level CR**
  How to backup and restore all API Connect subsystem in a Cloud Pak for Integration, or OpenShift top-level CR deployment

Backing up and restoring the management subsystem

How to backup and restore the infrastructure configuration and database of your management subsystem.

The following topics cover how to backup, restore, and recover your management subsystem from a disaster.

- **Taking a management infrastructure configuration backup**
  How to backup your management subsystem deployment configuration.
- **Configuring management database backups**
  Configure scheduled database backups of your management subsystem.
- **Running an on-demand backup of the management database**
  Deploy the `Backup` CR to initiate a backup of the management database.
- **Restoring from a management database backup**
  Restore a management database backup, either with a `ManagementRestore` custom resource (CR), or by using a backup ID.
- **Recovering from a disaster**
  Reinstall the management subsystem by using your infrastructure configuration backup, then restore the management database backup.
- **Troubleshooting management database backup and restore**
  Common problems and how to diagnose issues with backup and restore.

Taking a management infrastructure configuration backup

How to backup your management subsystem deployment configuration.

About this task

Your infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:

- Subsystem YAML files (and top-level CR YAML file if used).
- Custom certificates.
- Encryption secrets.
- Backup secrets.

The infrastructure configuration backup is also referred to as the "config backup".

If you have a disaster, your config backup is essential for restoring your API Connect subsystems.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Export the management CR to a file called mgmt_cr_backup.yaml:

   ```
   kubectl -n <management namespace> get ManagementCluster -o yaml > mgmt_cr_backup.yaml
   ```

2. Export the management database encryption secret to a file called management_enc_key_backup.yaml:
   a. Get the name of the encryption secret:

      ```
      kubectl -n <management namespace> get mgmt -o yaml | grep encryption
      ```

   b. Take note of the `encryptionSecret` name returned:

      ```
      encryptionSecret: <management enc key>
      ```

   c. Backup the encryption secret to a YAML file:

      ```
      kubectl -n <management namespace> get secret <management enc key> -o yaml > management_enc_key_backup.yaml
      ```

3. Export your management database backup secret:

   ```
   kubectl -n <management namespace> get secret <mgmt backup secret> -o yaml > mgmt-backup-secret_backup.yaml
   ```

   The backup secret is created when you configure database backups: Create backup secret. If database backups are not yet configured, ensure that this secret is backed up when it is configured.

4. If you created a secret for your S3 store's CA certificate, take a backup of this secret:

   ```
   kubectl -n <management namespace> get secret <mgmt custom server ca> -o yaml > mgmt-custom-server-ca_backup.yaml
   ```

   The S3 CA secret is created when you configure database backups: Create S3 CA secret. If database backups are not yet configured, ensure that this secret is backed up when it is configured.
5. Export the management client application credential secrets to YAML files:
   a. Get the names of the credential secrets:

      ```
      kubectl -n <management namespace> get mgmt -o yaml | grep CredentialSecret
      ```

      Expected output is:

      ```
      atmCredentialSecret: management-atm-cred
      consumerToolkitCredentialSecret: management-ccli-cred
      consumerUICredentialSecret: management-cui-cred
      designerCredentialSecret: management-dsgr-cred
      discoveryCredentialSecret: management-discovery-cred
      governanceCredentialSecret: management-governance-cred
      juhuCredentialSecret: management-juhu-cred
      toolkitCredentialSecret: management-cli-cred
      uiCredentialSecret: management-ui-cred
      aiCredentialSecret: management-ai-cred
      ```

   b. Backup each credential secret to a YAML file:

      ```
      kubectl -n <management namespace> get secret <secret name> -o yaml > <secret name>_backup.yaml
      ```

      For example, to backup the ATM credential secret:

      ```
      kubectl -n <management namespace> get secret management-atm-cred -o yaml > management-atm-cred_backup.yaml
      ```

   c. Edit each credential secret YAML file and remove both the `ownerReferences` subsection and the `selfLink` property.
      Example of the `ownerReferences` and `selfLink` properties to be removed:

      ```
      ownerReferences:
        - apiVersion: management.apiconnect.ibm.com/v1beta1
          blockOwnerDeletion: true
          controller: true
          kind: ManagementCluster
          name: management
          uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
      selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
      ```

6. Export any other certificates that you customized. For example, if you customized the `apiManagerEndpoint` certificate, save the certificate by copying the corresponding secret to a YAML file:

   ```
   kubectl -n <management namespace> get secret apim-endpoint -o yaml > apim-endpoint_secret_backup.yaml
   ```

Configuring management database backups

Configure scheduled database backups of your management subsystem.

Before you begin

You must have a remote SFTP server or S3-compatible object-store for storing your management database backups. Example S3-compatible object-stores:

- AWS S3.
- IBM Cloud Object Storage.
- Custom S3 storage.

The object-store's backup folder must be empty.

About this task

Important points:

- Management database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a management database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see: Migrating from v10 to v10 on a different form factor.
- Ensure that you regularly take a Taking a management infrastructure configuration backup. If a disaster occurs and you lose your management subsystem configuration, then you cannot restore your management database backup without first restoring the config backup.
- Take portal database backups at the same time as you take management database backups.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Create a backup secret.
   The backup secret is a Kubernetes secret that contains your access key and secret for your SFTP server or object-store.
   Create the backup secret with the following command:
   - Object-store:

     ```
     kubectl -n <management namespace> create secret generic mgmt-backup-secret --from-literal=key='<access key>' \
     --from-literal=keysecret='<access secret>'
     ```

     where *<access key>* and *<access secret>* are the access credentials for your object-store.
   - SFTP username and password:

     ```
     kubectl -n <management namespace> create secret generic mgmt-backup-secret --from-literal=username='<username>' --
     from-literal=password='<password>'
     ```

   - SFTP username and SSH key:

     ```
     kubectl -n <management namespace> create secret generic mgmt-backup-secret --from-literal=username='<username>' --
     from-file=ssh-privatekey='<privatekeyfile>' [--from-literal=password='<privatekey_passphrase>']
     ```

   Take a backup of this secret and keep it with your Taking a management infrastructure configuration backup.

   Important: It is recommended to regularly update your backup secret:
   a. Run the same `kubectl create secret generic <secret name>` command, but with a new secret name and your updated access key and secret.
   b. Edit your management CR to update the secret name in `spec.databaseBackup.credentials`.
   c. Reload the secret in the management subsystem with:

      ```
      kubectl annotate mgmt <mgmt-subsystem-name> apiconnect-operator/management-db-reloaded-at=$(date -u +"%Y-%m-
      %dT%H:%M:%SZ") -n <management namespace> --overwrite
      ```

      where *<mgmt-subsystem-name>* is the name of your management subsystem CR.
2. If your object-store has a custom CA certificate, then create a Kubernetes secret that contains this CA certificate, so that your management subsystem trusts the object-store.
   a. Run the following command to create a Kubernetes secret from the certificate file:

      ```
      kubectl -n <management namespace> create secret generic mgmt-custom-objstore-ca --from-file=ca.crt=/path/to/cert.crt
      ```

      Note: Include the complete chain in your certificate file, for example:

      ```
      intermediate-certificate-1
      intermediate-certificate-2
      . . .
      intermediate-certificate-n
      root-certificate
      ```

      The first certificate (intermediate-certificate-1) is the issuer of the object-store server certificate, and each subsequent certificate is the issuer of the preceding certificate. The root certificate must be self-signed.
      If the certificate includes no intermediate certificates, then the file contains only the root certificate.

   b. Take a backup of the new secret.

      ```
      kubectl -n <management namespace> get secret mgmt-custom-objstore-ca -o yaml > mgmt-custom-objstore-ca.yaml
      ```

      Keep the generated mgmt-custom-objstore-ca.yaml file with your management infrastructure backup.
3. **Kubernetes and OpenShift individual subsystem CR users:** Edit your `ManagementCluster` CR:

   ```
   kubectl -n <management namespace> edit ManagementCluster
   ```

4. **Cloud Pak for Integration and OpenShift top-level CR users:** Edit your `APIConnectCluster` CR:

```
oc -n <apic namespace> edit APIConnectCluster
```

5. Configure your backup settings in the `databaseBackup` section of the `spec` object:

```
spec:
  databaseBackup:
    host: <host>/<region>
    port: <port number>
    protocol: [local|sftp|objstore]
    path: <path>
    credentials: <backup secret>
    backupCerts: <custom CA certificate>
    schedule: "<cron schedule>"
    repoRetentionFull: <number of days>
    backups3URIStyle: <path/host> # host or virtual style is the default
```

Note: On Cloud Pak for Integration and OpenShift when using the top-level CR, add the `databaseBackup` section to the `spec.management` section.
Set the properties as follows:

- `host` hostname of your remote SFTP server or object-store endpoint. If you are using an object-store and your endpoint does not have a region, then omit */<region>*.
- `port` is the listening port on your remote SFTP server or object-store. Defaults are 22 for SFTP and 443 for object-store.
- `path` is the location for your backups on your remote SFTP server or object-store. If you are using an object-store the format must be: `bucket_name/folder`.
- `protocol`: Type of remote backup site, `objstore` or `sftp`. If you do not have a remote backup site then, set to `local`.
- `credentials` is the name of the backup secret that you created in step 1.
- `backupCerts` is the CA certificate secret that is created in step 2.
- `schedule` is the schedule for when database backups are run, in `cron` format:

  ```
  * * * * * *
  - - - - - -
  | | | | | |
  | | | | | +----- day of week (0 - 6) (Sunday=0)
  | | | | +------- month (1 - 12)
  | | | +--------- day of month (1 - 31)
  | | +----------- hour (0 - 23)
  | +------------- min (0 - 59)
  +--------------- sec (0 - 59)
  ```

  For example:

  ```
  0 0 1 * * *
  ```

  runs a backup at 1 AM every day.

  The default is an empty string (no backup configured).

  Note: Set the same schedule as your developer portal database backups.
- `repoRetentionFull` is the number of days to retain backups for. For example, if `repoRetentionFull` is set to 30, then any backups older than 30 days are deleted.

  ```
  Minimum: 1
  Maximum: 9999999
  Default: 0 (No retention)
  ```

  Important points:
  - The `repoRetentionFull` start day is reset to the current day when you restore a management database backup.
  - `repoRetentionFull` applies to both manual backups and scheduled backups.
  - When older backups are deleted, their corresponding `backup` CR is deleted.
- `backups3URIStyle` applies to backups to object-store only. Indicates whether URIs to your object-store backup specify a host or a path value. Set to either `host` or `path`. The default is `host`.
  Some custom object-store providers require URI style to be set to `path`. For example, MinIO supports both host and path style setup. You can create a MinIO S3 server to accept only path style client communications.

  Important: Contact your custom object-store administrator before you configure this field. If not properly configured, an upstream custom object-store can reject connections from the client, such as the management subsystem.

What to do next

Run an on-demand backup to confirm that your backup configuration is correct, see Running an on-demand backup of the management database.

Running an on-demand backup of the management database

Deploy the `Backup` CR to initiate a backup of the management database.

About this task

If you are taking a management database backup, you should also take a portal database backup for all registered portal services. Management and portal databases must be kept in sync.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Verify the health of your **ManagementCluster**:

   ```
   kubectl -n <management namespace> get ManagementCluster
   ```

   The status should show **Running**, and all pods should be up:

   ```
   NAME    READY   STATUS    VERSION      RECONCILED VERSION   AGE
   mgmt    n/n     Running   10.0.8.0     10.0.8.0             19h
   ```

   Note: On Cloud Pak for Integration a **keycloak** cluster is also shown in this output. Check the status on the **ManagementCluster** only.
2. Identify the management database cluster name:

   ```
   kubectl -n <management namespace> get cluster
   ```

   Example output that shows the database cluster name is **m1-dc1-db**:

   ```
   NAME         AGE    INSTANCES   READY   STATUS                     PRIMARY
   m1-dc1-db    8d     3           3       Cluster in healthy state   m1-dc1-db-1
   ```

3. Create a file called mgmtbackup_cr.yaml and paste in the following text:

   ```
   apiVersion: postgresql.k8s.enterprisedb.io/v1
   kind: Backup
   metadata:
     generateName: mgmt-backup- # prefix for the name of the backup CR that is generated.
   spec:
     cluster:
       name: <database cluster name>
   ```

   where *<database cluster name>* is the cluster name that you identified in step 2.

4. Create the **Backup** CR from the mgmtbackup_cr.yaml file:

   ```
   kubectl -n <management namespace> create -f mgmtbackup_cr.yaml
   ```

5. Verify that the backup is running with:

   ```
   kubectl -n <management namespace> get backup -o custom-
   columns="name:.metadata.name,backupId:.status.backupId,endpoint:.status.endpointURL,path:.status.destinationPath,servernam
   e:.status.serverName,status:.status.phase"
   ```

   The expected output when the backup is completed is:

   ```
   name                  backupId          endpoint                                  path                        servername
   status
   test-backup-1.17.1    20230831T110022   https://apic-mgmt-s3proxy.default.svc:8765   s3://backups/backup01ibm    apic-mgmt-
   d54a2194-db-2023-08-31T11:49:10+01:00   completed
   ```

   Do not delete the **Backup** CR when the backup is complete. The **Backup** CR is required to restore the backup.

What to do next

Take a database backup of any portal subsystems that are registered with this management subsystem: Running an on-demand backup of the portal database.

Restoring from a management database backup

Restore a management database backup, either with a **ManagementRestore** custom resource (CR), or by using a backup ID.

Use a **ManagementRestore** CR when your management subsystem still has the **Backup** CR that was used to take the backup you want to restore.

Restore with a backup ID when your management subsystem does not have the **Backup** CR corresponding to the backup you want to restore. This situation can occur if the **Backup** CR was deleted, or in a disaster recovery situation where reinstall of the management subsystem is required.

- **Restoring the management database with a backup CR**
  Create a **ManagementRestore** CR that references the **Backup** CR of the backup you want to restore.
- **Restoring the management database with a backup ID**
  If the **Backup** CR is missing, but the backup is present on your remote SFTP server or object-store, you can restore the backup by using the backup ID.

Restoring the management database with a backup CR

Create a **ManagementRestore** CR that references the **Backup** CR of the backup you want to restore.

About this task

- Management database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a management database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.

- When you restore a management database backup, you must also restore the database backups of all registered developer portal services, so that the portal and management databases remain in sync.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Identify the existing backup CR that you want to restore:

   ```
   kubectl -n <management namespace> get backup -o custom-
   columns="name:.metadata.name,backupId:.status.backupId,endpoint:.status.endpointURL,path:.status.destinationPath,servernam
   e:.status.serverName,status:.status.phase"
   ```

   Example output:

   ```
   NAME                  BACKUPID          ENDPOINT                          PATH                          SERVERNAME
   STATUS
   test-backup-1.17.1    20230831T110022   https://seaweed.default.svc:30333   s3://backups/backup01ibm    apic-mgmt-d54a2194-
   db-2023-08-31T11:49:10+01:00   completed
   ```

   The backup name in this example is **test-backup-1.17.1**. You can restore the management database from any backup where the `STATUS` is `completed`.

   If you cannot find the backup CR you want, but it is present on your remote SFTP server or object-store, then you can restore with the backup ID: Restoring the management database with a backup ID.

2. Verify that the backup is present in your remote SFTP server or object-store:
   For example, on an AWS S3 store, run:

   ```
   aws s3 ls <path>
   ```

   where *<path>* is the location on your object-store store you configured for your management database backups.
3. Create a file called mgmtrestore_cr.yaml, and paste in the following text:

   ```
   apiVersion: management.apiconnect.ibm.com/v1beta1
   kind: ManagementRestore
   metadata:
     generateName: management- # this the prefix for the name of the restore CR that is created
   spec:
     backupName: <backup CR name>
     subsystemName: <management CR name>
   ```

   where
   - *<backup CR name>* is the backup name that you identified in step 1.
   - *<management CR name>* is the name of your `ManagementCluster` CR, run `kubectl get mgmt` to see what this name is.

   Note: If the management database encryption key was changed since the backup was taken (because you followed the steps in Changing the database encryption key), then you must restore the original encryption key before you apply the restore CR. See restore old encryption key.
4. Start the restore by creating the `ManagementRestore` CR from the YAML file:

   ```
   kubectl -n <management namespace> create -f mgmtrestore_cr.yaml
   ```

5. Verify that the restore is running with:

   ```
   kubectl -n <management namespace> get ManagementRestore --sort-by=.metadata.creationTimestamp
   ```

   Example output:

   ```
   NAME                  STATUS      BACKUP               CLUSTER       MESSAGE                                                PITR
   AGE
   mgmt-restore-hr9zx    Complete    mgmt-backup-xnjkl    m1            Restore process completed (DB Restore + DRR job)    9m8s
   ```

What to do next

Restore the database backups of any developer portal services that are registered with the management subsystem: Restoring from a portal database backup.

Restoring the management database with a backup ID

If the `Backup` CR is missing, but the backup is present on your remote SFTP server or object-store, you can restore the backup by using the backup ID.

About this task

Restore of the management database with a backup ID is required in a disaster recovery scenario, where you redeployed your management subsystem and restored your infrastructure configuration from your config backup.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Identify the backup ID and path of the backup that you want to restore from your remote SFTP server or object-store.
   Management database backups appear as folders that use a datestamp for their name, and are located inside the backup path. Example of a management database backup with its full path:

   ```
   apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z/base/20230914T013040
   ```

- `apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z` is the backup path. The datestamp `2023-09-14T01:30:40Z` indicates when the management database was created (not when the backup was created). The management database is created on initial installation, and re-created when a backup restore is run. The path with the most recent datestamp should contain the most recent backups.
- `20230914T013040` is the backup ID. The format indicates the date and time that the backup was taken.

2. Create a file called mgmt-restore.yaml and paste in the following text:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
  generateName: management- # this the prefix for the name of the restore CR that is created
spec:
  subsystemName: <management CR name>
  backup:
    protocol: [sftp|objstore]
    host: <host>/<region>
    port: <port number>
    path: <path>
    credentials: <backup secret>
    backupCerts: <custom CA certificate>
    backups3URIStyle: <path/host> # host or virtual style is the default
  backupId: <backup ID>
```

where:

- `subsystemName` is the name of your `ManagementCluster` CR, run `kubectl get mgmt` to see what this name is.
- `protocol` is the remote backup server type. Set to `sftp` or `objstore`.
- `host` is the remote SFTP server hostname or object-store endpoint. If you are using an object-store and your endpoint does not have a region, then omit */<region>*.
- `port` is the listening port on your remote SFTP server or object-store. Defaults are 22 for SFTP and 443 for object-store.
- `path` is the path that you identified in step 1.
- `credentials` is the backup secret that you configured to authenticate with the remote backup site. See Create backup secret.
- `backupCerts` is the CA certificate secret of the remote SFTP server or object-store. See step 2 on Configuring management database backups. If you did not create this secret during backup configuration, then omit this property.
- `backups3URIStyle` applies to backups to object-store only. Indicates whether URIs to your object-store backup specify a host or a path value. Set to either `host` or `path`. The default is `host`.
- `backupId` is the ID that you identified in step 1.

Example mgmt-restore.yaml file that uses the values from step 1:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
  generateName: management-
spec:
  subsystemName: management
  backup:
    protocol: objstore
    host: s3.ibm.com/us-west
    path: pic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z
    credentials: mgmt-backup-secret
  backupId: 20230914T013040
```

Note: If the management database encryption key was changed since the backup was taken (because you followed the steps in Changing the database encryption key), then you must restore the original encryption key before you apply the restore CR. See restore old encryption key.

3. Start the restore by creating the `ManagementRestore` CR from the mgmt-restore.yaml file:

```
kubectl -n <management namespace> create -f mgmt-restore.yaml
```

4. Verify that the restore is running with:

```
kubectl -n <management namespace> get ManagementRestore --sort-by=.metadata.creationTimestamp
```

Example output:

```
NAME                  STATUS      BACKUP               CLUSTER       MESSAGE                                                PITR
AGE
mgmt-restore-hr9zx    Complete    mgmt-backup-xnjkl    m1            Restore process completed (DB Restore + DRR job)    9m8s
```

What to do next

Restore the database backups of any developer portal services that are registered with the management subsystem: Restoring from a portal database backup.

Recovering from a disaster

Reinstall the management subsystem by using your infrastructure configuration backup, then restore the management database backup.

Before you begin

To successfully recover the management subsystem, you must have the following backups:

- Management infrastructure configuration backup.
- Management database backup

About this task

- Management subsystem backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a management subsystem backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.
- When you restore a management database backup, you must also restore the database backups of all registered developer portal services, so that the portal and management databases remain in sync.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Reinstall your management subsystem by using the YAML files from your infrastructure configuration backup.
   Your infrastructure configuration backup consists of:
   - Management CR YAML: mgmt_cr_backup.yaml.
   - Management database encryption secret: management_enc_key_backup.yaml.
   - Management backup secret: mgmt-backup-secret_backup.yaml
   - Multiple <credential secret>_backup.yaml files, one for each credential secret.
   - If you customized any certificates, a YAML file of the secret for each customized certificate. For example: apim-endpoint_secret_backup.yaml.

   a. Create the database encryption secret with the management_enc_key_backup.yaml file:

   ```
   kubectl -n <management namespace> apply -f management_enc_key_backup.yaml
   ```

   b. Create the backup credential secret with your mgmt-backup-secret_backup.yaml file:

   ```
   kubectl -n <management namespace> apply -f mgmt-backup-secret_backup.yaml
   ```

   c. Create the credential secrets with the <credential secret>_backup.yaml files you saved in step 5 of Taking a management infrastructure configuration backup:

   ```
   kubectl -n <management namespace> apply -f <credential secret backup file>
   ```

   d. Set the object-store CA secret (if required) from your backup file:

   ```
   kubectl -n <management namespace> apply -f mgmt_custom_objstore_ca.yaml
   ```

   e. Create the secrets for any customized certificates from their backup files:

   ```
   kubectl -n <management namespace> apply -f <custom certificate secret backup file>
   ```

   f. Install the management subsystem. Follow Installing the management subsystem, but use the settings from the `spec` section of your mgmt_cr_backup.yaml file.
2. Restore your management database: Restoring the management database with a backup ID.

What to do next

Restore the backups of any portal subsystems that are registered with the management subsystem. See Backing up and restoring the developer portal.

Troubleshooting management database backup and restore

Common problems and how to diagnose issues with backup and restore.

Common problems with backup and restore

These are some frequent issues that can cause backup or restore to fail:

- Invalid login credentials for your remote backup server. Check that the username and password that you configured in your subsystem database backup settings is correct.
- The user does not have write permissions on the backup server. Check that the username you configured in your subsystem database backup settings has write permission to the specified backup path.
- Remote backup server storage full. Check your remote backup server and if the storage is full either extend the storage space or delete older backups.
- No network access to the remote backup server. Check that you can communicate with your remote backup server from your API Connect environment.
- TLS handshaking failure with the remote backup server. If your remote backup server has a self-signed CA certificate, check that this certificate is trusted by your API Connect deployment, see the database backup configuration steps for your subsystem for more information.

Backup or restore CR stuck in running or in a failed state.

Describe the backup or restore CR for more information on the problem:

```
kubectl -n <namespace> describe backup backup-1700143802
```

```
Name:         management-1700143800

Unable to find database backup CRs

If **kubectl get backup** does not return the backup that you want to restore, then search for the backup on your SFTP server or object-store.

The path to API Connect management database backups on the remote SFTP server or object-store has the following format:

<backup path>/<mgmt db cluster name>-<time when db was created>/base/<backup ID>

- *<backup path>* is the path that is defined in your management CR: backup settings. The format is **bucket_name/folder**.
  If your API Connect deployment was upgraded from v10.0.6.0 or earlier, then **/edb** is appended to the path.
- *<mgmt db cluster name>* is the name of your management database cluster. Identify this name with:

  ```
  kubectl -n <management namespace> get cluster -n active
  ```

  See get cluster name.
- *<time when db was created>* is a timestamp of when the management subsystem database was created. The format is: **2023-12-25T00:00:00Z**.
  Whenever you do a management database restore, a new management database is created, and so a new directory is created where subsequent database backups are stored.
- *<backup ID>* is the ID of a management database backup. The format is **YYYYMMDDTHHMMSS**. This is a directory that contains all the files that comprise the database backup.

Example path:

```
s3bucket1/folder2/mgmt-db-2023-12-25T00:00:00Z/base/20231225T094400
```

With the information identified, you can restore the backup by using the Restoring the management database with a backup ID method.

Error when restoring a management subsystem with the API discovery service

If you enable the API discovery service, the backups that you take can be restored only onto a management subsystem that also has the API discovery service enabled. If you try to restore a backup onto a management subsystem that doesn't have the API discovery service enabled, the database recovery jobs will go into an error state, and the logs will contain the following tablespaces directory error:

```
[Errno 30] Read-only file system: '/var/lib/postgresql/tablespaces'
```

The status of the management job pods will look like the following output:

```
management-apim-restore-1bc41b74-sjzzp                            0/1     Completed   0               3h28m
management-bf631b70-db-1-full-recovery-41bdv                      0/1     Error       0               11m
management-bf631b70-db-1-full-recovery-72519                      0/1     Error       0               13m
management-bf631b70-db-1-full-recovery-8mhdk                      0/1     Error       0               103s
```

In this case, you must take the following steps.

1. Update the **ManagementCluster** CR to enable the API discovery service:

   ```
   spec:
     ...
     discovery:
       enabled: true
       proxyCollectorEnabled: true
   ```

2. Apply the updated CR by running the following command:

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
3. Find the name of the EDB PostgreSQL cluster, by running the following command:

   ```
   kubectl get cluster -n <namespace>
   ```

   The output will look similar to the following output:

   ```
   NAME                      AGE    INSTANCES   READY   STATUS                 PRIMARY
   management-bf631b70-db    13m    1                   Setting up primary
   ```

4. Wait until the EDB PostgreSQL cluster has been updated with the `tablespaces` configuration. You can check this status by running the following command:

   ```
   kubectl get cluster <cluster-name> -o yaml -n <namespace>
   ```

   Look in the output for the `tablespaces` entry, which looks like the following example:

   ```
       tablespaces:
       - name: apidiscoverysvc
         owner:
           name: apicuser
         storage:
           resizeInUseVolumes: false
           size: 10Gi
           storageClass: local-storage
         temporary: false
   ```

   Note that the cluster status will still be `Setting up primary` at this point.
5. Delete the EDB PostgresSQL cluster by running the following command:

   ```
   kubectl delete cluster <cluster-name> -n <namespace>
   ```

6. After a few moments the EDB PostgreSQL cluster will be recreated by the IBM® API Connect operator. You can check this by running the following command:

   ```
   kubectl get cluster -n <namespace>
   ```

7. The database recovery jobs will eventually be recreated, and succeed. You can then verify that the PVCs for the `tablespaces` have been recreated by running the following command:

   ```
   kubectl get pvc -n <namespace>
   ```

   The output of this command will show that there are one or more PVCs present, with a name similar to `management-bf631b70-db-1-tbs-apidiscoverysvc`.
8. The API discovery service pods will now start, and the restore operation will complete.

For more information about the API discovery service, see Enabling API discovery on Kubernetes.

Backing up and restoring the developer portal

How to backup and restore the infrastructure configuration and database of your portal subsystem.

- **Taking a portal infrastructure configuration backup**
  Create YAML backup files of your portal subsystem's Kubernetes configuration.
- **Configuring portal database backups**
  Configure scheduled database backups of your portal subsystem.
- **Running an on-demand backup of the portal database**
  Deploy the `PortalBackup` CR to initiate a backup of the portal database.
- **Managing your remote portal database backups**
  How to manage your remote portal database backup resources.
- **Restoring from a portal database backup**
  Create a `PortalRestore` CR to restore your management database.
- **Recovering from a disaster**
  Reinstall the portal subsystem by using your infrastructure configuration backup, then restore the portal database backup.
- **Troubleshooting portal database backup and restore**
  Troubleshoot problems with portal database backups and restores.

Taking a portal infrastructure configuration backup

Create YAML backup files of your portal subsystem's Kubernetes configuration.

About this task

A portal infrastructure configuration backup is essential for disaster recovery. Take an infrastructure configuration backup after installation, and whenever you make an update to your portal's Kubernetes configuration.

If you have multiple portal clusters in the same namespace, include the portal CR name in all `kubectl get PortalCluster` commands provided in this topic. For example:

```
kubectl -n <portal namespace> get PortalCluster <portal CR name>
```

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Export the portal CR to a file called portal_cr_backup.yaml:

   ```
   kubectl -n <portal namespace> get PortalCluster -o yaml > portal_cr_backup.yaml
   ```

2. Export the portal database encryption secret to a file called portal_enc_key_backup.yaml:
   a. Get the name of the encryption secret:

      ```
      kubectl -n <portal namespace> get ptl -o yaml | grep encryption
      ```

   b. Take note of the `encryptionSecret` name returned:

      ```
      encryptionSecret: <portal enc key>
      ```

   c. Backup the encryption secret to a YAML file:

      ```
      kubectl -n <portal namespace> get secret <portal enc key> -o yaml > portal_enc_key_backup.yaml
      ```

3. Export your portal database backup secret:

   ```
   kubectl -n <portal namespace> get secret <portal backup secret> -o yaml > ptl-backup-secret_backup.yaml
   ```

   The backup secret is created when you configure portal database backups. If database backups are not yet configured, remember to backup this secret when they are configured.
4. If used, export your remote portal backup server's CA secret:

   ```
   kubectl -n <portal namespace> get secret <portal custom server ca> -o yaml > portal-custom-server-ca_backup.yaml
   ```

   The S3 CA secret is created when you configure database backups: Create backup server CA secret. If database backups are not yet configured, remember to backup this secret when they are configured.
5. Export any other certificates that you customized. For example, if you customized the `portalWeb` endpoint certificate, save the certificate by copying the corresponding secret to a YAML file:

   ```
   kubectl -n <portal namespace> get secret <portalWeb secret> -o yaml > portalWeb_secret_backup.yaml
   ```

What to do next

Configure scheduled database portal backups: Configuring portal database backups.
Important: If you update your portal subsystem's Kubernetes configuration, remember to update your infrastructure configuration backup.

Configuring portal database backups

Configure scheduled database backups of your portal subsystem.

About this task

The developer portal by default takes database backups of itself every 24 hours and stores the last three days of backups in the portal subsystem PVCs (older backups are automatically deleted). These backups are called local backups because they are stored locally rather than on remote backup servers. For disaster recovery, you must configure the portal to create and store backups on a remote server.

Supported remote servers for backup storage are:

- S3 object-store, for example:
  - AWS S3.
  - IBM Cloud Object Storage.
  - Custom S3 storage.

  Only password-based authentication is supported for S3, not authentication based on public certificates and private keys. Password-based authentication for S3 requires that you generate an access key and secret.
- SFTP
  Supported credentials types:
  - Username and password.
  - Username and SSH-key. Only OpenSSH keys are supported.[1]

Important points:

- Portal database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a portal database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see: Migrating from v10 to v10 on a different form factor.
- Keep your portal's Infrastructure configuration backup up to date with any changes in your portals Kubernetes configuration. If a disaster occurs and you lose your portal subsystem configuration, then you cannot restore your portal database backup without first restoring the config backup.
- Take management database backups at the same time as you take portal database backups. One backup per day is recommended.
- The portal keeps a log of the last 30 days of remote backups that are taken, configured with the `backupRecordDays` property. Configure the retention policy on your remote backup server to match or exceed the `backupRecordDays` value.
- To disable scheduled database backups, you must remove the entire `databaseBackup` section from the portal CR. Local backups continue to be taken in all cases.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Create your backup secret:
   - For SFTP backup destination, use:
     - Username and password credentials:

       ```
       kubectl create secret generic portal-backup-secret --from-literal=username='<username>'
       --from-literal=password='<password>' -n <portal namespace>
       ```

     - Username and SSH-key credentials:

       ```
       kubectl create secret generic portal-backup-secret --from-literal=username='<username>'
        --from-file=ssh-privatekey='<private key filepath>' -n <portal namespace>
       ```

   - For S3 backup destination, use:

     ```
     kubectl create secret generic portal-backup-secret --from-literal=username='<S3 access key or username>'
         --from-literal=password='<S3 access key secret or password>' -n <portal namespace>
     ```

   Keep the backup secret in your Infrastructure configuration backup.

2. **S3 storage only:** If your S3 store has a custom CA certificate, then create a Kubernetes secret that contains this CA certificate, so that your portal subsystem trusts the S3 store.
   a. Run the following command to create a Kubernetes secret from the certificate file:

      ```
      kubectl -n <portal namespace> create secret generic portal-custom-server-ca --from-file=ca.crt=/path/to/cert.crt
      ```

      Note: Include the complete chain in your certificate file, for example:

      ```
      intermediate-certificate-1
      intermediate-certificate-2
      . . .
      intermediate-certificate-n
      root-certificate
      ```

      The first certificate (intermediate-certificate-1) is the issuer of the object-store server certificate, and each subsequent certificate is the issuer of the preceding certificate. The root certificate must be self-signed.
      If the certificate includes no intermediate certificates, then the file contains only the root certificate.

   b. Take a backup of the new secret.

      ```
      kubectl -n <portal namespace> get secret portal-custom-server-ca -o yaml > portal_custom_s3_ca.yaml
      ```

      Keep the generated portal_custom_s3_ca.yaml file with your Infrastructure configuration backup.

3. **Kubernetes and OpenShift individual subsystem CR users:** Edit your `PortalCluster` CR:

   ```
   kubectl -n <portal namespace> edit PortalCluster
   ```

4. **Cloud Pak for Integration and OpenShift top-level CR users:** Edit your `APIConnectCluster` CR:

   ```
   oc -n <apic namespace> edit APIConnectCluster
   ```

5. Configure your backup settings in the `portalBackup` section of the `spec` object:
   - For S3 object-store backup destination, use:

     ```
     spec:
       portalBackup:
         credentials: <portal backup secret>
         host: <host>/<region>
         path: <path>
         port: <port>
         protocol: objstore
         backupCerts: <custom CA certificate>
         backups3URIStyle: <path/host>
         schedule: '<cron schedule>'
         backupRecordDays: 30
     ```

   - For SFTP backup destination, use:

     ```
     spec:
       portalBackup:
         credentials: <portal backup secret>
         host: <sftp server hostname>
         path: <directory path>
         port: <port>
         protocol: sftp
         schedule: '<cron schedule>'
         backupRecordDays: 30
     ```

   Note: On Cloud Pak for Integration and OpenShift when using the top-level CR, add the `databaseBackup` section to the `spec.portal` section.
   Set the properties as follows:

Table 1. Developer Portal backup settings

Setting	Description
`credentials`	The name of the secret you created in step 1.

Setting	Description
`host`	The hostname or your remote backup storage target: • S3 - `host`: is the S3 endpoint and region (if your S3 endpoint has a region) in the format `<S3endpoint>` or `<S3endpoint>/<S3region>`. • SFTP - the hostname of the SFTP server Note: If your S3 object-store is AWS S3 and the endpoint is from the list of regions created after March 20, 2019, the S3 endpoint is required to be in the format `s3.<S3region>.amazonaws.com`, as AWS uses regional endpoints for these regions. Ensure that you use the correct region in the endpoint to avoid any issues with connectivity or data access. In this case, the host is: `s3.<S3region>.amazonaws.com/<S3region>`.

`path`	The location for the backups on your remote storage target:
	• S3 - the name of your S3 bucket and path. Valid examples:
	`bucket`
	`bucket/path`
	`bucket/lots/of/paths`
	• SFTP - the full absolute path of the folder on the SFTP server, beginning with `/`.

`port`	The port on the remote storage target. Defaults are: • S3 - 443. • SFTP - 22.
`protocol`	The backup type. Specify one of the following values: • `sftp` - For backups to a remote SFTP server. • `objstore` - For backups to a remote S3 object-store. • `local` - To store backups locally, in the portal subsystem's PVCs. Note: If a disaster occurs your portal PVCs might be lost or corrupted, so it is recommended to use one of the remote backup server options.
`backupCerts`	**S3 storage only:** The secret that contains your S3 store's CA certificate, that you create in step: 2.
`backups3URIStyle`	**S3 storage only:** `backups3URIStyle` indicates whether URIs to your S3 backup should specify a host or a path value. Default is `host`. Valid values: `host` and `path`. Some custom S3 providers require URI style to be set to `path`. For example, MinIO supports both `host` and `path` style setup. You can create a MinIO S3 server to accept only `path` style client communications. Important: Contact your custom S3 administrator before you configure this field. If not properly configured, an upstream custom S3 object-store can reject connections.

`schedule`	The schedule for how often automatic Developer Portal backups are run. The format for the schedule is any valid cron string. The time zone for backups is Coordinated Universal Time.
	Valid for all backup types: S3, SFTP, and local.
	`spec:`
	`  portalBackup:`
	`  ...`
	`  schedule: '0 2 * * *'`
	If the schedule property is omitted, the default schedule of one backup per day is implemented.

`backupRecordDays`	The `backupRecordDays` setting denotes the number of days that backup records (backups that exist on the remote backup server) are shown when you list your remote backups. It is defaulted to 30 days.

6. Update the `PortalCluster` CR backup in your Infrastructure configuration backup.
   If you are using Cloud Pak for Integration or OpenShift with the top-level CR, also update your `APIConnectCluster` CR backup.

What to do next

Run an on-demand backup to confirm that your backup configuration is correct, see Running an on-demand backup of the portal database.

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Running an on-demand backup of the portal database

Deploy the `PortalBackup` CR to initiate a backup of the portal database.

About this task

Note: If you are taking a portal database backup, you must also take a management database backup at the same time. Management and portal databases must be kept in sync.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Decide which type of backup you want to take:
   - `all`: backs up the Developer Portal system and all its sites.
   - `system`: backs up the Developer Portal system only.
   - `site`: backs up a specific Developer Portal site.

   Note: Developer Portal system backup includes all the portal configuration that is not specific to sites, such as IP allowlist.
2. Identify the name of the portal cluster that you want to backup:

   ```
   kubectl -n <portal namespace> get PortalCluster
   ```

3. Create a file called portalbackup_cr.yaml and paste in the following text:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup
metadata:
  generateName: portal-bup-
spec:
  type: <type>
  portalCluster: <portal cluster name>
  crType: create
  siteName: <site to backup>
  comment: "<comment>"
```

where:

- `type` is the backup type that you decided in step 1.
- `portalCluster` is the cluster name that you identified in step 2.
- `siteName` is the name of the portal site that you want to backup. This property applies only when backup type of `site` is specified. Valid settings are:
  - Site UUID or URL - back up the specified site only.
  - `installed` - backups all installed sites.
- `comment` is a text comment to help you identify the reason for the backup, for example: "pre-upgrade backup".

4. Create the `PortalBackup` CR from the portalbackup_cr.yaml file:

```
kubectl -n <portal namespace> create -f portalbackup_cr.yaml
```

5. Verify that the backup is running with:

```
$ kubectl -n <portal namespace> get portalbackup --sort-by=.status.backupId
```

The expected output for an `all` type backup is:

```
NAME                    ID                TASK ID  STATUS     TYPE     CR TYPE   CLUSTER    AGE     COMMENT
portal-record-89dgz     20200526.142449   n/a      Ready      system   record    portal     55m
portal-record-89dgz     20200526.142458   n/a      Ready      site     record    portal     54m
p1-bup-st4l2                              n/a      Ready      all      create    portal     56m     y
```

For every on-demand backup triggered at least two `PortalBackup` CRs are created:

- `Create`. The `create` CR type is the first CR to be created. The `create` CR does not create the portal database backup itself, but is responsible for creating `record` type `PortalBackup` CRs, which are representations of individual backups.
- `Record`. The `record` `PortalBackup` CR has two types:
  - `System`. The `System` record type represents one system backup file, containing the portal configuration that applies to all sites
  - `Site`. The `Site` record type represents a backup file for one site. Site backups contain any Drupal customizations made to the site.

6. You can get a detailed view of a specific backup CR by using the command:

```
kubectl -n <portal namespace> get portalbackup <backup name> -o yaml
```

Example output for a `create` type backup CR:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup

Observe the property showing the filename of the backup: portal_system_backup-20230922.083722.tar.gz.

What to do next

Take a database backup of the management subsystem that your portal is registered with. You must have management and portal database backups that are in sync with each other: Running an on-demand backup of the management database.

Managing your remote portal database backups

How to manage your remote portal database backup resources.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.
When you run the command `kubectl get portalbackup -o wide`, you see a list of all the backups that ran during the past 30 days:

```
NAME                  ID               TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE   COMMENT   FILENAME
my-backup-f91ms       n/a              20b47fe090f5 Ready    all      create    portal    58m
portal-record-2vcgs   20231105.181212  n/a          Ready    system   record    portal    55m
_portal_system_backup-20231105.181212.tar.gz
portal-record-9j8lt   20231104.095949  n/a          Ready    system   record    portal    55m
_portal_system_backup-20231104.095949.tar.gz
portal-record-c4d5s   20231106.121946  n/a          Ready    site     record    portal    25m             portal.fyre-ci-
162245-master.fyre.ibm.com@ibm@api-connect-catalog-2-20231106.121946.tar.gz
portal-record-c7p5q   20231106.110330  n/a          Ready    system   record    portal    55m
_portal_system_backup-20231106.110330.tar.gz
portal-record-f5h2h   20231106.115701  n/a          Ready    system   record    portal    55m
_portal_system_backup-20231106.115701.tar.gz
```

`PortalBackup` CRs with `CR TYPE` of `create` can be ignored. Create type CRs are generated when a backup is triggered manually, they are used to generate the `record` type `PortalBackup` CRs that hold the actual portal database backup. You can delete `create` type CRs after its corresponding `record` type CRs are created.
You can filter out `create` type CRs from `kubectl get portalbackup` output with **grep**:

```
kubectl get portalbackup | grep record
```

When you create a backup of type 'all', the following `PortalBackup` CRs are created:

- `PortalBackup` CR of type 'system' that contains the portal system data, which is everything in the portal database that applies to all sites.
- For each site, a `PortalBackup` CR of type 'site' that contains all the data that is related to the site, such as Drupal site customizations.

For example if your portal has three sites, you get 4 `PortalBackup` CRs:

```
portal-record-222cg   20230108.010033                Ready    system   record
portal-record-22xdc   20230108.010035                Ready    site     record
portal-record-245j7   20230108.010037                Ready    site     record
portal-record-246hm   20230108.010040                Ready    site     record
```

The portalBackupRecordDays property defines how many `PortalBackup` CRs are shown in the output of `kubectl get portalbackup`. The default is the last 30 days of CRs.

Portal performance can be negatively impacted if you have too many `PortalBackup` CRs, particularly during an upgrade. If you are taking backups more frequently than once a day, or have many sites, then it is recommended to reduce the `portalBackupRecordDays` property to a lower value. You can still keep as many backups as you want on your remote server, but if they don't have a corresponding `PortalBackup` CR then you must restore them using the .tgz file name or `timestamp`, see: Restoring from a portal database backup.

Portal backup .tgz files

For most operations that involve portal database backups, you work with a backup ID or a datestamp of the backup you want to restore, but some operations might require identifying the backup file name.

Portal database backups are contained in compressed archived files (TGZ), the name of the file is shown in the last column of the `kubectl get portalbackup -o wide` output:

```
kubectl -n <portal namespace> get portalbackup -o wide
```

Example output:

```
NAME                  ID                TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE   COMMENT   FILENAME
portal-record-2vcgs   20231105.181212   n/a          Ready    system   record    portal    55m
_portal_system_backup-20231105.181212.tar.gz
```

Restoring from a portal database backup

Create a `PortalRestore` CR to restore your management database.

Before you begin

Restore the management database backup on your management subsystem first. Restore from a management database backup that was taken at the same time as the portal database backup you want to restore.

About this task

- Portal database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a portal database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.
- Two data center disaster recovery deployments have extra backup and restore considerations. Review Backup and restore requirements for a 2DCDR deployment before you follow the instructions in this topic.

Three types of restore are available:

- `all`: restores the Developer Portal system and all the sites that are contained in the specified database backup.
- `system`: restores the Developer Portal system but not any sites from the database backup.
- `site`: restores a specific Developer Portal site from the database backup.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Identify the portal backup that you want to restore with:

   ```
   $ kubectl -n <portal namespace> get portalbackup -o wide --sort-by=.status.backupId | grep record
   ```

   Example output:

   ```
   NAME                  ID                TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE   COMMENT   FILENAME
   portal-record-2vcgs   20231105.181212   n/a          Ready    system   record    portal    55m
   _portal_system_backup-20231105.181212.tar.gz
   portal-record-9j81t   20231104.095949   n/a          Ready    system   record    portal    55m
   ```

```
_portal_system_backup-20231104.095949.tar.gz
portal-record-c4d5s   20231106.121946   n/a          Ready    site     record    portal    25m             portal.fyre-ci-
162245-master.fyre.ibm.com@ibm@api-connect-catalog-2-20231106.121946.tar.gz
portal-record-c7p5q   20231106.110330   n/a          Ready    system   record    portal    55m
_portal_system_backup-20231106.110330.tar.gz
portal-record-f5h2h   20231106.115701   n/a          Ready    system   record    portal    55m
_portal_system_backup-20231106.115701.tar.gz
```

Note: You can restore the portal database only from backups where the **CR TYPE** is **record**.
You can get more information on a specific backup with:

```
kubectl -n <portal namespace> get portalbackup <backup name> -o yaml
```

2. Verify that the backup you want to restore exists on the remote server.
3. Identify the name of the portal cluster that you want to restore to:

```
kubectl -n <portal namespace> get PortalCluster
```

4. Create a file called portalrestore_cr.yaml. The text that you paste into the YAML file depends on the type of backup you want to restore:
   - Restore type **all**. Restore the full portal database, including all sites:

     ```
     apiVersion: portal.apiconnect.ibm.com/v1beta1
     kind: PortalRestore
     metadata:
       generateName: portal-restore-
     spec:
       type: all
       portalCluster: <portal cluster name>
       dryRun: <true or false>
       timestamp: <datestamp>
       priorityList:
         - <most important site to restore>
         - <second most important site to restore>
     ```

     where:
     - **portalCluster** is the cluster name that you identified in step 3.
     - **dryRun** if you want to test restore of the backup, without overwriting your portal, set **dryRun** to **true**.
     - **timestamp** specify a timestamp to retrieve the backup from. The nearest backup, searching backwards from this timestamp, is used. Format is *'YYYYMMDD.HHMMSS'*, or set to **now** to restore the most recent backup.
     - **priorityList** Prioritizes the restore of specific site. The sites are restored in the order in which they are listed in **priorityList**, followed by any remaining unlisted sites. Example contents:

       ```
       priorityList:
           - production.site.com
           - test.site.com
       ```

       If you have no preference for site restore priority, then omit this property.
   - Restore type **site**. Restore backup of a particular site:

     ```
     apiVersion: portal.apiconnect.ibm.com/v1beta1
     kind: PortalRestore
     metadata:
       generateName: portal-restore-
     spec:
       type: site
       portalCluster: <portal cluster name>
       siteName: <portal site to restore>
     ```

     where:
     - **portalCluster** is the cluster name that you identified in step 3.
     - **siteName** is either:
       - The UUID or URL of the site you want to restore, for example: **myportal.com**, in this case the latest backup of this site restored.
       - The backup ID of the backup that contains the site that you want to restore.
       - **all** - restore all sites in the latest backup.
       - **installed** - restore from the latest backup only sites that currently exist. For cases where your backup contains site backups for sites that no longer exist on your portal.
       - Backup .tgz file name. For example: site-1234.tgz restores the site from the backup file name. The file name of the backup is shown in the last column of the **kubectl get portalbackup -o wide** output.
   - Restore type **system**. Restore portal system backup, but no sites.

     ```
     apiVersion: portal.apiconnect.ibm.com/v1beta1
     kind: PortalRestore
     metadata:
       generateName: portal-restore-
     spec:
       type: system
       portalCluster: <portal cluster name>
       systemName: <backup ID>
     ```

     where:
     - **portalCluster** is the cluster name that you identified in step 3.
     - **systemName** is either:
       - The backup ID of a portal backup CR. You can restore only portal database backups that are of **type** system and **crType** record.
       - Filename of the backup's .tgz file. Restores the system from the specified backup file name. The file name of the backup is shown in the last column of the **kubectl get portalbackup -o wide** output.
       - **latest**: restores from latest system backup that is available.

5. Optional: If the `API` hostname of your management subsystem platform API changed since taking the backup you are restoring, then add the property `customPlatformApiHostname` to your portalrestore_cr.yaml file and set it to the new platform API hostname of the management subsystem. For example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  generateName: portal-restore-
spec:
  ...
  customPlatformApiHostname: mgmt.platformapi.host
  ...
```

6. Create the `PortalRestore` CR from the portalrestore_cr.yaml file:

```
kubectl -n <portal namespace> create -f portalrestore_cr.yaml
```

7. Verify that the restore is running with:

```
kubectl -n <portal namespace> get portalrestore
```

Example output for a restore type of `all`:

```
NAME                   TYPE   TASK ID            STATUS    MESSAGE                                                  AGE
portal-restore-2xsgl   all    t3wz85rxz61jam92   Running   Sites Restored: 2, Sites Failed: 0, Sites Pending: 1
```

Example output for a restore type of `system`:

```
NAME                   TYPE     TASK ID             STATUS   MESSAGE                                                CLUSTER
AGE
portal-restore-xtjjt   system   yrwtcw5ult08p786   Ready    Please describe the CR to see the full message.   portal
72s
```

8. To see more information about the restore, run:

```
kubectl -n <portal namespace> get portalrestore <restore name> -o yaml
```

Example output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:

9. When the restore completes `RestorePortal` CR shows Ready state, regardless of whether the restore was successful or not.

```
NAME                    TYPE    TASK ID            STATUS    MESSAGE                                                    AGE
portal-restore-2xsgl    all     t3wz85rxz61jam92   Ready     Sites Restored: 3, Sites Failed: 0, Sites Pending: 0
```

10. If a site fails to restore, check for messages in the restore description:

    ```
    kubectl -n <portal namespace> get portalrestore <restore name> -o yaml
    ```

    Also, check the logs of the admin container in the `www` pod:

    ```
    kubectl -n <portal namespace> logs <portal www pod> -c admin
    ```

Recovering from a disaster

Reinstall the portal subsystem by using your infrastructure configuration backup, then restore the portal database backup.

Before you begin

To successfully recover the portal subsystem, you must have the following backups:

- Infrastructure configuration backup.
- Portal database backup.

About this task

- Portal subsystem backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a portal subsystem backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.
  Note: If your management platform API endpoint changed since the portal database backup was created, you can update this setting during portal database restore by using the `customPlatformApiHostname` property in the `PortalRestore` CR. This is the only exception to the identical endpoints requirement. See Restore portal database.
- When you restore a portal database backup, you must first restore the database backup of the management subsystem that the portal is registered with. Portal and management databases must remain in sync.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Reinstall your portal subsystem by using the YAML files from your Infrastructure configuration backup.
   Your infrastructure configuration backup consists of:
   - Portal CR YAML: portal_cr_backup.yaml.
   - Portal database encryption secret: portal_enc_key_backup.yaml.
   - Portal backup server credentials secret: ptl-backup-secret_backup.yaml.
   - If required, the portal backup server CA certificate secret: portal_custom_s3_ca.yaml.
   - If you customized any portal certificates, a YAML file of the secret for each customized certificate. For example: portalWeb_secret_backup.yaml.

   a. Create the database encryption secret with the portal_enc_key_backup.yaml:

      ```
      kubectl -n <portal namespace> apply -f portal_enc_key_backup.yaml
      ```

   b. Create the backup credential secrets with your ptl-backup-secret_backup.yaml file:

      ```
      kubectl -n <portal namespace> apply -f ptl-backup-secret_backup.yaml
      ```

   c. Create the S3 CA secret (if required) with:

      ```
      kubectl -n <portal namespace> apply -f portal_custom_s3_ca.yaml
      ```

   d. Create the secrets for any customized certificates from their backup files:

      ```
      kubectl -n <portal namespace> apply -f <custom certificate secret backup file>
      ```

   e. Install the portal subsystem. Follow the installation procedures for your platform: Deployment procedures, but use the settings from the `spec` section of your portal_cr_backup.yaml file.
      Note:
      - Cloud Pak for Integration users: Many of the portal configuration settings can be configured in Cloud Pak for Integration Platform UI. You do not need to edit the YAML directly.
2. Restore your portal database: Restoring from a portal database backup.

Troubleshooting portal database backup and restore

Troubleshoot problems with portal database backups and restores.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.
Check the status section of the PortalBackup or PortalRestore CR:

```
kubectl -n <portal namespace> get <portalbackup/portalrestore> <bup-name/restore-name> -o yaml
```

Example output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  creationTimestamp: "2020-05-26T13:10:46Z"
  generateName: portal-restore-
  generation: 1
  name: portal-restore-x2bf9
  namespace: portal
  resourceVersion: "1493471"
  selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/portal/portalrestores/portal-restore-x2bf9
  uid: 9f6a1e22-55ab-4595-8b98-bdfaec40d58c
spec:
  portalCluster: portal
  type: site
status:
  backupId: ""
  commentLeft: ""
  conditions:
  - lastTransitionTime: "2020-05-26T13:10:49Z"
    message: |
      Please provide a site to restore. To restore all sites use value 'all' in the CR
    status: Failed
    type: Ready
  fullBackupName: ""
  id: ""
  message: ""
```

Check operator pod logs. Look for information in the logs of the `ibm-apiconnect` pod:

- Locate the `ibm-apiconnect` pod with:

  ```
  kubectl get pods -n <namespace-of-portal-subsystem>
  ```

- View the logs with:

  ```
  kubectl logs <ibm-apiconnect-pod-NAME> -n <namespace-of-portal-subsystem>
  ```

Common problems with backup and restore

These are some frequent issues that can cause backup or restore to fail:

- Invalid login credentials for your remote backup server. Check that the username and password that you configured in your subsystem database backup settings is correct.
- The user does not have write permissions on the backup server. Check that the username you configured in your subsystem database backup settings has write permission to the specified backup path.
- Remote backup server storage full. Check your remote backup server and if the storage is full either extend the storage space or delete older backups.
- No network access to the remote backup server. Check that you can communicate with your remote backup server from your API Connect environment.
- TLS handshaking failure with the remote backup server. If your remote backup server has a self-signed CA certificate, check that this certificate is trusted by your API Connect deployment, see the database backup configuration steps for your subsystem for more information.

Backing up and restoring the analytics subsystem

How to configure analytics backups and recover from a disaster.

For information about analytics backup, restore, and disaster recover, refer to Configuring analytics backups.

Backing up and restoring on OpenShift top-level CR

How to backup and restore your top-level CR deployment of API Connect

- **Backing up your OpenShift top-level CR API Connect deployment**
- **Disaster recovery on OpenShift top-level CR**

Backing up your OpenShift top-level CR API Connect deployment

About this task

A full API Connect backup consists of:

- Infrastructure configuration backup: The infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:
  - Custom resource (CR) YAML files.
  - Custom certificates.
  - Encryption secrets.
  - Backup secrets.
- Subsystem database backups: The management, portal, and analytics subsystems all have their own databases that must be backed up:

- Management database contains everything users configure in the management UIs, REST API, toolkit CLI, and portal sites (excluding Drupal customizations).
- Portal database contains all portal and site customizations.
- Analytics database contains all API event data, and the settings of analytics features configured in the management UIs.

Procedure

1. Take a backup of your top-level CR:

   ```
   oc -n <namespace> get ApiconnectCluster -o yaml > apic_cr_backup.yaml
   ```

2. Take backups of each subsystem, following the documented steps:
   - Backing up and restoring the management subsystem
   - Backing up and restoring the developer portal
   - Backing up and restoring the analytics subsystem

Disaster recovery on OpenShift top-level CR

About this task

To recover your API Connect deployment, follow the steps in this topic along with the instructions for Installing with the top-level CR on OpenShift.

Note: The steps that are detailed in this topic use the Kubernetes `kubectl` command, which does work on OpenShift®, but if you want you can replace `kubectl` with the OpenShift equivalent command: `oc`.

Procedure

1. Create the management subsystem Kubernetes secrets from the backup YAML files that you created in Management infrastructure configuration backup.
   a. Create the database encryption secret with the management_enc_key_backup.yaml file:

      ```
      kubectl -n <management namespace> apply -f management_enc_key_backup.yaml
      ```

   b. Create the backup credential secret with your mgmt-backup-secret_backup.yaml file:

      ```
      kubectl -n <management namespace> apply -f mgmt-backup-secret_backup.yaml
      ```

   c. Create the credential secrets with the <credential secret>_backup.yaml files you saved in step 5 of Taking a management infrastructure configuration backup:

      ```
      kubectl -n <management namespace> apply -f <credential secret backup file>
      ```

   d. Set the object-store CA secret (if required) from your backup file:

      ```
      kubectl -n <management namespace> apply -f mgmt_custom_objstore_ca.yaml
      ```

   e. Create the secrets for any customized certificates from their backup files:

      ```
      kubectl -n <management namespace> apply -f <custom certificate secret backup file>
      ```

2. Create the portal subsystem Kubernetes secrets from the backup YAML files that you created in Portal infrastructure configuration backup.
   a. Create the database encryption secret with the portal_enc_key_backup.yaml:

      ```
      kubectl -n <portal namespace> apply -f portal_enc_key_backup.yaml
      ```

   b. Create the backup credential secrets with your ptl-backup-secret_backup.yaml file:

      ```
      kubectl -n <portal namespace> apply -f ptl-backup-secret_backup.yaml
      ```

   c. Create the S3 CA secret (if required) with:

      ```
      kubectl -n <portal namespace> apply -f portal_custom_s3_ca.yaml
      ```

   d.
   e. Create the secrets for any customized certificates from their backup files:

      ```
      kubectl -n <portal namespace> apply -f <custom certificate secret backup file>
      ```

3. Re-create the analytics secrets that you backed up. See Backup analytics secrets.
4. To prepare for disaster recovery when using a top-level API Connect cluster CR, follow these steps:
   a. Copy and paste the `spec` section from your apic_cr_backup.yaml file.
   b. Set the following required fields under `spec.management` and `spec.portal`:

      `siteName`:
      Copy the value from the original subsystem CR.
      `originalUID`:
      Copy the value from the `spec.originalUID` field or the `metadata.uid` field in the original subsystem CR.
      `encryptionSecret`:
      Use the name of the encryption secret that you created in step 1(a) and 2(a).
      `customApplicationCredentials`:
      Include all secret references that were used during the original installation. This field applies only to the Management subsystem.

      Note: If your cluster name is longer than 10 characters, and the `siteName` and `originalUID` fields are missing, the restore operation will fail due to secret mismatches.
      Example:

```
spec:
  management:
    siteName: "a2a5e6e2"
    originalUID: "fa0f6f49-b931-4472-b84d-0922a9a92dfd"
    encryptionSecret:
      secretName: mgmt-enc-key
    customApplicationCredentials:
    - name: atm-cred
      secretName: management-atm-cred
    ...
  portal:
    siteName: "890772e3"
    originalUID: "447ea4b3-9514-4a84-a34b-ce0b349838da"
    encryptionSecret:
      secretName: portal-enc-key
```

5. Create the API Connect deployment from the YAML file.
   Refer to the installation steps in Installing with the top-level CR on OpenShift.
   Wait for all subsystems to be created and ready. Monitor the installation progress with the command:

   ```
   oc -n <namespace> get ApiconnectCluster
   ```

6. Restore the subsystem databases:
   a. Restoring the management database with a backup ID.
      Verify that the restoration completed successfully and that the management subsystem is Ready, then proceed to the next step and restore the portal subsystem.

   b. Restoring from a portal database backup.
      Use the restore type **all** to ensure that you restore the complete subsystem and all portal sites.

   c. Restoring the analytics database.

Backing up and restoring on Cloud Pak for Integration and OpenShift top-level CR

How to backup and restore all API Connect subsystem in a Cloud Pak for Integration, or OpenShift top-level CR deployment

- **Backing up your Cloud Pak for Integration API Connect deployment**
  How to backup your API Connect configuration and subsystem databases.
- **Recovering from a disaster on Cloud Pak for Integration**
  Prepare your Cloud Pak for Integration environment for installation of the replacement API Connect deployment. Install API Connect. Restore the database backups of each subsystem.

Backing up your Cloud Pak for Integration API Connect deployment

How to backup your API Connect configuration and subsystem databases.

About this task

A full API Connect backup consists of:

- Infrastructure configuration backup: The infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:
  - Custom resource (CR) YAML files.
  - Custom certificates.
  - Encryption secrets.
  - Backup secrets.
- Subsystem database backups: The management, portal, and analytics subsystems all have their own databases that must be backed up:
  - Management database contains everything users configure in the management UIs, REST API, toolkit CLI, and portal sites (excluding Drupal customizations).
  - Portal database contains all portal and site customizations.
  - Analytics database contains all API event data, and the settings of analytics features configured in the management UIs.

To backup your Cloud Pak for Integration or OpenShift top-level CR deployment, backup the infrastructure configuration and databases of each subsystem.
Important:
When you backup API Connect from a primary site to a disaster recovery (DR) site, API Connect that you deployed as part of CP4I uses Keycloak as an OIDC registry. The Keycloak endpoints are generated based on the ***.apps.cluster.basedomain** for a particular cluster. If API Connect backups from a primary site are restored on the DR site, the Keycloak endpoints at DR point to the ones at the primary site, since this configuration is a part of the management subsystem backup. This can cause login failures for you while using this registry, as now the OAuth call is redirected to the primary site endpoint.

To resolve this issue, after restoring API Connect, update the Keycloak configuration and verify the test user authentication to ensure that the Keycloak endpoints are correctly configured.

Procedure

1. Save the CP4I credentials secret.

   ```
   oc -n <namespace> get secret <instance_name>-cp4i-creds -o yaml > cp4i_credentials_secret_backup.yaml
   ```

   Edit the saved YAML file and remove both the **ownerReferences** subsection and the **selfLink** property, and then save the updated file.

2. If you did not change the cloud administrator password after installation, backup the cloud admin password secret.

   ```
   oc -n <namespace> get secret <instanceName>-mgmt-admin-pass -o jsonpath="{.data.password}" | base64 -d
   ```

3. Backup the API Connect CR.

   ```
   oc -n <namespace> get ApiconnectCluster -o yaml > apic_cr_backup.yaml
   ```

4. Follow the backup steps for each subsystem.
   - Backing up and restoring the management subsystem
   - Backing up and restoring the developer portal
   - Backing up and restoring the analytics subsystem

   Important: Ensure that you backup all subsystem CRs, and not just the top-level CR. The subsystem CRs contain additional information about each subsystem, which is required for disaster recovery.

Recovering from a disaster on Cloud Pak for Integration

Prepare your Cloud Pak for Integration environment for installation of the replacement API Connect deployment. Install API Connect. Restore the database backups of each subsystem.

About this task

To recover from a disaster, re-create your API Connect deployment, referring to the backup files and artifacts you took when you followed the backup process: Backing up your Cloud Pak for Integration API Connect deployment.

Note: Your recovery installation of Cloud Pak for Integration must include the Platform UI if your original deployment used it. In addition, the CR must use the same settings as in the original deployment.

Procedure

Preparing the Cloud Pak for Integration environment.

1. Prepare your Cloud Pak for Integration environment for deploying API Connect as explained in the appropriate version of the Cloud Pak for Integration documentation.
   After you prepare your environment, return to this procedure to configure the installation CR, deploy API Connect, and then restore the subsystem database backups to your API Connect subsystems.

2. Create management and portal encryption secrets from your backups of these secrets.
   a. Create the management database encryption secret.

      ```
      oc -n <namespace> apply -f management_enc_key_backup.yaml
      ```

      where management_enc_key_backup.yaml is the encryption secret backup that you created in step 2.c of Taking a management infrastructure configuration backup

   b. Create the portal database encryption secret.

      ```
      oc -n <namespace> apply -f portal_enc_key_backup.yaml
      ```

      where portal_enc_key_backup.yaml is the encryption secret backup that you created in step 2.c of Taking a portal infrastructure configuration backup.

3. Create the Cloud Pak for Integration credentials secret.

   ```
   oc -n <namespace> apply -f cp4i_credentials_secret_backup.yaml
   ```

   where cp4i_credentials_secret_backup.yaml is the credentials backup file that you created in step 1 of Backing up your Cloud Pak for Integration API Connect deployment.

4. Generate the Kubernetes secret for each subsystem's database backups, by using the backup files that you created for each subsystem.

   a. `oc -n <namespace> apply -f mgmt-backup-secret_backup.yaml`

      where mgmt-backup-secret_backup.yaml was created in step 3 on Taking a management infrastructure configuration backup.

   b. `oc -n <namespace> apply -f ptl-backup-secret_backup.yaml`

      where ptl-backup-secret_backup.yaml was created in step 3 on Taking a portal infrastructure configuration backup.

   c. `oc -n <namespace> apply -f analytics-backup-secret_backup.yaml`

      where analytics-backup-secret_backup.yaml was created in Configuring analytics backups.

5. Create each of the management client application credential secrets.
   Run the following command to apply each secret, by using the backup YAML files that you created in step 5 of Taking a management infrastructure configuration backup.

   ```
   oc -n <namespace> apply -f <secretName>.yaml
   ```

   Example:

   ```
   atmCredentialSecret: management-atm-cred
   consumerToolkitCredentialSecret: management-ccli-cred
   consumerUICredentialSecret: management-cui-cred
   designerCredentialSecret: management-dsgr-cred
   discoveryCredentialSecret: management-discovery-cred
   governanceCredentialSecret: management-governance-cred
   juhuCredentialSecret: management-juhu-cred
   ```

```
toolkitCredentialSecret: management-cli-cred
uiCredentialSecret: management-ui-cred
```

Prepare draft API Connect installation YAML file.

6. Log in to the IBM Cloud Pak Platform UI and create a draft API Connect YAML.
   In this step, you complete the initial steps for deploying API Connect in Cloud Pak for Integration, but you do not begin the actual installation until step 8. Instead, you update the draft API Connect YAML to match the API Connect YAML you backed up in Backing up your Cloud Pak for Integration API Connect deployment.

   a. Log in to the Platform UI.
   b. On the home page, click Create an instance.
   c. Select the API management tile and click Next.
   d. On the Create an instance of API management page, select the deployment type, and click Next.
      Choose the same deployment type that you used when you originally deployed API Connect.

   e. On the deployment settings page, click the YAML tab to edit the installation CR in YAML format.

Update draft API Connect YAML with values from your CR backup files.

7. Refer to your CR backup files apic_cr_backup.yaml and *<subsystem>*_cr_backup.yaml to update the properties in your draft YAML.
   a. Set **`metadata.name`** to the value from your backup apic_cr_backup.yaml.
   b. Set the following required fields under **`spec.management`** and **`spec.portal`**:

      `siteName`:
      Copy the value from the original subsystem CR.

      `originalUID`:
      Copy the value from the **`spec.originalUID`** field or the **`metadata.uid`** field in the original subsystem CR.

      `encryptionSecret`:
      Use the name of the encryption secret that you created in step 2.

      `customApplicationCredentials`:
      Include all secret references that were used during the original installation. This is applicable only to the management subsystem. This field applies only to the management subsystem.

      Note: If your cluster name is longer than 10 characters, and the **`siteName`** and **`originalUID`** fields are missing, the restore operation will fail due to secret mismatches.
      Example:

```
spec:
  management:
    siteName: "a2a5e6e2"
    originalUID: "fa0f6f49-b931-4472-b84d-0922a9a92dfd"
    encryptionSecret:
      secretName: mgmt-enc-key
    customApplicationCredentials:
    - name: atm-cred
      secretName: management-atm-cred
    ...
  portal:
    siteName: "890772e3"
    originalUID: "447ea4b3-9514-4a84-a34b-ce0b349838da"
    encryptionSecret:
      secretName: portal-enc-key
```

   c. Set each of the credential secrets in **`spec.management`** section, to the secrets you created in step 5.
      Example:

```
spec:
  management:
    customApplicationCredentials:
    - name: atm-cred
      secretName: management-atm-cred
    - name: ccli-cred
      secretName: management-ccli-cred
    - name: cui-cred
      secretName: management-cui-cred
    - name: dsgr-cred
      secretName: management-dsgr-cred
    - name: governance-cred
      secretName: management-governance-cred
    - name: juhu-cred
      secretName: management-juhu-cred
    - name: cli-cred
      secretName: management-cli-cred
    - name: ui-cred
      secretName: management-ui-cred
```

   d. If you are restoring your deployment in a different data center, explicitly set your endpoints to prevent auto-generation of different endpoints.
      If you are restoring your deployment in a different data center, the endpoints that are used in your original deployment must be the same in your new data center. The Platform UI in Cloud Pak for Integration auto-generates the endpoints if they are left empty in the YAML, therefore ensure that you explicitly set the endpoints in the CR to match what is set in your <subsystem>_cr_backup.yaml files.

      For example:

```
apiManagerEndpoint:
      annotations:
        cert-manager.io/issuer: prod-ingress-issuer
        haproxy.router.openshift.io/timeout: 240s
```

```
    hosts:
      - name: prod-api-manager.example.com
      secretName: prod-be787dd3-api-manager
```

e. Set the subsystem database backup and restore settings to match what you have in apic_cr_backup.yaml.
The **spec.<*subsystem name*>.databaseBackup** sections for each subsystem contain the database backup settings.

Start API Connect deployment.

8. On the deployment page, install API Connect by clicking Create.
Wait for all subsystems to be created and ready. Monitor the installation progress with the command:

```
oc -n <namespace> get ApiconnectCluster
```

9. Restore the subsystems' database backups in the following sequence:
   a. Restoring the management database with a backup ID.
   Verify that the restoration completed successfully and that the management subsystem is Ready, then proceed to the next step and restore the portal subsystem.

   b. Restoring from a portal database backup.
   Use the restore type **all** to ensure that you restore the complete subsystem and all portal sites.

   c. Restoring the analytics database.
   Use the restore type **replace** to ensure that you restore all analytics data.

10. Force the configurator to run again.
The cluster will still not be ready after restore at this stage because the configurator has yet to successfully complete. For the configurator to run again, delete the associated job so that a new pod starts running:

    a. Run the following command to get the list of jobs:

    ```
    oc get jobs -n <APIC_namespace>
    ```

    b. Run the following command to determine the name of your API Connect instance:

    ```
    oc get apiconnectcluster -n <APIC_namespace>
    ```

    c. Run the following command to delete the configurator job:

    ```
    oc -n <APIC_namespace> delete job <instance_name>-configurator
    ```

11. Verify that the recovery was successful:
    a. Ensure that you can log in to the Cloud Manager UI.
    b. Verify that your provider organizations exist.
    c. Ensure that you can log in to each portal site.
    d. Ensure that the analytics dashboard contains your restored analytics data.

Maintaining a two data center deployment

How to maintain a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift, including information about normal operation, failure handling, and recovery.

See the following topics for information about failure handling, backup, upgrade, and removing a 2DCDR deployment.

For general information about two data center disaster recovery in API Connect, see Two data center warm-standby deployment on Kubernetes and OpenShift.

- **Key concepts of 2DCDR and failure scenarios**
  Understand how API Connect 2DCDR works and what to do when a data center fails.
- **Failing over to the warm-standby**
  How to complete service failover in a 2DCDR deployment on Kubernetes, OpenShift, and Cloud Pak for Integration, for API Connect.
- **Backup and restore requirements for a 2DCDR deployment**
  Points to consider when you configure database backup and restore settings on a two data center disaster recovery (2DCDR) deployment.
- **Removing a two data center deployment**
  Convert your 2DCDR deployment to a stand-alone deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.
- **Verifying replication between data centers**
  How to verify that your API Connect data is replicating to your warm-standby data center.
- **Synchronizing the ingress-ca certificates between sites**
- **Troubleshooting a two data center deployment**
  What to check when a 2DCDR deployment is not starting or not replicating data.

Related concepts

- Two data center warm-standby deployment on Kubernetes and OpenShift

Key concepts of 2DCDR and failure scenarios

Understand how API Connect 2DCDR works and what to do when a data center fails.

This topic discusses the concepts around the operation and maintenance of an API Connect 2DCDR deployment. For information on the planning and installation of a 2DCDR deployment, see: Two data center warm-standby deployment on Kubernetes and OpenShift.

Failover

Failover is a manual operation that requires updating the active management, portal, or both subsystems to become warm-standby, and the warm-standby subsystems to become active. The typical situations for completing a failover operation are:

- Operational failover: Where your active API Connect subsystems and data center are functioning normally, but you want to switch data centers for operational reasons, or to test the failover process.
  In this scenario, the active management and portal subsystems are converted to warm-standby first, and then the original warm-standby subsystems are converted to active.

- System down failover: Where your active data center, or the API Connect subsystems in that data center are in a failed state, and you must failover to the warm-standby to restore your API Connect service.
  In this scenario, the subsystems in the warm-standby data center are converted to active, and the network connectivity to and from the failed active subsystems is disabled - until it is possible to convert them to warm-standby.

Important:

- In all scenarios, an active-active configuration must be avoided. An active-active configuration is where the API Connect subsystems in both data centers are configured as active. This situation is commonly known as a split-brain. An active-active configuration means that the subsystem databases in each data center diverge from each other, and two management subsystems are both attempting to manage the other API Connect subsystems.
- When the active management subsystem is set to warm-standby, all data is deleted from its database. The management data from the new active (what was the warm-standby) is replicated to the new warm-standby data center. Do not set the active data center to warm-standby until you confirm that data replication is working, see: Verifying replication between data centers, or you have backups of your management data.

Reverting to a stand-alone deployment

If you want to revert to a stand-alone API Connect deployment, before you start the process, ensure that the data center where you choose to keep API Connect is set to active.

- When API Connect is reverted to be a stand-alone deployment on the warm-standby data center, all management and portal data is deleted from that data center. It becomes an empty stand-alone deployment.
- When API Connect on the active data center is reverted to be a stand-alone deployment, all management and portal data remains.

Failure scenarios

The action that you should take when a failure occurs depends on the type of failure and which data center the failure occurs in:

API Connect failure in the active data center.
When the active data center is still working correctly, and still has connectivity to the warm-standby data center, but API Connect is not working correctly:

1. It might be possible to recover API Connect on the active data center. Review the troubleshooting documentation:
   - Troubleshooting two data center replication problems.
   - Installation troubleshooting.
   - Troubleshooting operational problems.
2. Follow the failover steps to make the warm-standby the active data center. If your failed data center cannot be changed to warm-standby, then disable network connectivity to and from it, to avoid an active-active situation if the data center recovers unexpectedly.
3. Gather API Connect logs from the failed data center and open a support request: Gathering logs.
4. Do not restore the network connectivity to and from the API Connect subsystems in the failed data center until they are set to warm-standby.

Complete active data center failure
When the active data center has a failure, and API Connect is not accessible, follow these steps:

1. Disable the network connections from and to your active subsystems. Network disablement is required to prevent an active-active scenario if your failed data center recovers before you can change it to warm-standby.
2. Follow the failover steps to convert the warm-standby data center to active: Failing over to the warm-standby.
3. Do not restore the network connectivity to and from the API Connect subsystems in the failed data center until they are set to warm-standby.

Network failure that prevents API calls or user access to Management and Portal subsystems on active data center.
In this scenario, the API Connect 2DCDR deployment is working correctly, but unusable because the active data center is not accessible for API calls or for Management and Portal UI/CLI/REST API users.

1. Complete a failover, setting warm-standby to active, and the active to warm-standby: Failing over to the warm-standby.

API Connect failure on the Warm-standby data center
Where the API Connect pods on the warm-standby data center are not running as expected.

1. Review the troubleshooting documentation Troubleshooting two data center replication problems.
2. Gather API Connect logs from the failed data center and open a support case: Gathering logs.

Warm-standby data center failure
The data center where API Connect was running as warm-standby fails. In this case when the data center is recovered:

1. Verify that API Connect is running correctly as warm-standby and that the data from the active is replicated to it: Verifying replication between data centers.

Network failure between data centers
When the network connection between data centers is recovered, verify that 2DCDR database replication resumes: Verifying replication between data centers.

Management 2DCDR operational modes and statuses

The management CR `status` section includes information on the current 2DCDR mode of the management subsystem, and its status. The status section is included in the output of

```
kubectl -n <namespace> get mgmt -o yaml

...
status:
...
  haMode: active
  ...
  haStatus:
```

Table 1. 2DCDR Management subsystem operational modes (`status.haMode`)

Operational mode	Description
`active`	The subsystem pods are ready and in the correct disaster recovery state for the active data center.
`passive`	The subsystem pods are ready and in the correct disaster recovery state for the warm-standby data center.
`standalone`	The management subsystem is not configured for 2DCDR.

Table 2. Management subsystem 2DCDR statuses (`status.haStatus`)

`status.haStatus`	Description
Pending	2DCDR initial state.
Warning	Replication is failing.
Ready	Replication is running.
Error	Error in 2DCDR configuration.
PeerNotReachable	The subsystem cannot contact the subsystem on the other site, and so replication is failing.
BlockedWarmStandbyConversion	The warm-standby subsystem is in `Blocked` state, waiting for other site to become active. This state occurs when user converts existing warm-standby to active.
PromotionBlocked	Current warm-standby site promotion to active is blocked
ReadyForPromotion	Current warm-standby site is ready for promotion
PGStateSetupBlocked	Appears on active data center only. This status means that warm-standby did not initiate operator-level communication to the active yet. The active management subsystem is blocking incoming database-level connection attempts from the warm-standby.

Portal 2DCDR operational states

The portal subsystem has various transitory states that it passes through during startup and failover. The current 2DCDR operational state can be observed from the CR status section, for example:

```
kubectl get ptl -o yaml

...
status:
...
  haMode: active
  ...
  haStatus:
```

Table 3. 2DCDR Portal subsystem operational states

Operational state	Description
`progressing to active`	Pods are progressing to the active state, but the subsystem is not capable of serving traffic.
`progressing to active (ready for traffic)`	At least one pod of each type is ready for traffic. The dynamic router can be linked to this service.
`active`	The subsystem pods are ready and in the correct disaster recovery state for the active data center.
`progressing to passive`	Pods are progressing to the warm-standby state. The subsystem is not capable of serving traffic.
`progressing to passive (ready for traffic)`	At least one pod of each type is ready for traffic.
`passive`	The subsystems are ready and in the correct disaster recovery state for the warm-standby data center.
`progressing to down`	Portal is preparing to do a factory reset. This happens to the warm-standby portal when the `multiSiteHA` section is removed.

Failing over to the warm-standby

How to complete service failover in a 2DCDR deployment on Kubernetes, OpenShift, and Cloud Pak for Integration, for API Connect.

Before you begin

Ensure that you have read and understand the 2DCDR concepts and reviewed the failure scenarios that are described in Key concepts of 2DCDR and failure scenarios. Do not proceed with the failover operation until you confirm that failover is the correct course of action for your situation.

About this task

Be aware of the following important points:

- The first step in the process is to convert the active data center to warm-standby. When the active data center is converted to warm-standby, all data is deleted from the active data center's management database, to be replaced by data that is copied from the warm-standby when it becomes active.
  Do not proceed with failover if you suspect the warm-standby data center also has problems, and you are unsure it has the most recent management data. See Verifying replication between data centers, and consider restoring your active site from backup instead of attempting a failover: Backup and restore requirements for a 2DCDR deployment.

- In all scenarios, an active-active configuration must be avoided. An active-active configuration is where the API Connect subsystems in both data centers are configured as active. This situation is commonly known as a split-brain. An active-active configuration means that the subsystem databases in each data center diverge from each other, and two management subsystems are both attempting to manage the other API Connect subsystems.
- If the active data center failure prevents you from converting it to warm-standby, then you must disable the network connectivity to and from the failed management and portal subsystems on this data center, to prevent an accidental active-active situation if your failed data center recovers unexpectedly.
- If you are doing an operational failover, the process causes a temporary management and portal UI outage, until the new warm-standby completes the conversion to active.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR you must edit the `multiSiteHA` section for the subsystem in the top-level CR, instead of directly in the subsystem CRs.

Procedure

- **Management subsystem failover**
  In these example steps, DC1 is the active data center and DC2 is the warm-standby data center.

  To complete a failover from DC1 to DC2, you first set DC1 to warm-standby before you set DC2 to active. This order is required to prevent an active-active situation.

  1. Set the DC1 management subsystem to be warm-standby.
     - On Kubernetes and OpenShift individual subsystem CR deployments: Create a file called demote-to-warm-standby.yaml, and paste in the following text:

       ```
       metadata:
         annotations:
           apiconnect-operator/dr-data-deletion-confirmation: "true"
       spec:
         multiSiteHA:
           mode: passive
       ```

       Apply the updates that are specified in the demote-to-warm-standby.yaml file to your management CR:

       ```
       kubectl patch mgmt <mgmt cr name> --type merge --patch "$(cat demote-to-warm-standby.yaml)"
       ```

     - On Cloud Pak for Integration and OpenShift top-level CR deployments: Create a file called demote-to-warm-standby.yaml, and paste in the following text:

       ```
       metadata:
         annotations:
           apiconnect-operator/dr-data-deletion-confirmation: "true"
       spec:
         management:
           multiSiteHA:
             mode: passive
       ```

       Apply the updates that are specified in the demote-to-warm-standby.yaml file to your API Connect CR:

       ```
       oc patch apiconnectcluster <apic cr name> --type merge --patch "$(cat demote-to-warm-standby.yaml)"
       ```

     Note: If API Connect on DC1 is down, such that you can't set it to be warm-standby, you must ensure that the network connectivity to and from the management subsystem in DC1 is disabled, to prevent an accidental active-active situation if DC1 recovers unexpectedly. Do not restore network connectivity until DC1 is set to warm-standby.
  2. Run the following command on DC1 to check that the management subsystem HA mode is no longer `active`:

     ```
     kubectl get mgmt -o yaml
     ```

     During transition to warm-standby, the `status.haMode` shows `BlockedWarmStandbyConversion`. You can monitor the transition with:

     ```
     kubectl get mgmt -o=jsonpath='{"Status: "}{.status.phase}{"\n - HA Mode: "}{.status.haMode} {"\n - Ha Status: "}
     {.status.haStatus[?(@.status=="True")].type}{"\n"}'

     Status: Blocked
      - HA Mode: BlockedWarmStandbyConversion
      - Ha Status: BlockedWarmStandbyConversion
     ```

  3. Change the DC2 management subsystem from warm-standby to active.
     Check the DC2 management subsystem `haStatus`:

     ```
     kubectl get mgmt -o yaml

     status
       ...
       haMode: ReadyForPromotion
         haStatus:
           ...
           type: ReadyForPromotion
       ...
     ```

     wait until the `haStatus` shows `ReadyForPromotion` before proceeding. You can monitor the transition with:

     ```
     kubectl get mgmt -o=jsonpath='{"Status: "}{.status.phase}{"\n - HA Mode: "}{.status.haMode} {"\n - Ha Status: "}
     {.status.haStatus[?(@.status=="True")].type}{"\n"}'

     Status: Blocked
      - HA Mode: ReadyForPromotion
      - Ha Status: ReadyForPromotion
     ```

     - On Kubernetes and OpenShift individual subsystem CR deployments:
       Edit the DC2 management CR:

       ```
       kubectl edit mgmt
       ```

Change `spec.multiSiteHA.mode` to `active`:

- On Cloud Pak for Integration and OpenShift top-level CR deployments:
  Edit the DC2 `APIConnectCluster` CR:

  ```
  oc edit apiconnectcluster
  ```

  Change `spec.management.multiSiteHA.mode` to `active`.

4. Run the following command on both data centers to confirm when management subsystem failover is complete:

   ```
   kubectl get mgmt
   ```

   Example output:

   ```
   production-mgmt   n/n   Running   10.0.x.y   10.0.x.y        Management is ready. HA status Ready - see HAStatus in
   CR for details
   ```

   Note: Failover can take 10 minutes or more to complete. If failover does not complete, you can check the API Connect operator pod log for errors (search for the word "Multi").
5. Update your dynamic router to redirect all traffic to DC2 instead of DC1. Until the DC2 site becomes `active`, the UIs might not be operational.
6. Cloud Pak for Integration only: Check the APIConnectCluster CR status:

   ```
   oc get apiconnectcluster
   ```

   If the status returns `Warning`:

   ```
   NAME          READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                        AGE
   production    4/5     Warning   10.0.8.0   10.0.8.0-7178        Warning - see status condition for details   7d9h
   ```

   then check the status conditions:

   ```
   oc get apiconnectcluster <apiconnectcluster cr name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
   ```

   If the output shows the following condition:

   ```
   {
     "lastTransitionTime": "2024-05-29T18:15:16Z",
     "message": "an error occured while running job apic/production-configurator",
     "reason": "na",
     "status": "True",
     "type": "Warning"
   }
   ```

   then run the following command on your new active data center:

   ```
   oc -n <namespace> delete job -l app.kubernetes.io/component=configurator
   ```

   where *<namespace>* is the namespace of your APIConnectCluster.

- **Developer Portal subsystem failover**
  In these example steps, DC1 is the active data center and DC2 is the warm-standby data center.

  If you have multiple Developer Portal services, you must repeat these steps for each Developer Portal subsystem that you want to failover.

  1. Set the DC1 Developer Portal subsystem to be warm-standby.
     - On Kubernetes and OpenShift individual subsystem CR deployments:
       Edit the DC1 `PortalCluster` CR:

       ```
       kubectl edit ptl
       ```

       Change `multiSiteHA.mode` to `passive`.
     - On Cloud Pak for Integration and OpenShift top-level CR deployments:
       Edit the DC1 `APIConnectCluster` CR:

       ```
       oc edit apiconnectcluster
       ```

       Change `spec.portal.multiSiteHA.mode` to `passive`.

     Note: If API Connect on DC1 is down, such that you can't set it to be warm-standby, you must ensure that the network connectivity to and from the portal subsystem in DC1 is disabled, to prevent an accidental active-active situation if DC1 recovers unexpectedly. Do not restore network connectivity until DC1 is set to warm-standby.
  2. Run the following command on DC1 to check the Developer Portal subsystem status:

     ```
     kubectl get ptl -o yaml
     ```

     Continue to the next step when `status.haMode` is set to `progressing to passive`, or any of the `passive` states.
     For example:

     ```
     status:
       ...
       haMode:                              progressing to passive
       ...
     ```

  3. Change the DC2 Developer Portal subsystem from warm-standby to active.
     - On Kubernetes and OpenShift individual subsystem CR deployments:
       Edit the DC2 `PortalCluster` CR:

       ```
       kubectl edit ptl
       ```

       Change `spec.multiSiteHA.mode` to `active`.
     - On Cloud Pak for Integration and OpenShift top-level CR deployments:
       Edit the DC2 `APIConnectCluster` CR:

       ```
       oc edit apiconnectcluster
       ```

Change `spec.portal.multiSiteHA.mode` to `active`.

4. Update your dynamic router to redirect all traffic to DC2 instead of DC1.
5. Run the following command to check that the Developer Portal services on DC1 and DC2 are ready for traffic:

   ```
   kubectl get ptl -o yaml
   ```

   The services are ready for traffic when the `status.haMode` is set to `passive` on DC1, and is set to `active` on DC2.

- **Failover of both management and portal subsystems**
  Failover the management subsystem first, followed by the portal subsystem.

  How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. Approximate timings are:

  For the management subsystem:
  - `warm-standby` to `active`: 5 minutes
  - `active` to `warm-standby`: 15 minutes

  For the Developer Portal:
  - `warm-standby` to `active`: 15 - 40 minutes
  - `active` to `warm-standby`: 10 minutes

What to do next

If the original active data center was successfully converted to warm-standby, then verify that replication is working: Verifying replication between data centers. If replication is working, you can either:

- Revert your 2DCDR deployment to the original active and warm-standby data center designations. To revert your deployment, follow the same failover steps in this topic.
- Do nothing, and continue with your current active and warm-standby data center designations.

If your failed data center cannot be updated to warm-standby, then ensure that the network links to and from your management and portal subsystems in the failed data center are disabled. If the network links remain enabled, then an accidental active-active situation might occur if your failed data center recovers unexpectedly.

When you are able to recover the failed data center, ensure that the management and portal subsystems are set to warm-standby before you restore the network connectivity to prevent an active-active situation.
Note: The longer your original active data center was in a failed state, the longer data replication takes when it is recovered to warm-standby.
If you expect your failed data center to be down for a long time, then convert your active data center to a stand-alone deployment. See Removing a two data center deployment.

Backup and restore requirements for a 2DCDR deployment

Points to consider when you configure database backup and restore settings on a two data center disaster recovery (2DCDR) deployment.

In a 2DCDR deployment, the backup requirements are different for the portal and management databases.

Management database 2DCDR backup and restore requirements

- Different remote backup locations must be specified for each data center.
- Both active and warm-standby management subsystems run the scheduled database backup job.
- For manual database backups, always run the warm-standby backup first.
- For scheduled database backups, configure the warm-standby's backup to run one minute before the active site's backup.
- To restore the management database, you must convert both sites to standalone (non-2DCDR) before you can run the restore process.
- To restore a management database backup, follow these steps:
  1. Make each management data center a stand-alone API Connect deployment: Temporary conversion to stand-alone.
  2. Restore the database backup to your previously active data center: Restoring from a management database backup.
  3. Restore the 2DCDR configuration to the management CR in the restored data center. Ensure that the `multiSiteHA` section defines the data center as the active.
  4. Restore the 2DCDR configuration to the other data center. Ensure that the `multiSiteHA` section defines the data center as the warm-standby (passive).
  5. The management database takes some time to synchronize across the data centers. To confirm that replication is working, see: Verifying replication between data centers.

  Note: If you want to restore the backup to your previously warm-standby data center, and make that the active, then after step 1 follow these steps:
  1. To prevent an active-active situation, disable network connectivity to the management subsystem in your previously active data center.
  2. Restore the backup to your previously warm-standby data center.
  3. Restore the 2DCDR configuration to the management CR in the restored data center. Ensure that the `multiSiteHA` section defines the data center as the active.
  4. Restore the 2DCDR configuration to the management CR to the other data center. Ensure that the `multiSiteHA` section defines the data center as the warm-standby (passive).
  5. Enable network connectivity to your new warm-standby data center.
  6. The management database takes some time to synchronize across the data centers. To confirm that replication is working, see: Verifying replication between data centers.

Portal subsystem 2DCDR backup requirements

- The backup settings for both the active and warm-standby portal must be identical.
- Only the active data center portal takes backups. On failover, the backup job of the new warm-standby is disabled, and the backup job of the new active is enabled.
- Restore portal database backups on the active data center.

Configuring database backups

The steps for configuring database backups for both subsystems are the same as for a single API Connect deployment, but keep the additional 2DCDR requirements in mind when following the steps in Backing up, restoring, and disaster recovery.

Related concepts

- Two data center warm-standby deployment on Kubernetes and OpenShift

Removing a two data center deployment

Convert your 2DCDR deployment to a stand-alone deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.

Ensure that you have read and understand the concepts of 2DCDR. See Two data center warm-standby deployment on Kubernetes and OpenShift and Key concepts of 2DCDR and failure scenarios.
Note: When you convert the warm-standby data center to stand-alone, all data is deleted from its management database. Data deletion is to prevent an active-active situation, where the warm-standby attempts to communicate with existing portal, gateway, and analytics subsystems that the formally active data center is also communicating with.
Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR you must edit the `multiSiteHA` section for the subsystem in the top-level CR, instead of directly in the subsystem CRs.
Note: 2DCDR system endpoints must be changed to standalone when converting to standalone to avoid new health check issues.

Temporary conversion to stand-alone

Some API Connect maintenance operations, such as management database restore require that 2DCDR is temporarily disabled.

To convert a 2DCDR management or portal subsystem to stand-alone, follow these steps:

1. Take a backup of your current 2DCDR configuration, by backing up the subsystem CRs.
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, take the management subsystem CR backup with:

      ```
      kubectl get mgmt -o yaml > mgmt_<dr status>_2dcdr_backup.yaml
      ```

      and take the portal CR backup with:

      ```
      kubectl get ptl -o yaml > portal_<dr status>_2dcdr_backup.yaml
      ```

      where *<dr status>* is the current 2DCDR status of the subsystem, either active or warm-standby.
   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

      ```
      kubectl get apiconnectcluster -o yaml > apic_<dr status>_2dcdr_backup.yaml
      ```

      where *<dr status>* is the current 2DCDR status of the subsystem, either active or warm-standby. The `APIConnectCluster` CR contains the 2DCDR settings for both management and portal subsystems.
2. Remove the 2DCDR configuration from the management subsystem. The steps to take are different for active and warm-standby:
   a. Active management subsystem:
      i. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

      ```
      kubectl patch managementcluster <mgmt cr name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
      ```

      ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used:

      ```
      kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
      "/spec/management/multiSiteHA"}]'
      ```

   b. Warm-standby management subsystem:
      To convert the management subsystem from warm-standby to stand-alone, you must acknowledge acceptance of this in an annotation in the management CR. The steps to convert warm-standby management to stand-alone are:
      i. On Kubernetes and OpenShift where individual subsystem CRs are used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml, and paste in the following text:

      ```
      metadata:
        annotations:
          apiconnect-operator/dr-data-deletion-confirmation: "true"
      spec:
        multiSiteHA: null
      ```

      Apply the file to your management CR with:

      ```
      kubectl patch managementcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-
      standby.yaml)"
      ```

      ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml and paste in the following text:

      ```
      metadata:
        annotations:
          apiconnect-operator/dr-data-deletion-confirmation: "true"
      spec:
        management:
          multiSiteHA: null
      ```

      Apply the file to your top-level CR with:

      ```
      kubectl patch apiconnectcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-
      standby.yaml)"
      ```

3. Remove the 2DCDR configuration from the portal subsystem:
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

      ```
      kubectl patch portalcluster <portal CR name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
      ```

      Delete the `spec.multiSiteHA` section.
   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

      ```
      kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
      "/spec/portal/multiSiteHA"}]'
      ```

4. Complete the maintenance operation that required the temporary conversion to stand-alone, such as management database restore.
5. Restore the 2DCDR configuration by adding back the `multiSiteHA` sections to your subsystem CRs. You can restore these sections by copying the `multiSiteHA` sections from the backup files you took in step 1, and pasting them into the corresponding CRs:
   a. On Kubernetes and OpenShift where individual subsystem CRs are used:
      i. Edit the management CR:

         ```
         kubectl edit mgmt
         ```

         and paste in the `multiSiteHA` section from your backup mgmt_*<dr status>*_2dcdr_backup.yaml.
      ii. Edit the portal CR:

         ```
         kubectl edit ptl
         ```

         and paste in the `multiSiteHA` section from your backup portal_*<dr status>*_2dcdr_backup.yaml.
   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, edit the top-level CR:

      ```
      kubectl edit apiconnectcluster
      ```

      and in the `spec.management.multiSiteHA`, paste in the contents from the corresponding `multiSiteHA` sections of your apic_*<dr status>*_2dcdr_backup.yaml

Permanently revert to stand-alone

If you want to revert to a single data center topology:

1. Decide which data center you want to keep. If this data center is not the current active data center, then complete the failover operation to make it the active: Failing over to the warm-standby.
2. Remove the 2DCDR configuration section from the management subsystem CR on the active data center.
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

      ```
      kubectl patch managementcluster <mgmt cr name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
      ```

   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

      ```
      kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
      "/spec/management/multiSiteHA"}]'
      ```

3. Remove the 2DCDR configuration from the portal subsystem:
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

      ```
      kubectl patch portalcluster <portal CR name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
      ```

      Delete the `spec.multiSiteHA` section.
   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

      ```
      kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
      "/spec/portal/multiSiteHA"}]'
      ```

4. The next action that you take depends on what you want to do with your warm-standby data center:
   a. If you want to permanently revert to a single data center topology, then uninstall API Connect on the warm-standby data center. See: Uninstalling API Connect.
   b. Leave your warm-standby as it is, in case you decide to revert your stand-alone data center to a 2DCDR active.
   c. Convert your warm-standby subsystems to stand-alone. This operation erases all data from the management and portal databases.
      To convert the management subsystem from warm-standby to stand-alone, you must acknowledge acceptance of this in an annotation in the management CR. The steps to convert warm-standby management to stand-alone are:
      i. On Kubernetes and OpenShift where individual subsystem CRs are used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml, and paste in the following text:

         ```
         metadata:
           annotations:
             apiconnect-operator/dr-data-deletion-confirmation: "true"
         spec:
           multiSiteHA: null
         ```

         Apply the file to your management CR with:

         ```
         kubectl patch managementcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-
         standby.yaml)"
         ```

      ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml and paste in the following text:

         ```
         metadata:
           annotations:
             apiconnect-operator/dr-data-deletion-confirmation: "true"
         spec:
           management:
             multiSiteHA: null
         ```

Apply the file to your top-level CR with:

```
kubectl patch apiconnectcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-standby.yaml)"
```

To convert portal from warm-standby to stand-alone, manually remove the `spec.multiSiteHA` section from the portal CR:

i. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

```
kubectl edit ptl
```

Delete the `spec.multiSiteHA` section.

ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

```
kubectl edit apiconnectcluster
```

Delete the `spec.portal.multiSiteHA` section.

Verifying replication between data centers

How to verify that your API Connect data is replicating to your warm-standby data center.

The management and portal UIs are not accessible on the warm-standby data center, so it is not possible to check that data replication is working by logging in to the UIs. Instead, you can verify that the warm-standby management and portal databases are in sync with command-line operations.
Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Verifying Management replication

The management CR reports a warning if it detects a problem with management data replication:

```
kubectl get mgmt
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
kubectl get mgmt -o yaml
```

```
...
status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "Warning"
    }
```

If the warning persists, then see Troubleshooting a two data center deployment.
To verify replication by creating new data on the active and checking that it is copied to the warm-standby, follow these steps:

1. Login to the Cloud Manager UI.
2. Create a local user registry called `2dcdrtest`: Configuring a Local User Registry.
3. Run the following command in your warm-standby data center to query the management database for the new user registry:

   ```
   kubectl exec -n <namespace> `kubectl -n <namespace> get po -l role=primary -o name` -- bash -c "psql -U postgres apim -c \"select name,created_at from user_registry where name = '2dcdrtest'\""
   ```

   Expected output is:

   ```
   Defaulted container "database" out of: database, set-libpq-certs (init)
      name     |        created_at
   ------------+-------------------------
    2dcdrtest | <date and time when step 2 was done>
   (1 row)
   ```

   If `2dcdrtest` is returned and has a creation time consistent with when you did step 2, then replication is working. If it is not returned, then either replication is not working, or the data is not yet replicated. If an older creation date is returned, then it's possible the registry was not deleted after a previous check, in which case delete the registry and repeat this test. If replication is not working, follow the 2DCDR troubleshooting steps: Troubleshooting a two data center deployment.
4. Return to the Cloud Manager UI, and delete the `2dcdrtest` user registry.

Verifying Portal replication

Follow these steps to verify that the portal database is replicating from the active data center to the warm-standby data center.

1. In the active data center, identify the active db pod:

   ```
   kubectl get pods -n <namespace> | grep "<active site name>-db"
   ```

   Example output:

   ```
   <portal instance name>-<active site name>-db-0                                    2/2     Running     0
   22h
   ```

where *<active site name>* is the **siteName** property from the portal CR on your active data center. The active data center db pods have 2 containers, so show a status of 2/2. A three replica deployment has three db pods and you can pick any one of them for the next step.

2. In the active data center, run the following command:

```
kubectl exec -ti -n <namespace> <active portal db pod> -c db -- bash -ic "dbstatus 2>&1 | grep Last | sed 's/.*committed: \([0-9]*\).*/\1/'"
```

Example output:

```
355175
```

where *<active portal db pod>* is the pod name that is returned from step 1. The command returns a number.

3. In the warm-standby data center, identify the warm-standby db pod:

```
kubectl get pods -n <namespace> | grep "<warm-standby site name>-db"
```

Example output:

```
<portal instance name>-<warm-standby site name>-db-0                                                  2/2     Running     0
22h
```

where *<warm-standby site name>* is the **siteName** property from the portal CR on your warm-standby data center. The warm-standby data center db pods have 1 container, so show a status of 1/1. A three replica deployment has three db pods and you can pick any one of them for the next step.

4. In the warm-standby data center, run the following command:

```
kubectl exec -ti -n <namespace> <passive portal db pod> -c db -- bash -ic "dbstatus 2>&1 | grep Last | sed 's/.*committed: \([0-9]*\).*/\1/'"
```

Example output:

```
355495
```

where *<passive portal db pod>* is the pod name that is returned from step 3. The command returns a number.

5. The numbers that are returned from steps 2 and 4 represent the portal database's last committed transaction number. When the active data center commits a new transaction the number is incremented, this update is replicated to the warm-standby data center. If replication is working the number that is returned from the warm-standby data center should always be close to the number that is returned from the active data center. It is unlikely to be the same number that is returned, unless you are able run step 4 and step 2 at precisely the same time.
6. Repeat steps 2 and 4 several times to confirm that the warm-standby number is keeping up with the active number. If the number returned from the warm-standby data center is far behind, or ahead of the number that is returned from the active, then there is likely to be a replication problem, see Troubleshooting a two data center deployment.

Synchronizing the ingress-ca certificates between sites

The X.509 CA certificate that is used for TLS communication between the API Connect deployments in each data center is referred to as the **ingress-ca** X.509 certificate. This certificate is stored in the **ingress-ca secret** in both data centers, and it must be the same in each data center for 2DCDR to function.

The cert-manager has a separate object that is referred to as the **ingress-ca** Kubernetes cert-manager certificate object. Cloud Pak for Integration and OpenShift top-level CR deployments has the **ingress-ca** Kubernetes cert-manager certificate object in both data centers. Kubernetes and OpenShift individual subsystem installations, has the **ingress-ca** Kubernetes cert-manager certificate object in only one of the data centers, the data center that was the original active data center when 2DCDR was first configured.

Ingress-ca on Kubernetes and OpenShift individual subsystem installations

In Kubernetes and OpenShift individual subsystem CR installations, the **ingress-ca** Kubernetes cert-manager certificate object exists on only one of the data centers in a 2DCDR deployment. The **ingress-ca secret** object exists in both data centers and must contain the same certificate string:

```
kubectl -n <namespace> get secret ingress-ca -o yaml

apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
...
```

To identify the data center that has the **ingress-ca** Kubernetes cert-manager certificate object, run:

```
kubectl -n <namespace> get cert ingress-ca

   NAME         READY   SECRET       AGE
   ingress-ca   True    ingress-ca   30h
```

Note: If the data center that has the **ingress-ca** Kubernetes cert-manager certificate object is in a failed state and is unrecoverable, a new **ingress-ca** Kubernetes cert-manager certificate object can be created on the active data center by using the **ingress-ca** certificate section of the installation YAML file: **helper_files/ingress-issuer-v1.yaml**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ingress-ca
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-ca"
  }
```

```
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
```

Synchronizing the `ingress-ca` X.509 certificate across data centers

Follow these steps to extract your **ingress-ca** X.509 certificate from your source data center and prepare it for application on your target data center:

1. Extract the **ingress-ca** **secret** from your source data center to a file called **new-ca-issuer-secret.yaml**:

   ```
   kubectl get secret ingress-ca -o yaml -n <namespace>  > new-ca-issuer-secret.yaml
   ```

2. Edit the **new-ca-issuer-secret.yaml** file and remove the **creationTimestamp**, **resourceVersion**, **uid**, **namespace**, and **managedFields**. Remove the labels and annotations sections completely. The resulting contents should include the **ingress-ca** X.509 certificate, and the secret name:

   ```
   apiVersion: v1
   data:
     ca.crt: <long cert string>
     tls.crt: <long cert string>
     tls.key: <long cert string>
   kind: Secret
   metadata:
     name: ingress-ca
   type: kubernetes.io/tls
   ```

3. Copy the **new-ca-issuer-secret.yaml** to the target data center.

Follow these steps to apply the extracted **ingress-ca** X.509 certificate on your target data center:

1. To apply the **new-ca-issuer-secret.yaml** file, run:

   ```
   kubectl apply -f new-ca-issuer-secret.yaml -n <namespace>
   ```

2. Regenerate all **ingress-ca** end-entity certificates:

   ```
   kubectl get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-
   manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n
   <namespace>
   ```

   All affected pods should automatically restart. For more information about regenerating certificates, see: Renewing cert-manager controlled certificates.

Troubleshooting a two data center deployment

What to check when a 2DCDR deployment is not starting or not replicating data.

Typical causes of 2DCDR failures are network problems between data centers, TLS certificate mismatches, or environmental problems on one of the data centers.

Note: For OpenShift® users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Check that API Connect pods are running

Confirm that all the pods are ready and running:

- To check portal, run:

  ```
  kubectl get ptl -n <namespace>
  ```

  ```
  NAME                          READY                                 STATUS    VERSION    RECONCILED VERSION   MESSAGE
  AGE
  <portal instance name>        <ready pods>/<total number of pods>   Running   10.0.5.x   10.0.5.x-xxxx        Serving 1
  site   14d
  ```

- To check management, run:

  ```
  kubectl get mgmt -n <namespace>
  ```

  ```
  NAME                          READY                                 STATUS    VERSION    RECONCILED VERSION   AGE
  <management instance name>    <ready pods>/<total number of pods>   Running   10.0.5.x   10.0.5.x-xxxx        14d
  ```

The number of *<ready pods>* must match the *<total number of pods>*. If not all the pods are in ready state, run

```
kubectl get <mgmt or ptl> -n <namespace> -o yaml
```

and check the **status.conditions** output, for example:

```
  conditions:
  - lastTransitionTime: "2022-09-27T21:37:21Z",
    message: "Management installation in progress. Not all services are ready, pending services: analytics-proxy, apim, client-
downloads-server, juhu, ldap, ...",
    reason: na
    status: "True"
    type: Pending
```

Also, check which pods are not running with:

```
kubectl get pods -n <namespace>
```

and review their logs:

```
kubectl logs <pod name> -n <namespace>
```

Note: The warm-standby management subsystem has fewer pods than the active management subsystem. The active and warm-standby portal subsystems have the same number of pods.

Check the multiSiteHA sections of the management and portal CRs

Run `kubectl describe` on your management and portal CRs to confirm that the `multiSiteHA` specification and status sections of the CR are as expected. For example, on the warm-standby management CR you should see:

```
kubectl describe mgmt -n <namespace>
```

```
...
spec:
  Multi Site HA:
    Mode:  passive
    Replication Endpoint:
      Annotations:
        cert-manager.io/issuer:  ingress-issuer
      Hosts:
        Name:                mgmt-replication.apps.example.com
        Secret Name:         mgmt-replication-server
    Replication Peer FQDN:  mgmt-replication.apps.example.com
    Tls Client:
      Secret Name:  mgmt-replication-client
...
Status
...
  Ha Mode:                                passive
...
  Multi Site HA:
    Remote Site Deployment Name:  management
    Remote Site Name:             passive
    Remote UUID:                  c736b702-b1ab-4fe2-b132-9c9d3b3a3bd3.9f986be1-14fc-4b3a-8eee-094217ce361e
    Replication Peer:             https://mgmt-replication.apps.example.com/
```

Check that the `Hosts` and `Replication Peer` properties are set correctly in the `multiSiteHA` section, and that the hostnames resolve correctly in each data center.

Check the `ingress-ca` X.509 certificates match

Replication fails if both data centers do not have the same X.509 certificate in their `ingress-ca` secrets. Run the following command in both data centers to see the X.509 certificate, and check that the output is the same:

```
openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk
'{print $2}' | base64 -d)
```

If you do not have the `openssl` command available, you can instead run only the `kubectl` part, which produces a larger output:

```
kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
```

if the outputs are different, follow these steps to synchronize the certificates:

1. If you installed API Connect on Kubernetes or OpenShift using individual subsystem CRs, determine which data center has the `ingress-ca` Kubernetes cert-manager certificate object:

   ```
   kubectl get certificates -n <namespace> | grep ingress-ca
   ```

   this is your source data center.
   Note: If no certificates are returned when you run:

   ```
   kubectl get certificates -n <namespace> | grep ingress-ca
   ```

   on either data center, then create a new `ingress-ca` Kubernetes cert-manager certificate object can be created on the active data center by using the `ingress-ca` certificate section of the installation YAML: `helper_files/ingress-issuer-v1.yaml`:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: ingress-ca
     labels: {
       app.kubernetes.io/instance: "management",
       app.kubernetes.io/managed-by: "ibm-apiconnect",
       app.kubernetes.io/name: "ingress-ca"
     }
   spec:
   ```

```
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
```

The **ingress-ca** certificate can be lost in certain scenarios, such as redeployment of one of the data centers as warm-standby after a failure.

2. If you installed API Connect on Cloud Pak for Integration, use the current active data center as the source data center, and the warm-standby as the target data center.
3. Extract the **ingress-ca secret** from your source data center to a file called **new-ca-issuer-secret.yaml**:

```
kubectl get secret ingress-ca -o yaml -n <namespace>  > new-ca-issuer-secret.yaml
```

4. Edit the **new-ca-issuer-secret.yaml** file and remove the **creationTimestamp**, **resourceVersion**, **uid**, **namespace**, and **managedFields**. Remove the labels and annotations sections completely. The resulting contents should include the **ingress-ca** X.509 certificate, and the secret name:

```
apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
metadata:
  name: ingress-ca
type: kubernetes.io/tls
```

5. Copy the **new-ca-issuer-secret.yaml** to the target data center.

Follow these steps to apply the extracted **ingress-ca** X.509 certificate on your target data center:

1. To apply the **new-ca-issuer-secret.yaml** file, run:

```
kubectl apply -f new-ca-issuer-secret.yaml -n <namespace>
```

2. Regenerate all **ingress-ca** end-entity certificates:

```
kubectl get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-
manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n
<namespace>
```

All affected pods should automatically restart. For more information about regenerating certificates, see: Renewing cert-manager controlled certificates.

Check the operator and tunnel pod logs

The API Connect operator pod manages the 2DCDR deployment. The tunnel pods manage the communication between data centers.

Check the logs of the API Connect operator pod and search for the text "multi" to see any errors that are related to 2DCDR. For example:

```
kubectl logs <ibm-apiconnect operator pod> -n <operator namespace> | grep -i multi
```

The *<ibm-apiconnect operator pod>* has **ibm-apiconnect** in its name, and might be in a different namespace to your API Connect operand pods.

Check the logs of your API Connect **tunnel** pods. These pods always have **tunnel** in their name. For example:

```
kubectl logs portal-tunnel-0 -n <namespace> --since=10m
```

```
...
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.786Z    INFO    tls     incoming
request {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.786Z    INFO    tls     connect to
upstream        {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.817Z    INFO    tls     closing
connection      {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 10.254.20.144 - - [02/Dec/2022:12:27:33 +0000] "GET
/portal-active-db-0/3060 HTTP/1.1" 101 0
```

Note: It is normal for the management tunnel pod to repeatedly log:

```
2022/12/02 12:29:17 http: TLS handshake error from 10.254.16.1:44812: EOF
```

This message can be filtered out with **grep -v**:

```
kubectl logs management-tunnel-574bdcd865-48zh6 -n <namespace> | grep -v "http: TLS handshake error from"
```

Renewing TLS certificates

Renew TLS certificates in your API Connect deployment.

A default API Connect deployment uses cert-manager to create *issuers*, *CA certificates*, *server certificates*, and *client certificates*. Cert-manager monitors all the certificates that it creates, and renews them before they expire.
Note: If you are not using cert-manager, or if you customized some or all or your API Connect certificates, then you are responsible for monitoring and renewing those certificates.
Certain API Connect configuration and maintenance operations can require that some or all TLS certificates that are used by API Connect are renewed before their expiry. The process of updating API Connect TLS certificates is called "certificate renewal". The process to renew certificates involves the following steps:

1. Manually deleting Kubernetes secrets that contain the TLS certificates that need renewal.
2. Cert-manager detecting the deletion of these secrets, and automatically creating new secrets that contain newly generated x509 certificates.

Steps steps for identifying and renewing API Connect certificates are described in the following topics:

- **Renewing cert-manager controlled certificates**
  Use cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.
- **Renewing custom certificates**
  If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.
- **List of Issuers, CA certificates, and secrets**
  A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment.
- **List of ingress certificates**
  A summary of certificates that are used for communications between subsystems and clients in an API Connect deployment.
- **List of intra-subsystem certificates**
  A summary of certificates used for communications within subsystems in an API Connect deployment.
- **V2018 upgrade: List of certificates to update manually**
  If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.
- **Renewing certificates in a two data center deployment on Kubernetes and OpenShift**
  Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.

Related information

- API Connect TLS certificates reference page.

Renewing cert-manager controlled certificates

Use cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.

Cert-manager monitors and automatically renews all API Connect certificates before they expire. However, some API Connect maintenance operations require the manual renewal of certificates. The topics in this section describe how to manually trigger cert-manager to renew the certificates that it manages.

Key points to understand:

- If you replaced any cert-manager certificates with custom certificates, you must update these certificates manually before they expire. Cert-manager does not monitor custom certificates.
- Some API Connect pods must be restarted when certain API Connect certificates are renewed. See Pods that require restart after certificate renewal.
- When you renew a CA certificate, you must renew all the end-entity certificates that the CA signs. See API Connect TLS certificates reference.

Note: If your API Connect deployment was originally installed at v10.0.1.2 or earlier, then the certificate might be missing the `duration` and `renewBefore` properties. Before you renew any API Connect connect certificates, verify that your certificates have these properties, and if not then add them:

1. Run the following command to list of all the certificate names, with their `duration` and `renewBefore` properties:

   ```
   kubectl -n <namespace> get certificate -o custom-
   columns=NAME:metadata.name,DURATION:spec.duration,RENEWBEFORE:spec.renewBefore
   ```

   Example output where `management-ca` is missing the `duration` and `renewBefore` properties:

   ```
   NAME                                    DURATION     RENEWBEFORE
   analytics-ai-endpoint                   17520h0m0s   720h0m0s
   ...
   management-ca                           <none>       <none>
   ```

2. For each certificate output from step 1 that shows `<none>` for `duration` and `renewBefore`, edit the certificate and add these properties:

   ```
   kubectl -n <namespace> edit certificate <certificate name>
   ```

   Add the `duration` and `renewBefore` properties under the `spec` property as shown in the following example:

   ```
   ...
   spec:
   ...
     duration: <duration>
     renewBefore: 720h # 30 days
   ...
   ```

   where *<duration>* is:
   - `87600h` for CA certificates.
   - `17520h` for all other certificates.

- **Renewing the management-ca with the ManagementSecretRotation CR**
  Use the `ManagementSecretRotation` CR to renew the `management-ca` certificate and all end-entity certificates that `management-ca` signs.
- **Renewing the portal-ca with the PortalSecretRotation CR**
  Use the `PortalSecretRotation` CR to renew the `portal-ca` and all end-entity certificates that the `portal-ca` certificate signs.

- **Renewing the analytics CA**
  Renew the analytics CA certificate, and all end-entity certificates that the analytics CA signs.
- **Renewing the ingress-ca**
  Renew the ingress CA certificate, and all the end-entity certificates that the ingress CA signs.
- **Renewing end-entity certificates**
  Renew an API Connect end-entity certificate.
- **Monitoring cert-manager certificate renewal**
  How to monitor when your certificates are nearing their expiry, confirm that cert-manager is renewing them, and verify that dependent certificates are also renewed and related pods are restarted.

Renewing the `management-ca` with the ManagementSecretRotation CR

Use the **`ManagementSecretRotation`** CR to renew the **`management-ca`** certificate and all end-entity certificates that **`management-ca`** signs.

About this task

Applying the **`ManagementSecretRotation`** CR (Custom Resource) is the recommended method for renewing the **`management-ca`** and all its end-entity certificates. The alternative method is to manually renew the **`management-ca`** certificate and then each of its end-entity certificates, which you can identify from the certificates table Management certificates.

Restriction: The **`ManagementSecretRotation`** CR is for use with a single data center deployment. Do not attempt to use it with a two data center disaster recovery deployment. See Renewing certificates in a two data center deployment on Kubernetes and OpenShift.

Procedure

1. Create a file called management_cert_rotate.yaml and paste in the following contents:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: mgmt-rotate-issuer
spec:
  managementCluster: <management CR name>
  rotateCertificates:
    certificates:
    - <management CR name>-ca
```

   where *<management CR name>* is the name of your **`ManagementCluster`** CR. You can identify this name with:

```
kubectl get ManagementCluster -n <management namespace>
```

2. Apply the CR by running the following command:

```
kubectl create -f management_cert_rotate.yaml -n <management namespace>
```

   Applying the CR updates the **`management-ca`**, and all end-entity certificates that **`management-ca`** signs. To view a list of the renewed certificates, run the following command:

```
kubectl describe ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

   The **`status`** block in the command output shows the renewed certificates:

```
Status:
...
  Phase:                    Completed
  Rotated Certs:
    def-management-ca
    def-management-client
    def-management-db-client-postgres
    def-management-natscluster-mgmt
    def-management-site1-postgres
    def-management-db-client-apicuser
    def-management-server
  State:  1/1
...
```

3. When certificate rotation is successfully completed, delete the **`ManagementSecretRotation`** CR.
   Confirm that certificate rotation is finished with the command:

```
kubectl get ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

   The output should show **`Completed`**:

```
NAME                  READY   STATUS      AGE
mgmt-rotate-issuer    1/1     Completed   6m52s
```

   Then delete the CR:

```
kubectl delete ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

Renewing the `portal-ca` with the PortalSecretRotation CR

Use the `PortalSecretRotation` CR to renew the `portal-ca` and all end-entity certificates that the `portal-ca` certificate signs.

About this task

Applying the `PortalSecretRotation` CR (Custom Resource) is the recommended method for renewing the `portal-ca` certificate and all its end-entity certificates. The alternative method is to manually renew the `portal-ca` certificate and then each of its end-entity certificates, which you can identify from the certificates table Portal certificates.

Restriction: The `PortalSecretRotation` CR is for use with a single data center deployment. Do not attempt to use it with a two data center disaster recovery deployment. See Renewing certificates in a two data center deployment on Kubernetes and OpenShift.

Procedure

1. Create a file called portal-secret-cr.yaml and paste in the following contents:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalSecretRotation
metadata:
  name: portal-rotate-secret
spec:
  portalCluster: <portal CR name>
  # List of certificates you want to rotate (Listing an issuer will rotate any certs issued by the issuer e.g listing just
portal-ca will rotate portal-ca, portal-client and portal-server)
  rotateCertificates:
    certificates:
    - <portal CR name>-ca
  rotateEncryptionSecret:
    # Set to true if you want to rotate the encryption secret.
    rotate: true
    # Optional value to set the encryption secret to, if supplied secret exists in the env. If not supplied the rotated
secret will be random.
    encryptionSecret: new-encyption-secret
```

   where *<portal CR name>* is the name of your `PortalCluster` CR. You can identify this name with:

```
kubectl get PortalCluster -n <portal namespace>
```

   If you set `rotate: true` in the `rotateEncryptionSecret` section, the portal-encryption-secret is updated and the following changes are made:
   - Change the root MySQL password.
   - Generate a new, site-specific MySQL password for each site.
   - Reencrypt all client_ids and client_secrets in the portal database.
2. Apply the CR by running the following command:

```
kubectl create -f portal-secret-cr.yaml -n <portal namespace>
```

   Applying the CR updates the `<portal CR name>-ca`, along with all end-entity certificates that it signs. To view a list of the updated certificates, run the following command:

```
kubectl describe PortalSecretRotation portal-rotate-secret -n <portal namespace>
```

   The `status` block in the command output shows the renewed certificates:

```
Status:
  ...
  Phase:                    Completed
  Rotated Certs:
    def-portal-ca
    def-portal-server
    def-portal-client
  State:  Completed Portal Secret Rotation.
...
```

3. When the certificate rotation is finished, delete the `PortalSecretRotation` CR.
   Confirm that certificate rotation is finished with the command:

```
kubectl get PortalSecretRotation portal-rotate-issuer -n <portal namespace>
```

   The output should show `Completed`:

```
NAME                    STATUS      MESSAGE                              AGE
portal-rotate-secret    Completed   Completed Portal Secret Rotation.    7m50s
```

   Then delete the CR:

```
kubectl delete PortalSecretRotation portal-rotate-issuer -n <portal namespace>
```

Renewing the analytics CA

Renew the analytics CA certificate, and all end-entity certificates that the analytics CA signs.

About this task

The pods that comprise the analytics subsystem communicate with each other using certificates that are signed by the analytics CA certificate. If you renew the analytics CA certificate, you must also renew the analytics end-entity certificates that the analytics CA signs.

For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Run the following command to renew the analytics CA certificate:

   ```
   kubectl -n <analytics namespace> get certificate <analytics CA name> -o=jsonpath='{.spec.secretName}' | xargs kubectl -n
   <analytics namespace> delete secret
   ```

   where *<analytics CA name>* is the name of the analytics CA certificate. On Kubernetes and OpenShift individual subsystem installations this name is **analytics-ca**. On Cloud Pak for Integration and OpenShift top-level CR installations, this name is ***<apic instance name>*-a7s-ca**.
   Verify that a new *<analytics CA name>* **secret** is created:

   ```
   kubectl -n <analytics namespace> get secret
   ```

   Output should show a new *<analytics CA name>* secret:

   ```
   NAME                                                    TYPE                DATA   AGE
   ...
   <analytics CA name>                                     kubernetes.io/tls   4      28s
   ```

   Check that the **AGE** column shows the secret was recently created.
2. Renew the end-entity certificates signed by the analytics CA. Run the following command for each certificate:

   ```
   kubectl get certificate <analytics certificate> -o=jsonpath='{.spec.secretName}' | xargs kubectl delete secret
   ```

   where *<analytics certificate>* is the name of the end entity certificate. The analytics end-entity certificates are:
   - **analytics-client** or **a7s-client**.
   - **analytics-server** or **a7s-server**.

   On Cloud Pak for Integration and OpenShift top-level CR installations, the certificate name is prefixed with ***<apic instance name>*-**.
3. Verify that the **storage** and **warehouse** pods restarted, and manually restart the analytics **ingestion** and **director** pods so that they use the renewed certificates.

   ```
   kubectl get pods
   ```

   Check that **storage** and **warehouse** pods restarted:

   ```
   NAME                                    READY   STATUS              RESTARTS        AGE
   a7s-director-5b57848786-lg5w6           1/1     Running             0               10d
   a7s-ingestion-0                         1/1     Running             0               6d16h
   a7s-mtls-gw-5f5cb85744-gcwfw            1/1     Running             0               37d
   a7s-oscron-28600035-gnb2p               0/1     Completed           0               19d
   a7s-oscron-28600050-jgh4j               1/1     Running             3 (19d ago)     19d
   a7s-storage-0                           0/1     ContainerCreating   1               5s
   a7s-warehouse                           0/1     ContainerCreating   1               5s
   ```

   Note: Warehouse pods exist only when analytics backups are enabled.
   Then delete the **ingestion** and **director** pods:

   ```
   kubectl delete pod <analytics ingestion pod name>
   ```

   ```
   kubectl delete pod <analytics director pod name>
   ```

   Tip: For convenience, you can restart all analytics pods with a single command:

   ```
   kubectl delete pod -l app.kubernetes.io/instance=<analytics CR name>
   ```

Renewing the ingress-ca

Renew the ingress CA certificate, and all the end-entity certificates that the ingress CA signs.

About this task

The ingress CA certificate signs all user-facing and inter-subsystem certificates. When you renew the ingress CA, you must renew all the end-entity certificates that the ingress CA signs.
For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Run the following command to renew the ingress CA certificate:

   ```
   kubectl -n <management namespace> get certificate <ingress CA name> -o=jsonpath='{.spec.secretName}' | xargs kubectl -n
   <management namespace> delete secret
   ```

   where *<ingress CA name>* is the name of the ingress CA certificate. On Kubernetes and OpenShift individual subsystem installations this name is **ingress-ca**. On Cloud Pak for Integration and OpenShift top-level CR installations, this name is ***<apic instance name>*-ingress-ca**.
2. Run the following command to renew all the end-entity certificates that the ingress CA signs:

```
kubectl get secrets -n <management namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <management namespace>
```

3. If you have other subsystems that are in different namespaces from the management subsystem, then follow the steps in Copying renewed ingress-ca to subsystems in different namespaces.
4. Verify analytics in the developer portal.
   Due to a known issue, when the `ingress-ca` is renewed, it is possible that Analytics in the Developer Portal might stop working. If this happens, complete the following steps to ensure that certificate changes take effect:
   a. Log in to the Cloud Manager user interface.
   b. In the navigation list, click Topology.
   c. Edit the Analytics service.
   d. On the Analytics page, edit the Summary field to force a change; for example, by adding a space to the end of a sentence.
   e. Click Save.

Copying renewed ingress-ca to subsystems in different namespaces

When the ingress CA certificate on the management subsystem is renewed, you must copy the renewed certificate to any subsystems that are in a different namespace.

Before you begin

Complete the steps in Renewing the ingress-ca to renew the ingress CA in your management subsystem namespace.
Note: If all your API Connect subsystems are in the same namespace, you do not need to follow this procedure.

About this task

The ingress CA signs all the inter-subsystem communication certificates that are used between API Connect subsystems. If your subsystems are installed in different namespaces, then the ingress CA must be manually synchronized across all those namespaces.

These steps must be repeated for all namespaces where you have subsystems that are registered with your management subsystem.

For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Export the management namespace ingress CA secret to a YAML file called ingress-ca.yaml:

   ```
   kubectl -n <management namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
   ```

2. Edit `ingress-ca.yaml` and remove all `metadata` fields except for the secret name. The resulting file contents look like this:

   ```
   apiVersion: v1
   data:
     ca.crt: ...
     tls.crt: ...
     tls.key ...
   kind: Secret
   metadata:
     name: ingress-ca
   type: kubernetes.io/tls
   ```

3. Apply the updated the `ingress-ca.yaml` in the namespace of the other subsystem:

   ```
   kubectl -n <other subsystem namespace> apply -f ingress-ca.yaml
   ```

4. Verify that the ingress CA is now identical in both namespaces.
   a. Extract your `ingress-ca` secret to a file in your management namespace:

      ```
      kubectl -n <management namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d > ingress.pem.mgmt
      ```

   b. Extract your `ingress-ca` secret to a file in your other subsystems' namespace:

      ```
      kubectl -n <other subsystem namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d > ingress.pem.other
      ```

   c. Verify that the files that are created for each namespace are identical:

      ```
      diff ingress.pem.mgmt ingress.pem.mgmt
      ```

5. Run the following command to renew all the `ingress-ca` end-entity certificates in the other subsystems' namespace:

   ```
   kubectl get secrets -n <other subsystem namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <other subsystem namespace>
   ```

Renewing end-entity certificates

Renew an API Connect end-entity certificate.

About this task

To renew an end-entity certificate, delete the secret that corresponds to the certificate. Cert-manager detects the deletion of the secret and re-creates it with a new x509 certificate.

For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Get a list of all certificates in your API Connect namespace:

   ```
   kubectl -n <namespace> get certificates
   ```

   The output lists all certificates with their status, age, and the name of the corresponding secret. In this example, the certificate that is used by the API Manager UI is shown:

   ```
   NAME                                    READY   SECRET                                  AGE
   ...
   apim-endpoint                           True    apim-endpoint                           13d
   ...
   ```

   By default the secret names are identical to the certificate names.

2. Delete the secret for the certificate that you want to renew:

   ```
   kubectl -n <namespace> delete secret <secret name>
   ```

   Cert-manager detects the deletion of the secret and creates a new secret with a newly generated x509 certificate.

Monitoring cert-manager certificate renewal

How to monitor when your certificates are nearing their expiry, confirm that cert-manager is renewing them, and verify that dependent certificates are also renewed and related pods are restarted.

CA certificate renewal

If cert-manager renews a CA certificate, you must renew all the certificates that the CA signs. See API Connect TLS certificates reference.

Monitoring when your certificates are due to expire

Check when your certificates are due to expire with the following command:

```
kubectl -n <namespace> get certificate -o custom-
columns=NAME:metadata.name,DURATION:spec.duration,RenewBEFORE:spec.renewBefore,NotAFTER:status.notAfter
```

Example output:

```
NAME                                    DURATION     RenewBEFORE   NotAFTER
analytics-ingestion-client              17520h0m0s   720h0m0s      2025-08-28T08:25:58Z
api-endpoint                            17520h0m0s   720h0m0s      2025-08-28T08:28:40Z
apim-endpoint                           17520h0m0s   720h0m0s      2025-08-28T08:28:21Z
```

The example output shows that your `analytics-ingestion-client` is due to expire at `2025-08-28T08:25:58Z`. The `RenewBEFORE` property shows that cert-manager should renew this certificate 720 hours before it expires.

Monitoring the cert-manager manager logs

Monitor the cert-manager logs to confirm when certificates are renewed. Run the following command to display the cert-manager log:

```
kubectl logs <cert-manager pod name> -n <cert-manager namespace>
```

Example output:

```
I0108 14:23:18.001074       1 controller.go:129] cert-manager/controller/certificates "level"=0 "msg"="syncing item"
"key"="default/test-cert"
I0108 14:23:18.009940       1 issue.go:109] cert-manager/controller/certificates/certificates/issue "level"=0
"msg"="certificate issued" "related_resource_kind"="Secret" "related_resource_name"="test-cert"
"related_resource_namespace"="default"
I0108 14:23:18.018664       1 sync.go:331] cert-manager/controller/certificates/certificates "level"=0 "msg"="certificate
scheduled for renewal" "duration_until_renewal"="-5.018566857s" "related_resource_kind"="Secret" "related_resource_name"="test-
cert" "related_resource_namespace"="default"
I0108 14:23:18.019070       1 controller.go:135] cert-manager/controller/certificates "level"=0 "msg"="finished processing work
item" "key"="default/test-cert"
```

The 4 statements (shown in the example) indicate when a certificate is about to be renewed, and when the renewal is complete a few seconds later.
Tip: Set up a logs-based alerting mechanism that informs you when cert-manager renews any certificate.

Pods that require restart after certificate renewal

Some API Connect pods must be restarted when certificates that are used by the pod are renewed. The certificates that require pods to be restarted after renewal are:

- **analytics-ingestion-client** or **a7s-ing-client**. Restart **apim**, **taskmanager**, and **analytics-proxy** pods on the management subsystem.
- **gateway-client-client** or **gw-dr-client**. Restart the **apim** and **taskmanager** pods on the management subsystem.
- **analytics-ai-endpoint** or **a7s-ai-endpoint**. Restart the **mtls-gw** pod on the analytics subsystem.

Renewing custom certificates

If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.

Procedure

1. Renew the certificates that you created:
   Use one of the following methods to renew the certificates that you created:
   - Update the secret that contains the certificate with your new certificate.
   - Delete and then re-create the secret with a new certificate.
   - Create a new secret (with a new name) that contains your new certificate. Update the appropriate API Connect CR to reference the new secret name.
2. Some pods require a restart after you update certain certificates. Refer to API Connect certificate reference to check whether any of the certificates you updated require pod restarts.

List of Issuers, CA certificates, and secrets

A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment.

Table 1 presents a list of the certificate issuers used in an API Connect deployment, with the CA issued by each, and the corresponding secret used to sign certificates. The **selfsigning-issuer** is used only for creating CAs, and does not have a corresponding certificate or secret of its own. If you have customized certificates, the certificates generated by the issuers in Table 1 use the custom-certs-external.yaml template.

Table 1. Issuers, CAs, and secrets

Issuer	CA certificate	Secret
selfsigning-issuer	N/A	N/A
ingress-issuer	**ingress-ca** issued by **selfsigning-issuer**	**ingress-ca** Attention: If you change the **ingress-ca** secret in a two data center deployment, you must change it to the same value in both data centers.
analytics-ca	**analytics-ca** issued by **selfsigning-issuer**	**analytics-ca**
management-ca	**management-ca** issued by **selfsigning-issuer**	**management-ca**
portal-ca	**portal-ca** issued by **selfsigning-issuer**	**portal-ca**

Note: On Cloud Pak for Integration, and OpenShift® top-level CR deployments, some certificate names are contracted and prefixed with the **APIConnectCluster** instance name. For example, the certificate **managment-ca** is called ***<apic instance name>*-mgmt-ca**.

List of ingress certificates

A summary of certificates that are used for communications between subsystems and clients in an API Connect deployment.

Note: On Cloud Pak for Integration, and OpenShift® top-level CR deployments, some certificate names are contracted and prefixed with the **APIConnectCluster** instance name. For example, the certificate **managment-ca** is called ***<apic instance name>*-mgmt-ca**.

User-facing certificates

Table 1 presents a list of user-facing certificates. The corresponding secrets use the same names. If you customized your certificates, the certificates in Table 1 use the custom-certs-external.yaml template.

Table 1. User-facing certificates

Certificate name	Issuer	Description
api-endpoint or mgmt-platform-api	**ingress-issuer**	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
consumer-endpoint or mgmt-consumer-api	**ingress-issuer**	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
consumer-catalog-endpoint	**ingress-issuer**	Consumer catalog endpoint server certificate.

Certificate name	Issuer	Description
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`portal-web`	`ingress-issuer`	The server certificate used on the `portalUIEndpoint`. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default `portal-web` certificate is issued by the `ingress-issuer`, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the `portal-web` ingress (`portal-web` route on Red Hat OpenShift).
`hub-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the `hub-endpoint`. If there is a problem with this certificate, then the user's browser shows a warning or error message.

Inter-subsystem certificates

Table 2 lists all of the common subsystem communication certificates. The corresponding secrets use the same names. If you have customized your certificates, the certificates in Table 2 use the custom-certs-external.yaml template.

Table 2. Inter-subsystem certificates

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with **kubectl**. When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the `portal-www` pods for the update to take effect.

`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have:
		
		• The same CA as the server certificate `analytics-ai-endpoint` on the analytics subsystem.
		• The common name must match the `spec.clientSubjectDN` in the analytics CR:
		
		`kubectl describe cert analytics-admin-client`
		
		`Spec:`
		`  Common Name:  a7s-ing-client`
		
		`kubectl get a7s -o yaml`
		
		`  spec:`
		`    clientSubjectDN: CN=a7s-ing-client`
		
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical.
		
		To update this certificate, use kubectl. Restart the `apim`, `taskmanager`, and `analytics-proxy` pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
		
		This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service.

Certificate name	Issuer	Description

`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have:
		• The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem.
		• The common name must match the `spec.adminClientSubjectDN` in the portal CR:
		`kubectl describe cert portal-admin-client`
		`Spec:`
		`Common Name: ptl-adm-client`
		`kubectl get ptl -o yaml`
		`spec:`
		`adminClientSubjectDN: CN=ptl-adm-client`
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
		This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service.

`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the `apim` and `taskmanager` pods after update. This certificate must have the same CA as the `gwv6-manager-endpoint or gw-gateway-manager` certificate on the gateway. This certificate is loaded by the management subsystem into the `Gateway management client TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the gateway, then create a new profile and specify it when you register the gateway service.
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`mgmt-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate used in the warm-standby data center's `<remote-sitename>-postgres` pod to connect to the active data center.
`mgmt-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<management_CR>-tunnel` pod. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the management CR.
`hub-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the `hub-endpoint`. If there is a problem with this certificate, then the user's browser shows a warning or error message.
`management-s3proxy-all`	`ingress-issuer`	Inter-subsystem certificate for communication between management subsystem and s3proxy pods. Used for management database local and SFTP backups.
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint in the `mtls-gw` pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the `analytics-ai-endpoint` certificate. If this certificate is updated, restart the `mtls-gw` pod for the update to take effect.
`portal-admin or ptl-director or portal-director`	`ingress-issuer`	Server certificate used on the `portalAdminEndpoint`. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the `portal-admin-client` certificate. This certificate must have the same CA as the `portal-admin-client` certificate on the management subsystem. This certificate is used by the `portal-nginx` pod.
`portal-web`	`ingress-issuer`	The server certificate used on the `portalUIEndpoint`. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default `portal-web` certificate is issued by the `ingress-issuer`, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the `portal-web` ingress (`portal-web` route on Red Hat OpenShift).
`ptl-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate that is used in the warm-standby data center's `<remote-sitename>-www` and `<remote-sitename>-db` pods to connect to the active data center. This certificate is used by all the portal pods that are related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.

Certificate name	Issuer	Description
`ptl-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<portal_CR>-tunnel` pod, the counterpart to the `ptl-replication-client` certificate. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the portal CR. This certificate is used by all the portal pods that are related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.
`gateway-peering or gw-peer`	`ingress-issuer`	This certificate secures the communication between gateways in your gateway cluster. If you update this certificate, then restart your gateway pods. See Changing the secret for gateway peering.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.
`gateway-service or gw-svc`	`ingress-issuer`	Legacy certificate that is not used.
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on the management subsystem If you update this certificate, then all gateway pods are restarted automatically.
`event-gateway-management-client`	`ingress-issuer`	The `event-gateway-management-client` certificate exists only on Cloud Pak for Integration deployments.

List of intra-subsystem certificates

A summary of certificates used for communications within subsystems in an API Connect deployment.

Note: On Cloud Pak for Integration, and OpenShift® top-level CR deployments, some certificate names are contracted and prefixed with the `APIConnectCluster` instance name. For example, the certificate `managment-ca` is called `<apic instance name>-mgmt-ca`.
Table 1 presents a list of certificates used for communications between pods in the same subsystem. The certificates are managed by cert-manager. For details of all the API Connect certificates, see API Connect certificates.

Table 1. Intra-subsystem certificates

Certificate name	Issuer	Description
`management-ca or mgmt-ca`	`selfsigning-issuer`	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using `in-cluster` communication. See In-cluster service communication between subsystems
`management-client or mgmt-client`	`management-ca`	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.

`management-server or mgmt-server`	`management-ca`	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`

`db-client-apicuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`natscluster-mgmt`	`management-ca`	Intra-subsystem certificate for the `nats` pods.
`analytics-ca or a7s-ca`	`selfsigning-issuer`	The issuer for the `analytics-client` and `analytics-server` certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If you update this certificate, you must then update the `analytics-client` and `analytics-server` server certificates, and then ensure that the following pods are restarted: • `storage`- Restarts automatically. • `warehouse`- Restarts automatically. • `ingestion`- Restarts automatically. • `director`- Restart manually.
`analytics-client or a7s-client`	`analytics-ca`	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, then the `storage`, `warehouse` and the `ingestion` pods restart automatically. You must manually restart the `director` pod.

Certificate name	Issuer	Description

`analytics-server or a7s-server`	`analytics-ca`	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`<instance name>-storage`
		`<instance name>-director`
		`<instance name>-ingestion`
		`<instance name>-mtls-gw`
		`<instance name>-storage-os-master`
		`<instance name>-warehouse`
		
		If this certificate is updated, then the **`storage`**, **`warehouse`** and **`ingestion`** pods restart automatically. Manually restart the **`director`** pod.

`portal-ca or ptl-ca`	`selfsigning-issuer`	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.
`portal-client or ptl-client`	`portal-ca`	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.

`portal-server or ptl-server`	`portal-ca`	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate.
		
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`*.<instance name>-<site name>-db-all.<namespace>.svc`
		`*.<instance name>-<site name>-www-all.<namespace>.svc`
		`*.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local`
		`*.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local`
		`*.<namespace>.svc.cluster.local`
		`<instance name>-db`
		`#<remote portal CR name>-db # For 2DCDR only.`
		
		<instance name> and *<remote portal CR name>* are truncated if more than 15 characters.
		This certificate is used by all portal pods.

V2018 upgrade: List of certificates to update manually

If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.

Ingress (front-end) certificates

Table 1 presents a list of the ingress certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

If multiple Portal web ingress endpoints have been configured, then the certificates for those additional endpoints must be updated manually as well.

Table 1. V2018 ingress certificates and affected pods

Certificate and Secret	Pods
`client-tls-`***`xxxxxxxxxx`***	• `analytics-mtls-gw-`***`hashed-suffix`***
`ingestion-tls-`***`xxxxxxx`***	• `analytics-mtls-gw-`***`hashed-suffix`***
`platform-api-tls-`***`xxxxxxx`***	N/A
`api-manager-tls-`***`xxxxxxxx`***	N/A
`cloud-manager-tls-`***`xxxxxx`***	N/A
`consumer-api-tls-`***`xxxxxxx`***	N/A
`v5GwName``-datapower-admin-credentials`	N/A
`v5GwName``-apic-gateway-peering-tls`	N/A
`v5GwName``-apic-gateway-service-tls`	N/A
`v6GwName``-datapower-admin-credentials`	N/A
`v6GwName``-apic-gateway-peering-tls`	N/A
`v6GwName``-apic-gateway-service-tls`	N/A

Certificate and Secret	Pods
`portal-uuid-admin`	• `portal-nginx`
`www-tls-xxxxxxxxxxxxx`	N/A

Subsystem communication certificates

Table 2 presents a list of the subsystem communication certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

Table 2. V2018 subsystem communication certificates and affected pods

Usage	Certificate and Secret	Pods
client	`managementUpgradeName-analytics-ingestion-client`	• `management-apim` • `management-taskmanager` • `gateway` (via webhook, no restart needed)
client	`managementUpgradeName-portal-admin`	• `management-apim` • `management-taskmanager` • `management-portal-proxy`
client	`gw-apic-gateway-service-tls`	• `gwv6` • `gwv5`
clientserver	`gw-apic-gateway-peering-tls`	• `gwv6` (redis) • `gwv5` (redis)

Database encryption key

The database encryption key is carried forward from V2018, and uses the name: `managementUpgradeName-encryption-secret`. You can update the value of this secret as explained in Changing the database encryption key.

Renewing certificates in a two data center deployment on Kubernetes and OpenShift

Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.

About this task

Begin the process by updating certificates as needed on data center 1 (DC1). Then,copy the `ingress-ca` from DC1 to data center 2 (DC2) before updating certificates on DC2. Finally, you will copy encryption keys for the Management and Portal subsystem from DC1 to DC2.

Procedure

Complete the following steps in the sequence shown to ensure that you do not overwrite information that was copied from DC1 while updating DC2.

1. DC1: Renew TLS certificates as explained in Renewing TLS certificates.
2. DC2: Complete the following steps to copy the `ingress-ca` from DC1:
   a. On DC1, export the `ingress-ca` secret to a YAML file by running the following command:

      ```
      kubectl -n namespace get secret ingress-ca -o yaml > ingress-ca.yaml
      ```

   b. Still on DC1, edit the `ingress-ca.yaml` file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
   c. Copy the `ingress-ca.yaml` to DC2.
   d. On DC2, apply the `ingress-ca.yaml` file by running the following command:

      ```
      kubectl -n namespace apply -f ingress-ca.yaml
      ```

   e. Validate that the `ingress-ca` on DC2 matches the `ingress-ca` on DC1:
      i. On DC1, run the following command to save the original `ingress-ca` as a PEM file:

         ```
         kubectl -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d > /tmp/ingress.pem.dc1
         ```

      ii. On DC2, run the following command to save the copied `ingress-ca` as a PEM file::

         ```
         kubectl -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d > /tmp/ingress.pem.dc2
         ```

      iii. Copy /tmp/ingress.pem.dc1 from DC1 and store it in the /tmp folder on DC2.
      iv. On DC2, run the following command to compare the two files and verify that there are no differences:

         ```
         diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
         ```

3. DC2: Update all external certificates that are based on the `ingress-ca` (see List of ingress certificates).
4. DC2: Update all of the internal certificates (see List of intra-subsystem certificates).
   At this point, DC1 and DC2 have the same `ingress-ca` secrets. Next, copy the encryption keys for the Management and Portal subsystems from DC1 to DC2.

5. Copy the encryption key for the Management subsystem to DC2 by completing the following steps:
   a. On DC1, copy the management encryption key:
      i. Get the name of the management encryption key by running the following command:

      ```
      $ kubectl -n namespace get mgmt -o yaml|grep enc
      ```

      The response looks like the following example:

      ```
      encryptionSecret: dallas-enc-key
      ```

      Make a note of the secret name for the next step. In the example, the key's name is **dallas-enc-key**.

      ii. Retrieve the secret from the encryption key by running the following command (substitute in the name of the key from the previous step):

      ```
      kubectl get secret dallas-enc-key -o yaml
      ```

      The output looks like the following example:

      ```
      apiVersion: v1
      data:
        encryption_secret.bin:
      VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
      pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
      kind: Secret
      metadata:
        creationTimestamp: "2020-08-28T12:53:41Z"
        labels:
          app.kubernetes.io/instance: m1
          app.kubernetes.io/managed-by: ibm-apiconnect
          app.kubernetes.io/name: dallas-enc-key
        name: dallas-enc-key
        namespace: default
        resourceVersion: "43039"
        selfLink: /api/v1/namespaces/default/secrets/m1-enc-key
        uid: 46c92395-9cc2-4421-b2c4-48e472c0cbb1
      type: Opaque
      ```

      iii. Copy the output and save it in a YAML file; for example dc1-enc-key.yaml.
      iv. Edit the file and make the following changes:
      - Delete the contents of the `metadata:` section (retain the section).
      - In the `metadata:` section, add in a `name:` attribute, with `dc1-enc-key` as the value.

      The following example shows the updated file:

      ```
      apiVersion: v1
      data:
        encryption_secret.bin:
      VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
      pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
      kind: Secret
      metadata:
        name: dc1-enc-key
      type: Opaque
      ```

      v. Copy the updated file (dc1-enc-key.yaml) to the /tmp folder on DC2.
   b. On DC2, run the following command to create a secret from the encryption key file (dc1-enc-key.yaml) that you copied from DC1:

   ```
   $ kubectl  -n namespace create -f /tmp/dc1-enc-key.yaml
   ```

   The response looks like the following example:

   ```
   secret/dc1-enc-key created
   ```

6. Update the encryption key for the Portal subsystem on DC1 and then copy it to DC2 as explained in Changing the secret for portal data and system tools.

Monitoring and health checks

Monitor your deployment and complete health checks on subsystems.

See:

- **Monitoring on Kubernetes**
  Monitor the API Connect subsystems on Kubernetes.
- **Monitoring on OpenShift**
  Monitor your API Connect deployment on OpenShift.
- **Monitoring on Cloud Pak for Integration**
  Monitor your API Connect deployment on Cloud Pak for Integration.
- **Obtaining simple health check data of Developer Portal sites by using a REST API call**
  Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.
- **Monitoring subsystem health checks**
  The periodic system checks validate the health of each subsystem by performing a predefined set of checks. These checks help identify issues that require your attention to maintain system stability.

Monitoring on Kubernetes

Monitor the API Connect subsystems on Kubernetes.

See:

- **Monitoring subsystems on Kubernetes**
  Use `kubectl get` to check the health of the API Connect clusters in your Kubernetes deployment.
- **Monitoring Postgres disk usage**
  Monitor disk usage by the Postgres database in the management subsystem.
- **Monitoring platform health using Kubernetes events**
  Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

Monitoring subsystems on Kubernetes

Use `kubectl get` to check the health of the API Connect clusters in your Kubernetes deployment.

The APIConnect operator controls the life-cycle of management subsystem microservices. When you install, you create the following custom resources (CRs) in order to install API Connect and all subsystems:

- `ManagementCluster` or `mgmt`
- `AnalyticsCluster` or `a7s`
- `PortalCluster` or `ptl`
- `GatewayCluster` or `gw`
  Every CR has a `status` section. The APIConnect operator regularly updates this section with the current status of the subsystem.

For example, use the following command to obtain the status of `ManagementCluster`:

```
kubectl get mgmt -n <namespace>
```

Example:

```
kubectl get mgmt
NAME    READY   STATUS    VERSION      RECONCILED VERSION      AGE
m1      16/16   Running   10.0.8.0      10.0.8.0-44   24m
```

Output:

- `NAME`: Name of the Management Subsystem
- `READY`: Current number of management subsystem which are up, followed by the expected number of management subsystem components which should be up. For example: `16/16`.
- `STATUS`: Current status of Management Subsystem
  During fresh install, upgrade or any maintenance operation, such as changing configuration for S3 backups, Management CR status can go to different states depending on the action, but ultimately it should **always** reach `Running` status.

  If the status says `Warning`, then run `kubectl describe mgmt -n <namespace>` and check for more details in the `Status` section.
- `VERSION`: Version chosen in `spec.version` in the management CR.
- `RECONCILED VERSION`: Current management subsystem version. Includes a build number.
- `AGE`: Age of the management subsystem CR.

Monitoring Postgres disk usage

Monitor disk usage by the Postgres database in the management subsystem.

Postgres Database is the core database used in Management Subsystem. It is important to monitor the Postgres disk usage.

The API Connect operator tracks the current disk usage of the Postgres components, and regularly updates the `ManagementCluster` status. When one or more of the Postgres components occupy 60% of the PVC (persistent volume claim) capacity, the API Connect operator changes the status from `Running` to `Warning`.

API Connect operator **brings down** Postgres if the disk allocation reaches **80%**. In this case, you must contact IBM support.

Note that there are various types of storage classes which can be used to deploy Management Subsystem. For example, `local-storage` or `ceph block`.

Management Cluster disk stats

The `ManagementCluster` instance has `.status.postgresDataStats` where the operator prints the current disk usage of Postgres components. For example:

```
kubectl get mgmt -o json | jq .status.postgresDataStats
[
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 184320,
```

```
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components occupy 60% usage, the operator marks the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message. The operator also updates the **postgresDataStats** section with the current data usage of the Postgres components.

Example of warning state:

```
kubectl get mgmt
NAME              READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
AGE
stv3-management   6/8     Warning   10.0.8.0   10.0.8.0-5363        Some services are not ready - see status condition for
details   3d20h
```

Example of list of warning conditions:

```
kubectl get mgmt -o json
...
status:
  conditions:
  - lastTransitionTime: "2022-06-02T19:38:09Z"
    message: Warning threshold=60%, Current disk usage=63%, Is wal archiving working?=false.
      Database shutdown starts at 80%. Please contact IBM Support immediately.
    reason: wal_disk_usage_more_than_warning_threshold
    status: "True"
    type: Warning
...
```

If you encounter the warning, contact IBM support to fix the root cause.

Error condition is populated at 80% usage

An error condition is populated when the operator brings down Postgres because is using 80% of available disk space. Postgres is brought down to avoid problems, such as disk corruption, that can occur if the disk becomes completely filled.

```
 status:
  conditions:
- lastTransitionTime: "2022-06-03T00:40:54Z"
    message: Error threshold=80%, Current disk usage=82%, Is wal archiving working?=false.
      Database is in shutdown mode and management services are disabled. Please contact
      IBM Support immediately.
    reason: wal_disk_usage_more_than_error_threshold
    status: "True"
    type: Error
```

If you encounter the error, contact IBM support to fix the root cause.

Important:
When **local-storage** is used, it uses the entire disk that is allocated to the worker node. In some cases, Kubernetes itself can face disk pressure before the operator reacts to 80% usage, and will start evicting pods.

Monitoring platform health using Kubernetes events

Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

What are the Kubernetes events?

The CR for every subsystem of API Connect has a status condition section, which is regularly updated by the API Connect operator with the current status. The API Connect operator additionally generates a Kubernetes event whenever there is a change in the CR status.

Events are enabled in API Connect operator for the following resources.

- **APIConnectCluster** CR
- **ManagementCluster** CR
- **GatewayCluster** CR
- **AnalyticsCluster** CR
- **PortalCluster** CR

Two types of events are generated when the CR status changes:

- **Normal** - Indicates that the status change is not causing any issues.
- **Warning** - Indicates that there a problem that requires your attention.

You can automatically monitor the status condition in your existing alerting system, or by integrating the Kubernetes events into a third-party alerting solution. For more information, see the following blog post: How to use Kubernetes events for effective alerting and monitoring.

Viewing the events

The default retention period of events in Kubernetes is 1 hour (controlled by **kube-apiserver**). To view the events, complete the following steps:

1. Run the **kubectl describe** against the resource you want to monitor; for example:

   ```
   kubectl describe APIConnectCluster
   ```

2. In the response, scroll to the end to see the events information, which looks like the following example:

   ```
          Name:           10.0.5.3-1
      Reconciled:         10.0.5.3-1
   Events:
     Type     Reason     Age    From                       Message
     ----     ------     ----   ----                       -------
     Normal   Running    10h    ibm-apiconnect-operator    All services ready.
     Normal   Deploying  10h    ibm-apiconnect-operator    Not all services are ready, pending services: management
   ```

Monitoring on OpenShift

Monitor your API Connect deployment on OpenShift.

See:

- **Monitoring the API Connect cluster on OpenShift**
  Monitor the status of the API Connect cluster on OpenShift using either the command line or the OpenShift web console.
- **Monitoring Postgres disk usage on OpenShift**
  In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.
- **Monitoring platform health on Red Hat OpenShift using Kubernetes events**
  Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

Monitoring the API Connect cluster on OpenShift

Monitor the status of the API Connect cluster on OpenShift using either the command line or the OpenShift web console.

Note: For information on viewing the Postgres disk status, see Monitoring Postgres disk usage on OpenShift.

Monitoring the API Connect cluster using the command line

Individual subsystem installations: Run the **oc get** command on each subsystem CR:

- Management:

  ```
  oc get mgmt
  ```

  ```
  NAME              READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE               AGE
  small-ocp-mgmt    18/18   Running   10.0.8.0   10.0.8.0-258         Management is ready   53d
  ```

- Portal

  ```
  oc get ptl
  ```

  ```
  NAME             READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE          AGE
  small-ocp-ptl    4/4     Running   10.0.8.0   10.0.8.0-258         Serving 1 site   53d
  ```

- Analytics

  ```
  oc get a7s
  ```

  ```
  NAME             READY   STATUS    VERSION    RECONCILED VERSION   AGE
  small-ocp-a7s    7/7     Running   10.0.8.0   10.0.8.0-258         53d
  ```

- Gateway

  ```
  oc get gw
  ```

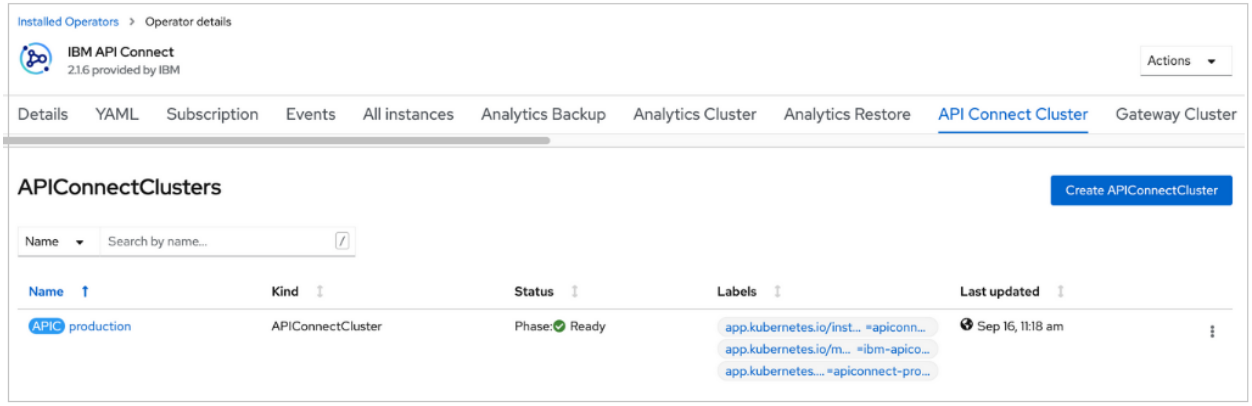
  ```
  NAME            READY   STATUS    VERSION    RECONCILED VERSION   AGE
  small-ocp-gw    2/2     Running   10.0.8.0   10.0.8.0-258         53d
  ```

Top-level CR installations: Run the following command to display the status of the API Connect cluster:

```
oc get apiconnectcluster -n <APIC_namespace>
```

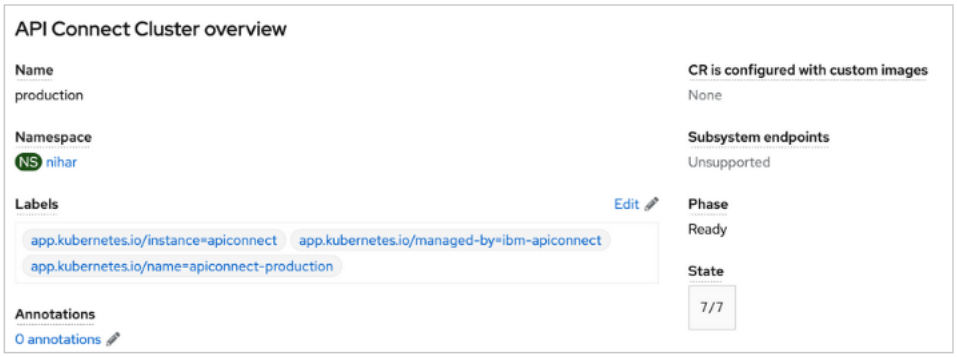
The response looks like the following example:

```
NAME          READY   STATUS    VERSION         RECONCILED VERSION   AGE
production    7/7     Ready     10.0.8.0    10.0.8.0-3323     24h
```



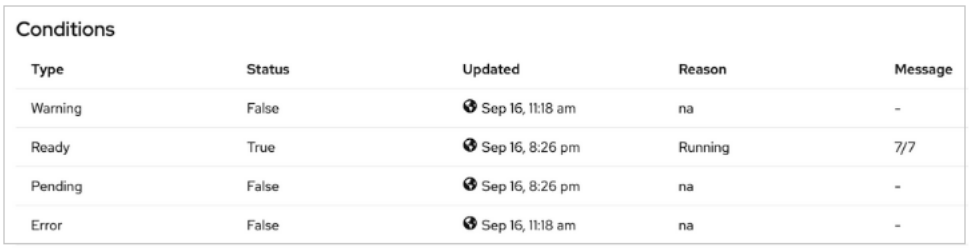
The following list explains the values in the response:

- **NAME**: Name of the API Connect cluster or subsystem instance.
- **READY**: Current number of components that are running **/** Expected number of components that should be running.
- **STATUS**: Current status of API Connect or the subsystem.
  If the status says **Warning**, then run **oc describe** ***<CR>*** and check for more details in the **Status** sections.



- **`VERSION`**: API Connect version specified in the CR's **`spec.version`** setting.
- **`RECONCILED VERSION`**: Current API Connect version.
- **`AGE`**: Age of the CR.

Monitoring the API Connect cluster using the OpenShift web console



1. Start the OpenShift web console.
2. Click Installed operators.
3. Locate the namespace (project) where you installed API Connect:
   - If you installed the API Connect operator in all namespaces, select openshift-operators
   - if you installed the API Connect operator in a single namespace, select specific project
4. Select the IBM API Connect operator.
5. Select All instances for an overview of all operands in your API Connect namespace.
6. If you have a top-level CR installation, then click API Connect Cluster.
   a. On the API Connect Clusters page, check the Status column.
   The status should display "Ready" as in the following image:

   b. Click the instance name (in the example, the instance name is production to display the status overview page.
   The overview page displays high-level information about your deployment, as in the following image:

   Also on the overview page, the "Conditions" section displays the list of possible service conditions, as in the following image:

   A healthy deployment displays "True" for the "Ready" status.

   During a fresh install, an upgrade or a day-2 operation (such as a Management backup S3 configuration change), the **`apiconnectcluster`** CR status might change to a different state depending on the action, but ultimately it should always reach the **`Ready`** status.

Monitoring Postgres disk usage on OpenShift

In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

The Postgres database is the core database used in the Management subsystem. It is important to monitor the Postgres disk usage to avoid running out of space and causing an outage in your deployment.

The **APIConnect** operator tracks the current disk usage of the Postgres components, and regularly updates the **ManagementCluster** CR's status. When one or more of the Postgres components occupy 60% of the PVC (persistent volume claim) capacity, the **APIConnect** operator changes the CR's status from **Running** to **Warning**.

Important: If the Postgres disk usage reaches 80%, then the **APIConnect** operator brings down Postgres. If this situation occurs, contact IBM Support.
Note that there are various types of storage classes which can be used to deploy Management subsystem; for example, **local-storage** or **ceph block**. When **local-storage** is used, the entire disk is allocated to the worker node. In some cases, before the **APIConnect** operator reacts to an 80% usage condition, Kubernetes itself might face disk pressure and start evicting pods.

Viewing the current disk usage

The **ManagementCluster** instance includes the **.status.postgresDataStats** field, where the operator displays the current disk usage of Postgres components. Run the following command to get the disk usage:

```
oc get mgmt -o json | jq .items[].status.postgresDataStats
```

The response looks like the following example:

```
[
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 184320,
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components uses 60% of its allocated space, the operator changes the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message. The operator also updates the **postgresDataStats** section with the current data usage of the Postgres components.

Attention: If you encounter the **Warning** condition, contact IBM Support for help correcting the root cause.
To view the status, run the following command:

```
oc get mgmt
```

The following example response shows the warning state:

```
NAME               READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
AGE
stv3-management   6/8     Warning   10.0.8.0   10.0.8.0-5363        Some services are not ready - see status condition for
details   3d20h
```

To view just the status, run the following command:

```
oc get mgmt -o json | jq .items[].status.phase
```

In this example, the status displayed in the response is "Warning":

```
"Warning"
```

To see the list of current status conditions, run the following command:

```
oc get mgmt -o json | jq .items[].status.conditions
```

The following example response displays the list of status conditions. Notice that the **Warning**"condition is set to "True" and the other conditions are set to "False":

```
status:
  conditions:
  - lastTransitionTime: "2022-06-02T19:38:09Z"
    message: Warning threshold=60%, Current disk usage=63%, Is wal archiving working?=false.
      Database shutdown starts at 80%. Please contact IBM Support immediately.
    reason: wal_disk_usage_more_than_warning_threshold
    status: "True"
    type: Warning
```

Error condition is populated at 80% usage

When one of the Postgres components uses 80% of its allocated space, the operator changes the overall status of the **ManagementCluster** to **Error** and brings down Postgres avoid problems that can occur if the disk becomes completely filled.

Attention: If you encounter the **Error** condition, contact IBM Support for help correcting the root cause.
In this case, when you run the following command to view the status conditions, you will see that the "Error" condition is set to "True:

```
oc get mgmt -o json | jq .items[].status.conditions
```

For example, the following condition shows the **Error** status set to "True" due to disk usage:

```
status:
  conditions:
- lastTransitionTime: "2022-06-03T00:40:54Z"
    message: Error threshold=80%, Current disk usage=82%, Is wal archiving working?=false.
      Database is in shutdown mode and management services are disabled. Please contact
      IBM Support immediately.
    reason: wal_disk_usage_more_than_error_threshold
    status: "True"
    type: Error
```

Monitoring platform health on Red Hat OpenShift using Kubernetes events

Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

What are the Kubernetes events?

The CR for every subsystem of API Connect has a status condition section, which is regularly updated by the API Connect operator with the current status. The API Connect operator additionally generates a Kubernetes event whenever there is a change in the CR status.

Events are enabled in API Connect operator for the following resources.

- **`APIConnectCluster`** CR
- **`ManagementCluster`** CR
- **`GatewayCluster`** CR
- **`AnalyticsCluster`** CR
- **`PortalCluster`** CR

Two types of events are generated when the CR status changes:

- **`Normal`** - Indicates that the status change is not causing any issues.
- **`Warning`** - Indicates that there a problem that requires your attention.

You can automatically monitor the status condition in your existing alerting system, or by integrating the Kubernetes events into a third-party alerting solution. For more information, see the following blog post: How to use Kubernetes events for effective alerting and monitoring.

Viewing the events

The default retention period of events in Red Hat OpenShift is 3 hours (controlled by **`kube-apiserver`**). To view the events, complete the following steps:

1. In the Web UI, click Operators > Installed Operators > IBM API Connect > API Connect Clusters.
2. Select an instance by clicking its name: Management cluster, Gateway cluster, Portal cluster, or Analytics cluster. If you installed using the top-level **`APIConnectCluster`** CR, you can additionally select API Connect cluster.
3. Select the Events tab to see all of the events that were generated for that instance.

Monitoring on Cloud Pak for Integration

Monitor your API Connect deployment on Cloud Pak for Integration.

See:

- **Monitoring the API Connect cluster on Cloud Pak for Integration**
  Monitor the status of the API Connect cluster on Cloud Pak for Integration using either the command line or the IBM Cloud Pak Platform UI.
- **Monitoring Postgres disk usage on Cloud Pak for Integration**
  In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

Monitoring the API Connect cluster on Cloud Pak for Integration

Monitor the status of the API Connect cluster on Cloud Pak for Integration using either the command line or the IBM Cloud Pak Platform UI.

In Cloud Pak for Integration, the API Management capability is provide by API Connect. You deploy the API Connect subsystems on Cloud Pak for Integration with the **`APIConnect`** operator and the **`apiconnectcluster`** CR. The CR contains a status section that is regularly updated by the operator to display the current status of the all the API Connect subsystems.

When you finish deploying API Connect, you can monitor the status of **`apiconnectcluster`** using the command line or the OpenShift web console.

- Monitoring the API Connect cluster using the command line
- Monitoring the API Connect cluster using the Platform UI

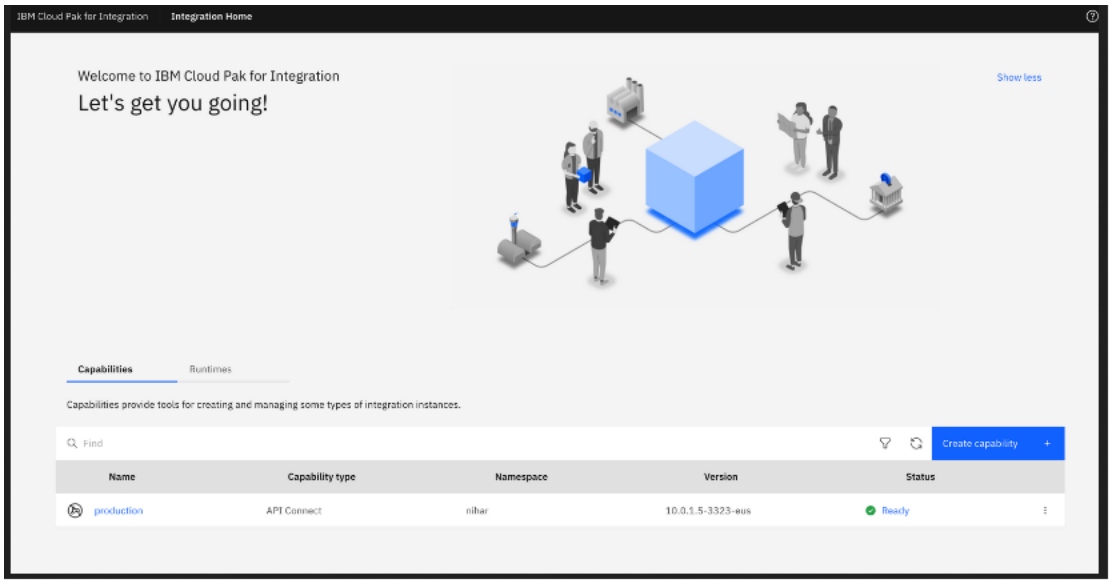
Note: You can also monitor the disk usage of Postgres microservices. The **`APIConnect`** operator continuously tracks the disk usage of postgres microservices and provides useful information in the **`ManagementCluster`** custom resource. For information on viewing the postgres disk status, see Monitoring Postgres disk usage on Cloud Pak for Integration.

Monitoring the API Connect cluster using the command line

Run the following command to display the status of the API Connect cluster:

```
oc get apiconnectcluster -n <APIC_namespace>
```

The response looks like the following example:



```
NAME          READY   STATUS   VERSION         RECONCILED VERSION   AGE
production    7/7     Ready    10.0.8.0        10.0.8.0-3323        24h
```

The following list explains the values in the response:

- **NAME**: Name of the API Connect instance (in the example, the instance name is "production").
- **READY**: Current number of subsystems and components that are running **/** Expected number of subsystems and components that should be running.
- **STATUS**: Current status of API Connect.
  If the status says **Warning**, then run **oc describe apiconnectcluster -n <*namespace*>** and check for more details in the **Status** sections.
- **VERSION**: API Connect version specified in the CR's **spec.version** setting.
- **RECONCILED VERSION**: Current API Connect version.
- **AGE**: Age of the **apiconnectcluster** CR.

Monitoring the API Connect cluster using the Platform UI

1. Start the Platform UI.
2. Click the Integration instances tab.
3. Locate the "API Connect" capability that uses the instance name that you specified as the Name during installation.
   A healthy API Connect deployment displays "Ready" in the Status column

4. Click the status value to display information about the current conditions, as in the following image:

A healthy deployment displays "True" for the "Ready" status.

During a fresh install, an upgrade or a day-2 operation (such as a Management backup S3 configuration change), the **apiconnectcluster** CR status might change to a different state depending on the action, but ultimately it should always reach the **Ready** status.

Monitoring Postgres disk usage on Cloud Pak for Integration

In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

The Postgres database is the core database used in the Management subsystem. It is important to monitor the Postgres disk usage to avoid running out of space and causing an outage in your deployment.

The **APIConnect** operator tracks the current disk usage of the Postgres components, and regularly updates the **ManagementCluster** CR's status. When one or more of the Postgres components occupy 60% of the PVC (persistent volume claim) capacity, the **APIConnect** operator changes the CR's status from **Running** to **Warning**.

Important: If the Postgres disk usage reaches 80%, then the **APIConnect** operator brings down Postgres. If this situation occurs, contact IBM Support.
Note that there are various types of storage classes which can be used to deploy Management subsystem; for example, **local-storage** or **ceph block**. When **local-storage** is used, the entire disk is allocated to the worker node. In some cases, before the **APIConnect** operator reacts to an 80% usage condition, Kubernetes itself might face disk pressure and start evicting pods.

Viewing the current disk usage

The **ManagementCluster** instance includes the **.status.postgresDataStats** field, where the operator displays the current disk usage of Postgres components. Run the following command to get the disk usage:

```
oc get mgmt <mgmt-cr-name> -o json | jq .status.postgresDataStats
```

The response looks like the following example:

```
[
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 184320,
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components uses 60% of its allocated space, the operator changes the overall status of the **ManagementCluster** CR and the **APIConnectCluster** CR to **Warning** with an appropriate warning message. The operator also updates the **postgresDataStats** section with the current data usage of the Postgres components.

Attention: If you encounter the **Warning** condition, contact IBM Support for help correcting the root cause.
To view the status from the command line, run the following command:

- **APIConnectCluster** CR:

  ```
  oc get apiconnect
  ```

  The following example response shows the warning status:

  ```
  NAME         READY
  STATUS   VERSION        RECONCILED VERSION   AGE
  production   Current WAL disk usage of production-mgmt-31be1757-postgres is 60 percent. DATABASE SHUTDOWN starts at 80
  percent utilization. Please contact IBM Support immediately.   Warning    10.0.8.0-eus   10.0.8.0-3394-eus    11d
  ```

- **ManagementCluster** CR:

  ```
  oc get mgmt
  ```

  The following example response shows the warning status:

  ```
  NAME              READY   STATUS    VERSION         RECONCILED VERSION   AGE
  production-mgmt   18/18   Warning   10.0.8.0-eus    10.0.8.0-3394-eus    43h

  Current WAL disk usage of m1-ed60c42d-postgres is 61 percent. DATABASE SHUTDOWN starts at 80 percent utilization. Please
  contact IBM Support immediately
  ```

To view the status in IBM Cloud Pak Platform UI, click the Integration instances tab to see the status displayed next to the instance name

Click the status value (Warning, for this example) to display the Conditions list where a detailed message explains why the condition was set:

Error condition is populated at 80% usage

When one of the Postgres components uses 80% of its allocated space, the operator changes the overall status of the **`ManagementCluster`** to **`Error`** and brings down Postgres avoid problems that can occur if the disk becomes completely filled.

Attention: If you encounter the **`Error`** condition, contact IBM Support for help correcting the root cause.
To view the status from the command line, run the following command:

- **`APIConnectCluster`** CR:

  `oc get apiconnect`

  The following example response shows the error status:

  ```
  NAME          READY
  STATUS    VERSION         RECONCILED VERSION    AGE
  production    Current disk usage is more than 80 percent. DATABASE will be shutdown. Please contact IBM Support
  immediately.    Error     10.0.8.0-eus    10.0.8.0-3394-eus     11d
  ```

- **`ManagementCluster`** CR:

  `oc get mgmt`

  The following example response shows the warning status:

  ```
  NAME                READY    STATUS    VERSION         RECONCILED VERSION    AGE
  production-mgmt     9/9      Error     10.0.8.0    10.0.8.0-3394     11d
  ```

To view the status in the Platform UI, click the Integration instances tab to see the status displayed next to the instance name

Click the status value (Error in this example) to display the Conditions list where a detailed message explains why the condition was set:

Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

Procedure

To call the site health REST API, append **`/health`** to the end of your Developer Portal site URL in your web browser, as follows:

***`site_url`*`/health`**

Where ***`site_url`*** is the URL of the Developer Portal site that you want to check.
If both the database and web server of the site are running, the web browser returns the current system time. For example:

```
1511367695
```

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.

Monitoring subsystem health checks

The periodic system checks validate the health of each subsystem by performing a predefined set of checks. These checks help identify issues that require your attention to maintain system stability.

Each subsystem periodically runs a cron job named **`<subsystem>-system-check`**. This job runs every hour for each subsystem and reports any warnings or errors detected in the subsystem's CR status conditions.
Tip: Error conditions indicate critical issues that require immediate resolution to restore normal system functionality. In contrast, warnings identify potential problems that, if left unaddressed, may escalate into errors — for example, a certificate set to expire within 60 days.

The system check job updates the status condition of each subsystem based on its results. The status condition message summarizes any failed checks. The system writes the full output of each job invocation to a `ConfigMap` for further review. If all checks pass and the subsystem is healthy, the status condition is set to Ready. You must address any errors or warnings promptly to restore the subsystem to a healthy state.
Note: System check jobs run on a scheduled interval. Therefore, the error or warning conditions remain in the CR until the next scheduled job completes. To update the CR status immediately after resolving an issue, you can run the system check on demand with the following command: `kubectl create job --from=cronjob/<cron-job-name> <job-name> -n <namespace>`.
Example

If the system check completes with a warning, the following status condition is set with the relevant details as depicted below:

```
- lastTransitionTime: '2024-10-07T17:11:24Z'
  message: 'System check completed with the following warning(s): APIC_APICOPS_0001W - Certificate "analytics-system-check-
28805350-pw77x" will expire soon. Date of expiry: "Sep 25 06:41:00 2026 GMT", see
  status.SystemCheck for more details.'
  reason: SystemCheckCompletedWithWarnings
  status: 'True'
  type: Warning
```

The following table provides details of certificates that are monitored during health checks:

Table 1. Certificates monitored during health checks

Certificate	Description
Subsystem certificates	Validating specific certificates for subsystem, such as `mgmt-ca`, `mgmt-client`,`mgmt-server`, and others. For more information about subsystem certificates, see Intra-subsystem certificates.
Endpoint certificates	Validating specific certificates for endpoints, such as `apiManagerEndpoint`, `cloudManagerEndpoint`, `consumerAPIEndpoint`, `platformAPIEndpoint`, or `hubEndpoint` for management, `ingestion-client` for analytics, `portalAdminEndpoint` for the portal, and `gatewayManagerEndpoint` for the gateway. For more information about endpoint certificates, see User-facing certificates.
Replication certificates	Validating replication certificates for 2DCDR deployments. For more information about replication certificates, see Inter-subsystem certificates.

Note: These certificate are monitored by the subsystem health checks. For more information about certificates, see TLS certificates organized by usage.
To troubleshoot system check related errors in the Analytics subsystem, see Analytics subsystem CR is in an error state.

Logging

Configure logging for your deployment on Kubernetes.

See:

- **Gathering logs**
  How to gather the API Connect system logs and configuration information for use in troubleshooting and diagnostics.
- **Changing logging levels**
  You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

Gathering logs

How to gather the API Connect system logs and configuration information for use in troubleshooting and diagnostics.

When you open a support case for API Connect, system logs and environment data are normally required to help diagnosis. Several tools are used for gathering this data:

- The apic-mustgather tool collects all the logs and system information from the API Connect deployment.
- The apicops tool gathers extra debug information about the synchronization of the management subsystem with the gateway and portal services.

Installing the apic-mustgather tool

Download the latest version of the apic-mustgather tool.

1. To download apic-mustgather tool, run the following command:

   ```
   curl -L -O https://github.com/ibm-apiconnect/v10-postmortem/releases/latest/download/apic-mustgather
   ```

The **apic-mustgather** tool gathers the logs of the currently running processes. The logs have a maximum size and older log messages are not retained when the maximum size is reached. To ensure that the logs gathered cover the time when the problem occurred, reproduce the problem and then gather the logs without delay. Offboarding the logs to an external server is the best practice for long-term storage of log data.

Running the apic-mustgather tool

1. Copy the **apic-mustgather** tool to your API Connect container environment and give it execute permissions:

   ```
   chmod +x apic-mustgather
   ```

   If your API Connect deployment has subsystems in different environments, then copy **apic-mustgather** to each environment.

2. Re-create the problem that you want to diagnose.
3. Run the **apic-mustgather** tool:

   ```
   ./apic-mustgather
   ```

The **apic-mustgather** tool gathers logs and status information for all API Connect resources and all related Kubernetes or OpenShift resources that it can find. The files are compressed to /tmp/apic-mustgather-*.tar.gz.

If your API Connect deployment has subsystems in different environments, then run **apic-mustgather** in each environment.

Note: The **apic-mustgather** checks if the apicops tool is present and if not then it attempts to download it. If you do not have the apicops tool locally and your environment does not have internet access to download it, then before you run **apic-mustgather** do the following:

a. Download apicops.
b. Give **apicops** execute permissions:

```
chmod a+x apicops
```

c. Copy **apicops** to the same location as **apic-mustgather**.

4. Upload the following to the support case:
   - /tmp/apic-mustgather-*.tar.gz
   - The steps to reproduce the problem (if applicable).
   - The time the problem occurred.
   - Screen capture of error (if applicable).

Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

About this task

For apim-v2 pods, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging `apim:webhookPayload` or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

Procedure

- Updating the settings in the APIM deployment YAML file
  Note: This action causes a pod restart.
  - The DEBUG variable works the same as prior releases.

    ```
    - env:
        - name: DEBUG
          value:
    audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:
    *
    ```

    To enable entry and exit trace, add `trace:*` to the start of the debug string:

    ```
    - env:
        - name: DEBUG
          value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:webhookAudit,bhendi:cassandra-
    transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:taskmanager:info
    ```

  - To enable large object logging:

    ```
    - env:
        - name: VELOX_LOG_FULL_PAYLOAD
          value: "true"
    ```

- Updating the settings by using the toolkit
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  apic log-spec:get
  apic log-spec:update  LOG_SPEC_FILE
  ```

  Where the spec file contains:

  ```
  {"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
  ```

- Updating the settings by using the REST API
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  GET /cloud/api/log-spec
  PUT /cloud/api/log-spec
  ```

  For example, to set debug level and large objects logging:

  ```
  curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
      -H "Accept: application/json" -d '{"specification":
  "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error","large_objects": true}'
      -H "Content-Type: application/json"
  ```

  The command responds with:

```
{
    "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
    "large_objects": true,
    "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
172.16.140.213"
}
```

Note: The response might include the following warning, which can be ignored:

```
WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7  Failed on IP(s): 1.2.3.4
```

To view the REST APIs for logging, go to API Connect REST APIs, and select IBM API Connect Platform - Cloud Management API 2.0.0 reference > Resource: Log Spec.

Troubleshooting

Troubleshooting problems with your API Connect subsystems.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, click the Product information tile to find out information about your product and Git package versions. The API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
For common operational problems with API Connect, such as UI login failure, or published APIs not running on your gateways, see: Troubleshooting API Connect.

For problems with the analytics subsystem, see Troubleshooting analytics.

For problems with the portal subsystem, see Troubleshooting the developer portal.

To run a power-cycling check on OpenShift and Cloud Pak for Integration, see Power-cycling check on OpenShift and Cloud Pak for Integration.

Power-cycling check on OpenShift and Cloud Pak for Integration

If you cycle the power on an API Connect cluster that is deployed on OpenShift or Cloud Pak for Integration, you might need to reset the IP address for the **`kubernetes.io/hostname`**.

About this task

You will know there is a problem if you cycle the power for the cluster and receive an error, or find that the deployment remains in the **`pending`** state indefinitely because some of the pods failed to start. Complete the following steps to resolve the problem:

Procedure

1. Run the following command to check the label on the worker nodes:

   ```
   oc get nodes -l kubernetes.io/hostname=localhost
   ```

   If the response shows the following message, then the power cycle did not cause a problem and you can skip the rest of this task:

   ```
   No resources found
   ```
   If the response looks like the following example (the IP address will be different), proceed to the next step:

   ```
   NAME                                         STATUS   ROLES    AGE   VERSION
   ip-233.252.0.0.us-west-1.compute.internal    Ready    worker   27h   v1.19.0+8d12420
   ```

2. Run the following command to correct the problem:

   ```
   for i in $(oc get nodes -l kubernetes.io/hostname=localhost|grep worker|awk '{print $1}'); do echo $i;  oc label nodes $i
   kubernetes.io/hostname=`echo $i|awk -F'.' '{print $1}'` --overwrite=true; done
   ```

Uninstalling API Connect

You can uninstall a Kubernetes deployment of API Connect.

About this task

You can choose to uninstall individual API Connect subsystems or you can uninstall the complete API Connect deployment. You can delete Custom Resource Definitions, Persistent Volumes, service accounts, secrets, operators and the namespace. Use one of the following topics.
Note: For information about how to maintain a two data center deployment, see Maintaining a two data center deployment.

- **Uninstalling API Connect subsystems**
  You can individually uninstall API Connect subsystems that have been deployed on Kubernetes.
- **Removing API Connect**
  You can remove all parts of the API Connect deployment on Kubernetes.
- **Removing API Connect on OpenShift or Cloud Pak for Integration**
  Remove your entire API Connect deployment on OpenShift or Cloud Pak for Integration.

Uninstalling API Connect subsystems

You can individually uninstall API Connect subsystems that have been deployed on Kubernetes.

Before you begin

If you want to disable the analytics subsystem without uninstalling it, see Shutting down the analytics subsystem.

About this task

- To delete the API Connect deployment in a Kubernetes runtime environment, you must use the Kubernetes command-line tool, kubectl.
- The API Connect operator and DataPower operator pods are needed to uninstall subsystems individually.
- If need to retain data to re-use during a re-installation later, follow the backup and restore procedures Backing up, restoring, and disaster recovery.
- If you want to delete **all** of API Connect, do not use this topic. Instead, see Removing API Connect.

Procedure

1. Uninstall the Management subsystem
   a. Save the management subsystem name:

      ```
      kubectl get mgmt -n <namespace> -o yaml
      ```

      This command returns the YAML format of the management custom resource. Make a note of the name.

   b. Delete the Management Subsystem.

      ```
      kubectl delete mgmt --all -n <namespace>
      ```

      Important:
      If your deployment uses default namespaces be cautious when using **`kubectl delete <entity> --all`** commands. There can be other pods, services, and more in the default namespace. When using the default namespace, keep in mind that using **`kubernetes delete <entity> --all`**, where <*entity*> can delete non-APIC entities, such as **`sa`** (Service Accounts), **`secrets`**, **`rolebindings`**, etc.

      The Management CR deletion will take some time because the apiconnect operator must delete the Postgres cluster.

   c. Manually delete secrets and PVCs:
      i. Get all of the secrets that use the management subsystem name (which you determined in Step 1.a):

         ```
         kubectl get secrets -n <namespace> | grep <management-subsystem-name>
         ```

      ii. For each secret that uses the management subsystem name, run the following command to delete the secret:

         ```
         kubectl delete secrets <secret_name> -n <namespace>
         ```

      iii. Get all the PVCs that use the management subsystem name:

         ```
         kubectl get pvc -n <namespace> | grep <management-subsystem-name>
         ```

      iv. For each PVC that uses the management subsystem name, run the following command to delete the PVC:

         ```
         kubectl delete pvc <pvc_name> -n <namespace>
         ```

   d. If management subsystem backup and restore CRs are left stale, delete them also:
      i. Get the names of the backup CRs:

         ```
         kubectl get Backup -n <namespace>
         ```

      ii. Delete the backup CRs:

         ```
         kubectl delete Backup <backup_cr_name> -n <namespace>
         ```

      iii. Get the names of the restore CRs:

         ```
         kubectl get ManagementRestore -n <namespace>
         ```

      iv. Delete the restore CRs:

         ```
         kubectl delete ManagementRestore <restore_cr_name> -n <namespace>
         ```

   Note: If you have management backup CRs from V10.0.6.0 or earlier, delete those too:
      i. Get the name of the backup CR:

         ```
         kubectl get mgmtb -n <namespace>
         ```

      ii. Delete the backup CR:

         ```
         kubectl delete mgmtb <backup_cr_name> -n <namespace>
         ```

      iii. Get the name of the restore CR:

         ```
         kubectl get mgmtr -n <namespace>
         ```

      iv. Delete the restore CR:

```
kubectl delete mgmtr <restore_cr_name> -n <namespace>
```

2. Uninstall Analytics subsystem
   a. Delete the Analytics subsystem, the Analytics backup, and the Analytics restore CRs.

   ```
   kubectl delete a7s --all -n <namespace>
   kubectl delete a7b --all -n <namespace>
   kubectl delete a7r --all -n <namespace>
   ```

   b. Manually delete the Analytics secrets:

   ```
   kubectl delete secrets <secret_name> -n <namespace>
   ```

   for each of the following secrets:

   ```
   analytics-ai-endpoint
   analytics-ca
   analytics-client
   analytics-server
   ```

   c. Manually delete analytics Persistent Volume Claims (PVCs):

   ```
   kubectl delete pvc <pvc_name> -n <namespace>
   ```

   for PVCs with the following naming pattern:

   ```
   data-analytics-storage
   ```

3. Uninstall the Developer Portal subsystem
   a. Delete the Developer Portal subsystem, and the Portal backup and restore CRs.

   ```
   kubectl delete ptl --all -n <namespace>
   kubectl delete pb --all -n <namespace>
   kubectl delete pr --all -n <namespace>
   ```

   b. Manually delete Developer Portal secrets:

   ```
   kubectl delete secrets <secret_name> -n <namespace>
   ```

   for secrets with the following naming pattern:

   ```
   portal-admin
   portal-admin-client
   portal-ca
   portal-client
   portal-db-ca
   portal-encryption-key-...
   portal-server
   portal-web
   ```

   c. Manually delete these Developer Portal PVCs:

   ```
   kubectl delete pvc <pvc_name> -n <namespace>
   ```

   for PVCs with the following naming pattern:

   ```
   admin-portal-...-www-...
   backup-portal-...-www-...
   db-portal-...-db-...
   dblogs-portal-...-db-...
   web-portal-...-www-...
   ```

4. Delete the DataPower Gateway subsystem.

   ```
   kubectl delete gw --all -n <namespace>
   ```

   Note: The following entries include both Multi-Protocol Gateway Service (v5-compatible) and API Gateway settings. Names that include "gwv5" refer to the Multi-Protocol Gateway Service (v5-compatible), and names that include "gwv6" refer to the API Gateway.
   a. Delete Service Accounts.

   ```
   kubectl delete sa <service_account> -n <namespace>
   ```

   for each of the following Service Accounts:

   ```
   gwv5-datapower
   gwv6-datapower
   ```

   b. Delete Secrets.

   ```
   kubectl delete secrets <secret_name> -n <namespace>
   ```

   for secrets with the following naming pattern:

   ```
   gwv5-datapower-token-...
   gwv5-dpm-sa-token-...
   gwv5-endpoint
   gwv5-manager-endpoint
   gwv6-datapower-token-...
   gwv6-dpm-sa-token-...
   gwv6-endpoint.
   gwv6-manager-endpoint
   ```

   c. Delete PVCs.

   ```
   kubectl delete pvc <pvc_name> -n <namespace>
   ```

for PVCs with the following naming pattern:

```
gwv5...
gwv6...
```

Removing API Connect

You can remove all parts of the API Connect deployment on Kubernetes.

About this task

These instructions completely remove API Connect, including PVCs and secrets.

- To delete the API Connect deployment in a Kubernetes runtime environment, you must use the Kubernetes command-line tool, kubectl.
- You must run the commands in the order shown in the procedure on this page. If you run commands out of order, you might encounter a problem where the deletion of namespaces hangs.
- If you want to retain the PVCs, which contain some of the data you built up when using the application, you must also keep the associated secret used to decrypt the data. To do this, you must backup each subsystem, and then uninstall the subsystems individually. In this case, do not use the instructions on this page. Instead, see Uninstalling API Connect subsystems.

Procedure

1. Delete all API Connect systems.

   ```
   kubectl delete apic --all -n <namespace>
   ```

   This command is the equivalent of deleting each of the individual subsystems one at a time, and also deleting all of their backup and restore CRs. The commands that run during this step are:

   - Subsystem CRs. For example:

     ```
     kubectl delete mgmt --all -n <namespace>
     kubectl delete a7s --all -n <namespace>
     kubectl delete ptl --all -n <namespace>
     kubectl delete gwv6 --all -n <namespace>
     ```

   - Backup and restore CRs:

     ```
     kubectl delete Backup --all -n <namespace>
     kubectl delete mgmtr --all -n <namespace>
     kubectl delete pb --all -n <namespace>
     kubectl delete pr --all -n <namespace>
     kubectl delete a7b --all -n <namespace>
     kubectl delete a7r --all -n <namespace>
     ```

     Note: If your deployment was previously on V10.0.6.0 or earlier, delete any pre-V10.0.7.0 management backup or restore CRs:

     ```
     kubectl delete mgmtb --all -n <namespace>
     kubectl delete mgmtr --all -n <namespace>
     ```

2. Delete the Operator deployments.

   ```
   kubectl delete deployment datapower-operator ibm-apiconnect -n <namespace>
   ```

3. Delete all Service Accounts in the namespace.
   Important:
   If your deployment uses default namespaces be cautious when using **kubectl delete <entity> --all** commands. There can be other pods, services, and more in the default namespace. When using the default namespace, keep in mind that using **kubernetes delete <entity> --all**, where <entity> can delete non-APIC entities, such as **sa** (Service Accounts), **secrets**, **rolebindings**, etc.

   ```
   kubectl delete sa --all -n <namespace>
   ```

4. Delete all Secrets in the namespace.

   ```
   kubectl delete secrets --all -n <namespace>
   ```

5. Delete all Rolebindings in the namespace.

   ```
   kubectl delete rolebindings --all -n <namespace>
   ```

6. Delete all Roles in the namespace.

   ```
   kubectl delete roles --all -n <namespace>
   ```

7. Clean up any remaining jobs.

   ```
   kubectl delete jobs --all -n <namespace>
   ```

8. Delete all PVCs in the namespace.

   ```
   kubectl delete pvc --all -n <namespace>
   ```

9. Delete Issuers in the namespace.
   Note that there might be none found.

   ```
   kubectl delete issuer --all -n <namespace>
   ```

10. Delete certificates in the namespace.
    Note that there might be none found.

    ```
    kubectl delete certificates --all -n <namespace>
    ```

11. If you are not using the default namespace, delete the Namespace
    Important: If your deployment uses the default namespace, do not delete it. There can be other pods, services, and more in the default namespace.

    ```
    kubectl delete ns <namespace>
    ```

12. Delete `validatingwebhookconfiguration`

    a. `kubectl get validatingwebhookconfiguration | awk /<ns>/'{print $1}' | xargs kubectl delete validatingwebhookconfiguration`

    b. `kubectl delete validatingwebhookconfiguration managements.validator.subsystem.apiconnect.ibm.com`

13. Delete `mutatingwebhookconfiguration`

    a. `kubectl get mutatingwebhookconfiguration | awk /$NS/'{print $1}' | xargs kubectl delete mutatingwebhookconfiguration`

    b. `kubectl get mutatingwebhookconfiguration | awk /apicop-management-defaulter/'{print $1}' | xargs kubectl delete mutatingwebhookconfiguration`

14. Delete the Apiconnect CRDs (custom resource definitions)

    ```
    kubectl delete crd analyticsbackups.analytics.apiconnect.ibm.com
    kubectl delete crd analyticsclusters.analytics.apiconnect.ibm.com
    kubectl delete crd analyticsrestores.analytics.apiconnect.ibm.com
    kubectl delete crd datapowerservices.datapower.ibm.com
    kubectl delete crd gatewayclusters.gateway.apiconnect.ibm.com
    kubectl delete crd backups.management.apiconnect.ibm.com
    kubectl delete crd managementclusters.management.apiconnect.ibm.com
    kubectl delete crd managementrestores.management.apiconnect.ibm.com
    kubectl delete crd natsclusters.nats.io
    kubectl delete crd natsserviceroles.nats.io
    kubectl delete crd natsstreamingclusters.streaming.nats.io
    kubectl delete crd portalbackups.portal.apiconnect.ibm.com
    kubectl delete crd portalclusters.portal.apiconnect.ibm.com
    kubectl delete crd portalrestores.portal.apiconnect.ibm.com
    ```

    Note: If your deployment was previously on V10.0.6.0 or earlier, delete any pre-V10.0.7.0 management backup or restore CRs:

    ```
    kubectl delete crd managementbackups.management.apiconnect.ibm.com
    ```

15. Delete EDB CRDs:

    a. Get a list of the EDB CRDs:

    ```
    kubectl -n <namespace> get crds | grep enterprisedb
    ```

    Expected output:

    ```
    backups.postgresql.k8s.enterprisedb.io                            2023-07-26T14:09:51Z
    clusters.postgresql.k8s.enterprisedb.io                           2023-07-26T14:09:51Z
    poolers.postgresql.k8s.enterprisedb.io                            2023-07-26T14:09:59Z
    scheduledbackups.postgresql.k8s.enterprisedb.io                   2023-07-26T14:10:02Z
    ```

    b. Delete the EDB CRDs:

    ```
    kubectl -n <namespace> delete crd <crd name>
    ```

    where *<crd name>* is the name of each CRD output in step 15.a.

16. If you installed cert-manager and want to remove it now, complete the following steps:
    Warning: If you are using shared clusters for API Connect with a common cert manager, be aware that this step removes the components of the cert manager from cluster wide scope.

    a. Delete the cert-manager

    ```
    kubectl delete deploy --all -n cert-manager
    kubectl delete service --all -n cert-manager
    kubectl delete sa -n cert-manager --all
    kubectl delete secrets -n cert-manager --all
    kubectl delete APIService v1beta1.webhook.cert-manager.io -n cert-manager
    kubectl delete MutatingWebhookConfiguration cert-manager-webhook -n cert-manager
    kubectl delete ValidatingWebhookConfiguration cert-manager-webhook -n cert-manager
    kubectl delete ns cert-manager
    ```

    b. Delete cert-manager CRDs

    - Delete the cert-manager CRDs with the following:

      ```
      kubectl delete crd issuers.cert-manager.io
      kubectl delete crd certificaterequests.cert-manager.io
      kubectl delete crd certificates.cert-manager.io
      kubectl delete crd challenges.cert-manager.io
      kubectl delete crd clusterissuers.cert-manager.io
      kubectl delete crd orders.cert-manager.io
      ```

    - Older API Connects versions may have cert-manager CRDs from an older version of cert-manager which had a different name, delete these CRDs with the following:

      ```
      kubectl delete crd certificaterequests.certmanager.k8s.io
      kubectl delete crd certificates.certmanager.k8s.io
      kubectl delete crd challenges.acme.certmanager.k8s.io
      ```

```
kubectl delete crd clusterissuers.certmanager.k8s.io
kubectl delete crd issuers.certmanager.k8s.io
kubectl delete crd orders.acme.certmanager.k8s.io
```

Removing API Connect on OpenShift or Cloud Pak for Integration

Remove your entire API Connect deployment on OpenShift or Cloud Pak for Integration.

About this task

These instructions completely remove API Connect, including PVCs and secrets.

Attention: Run the commands in the sequence shown on this page. If you run commands out of sequence, you might encounter a problem where the deletion of namespaces hangs.

Procedure

1. If Event Endpoint Management is installed, run the following command to determine the name of your Event Endpoint Management instance:

   ```
   oc get eem -n <APIC-namespace>
   ```

2. If you are using a top-level CR, run the following command to determine the name of your API Connect instance:

   ```
   oc get apiconnectcluster -n <APIC-namespace>
   ```

3. If you are using a top-level CR, run the following command to delete the API Connect operands (subsystems):

   ```
   oc delete apiconnectcluster <name_of_apic_instance> -n <APIC-namespace>
   ```

4. Run the following command to delete the API Connect backup and restore CRs:

   ```
   oc delete apic --all -n <APIC-namespace>
   ```

5. Run the following command to delete the secrets that are associated with your deleted API Connect cluster:

   ```
   oc get secrets --no-headers -n <APIC-namespace> | cut -d' ' -f1 | grep "^<first_10_characters_of_apic_instance_name>-" |
   xargs oc delete secret -n <APIC-namespace>
   ```

   Where *<first_10_characters_of_apic_instance_name>* refers to the name of your API Connect instance.

   Note: This step assumes that any secrets that you want to keep in your namespace do not have a name that starts with the same 10 first characters of the API Connect Cluster name.

6. If Event Endpoint Management is installed, run the following command to delete the secrets that are associated with your deleted Event Endpoint Management instance:

   ```
   oc get secrets --no-headers -n <APIC-namespace> | cut -d' ' -f1 | grep "^<first_10_characters_of_eem_instance_name>-" |
   xargs oc delete secret -n <APIC-namespace>
   ```

   Where *<first_10_characters_of_eem_instance_name>* refers to the name of your Event Endpoint Manager instance.

   Note: This step assumes that any secrets that you want to keep in your namespace do not have a name that starts with the same 10 first characters of the Event Endpoint Manager name.

7. Run the following commands to delete the API Connect secret rotation CRs for the cluster:

   ```
   oc delete mgmtsr -n <APIC-namespace>  --all
   oc delete ptlsr -n <APIC-namespace> --all
   ```

8. Optional: If you created a namespace specifically for API Connect, and are not using it for anything else, you can delete the namespace. If your API Connect operators are installed in this namespace, instead of in a shared global namespace, they are also deleted.

   ```
   oc delete ns <APIC-namespace>
   ```

   Deleting the namespace removes any remaining certificates and secrets.
   Note: Namespace deletion can get stuck, check that the namespace is deleted with:

   ```
   oc get ns <APIC-namespace>
   ```

   If the namespace is still present, to see why deletion is stuck, run:

   ```
   oc describe ns <APIC-namespace>
   ```

9. Optional: Delete the API Connect operator deployments.
   If your API Connect operator deployments are in a global namespace they are not deleted when your API Connect namespace is deleted. To delete the API Connect operators:
   a. Open the OpenShift web console and go to Installed Operators, in the namespace where the API Connect operators are installed.
   b. For each operator, click the options menu, and select Uninstall Operator.
   API Connect operator might have created a number of operand requests with IBM Cloud Pak foundational services (previously called Common Services) to deploy services such as Cert-Manager. In addition, API Connect requires the use of a DataPower Gateway, so the DataPower operator might be installed in the API Connect namespace. If those artifacts are no longer needed, uninstall them individually.
   Note: DataPower can be deployed on its own without API Connect. It is possible that the DataPower operator was installed for another purpose and not for use with API Connect, so check with your organization before you delete it.
   Deleting the operators from the web console ensures that related subscriptions, CSVs, and install plans are also removed.

Migrating from v10 to v10 on a different form factor

Migrate an API Connect v10 deployment from one form factor to a different form factor.

If you want to move your API Connect deployment to a different platform or network environment, use the form factor migration process.

For brevity, "form factor migration" is referred to as just "migration" in the rest of this topic.

The typical use cases for the migration process are:

- Moving your API Connect deployment from one platform to another, without changing anything else. For example, if you originally deployed on Kubernetes, but want to move to OpenShift.
- Changing the endpoints of your API Connect deployment. For example, the consumer API or portal web endpoint. It is not possible to update your API Connect endpoints after installation. Also, if you want to move your API Connect deployment to a different network, it is likely that the move requires changing the API Connect endpoints.
- Combination of moving to a different platform and changing endpoints.

You do not need to use the migration process for:

- Changing your API Connect deployment profile. See:
  - Changing deployment profiles on Kubernetes and OpenShift.
  - Changing deployment profiles on OpenShift top-level CR.
  - Changing the deployment profile on Cloud Pak for Integration.
- Backup, restore, and disaster recovery. See:
  - Backing up, restoring, and disaster recovery.

  Note:
  You can use the migration save script **`save_v10_source_configuration.py`** as an extra backup mechanism, but do not use the migration save script as an alternative to the standard backup process.

Key points and limitations of form factor migration:

- The API Connect version on the target system must match the API Connect version on the source system.
- The migration process applies only to the management and portal subsystems. The analytics and gateway subsystems do not require migration steps. The gateway receives its data from the management subsystem, and analytics database backups can be restored directly on the new deployment.

The supported migration paths are shown in the following table:

Table 1. Supported migration paths for API Connect v10

Source deployment platform of API Connect v10	Target deployment platform
Kubernetes	Cloud Pak for Integration..
Kubernetes	OpenShift Container Platform.
Kubernetes	Kubernetes.
OpenShift Container Platform	Cloud Pak for Integration, keeping the same endpoints.
OpenShift Container Platform	Cloud Pak for Integration, moving to a different cluster, resulting in endpoint changes.
OpenShift Container Platform	OpenShift Container Platform, moving to a different cluster, resulting in endpoint changes.
Cloud Pak for Integration	Cloud Pak for Integration, moving to a different cluster, resulting in endpoint changes.

  Migrate your API Connect v10 deployment from OpenShift to Cloud Pak for Integration, while remaining on the same cluster.
- **v10 migration troubleshooting**
  Troubleshoot problems with v10 migration.

v10 migration overview

Use migration scripts to migrate API Connect to another form factor, or to a different deployment on the same form factor.

The migration process consists of the following steps:

1. Extract the data from the management and portal subsystems databases of your source system, by using the provided Python script **`save_v10_source_configuration.py`**.
2. Install your target management and portal subsystems, setting new endpoints if required.
3. Specify the mapping of any changed endpoints in a YAML file.
4. Restore the data from your source system, by using the provided Python restore scripts.

Location of v10 migration scripts

You can obtain the scripts from Fix Central, search for **apiconnect-operator-release-files_*<version_number>***. The scripts are located in the helper_files/formFactorMigration directory:

```
apiconnect-operator-release-files_VERSION_NUMBER/helper_files/formFactorMigration
```

On Kubernetes, OpenShift, and Cloud Pak for Integration, the migration scripts are run from a client computer that has access to the Kubernetes or OpenShift cluster. Scripts are supported on Linux and macOS.

v10 migration planning

Consider the following information when you plan your v10 migration:

- **Data migration**
  There are two ways to migrate data:
  - Perform complete migration of data:

    Before starting migration steps on the target system, have the target system ready with the same or larger topology than what is present in the source system. This means the number of Gateways, Portals, and Analytics subsystems must be same or more than what is present in the source system. Start the migration process, map the endpoints between source and target systems, and complete the migration process. All data is migrated. The target system must be validated and tested.

    If you do not want to migrate data for some subsystems on the source system, skip those endpoints in the mapping. Then, after migration is complete, manually delete the data from Cloud Manager and the API Manager UI on the source system.
  - Perform migration in more than one step
    In this scenario, at the time of migration the API Connect target system does not have all the subsystems ready when compared to the total number of subsystems in the source system. Migration is run only for the Gateway and Portal subsystems that are available on the target system. At this point, the target system will still have some stale data related to the subsystems that are not migrated. You can then create additional subsystems (Gateways, Portals, or Analytics) on the target system, and run the necessary migration steps to complete the remaining migration process.
    - If additional Gateways or Analytics are added to the source system after completing the initial migration, you must:
      1. Add the new Gateway and Analytics related endpoints in the mapping file.
      2. Register Gateways and Portals on the target system. Complete Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
      3. Update the gateways in the catalog to point to the new Gateway systems. Complete Step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
    - If additional Portals are added to the source system after completing the initial migration, you must:
      1. Add the new Portal related endpoints in the mapping file.
      2. Register gateways and portals on the target system. Complete Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
      3. Update the portals in the catalog to point to the new portal systems. Complete Step 4 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
      4. Restore portal backups for each site on the namespace where the new portal is installed. Complete Step 5 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
    - The stale data for which migration is not complete will remain on the target system until you install the additional subsystems and complete migration, or until you use the Cloud Manager or API Manager UI to manually delete it.
- Reuse of Gateways from the source system:
  1. Export the **ingress-ca** secret from the source system using the **-export_cert** flag in Preparing the source system. The secret is saved to **data/MANAGEMENT_SUBSYSTEM_NAME/ingress-ca_secret.yaml**.
  2. Install the **ingress-ca** secret manually on the target cluster. This step must be completed before you begin Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
     - **If using top-level CR on OpenShift:** The top-level CR name you are going to use while installing API Connect must be used while creating the secret name and its contents.
     - The name of the ingress-ca secret must be ***TOP_CR_NAME*-ingress-ca** in case of OpenShift using top-level CR, or CP4I. For Kubernetes or OpenShift using individual subsystems, it must be **ingress-ca**.
     - An example of an **ingress-ca** secret is given in the following example. If top-level CR is used, replace **TOP_CR_NAME** with the top-level CR name you are going to use to install API Connect. For Kubernetes or OpenShift using individual subsystems, all the values will be just **ingress-ca**.
     - After modifying the contents of **ingress-ca** and saving the yaml, create the secret using **oc create -f filename.yaml -n NAMESPACE**.

     ```
     apiVersion: v1
     data:
       ca.crt: CA_CRT
       tls.crt: TLS_CRT
       tls.key: TLS_KEY
     kind: Secret
     metadata:
       annotations:
         cert-manager.io/alt-names: ''
         cert-manager.io/certificate-name: TOP_CR_NAME-ingress-ca
         cert-manager.io/common-name: ingress-ca
         cert-manager.io/ip-sans: ''
         cert-manager.io/issuer-group: ''
         cert-manager.io/issuer-kind: Issuer
         cert-manager.io/issuer-name: TOP_CR_NAME-self-signed
         cert-manager.io/uri-sans: ''
       name: <TOPCR>-ingress-ca
     type: kubernetes.io/tls
     ```

  3. Run the migration steps, starting with Step 1 in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration. Install API Connect, using the same TOP_CR_NAME (if using top-level CR), by following the remainder of the steps in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

4. When you complete Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, do not map the source system gateways that are to be reused. Just skip them.
5. Once the migration is complete, restart the gateways pods on the source system, wait for few minutes, and run the health check script to check the status of webhooks.
6. Validate the APIs running on the source system gateways.

- Delta changes
  Once the migration procedure is started, any delta changes in the source system databases are not handled by the migration scripts. These changes must be handled manually.
  - To avoid delta changes, shut down the Postgres database in the management subsystem.
    If you shutdown Postgres, you won't be able to login to the any of the API Connect UIs, or Toolkit CLI.
  - If there are delta changes to the management database after saving the configuration for the source system, you can optionally take another backup of the Management subsystem, just prior to restoring the Management subsystem. See Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Sizing
  Before installing the API Connect target system, make sure proper capacity planning is done to handle the production workloads. Ensure you have sufficient memory, CPU, and disk size as needed, based on the deployment profile being installed.
- Expected migration time
  The time required to complete migration can depend on the following:
  - The size of the management database. Backup and restore are dependent on this size.
  - Migration of the Portal and Gateway data in all the provider orgs depends on:
    - Number of provider orgs
    - Number of catalogs in these provider orgs
    - Whether Portals are configured for these catalogs
    - Total number of APIs published
  - Creation of Portal sites and restore of Portal backup depends on:
    - Deployment profile (n1, n3 etc) being used
    - Disk performance
    - Total number of Portal sites being create or restored
    - The amount of customization in a Portal site. Customization plays a role in the time needed to restore.

v10 migration requirements

Ensure your deployment meets the migrations prerequisites and requirements.

Subsystem requirements

All subsystems must be in a healthy state.

You must manually create storage classes like block storage or file system storage. Applies to all subsystems and, when installing on CP4I, to Platform Navigator.

Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

- Management subsystem:
  - You must configure management subsystems with either S3 or SFTP backups.
  - If s3 storage is being used, Postgres in the management subsystem must be stopped on the source system.
    Note:
    Shutting down Postgres is necessary in this scenario because two APIC deployments cannot both use the same S3 backup location. The target API Connect deployment will not start if Postgres on the source deployment is up and connecting to the same S3 backup location.

    When Postgres is stopped, there is no impact on the published APIs in the gateways. However, the Cloud Manager and API Manager UI will not available because the underlying microservices are down. Users are able to browse the APIs in the portal. But new consumer orgs or applications or users cannot be created.
  - If the Postgres cluster name on the target is different than the source system, restore will fail. For more information on configuring the target system, see Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Developer Portal subsystem:
  - Developer Portal subsystems must be configured with either S3 or SFTP backups.
  - For Developer Portal subsystem, you must have all the mappings between old and new endpoints and hostnames.
- Gateway subsystem:
  - If a custom gateway image is being used on the source system, the same image must be used on the target system
  - For a gateway subsystem, you must have all the mappings between old and new endpoints and hostnames.

Scripting requirements

- Python 3 and PyYAML python module must be present on the system where the scripts are run.
  To install the PyYAML module:

  ```
  pip3 install pyyaml
  ```

- Do not have any spaces in the complete directory path where the scripts are executed.
- Ensure that the API Connect version of the **apic** toolkit is the same version as for the scripts, and that the toolkit is located in the path where the scripts are executed. Validate toolkit commands to make sure the Cloud Manager and API Manager hostnames are resolved and able to run few commands. Make sure apic toolkit commands are working before trying out the scripts.
- If you are using hostnames, you may need to update the /etc/hosts file for the apic toolkit to work.

- When the scripts are run on the target system, the configuration (data directory) saved from the source system must be available in the location where scripts are present.
- Save the output logs for every script being executed.

Credentials requirements

- In all the scripts where the credentials are passed on the command line, these credentials are the admin org (Cloud Manager) credentials.
- You must be able to use **kubectl** (for native Kubernetes) or **oc** (OpenShift) commands to access the source system cluster and the target system cluster.
- To administer the admin org, you must have credentials with administrative role to access Cloud Manager.
- For provider orgs, if you do not use the migration user, and plan to use provider org credentials, you must have the provider org credentials for the API Manager interface.
- You must manually create:
  - Secrets for entitlement keys to download images from Docker registry.
  - DataPower admin credentials and secret, if the target system is native Kubernetes.
- After migration, the users on the target system will be in the same user registry as in the source system. For example, in CP4I, users from a local user registry (LUR) are not moved to a Zen user registry.

How to obtain hostnames

The hostnames used in the scripts (**--server** or **-s** or **-api_manager_hostname**) and also in the files **gateway_portal_mapping.yaml** or **provider_org_credentials.yaml** can be obtained using the following commands.

The command must be run on the source cluster or target cluster, based on the step for which the hostname is needed.

- Kubernetes:

  ```
  kubectl get ingress -n <NAMESPACE>
  ```

- OpenShift and Cloud Pak for Integration:

  ```
  oc get routes -n <NAMESPACE>
  ```

Example output on Kubernetes:

```
kubectl get ingress -n ask1
NAME                        CLASS    HOSTS                                              ADDRESS
PORTS     AGE
analytics1-ac-endpoint      <none>   ac1.testuser1-master.fyre.example.com

1.2.104.133,1.2.104.137,1.2.104.147,1.2.104.157,1.2.104.158,
```

How to obtain realm values

The value of realm (**--realm** or **-r**) used while running the scripts can be obtained as shown in the following examples. The realm values are for Cloud Manager (admin org) and provider org.

- Example for Cloud Manager (admin org):
  The value is passed as a command line option while running the script.

  ```
  apic identity-providers:list --scope admin --fields title,realm --server api.test1-master.fyre.example.com
  total_results: 3
  results:
    - title: Cloud Manager User Registry
      realm: admin/default-idp-1
    - title: googleoidc
      realm: admin/googleoidc
    - title: ldap1
      realm: admin/ldap1
  ```

- Example for provider org realm values:
  The value is used in **provider_org_credentials.yaml** while updating portal and gateway information in the provider orgs, when the default migration user is not used. See Step 4 and Step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

  ```
  apic identity-providers:list --scope provider --fields title,realm --server api.testuser1-master.fyre.example.com
  total_results: 3
  results:
  ```

```
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: googleoidc
    realm: provider/googleoidc
  - title: ldap1
    realm: provider/ldap1
```

Backing up subsystems

It is necessary to backup the management and portal subsystem databases on the source system:

- Backing up, restoring, and disaster recovery on Kubernetes and OpenShift

Limitations

1. Analytics service and data is not migrated.
2. If migrating from v10 non-CP4I environment (source apic cluster) to v10 CP4i environment (target apic cluster), make sure the Cloud Manager password for `admin` user is not `7iron-hide` on the source cluster. If default password `7iron-hide` is used, migration will fail after step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, as configurator job assumes that the install is a fresh installation, and changes the password automatically.

v10 migration steps

Complete the steps that are required for your v10 migration path.

Before you begin, ensure you have reviewed v10 migration overview and v10 migration requirements.
If migrating from OpenShift top-level CR to Cloud Pak for Integration on the same cluster, do not follow the steps here. Instead, refer to Migrating from OpenShift to Cloud Pak for Integration on the same cluster.

- **Preparing the source system**
  Run the `save_v10_source_configuration.py` script to gather the source system configuration.
- **Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  On the target system, configure a cluster, create the necessary secrets, and install API Connect.
- **Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  Restore the saved configuration and backups from the source system onto the target system.
- **Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  Verify that the target system is in a healthy state and fully configured.

Preparing the source system

Run the `save_v10_source_configuration.py` script to gather the source system configuration.

Before you begin

Review v10 migration requirements.

About this task

The `save_v10_source_configuration.py` script:

- Creates a data directory with all configuration saved in it.
- Generates two YAML files in the same directory as the script:
  - `gateway_portal_mapping.yaml`
  - `provider_org_credentials.yaml`

  Important: The YAML files must be filled in:
  - gateway_portal_mapping.yaml must be filled in if, when restoring onto the target system, you choose to run `register_gateway_portals_in_target.py` in silent mode. See step 3.c in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
  - provider_org_credentials.yaml must be filled in if, when restoring onto the target system, you choose not to use the migration user credentials while updating Portal and Gateway information. See step 4 and step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

To view script parameters:

```
python3 save_v10_source_configuration.py --help
```

Procedure

1. Create a directory called `FFM` and copy all python scripts to this directory.
2. Kubernetes, OpenShift, or Cloud Pak for Integration: Save configuration from the source system.
   To save the source system configuration, run `save_v10_source_configuration.py` with the appropriate parameters for your deployment:
   - If all subsystems are in the same namespace, and you are using username/password authentication.
     This command saves configuration of all the installed subsystems in the namespace:

     ```
     python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE
     ```

- If a subsystem needs to be skipped so that its configuration is not saved:
  - Skip Portal:

    ```
    python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE -skip_ptl
    ```

  - Skip Analytics:

    ```
    python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE -skip_a7s
    ```

- If all subsystems are in the same namespace, and you are using SSO authentication:

  ```
  python3 save_v10_source_configuration.py --sso -s PLATFORM_API_HOSTNAME -n NAMESPACE
  ```

- If all subsystems are in different namespace, and you are using username/password authentication:

  ```
  python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns <mgmt_namespace>  -ptl_ns <ptl_namespace> -gw_ns <gw_namespace> -a7s_ns  <a7s_namespace>
  ```

- If the cluster has multiple Gateways, Portals, or Analytics subsystems distributed across namespaces in the cluster, you can save the configuration of the source system using one of the ways shown below. Multiple namespaces need to be separated by "`|`" symbol. The namespaces used in below example command are **`ns1`**, **`ns2`**, **`ns3`**. Both commands work the same way.

  - **`python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n "ns1|ns2|ns3"`**

  - **`python3 save_v10_source_configuration.py -u USERNAME -p  PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns "ns1" -ptl_ns  "ns1|ns2" -gw_ns "ns1|ns2|ns3" -a7s_ns "ns1|ns2"`**

- If ingress-ca certificates must be saved or exported in the configuration, run the previous commands with **`-export_cert`** flag. Applicable only when you are saving management subsystem configuration.

What to do next

Configure your target deployment:

- Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

On the target system, configure a cluster, create the necessary secrets, and install API Connect.

Before you begin

- Complete Preparing the source system.
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Run the **`create_secrets_in_target.py`** script to create the necessary secrets. If necessary, shutdown the Postgres database, and then install API Connect, either manually or by running the **`install_apic_on_ocp.py`** script.

Note: For data migration, you have the option of performing a complete migration at once, or performing migration in more than one step. To review these options, see v10 migration planning.

Procedure

1. Configure a target cluster either Kubernetes or OpenShift or Cloud Pak for Integration, where you intend to migrate the source system data.
   - Note that this configuration is for the cluster only. No API Connect software is installed yet.
   - Make sure **`KUBECONFIG`** is set to this target cluster, so you can access the cluster using **`oc`** or **`kubectl`**.
2. Create the namespaces in the target cluster where you want the API Connect subsystems to run.
   - The namespaces can be different than the source system values.
   - If you have additional subsystems to be installed in different namespaces, create these namespaces also.
3. Run **`create_secrets_in_target.py`** to create the following secrets:
   - Database backup secrets for Management and Portal subsystems
   - Application credentials
   - Encryption secrets from the source system

   Usage examples:
   - If both Management and Portal are in the same namespace, or if Portal is not installed.

     ```
     python3 create_secrets_in_target.py -n NAMESPACE
     ```

   - If both Management and Portal are in different namespaces:

     ```
     python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE>
     ```

   - If you are creating multiple Portal subsystems in the target API Connect system, to match the configuration of the source system, you must run the script more than once for each Portal subsystem from the source system.

The script detects that there are two Portal subsystems in the source system, and prompts you to select the subsystem name that matches the target Portal, as shown in the following commands:

- For Management and first Portal on the target system:

  ```
  python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE1>
  ```

- For the second Portal on the target system:

  ```
  python3 create_secrets_in_target.py -skip_mgmt -ptl_ns <PTL_NAMESPACE2>
  ```

4. If applicable to your deployment, shutdown the Postgres database on your source system.
   You can shutdown the Postgres database now, to ensure that there are no delta changes to your source system while the remainder of the migration process takes place.

5. Launch the target API Connect system.
   a. Review prerequisites:
      - Have a new OpenShift cluster ready with enough resources (CPU, memory, and disk) as required for the installation profile you will use.
      - As needed, create an entitlement key to download the images related to API Connect.
      - The target system must match the topology (number of Gateways, Portals and Analytics) of the source system to ensure that all the data in the Management database is migrated. If all the data in the Management database is not migrated, the not migrated (stale) data must be manually deleted. Alternatively, you can attempt the remaining migration later after installing the additional Portals and Gateways. See v10 migration planning.

   b. Launch the target API Connect system either manually or by using the `install_apic_on_ocp.py` script:

      - To manually launch from the OpenShift cluster UI:

        This method is the recommended way to launch the target API Connect system for production systems.

        This method is also used for advanced customization or when using custom certificates while launching the target API Connect system.

        - Install and launch the target API Connect cluster. See the instructions for your deployment type:
          - API Connect on OpenShift: Deploying on OpenShift and Cloud Pak for Integration
          - Cloud Pak for Integration: Installation procedures with IBM Cloud Pak for Integration
        - Before creating the top level CR, use the yaml view to add the properties which you saved from the source system configuration.
          For the Management subsystem, the saved configuration is in `data/config.yaml`. For the Portal subsystem, the saved configuration is in `data/config_portal.yaml`.

          Important: If you do not use the configuration from the source system, the migration fails.
          - Management subsystem properties:
            - encryptionSecret
            - Management subsystem name
            - site name
            - database backup credentials
            - custom application credentials
            - originalUID
          - Portal subsystem properties:
            - encryptionSecret
            - site name
            - database backup credentials
            - originalUID

          Note: If target system is Kubernetes, the properties must be in the Management and Portal subsystem CRs.
        - The top level CR must look like the following example. The values for this top CR are from the generated artifacts (data/config.yaml and data/config_portal.yaml) after running Preparing the source system. Note that the example shows a value for `spec.management.name`. You can obtain this value from config.yaml.

          ```
          apiVersion: apiconnect.ibm.com/v1beta1
          kind: APIConnectCluster
          metadata:

    siteName: cb06099f
  profile: n1xc7.m48
  storageClassName: rook-ceph-block
  version: 10.0.8.0
```

- You can also use the script `install_apic_on_ocp.py` with `-no_install` flag to generate the top level CR yaml, and use the yaml in the OpenShift UI and customize further.

- To launch using the `install_apic_on_ocp.py` script:
  The script is used to launch API Connect on OpenShift or API Connect with Cloud Pak for Integration using a top level CR that specifies one of each subsystem type:
  - Management
  - Developer Portal
  - Analytics
  - API Gateway

  Prerequisite:
  - The OpenShift cluster must be ready, and accessible using `oc`.
  - **Important:** The script is used to launch **ONLY** the specific version of API Connect based on the downloaded version of the artifacts.

  Usage:

  - Run the script with `--help` option to show additional flags available like `-production and -profile`.
  - License use is set to `nonproduction` by default unless the flag `-production` is used while running this script.
  - The profile defaults to the one replica profile `n1xc7.m48`, to specify a different profile use the `-profile` flag. For details of the available profiles, see API Connect deployment profiles for OpenShift and Cloud Pak for Integration. The one replica profile deploys 1 replica of each pod and is only for light, non-critical workloads such as basic development and testing.
  - Optionally, you can use the `-no_install` flag if you want to generate the yaml files (top level CR and other files needed in installation) without installing. In the following example commands, add the `-no_install` flag to the existing command parameters. You can use this top level CR from the OpenShift UI, and create an API Connect cluster.
  - Note : If CP4I environment, check if configurator job is completed and also check the output of:

    ```
    oc get apiconnectcluster -n NAMESPACE
    ```

Example command invocations:

Note: Each of the example commands includes parameters for a three replica profile deployment: `-production -profile n3xc16.m48`. If you have a one replica profile, omit these parameters.

- API Connect on OpenShift:
  - If the apiconnect and DataPower operators must be installed in all namespaces:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME -production -profile n3xc16.m48
    ```

  - If the apiconnect and DataPower operators must be installed in a specific namespace:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE  -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME  -operator_in_specific_namespace -production -profile n3xc16.m48
    ```

- API Connect in Cloud Pak for Integration:
  - If operators are in all namespaces:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME1 -cp4i -production -profile n3xc16.m48
    ```

  - If operators are in a specific namespace:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME1 -cp4i -operator_in_specific_namespace -production -profile n3xc16.m48
    ```

  - If operators are in all namespaces, with additional flags `-production` (for license to be set to production) and `-profile` (using n3 profile in this example):

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME1 -cp4i -production -profile n3xc16.m48
    ```

6. Optional: Install any additional Gateways, Developer Portals, or Analytics subsystems that are needed.
   - Complete this step now if your target system will have additional Gateways, Developer Portals, or Analytics subsystems to match what is there in the source API Connect system, and you want to complete data migration for all subsystems in one pass through the procedures in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

- Skip this step now, and proceed to step 7 if either of the following cases are true:
  - If your target system will not need any additional Gateways, Developer Portals, or Analytics subsystems.
  - Your target system will have additional Gateways, Developer Portals, or Analytics subsystems but you want to first complete data migration based on the top CR installation (1 Management, 1 Portal, 1 Gateway, 1 Analytics), before you install any additional subsystems.

  Note: To review the data migration choices, see v10 migration planning.
  If you choose complete this step now, see:

  - Deploying on OpenShift and Cloud Pak for Integration
  - Installation procedures with IBM Cloud Pak for Integration
7. Next, restore the configuration from the source system. Continue with Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

Restore the saved configuration and backups from the source system onto the target system.

Before you begin

- Complete Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Use scripts to:

- Restore the Management subsystem
- Register Gateways and Portals on the target system
- Update Portals in the Catalog to point to new Portal systems
- Restore Portal backups for each site
- Update Gateways in the Catalog to point to new Gateway systems

All scripts run on the target system must be run from a location where the data directory is present so that the source configuration can be used.

Note: You can optionally run scripts in `--silent` mode, particularly for the following scenarios:

- Register Gateways and Portals in the target system. (Step 3)
- Update Portals in the Catalog to point to new Portal systems. (Step 4)
- Update Gateways in the Catalog to point to new Gateway systems. (Step 6)

If there are multiple Portals and Management subsystems present in the data directory (as saved during Preparing the source system), the restore script prompts you to select the subystem name to use for migration while running the script. If running in silent mode, that value must be supplied as an additional flag.

Deployments with multiple Portals and Gateways are a common scenario. The saved data can have multiple Management subsystems only if you ran **`save_v10_source_configuration.py`** against multiple clusters with different Management subsystem names, without cleaning the data directory.

Procedure

1. Before restoring the Management subsystem backup, determine whether there have been any delta changes to your source system since you backed up the Management subsystem database and Portal database.
   - If you shutdown the Postgres database, as instructed in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, there are no delta changes. Continue to step 2.
   - If you did not shutdown the Postgres database, there could be some delta changes to the Management database, because the Management subsystem on the source system remains in READY state. In this case, to ensure you capture the latest configuration, repeat Preparing the source system. By doing so, the Management and Portal databases are backed up again. The latest backup will then be used to restore to the target system.
2. Restore a Management subsystem backup onto the target system.
   a. On the target API Connect system, ensure that the Management subsystem is up and running,
   b. Login to the target cloud manager using toolkit and save the *cloud_name* value using the following commands.

      ```
      apic login -s <platform API hostname> -u <username> -p <password> -r <realm name>
      ```

      ```
      apic cloud-settings:get -s <platform API hostname> --fields cloud_name
      ```

      This will create a **`CloudSetting.yaml`** file.

   c. Run **`restore_management_db.py`**. Examples:
      - OpenShift or Kubernetes target system:

        ```
        python3 restore_management_db.py -n <mgmt namespace>
        ```

        or:

        ```
        python3 restore_management_db.py -mgmt_ns <mgmt namespace>
        ```

      - Cloud Pak for Integration target system:

        ```
        python3 restore_management_db.py -n <namespace> -s <platform API hostname>
        ```

      - If for some reason the management subsystem is not healthy, restore using the command:

        ```
        python3 restore_management_db.py -n <mgmt namespace> -ignore_health_check
        ```

d. Update the *cloud_name* with the value that is saved in step b.

```
apic cloud-settings:update -s <platform API hostname> CloudSetting.yaml
```

3. Register Gateways and Portals on the target system.
   a. Prerequisites:
      - The **register_gateway_portals_in_target.py** script must be run on the target system after the Management database from the source system has been restored.
      - The Gateway and Developer Portal subsystems that need to be registered must be in a healthy state.
   b. Usage notes:
      - The credentials provided from this step will be same as the credentials used on the source system, because the Management database from the source system is restored.
      - Keep the endpoints ready for the new Gateway and Portal services so that they can be registered by running **register_gateway_portals_in_target.py**. To view endpoints, use **oc get routes**.
      - If you run **register_gateway_portals_in_target.py** for a Cloud Pak for Integration target system, and you see the error **The API Connect Gateway Service is already registered to another API Manager instance**, restart all the gateway pods, wait for them to become healthy, and run **register_gateway_portals_in_target.py** again.
      - Make sure the mapping of old URLs with the new ones are correct. If wrongly mapped (wrong values provided) communication errors occur during Gateway registration. Example errors messages:
        - `"Error: An error occurred communicating with the gateways subsystem "`
        - `"error: 'Client network socket disconnected before secure TLS connection was established'"`
   c. Run **register_gateway_portals_in_target.py** in either interactive mode or silent mode:
      - Interactive mode
        The **register_gateway_portals_in_target.py** script displays the Portal and Gateway endpoints from the source system, and prompts the user to enter the corresponding values from the target system. Examples:
        - If Management, Portal and Gateway subsystems are in the same namespace:

          ```
          python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n <namespace>
          ```

        - If Management, Portal and Gateway subsystems are in different namespaces, use **-mgmt_ns**, **-ptl_ns**, and **-gw_ns** to specify each, for example:

          ```
          python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -gw_ns <gway namespace>
          ```

        - If you are using SSO authentication, replace:

          ```
          -u <username> -p <password>
          ```

          with:

          ```
          --sso
          ```

        - Multiple namespaces can alternatively be specified with **"ns1|ns2|ns3"** notation. For example:

          ```
          python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u admin -p <password> -s <platform API hostname> -r admin/default-idp-1 -silent
          ```

          ```
          python3 register_gateway_portals_in_target.py -s <platform API hostname> -u admin -p <password> -r admin/default-idp-1 -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
          ```

      - Silent mode
        The gateway_portal_mapping.yaml file, with mapping between old and new endpoints for Gateway, Portal, and Analytics endpoints, must be located in the same directory as **register_gateway_portals_in_target.py**.

        This gateway_portal_mapping.yaml file is generated when saving the source API Connect system configuration with properties data filled in. For every Gateway, Portal, and Analytics subsystem registered with Management in the source system, the yaml has the endpoint mapping between source and target systems.

        Remaining data must be filled to use the yaml in silent mode. All values must begin with **https://**.

        - Example:

          ```
          python3 register_gateway_portals_in_target.py -n <namespace> -u <username> -p <password> -s <platform API hostname> -r <realm name> -silent
          ```

        - Example: If the subsystems are in multiple namespaces.
          For example, ns1, ns2, ns3 namespaces contain the subsystems. Both of the following commands work the same way:

          ```
          python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u <username> -p <password> -s <platform API hostname> -r <realm name> -silent
          ```

          ```
          python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
          ```

        - Example gateway_portal_mapping.yaml file with:
          - Two Gateways
          - One Portal or Analytics subsystem
          - All data mapped to the target API Connect system:

          ```
          analytics_mapping:
            registered_analytics_name:
          ```

```
    https://ac.source-apic.example.com: https://a1-a7s-ac-endpoint-apic1.apps.vlxocp-
3278.cp.fyre.example.com
gateway_mapping:
  registered_apigw_name:
    https://rgw.source-apic.fyre.example.com: https://a1-gw-gateway-apic1.apps.vlxocp-
3278.cp.fyre.example.com
    https://rgwd.source-apic.fyre.example.com: https://a1-gw-gateway-manager-apic1.apps.vlxocp-
3278.cp.fyre.example.com
  registered_v5gw_name:
    https://gw.source-apic.fyre.example.com: https://v5gw.gw.apps.vlxocp-3278.cp.fyre.example.com
    https://gwd.source-apic.fyre.example.com: https://v5gw.gwd.apps.vlxocp-3278.cp.fyre.example.com
portal_mapping:
  registered_portal_name:
    https://api.portal.source-apic.fyre.example.com: https://a1-ptl-portal-director-apic1.apps.vlxocp-
3278.cp.fyre.example.com
    https://portal.source-apic.fyre.example.com: https://a1-ptl-portal-web-apic1.apps.vlxocp-
3278.cp.fyre.example.com
```

- Example gateway_portal_mapping.yaml file with:
  - Only two Gateways
  - One Portal or Analytics
  - One Gateway not mapped
    Note that "not mapped" means that the data in the Management subsystem related to this Gateway is not mapped, and the Gateway will not be migrated during this migration phase.

    The Gateway could be migrated later; for example, after the second Gateway is created on the target system. Until the data related to the not-migrated Gateway or Portal is migrated or deleted, there will be stale data in the database.

    The same behavior can be achieved by leaving the values empty, or removing the entire section (name and mapping).

```

3278.cp.fyre.example.com
```

4. Use **update_to_new_portals.py** to update Portals in the catalog to point to new Portal systems.
   Note:
   If there is no Portal subsystem on the source system, skip this step. Also, skip this step if no Portal sites are created in any of the provider orgs. Continue with 6.

   If there is no change in your portal endpoints, then include the flag **-dont_use_toolkit_for_portal_backup** when you run the **update_to_new_portals.py** script.

   a. Review prerequisites:
      - The Management and Portal subsystems on the target API Connect system must be in a healthy state.
      - The **update_to_new_portals.py** script must be run on the target system after the following actions have been completed:
        - The Management database from the source system has been restored.
        - The new Gateway or Portal instance is registered in the Cloud Manager, using script or from the UI.
      - The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.

   b. Run the **update_to_new_portals.py** script in one of two modes, based on how the Provide Org credentials are available. The modes are:
      - Using a common migration user created by the script
      - Using credentials provided by the user in a yaml file

      Important: The provider org credentials must have administrative access.

   Examples:

   - Using a common migration user created by the script :
     The **update_to_new_portals.py** script runs in this mode by default. This script creates a migration user **muser1** in **migrationur** local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

     Examples:

     - If the Management and Portal subsystems are in the same namespace

       ```
       python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n
       <namespace> -api_manager_hostname <platform API hostname>  -silent
       ```

     - If using SSO authentication:

       ```
       python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname
       API_MANAGER_HOSTNAME -silent
       ```

     - If the Management and Portal subsystems are in different namespaces:

```
python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns
<mgmt namespace> -ptl_ns <portal namespace>E -api_manager_hostname <platform API hostname>E -silent
```

- Using credentials provided by the user in a `provider_org_credentials.yaml` file:
  The `provider_org_credentials.yaml` file, with some data filled in, is generated by the `save_v10_source_configuration.py` script you ran in Preparing the source system. The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

  Examples:

  - If Management and Portal subsystems are in the same namespace:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n
    <namespace> -no_migration_user -silent
    ```

  - If using SSO authentication:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
    ```

  - If Management and Portal subsystems are in different namespaces:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -
    mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -no_migration_user -silent
    ```

  Example provider_org_credentials.yaml:

  - With credentials given for every provider org. In this example, only two orgs are present.

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      PORG_NAME_1:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      PORG_NAME_2:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      useSameCredentialsForAllProviderOrgs: false
    ```

  - With credentials given for just one provider org. Also requires `useSameCredentialsForAllProviderOrgs` set to true. This method can be used only when the same credentials are used for all provider orgs.
    Note: In some cases, there are multiple provider orgs in the Management database.

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      PORG_NAME_1:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      useSameCredentialsForAllProviderOrgs: true
    ```

  - With SSO credentials and just one provider org:
    Note: When users sign in by using the Toolkit login path (a URL that includes `?from=TOOLKIT`), the generated API key has a fixed time-to-live (TTL) of 5 minutes.

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      useSameCredentialsForAllProviderOrgs: false
      porg_anme:
        #sso authentication
        #the key(that can expire in sometime) has to be generated separately using
    https://<apiManagerHostname>/auth/manager/sign-in/?from=TOOLKIT
        apiKey: some_key
    ```

5. Restore Portal backups for each site.
   Note:
   If there is no Portal subsystem on the source system, skip this step. Continue with 6.

   If there is no change in your portal endpoints, then include the flag `-s <platform API hostname>` when you run the `restore_portal_db.py` script.

   To restore the Portal sites on the target system, you can either use the using script restore_portal_db.py or complete a manual restore.

   - Restoring through the script:

     ```
     python3 restore_portal_db.py -n PORTAL_SUBSYSTEM_NAMESPACE
     ```

   - Restoring through manual steps:
     - Log in to the Portal admin container:

       ```
       oc exec -it <www_pod> -c admin -- bash
       ```

     - List the site backups:

       ```
       remote_transfer_backup -l
       ```

       The list of backups that need to be restored is available in the output logs as a report of Step 4.

     - Download each site backup, and run it for all sites:

       ```
       remote_transfer_backup -d <SITE_BACKUP_FILENAME>
       ```

- Restore each of the site backups:

  ```
  restore_site -f -u <SITE_URL> <SITE_BACKUP_FILENAME>
  ```

Note: If there are more than one Portal subsystems on the target system, as needed to correspond to the Portal subsystems on the source system, run the script for each of the matching source and target Portal subsystems.
For example, if there are two Portals on the target system, matching what is on the source system, and these Portals are installed in namespaces **target1** (for the top-level CR) and **pt12** (for second portal), then the script will be run twice, as follows:

```
python3 restore_portal_db.py -n target1

python3 restore_portal_db.py -n pt12
```

6. Run **update_to_new_gateways.py** to update Gateways in the Catalog to point to new Gateway systems.
   a. Review prerequisites:
   - The Gateway subsystem must be in a healthy state.
   - The **update_to_new_gateways.py** script must be run on the target system after the following actions have been completed:
     - The Management database from the source system has been restored.
     - The new Gateway instance is registered in the Cloud Manager, using script or from the UI.
   - The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.

   b. Run the **update_to_new_gateways.py** script in one of two modes, based on how the Provider Org credentials are available. The modes are:
   - Using a common migration user created by the script
   - Using credentials provided by the user in a yaml file

   Important: The provider org credentials must have administrative access.
   - Using a common migration user created by the script:
     The **update_to_new_gateways.py** script runs in this mode by default. This script creates a migration user **muser1** in **migrationur** local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

     Examples:

     - If the Management and Gateway subsystems are in the same namespace:

       ```
       python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n <namespace> -api_manager_hostname <platform API hostname>  -silent
       ```

     - If using SSO authentication:

       ```
       python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname <platform API hostname> -silent
       ```

     - If the Management and Gateway subsystems are in different namespaces:

       ```
       python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -api_manager_hostname <platform API hostname> -silent
       ```

   - Using credentials provided by the user in a **provider_org_credentials.yaml** file:
     The **provider_org_credentials.yaml** file, with some data filled in, is generated by the **save_v10_source_configuration.py** script you ran in Preparing the source system. The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

     - If the Management and Gateway subsystems are in the same namespace:

       ```
       python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n <namespace> -no_migration_user -silent
       ```

     - If using SSO authentication:

       ```
       python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
       ```

     - If the Management and Gateway subsystems are in different namespaces:
       Note that if multiple gateway subsystems present across namespaces, you can give multiple namespaces separated by the "|" symbol for **-gw_ns**.

       ```
       python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -gw_ns GW_NAMESPACE -no_migration_user -silent
       ```

     - Example provider_org_credentials.yaml
       - With credentials given for every provider org, and only two orgs present:

         ```
         provider_org_credentials:
           apiManagerHostName: <platform API hostname>
           PORG_NAME_1:
             password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
             realm: provider/default-idp-2
             username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
           PORG_NAME_2:
             password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
             realm: provider/default-idp-2
             username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
           useSameCredentialsForAllProviderOrgs: false
         ```

       - With credentials given for just one provider org, and **useSameCredentialsForAllProviderOrgs** is set to **true**.
         This can be used only when same credentials are used for all provider orgs.

         Note: There can be multiple provider orgs in the Management database.

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  PORG_NAME_1:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  useSameCredentialsForAllProviderOrgs: true
```

- With SSO credentials and just one provider org:
  Note: When users sign in by using the Toolkit login path (a URL that includes `?from=TOOLKIT`), the generated API key has a fixed time-to-live (TTL) of 5 minutes.

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  useSameCredentialsForAllProviderOrgs: false
  porg_anme:
    #sso authentication
    #the key(that can expire in sometime) has to be generated separately using
https://<apiManagerHostname>/auth/manager/sign-in/?from=TOOLKIT
    apiKey: some_key
```

7. Continue to Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

Verify that the target system is in a healthy state and fully configured.

Before you begin

Complete Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

About this task

Check the health of the target system, complete any optional configuration, and validate data, APIs, and URLs.

Procedure

1. Use the `health_check_post_migration.py` script to health check the target system.
   Examples:

   - When all the subsystems are in the same namespace, and the deployments uses username/password authentication:

     ```
     python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n NAMESPACE
     ```

   - When all the subsystems are in the same namespace, and the deployments uses username/password authentication, with use of the optional flag `–check_portal_site_health` to check the health of Portal sites:

     ```
     python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -n NAMESPACE -check_portal_site_health
     ```

   - When subsystems are present in different namespaces, and the deployment uses username/password authentication

     ```
     python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -mgmt_ns NAMESPACE -gw_ns NAMESPACE
     ```

   - When all subsystems are in different namespaces, and the deployment uses username/password authentication:

     ```
     python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -mgmt_ns NAMESPACE -gw_ns NAMESPACE -ptl_s NAMESPACE -a7s_ns NAMESPACE
     ```

   - When all subsystems are in the same namespace, and the deployment uses SSO authentication:

     ```
     python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME
     ```

   - When all subsystems are in the same namespace, and the deployment uses SSO authentication silent mode:

     ```
     python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME -api_key API_KEY_VALUE
     ```

   - When there are multiple subsystems across namespaces:

     ```
     python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n "namespace1|namespace2|namespace3"
     ```

2. Complete any optional configuration steps needed for your deployment:
   a. If necessary, update redirect URLS in the authorization server.
      If OIDC or SSO authentication is being used, the redirect URLS must be updated in the authorization server after migration. For example, for Google OIDC, you must to add the new redirect URLs in Google Developer Console. The new redirect URLs can be found in the user registry in Cloud Manager.

   b. If necessary, complete configuration for Analytics.
      If the Analytics service is present on the target system, backups must be configured. Also, use the Cloud Manager UI to manually associate the Analytics with the Gateways, as needed.

   c. If the target system is Cloud Pak for Integration, you must use the password from the target API Connect system to log in to Platform Navigator.
   d. If necessary, update Portal and Gateway services names in scripts or utilities.

The migrated Portal and Gateway services will have new names (old_name + "new"). Any scripts and utilities written using the apic toolkit must be updated if they are using names as input parameter and not the ids. This is applicable to only Portal and Gateway names.

3. Validate configuration data:
   a. Validate the data in the target API Connect system by logging into Cloud Manager and API Manager UIs.
   b. Validate the APIs published in the Gateways.
   c. Validate the Portal site URLs
   d. If necessary, update the DNS mapping info.
   Once all of the APIs are verified, you may need to update the DNS mapping info, to redirect the calls to the new Gateways and Portals.

   The v10 migration is now complete.

4. After migration is finished, and verification of the target system is complete, you can uninstall API Connect on the source system.
   See Uninstalling API Connect.

Migrating from OpenShift to Cloud Pak for Integration on the same cluster

Migrate your API Connect v10 deployment from OpenShift to Cloud Pak for Integration, while remaining on the same cluster.

Before you begin

Your API Connect instance must use the top-level CR. Direct migration of individual API Connect subsystem installations to Cloud Pak for Integration by the steps described here is not supported. Alternative methods of migration if you are not using the top-level CR are:

- If the same subsystem endpoints can be used, deploy a new top-level CR API Connect and restore disaster recovery backups from your existing installation, see Backing up, restoring, and disaster recovery. The new top-level CR deployment can then be migrated to Cloud Pak for Integration following the steps here.
- If different subsystem endpoints need to be used, migrate your API Connect deployment to a new top-level CR OpenShift cluster first. Follow the form factor migration steps Migrating from v10 to v10 on a different form factor, and then return here to complete the OpenShift top-level CR to Cloud Pak for Integration migration.

About this task

Procedure

1. Update your **<*TOP_CR_NAME*>-mgmt-admin-pass** secret with your current Cloud Manager admin password:
   a. Check whether the **<*TOP_CR_NAME*>-mgmt-admin-pass** password already matches your Cloud Manager admin password with:

   ```
   oc get secret -n <APIC-namespace> | grep mgmt-admin-pass

   oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d &&
   echo ""
   ```

   If the passwords match then skip to 2.
   b. From where you run OpenShift CLI commands, use the base64 command to encode your Cloud Manager admin password.

   ```
   echo -n '<password>' | base64
   ```

   Note: If the **base64** command is not available, alternative commands or tools can be used.
   c. Edit the **<*TOP_CR_NAME*>-mgmt-admin-pass** secret:

   ```
   oc edit secret <TOP_CR_NAME>-mgmt-admin-pass -n <namespace>
   ```

   d. Replace the **data.password** value with your base64 encoded value from 1.b.

   ```
   ...
   data:
     email: ZXhhbXBsZUBleGFtcGxlLmNvbQ==
     password: <base64 encoded password>
   kind: Secret
   metadata:
   ...
   ```

   Note: The password in **<*TOP_CR_NAME*>-mgmt-admin-pass** is only used on API Connect installation, form factor migration, and disaster recovery. It does not need to be kept in sync with the Cloud Manager during normal API Connect usage.
2. Install IBM Cloud Pak Platform UI and create an instance of it.
3. Restart the **apiconnect** operator pod.
   The restarted operator pod detects Cloud Pak for Integration and reconciles the subsystems with it. Wait for the subsystems to be healthy.

4. Log in to Cloud Manager and check the services under the topology section.
   Known issue: If you see an additional Analytics service with a different name for the same Analytics endpoint, you must delete the newly created Analytics service.

5. Check that the configurator job is complete: :

   ```
   oc get pods -n <namespace>
   ...
   NAME                                                READY   STATUS      RESTARTS   AGE
   <instance name>-configurator-<random string>        0/1     Completed   0          2h
   ...
   ```

   Complete the following validation checks:
   - Verify you are able to login to the Cloud Pak for Integration Platform UI, and can see your API Connect instance.
   - Verify you are able to login to Cloud Manager UI, API Manager UI, and your portal sites.

- Test that your APIs are running, and analytics data is logged.
- Test lifecycle operations such as a product publish or delete, or an app creation.

v10 migration troubleshooting

Troubleshoot problems with v10 migration.

Topics:

- Script help
- Restarting migration
- Factory reset of portal subsystem
- Avoid error when a gateway is already registered to another API manager

Script help

```
python3 <SCRIPT_FILE_NAME> --help
```

Restarting migration

On the target system, after running **register_gateway_portals_in_target.py** or **update_to_new_portals.py** or **update_to_new_gateways.py** script:

- If you want to restore the Management database and try the steps again:
  - Run the restore Management db (Step 2 on Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration) with the **-reset_gateway_portal** flag as shown

    ```
    python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
    ```

    If running on a Kubernetes environment, supply the Cloud Manager admin password by using the **-p** flag. After this, continue with next steps of migration.
- If you deleted the data directory after registering Gateways or Portals, but want to use the same target API Connect system which you already installed, then:
  1. Complete Preparing the source system to create the data directory.
  2. Run the restore management db (Step 2 on Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration) with the **-reset_gateway_portal** flag as shown

     ```
     python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
     ```

     If running on a Kubernetes environment, supply the Cloud Manager admin password by using the **-p** flag. After this, continue with next steps of migration.

Factory reset of portal subsystem

You can do a factory reset of the Portal subsystem by either manually or by using a migration script.

- Using migration script
  The script will restore the Management database and will factory reset the Portal subsystem, and also delete Gateway pods. The gateway pods will get restarted.

  The script will factory reset the Portal subsystem and also delete Gateway pods. When Gateway pods are deleted, they are also restarted.

  ```
  python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
  ```

  If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the **-p** flag. After this command, you must run the remaining steps of migration, starting with Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

  ```
  python3 register_gateway_portals_in_target.py -n NAMESPACE -u USERNAME -p PASSWORD -s HOSTNAME -r REALM_NAME -reset_gateway_portal
  ```

- **Manual steps**
  1. Log in to the Portal www pod:

     ```
     kubectl exec -it PORTAL_WWW_POD_NAME -c admin -n NAMESPACE -- bash
     ```

  2. Run the command :

     ```
     curl -X DELETE -k --cert /etc/nginx/ssl/portal-director-client-both.pem  https://localhost:3009/v2/portal/factory-reset
     ```

  3. If any sites are there, use the **list_sites** command to check if all sites are deleted.
  4. Check health of the Portal subsystem.

Avoid error when a gateway is already registered to another API manager

Error messages

```
Error: An error occurred communicating with the gateways subsystem at 'some_url' (status: 400, response: '"Unable to perform initial registration for API Management.
Error: The API Connect Gateway Service is already registered to another API Manager instance"
```

You can fix the error condition manually, or use a script:

- Manual step, when Gateway is in a Kubernetes or OpenShift cluster:
  Restart all the gateway pods.
- Using the migration script when Gateway is in a Kubernetes or OpenShift cluster:

The script will restore the Management database, factory reset the Portal subsystem, and delete the Gateway pods. Once deleted, Gateway pods get restarted.

1. Run the following script:

   ```
   python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
   ```

   If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the **-p** flag.

2. After this command, you must run the remaining steps of migration, starting with Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

- Gateway is on an Appliance
  Reboot all the Gateway appliances.

The API Connect operations tool: apicops

Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.

The API Connect apicops tool is in active development and is available to download from github.com. It is available for Linux® and macOS. All suggestions, feedback, and bug reports can be raised in this repository.

Installing

Download the binary for your operating system from latest release. Rename the file to **apicops**, and give it execute permission: **chmod +x apicops**.

Running apicops

Apicops requires access to your Kubernetes or OpenShift environment. For more information about using apicops, see: Requirements for running apicops.

Using Config Sync to replicate consumer-side catalog data

Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

Topic relocated to Using Config Sync to replicate catalog data.

- **Downloading the Config Sync utility**
  Download and extract the API Connect Config Sync utility.
- **Running Config Sync as a standalone binary**
  The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

Downloading the Config Sync utility

Download and extract the API Connect Config Sync utility.

Topic relocated to Downloading and extracting the API Connect Config Sync utility.

Running Config Sync as a standalone binary

The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

Topic relocated to Running Config Sync as a standalone binary.

Configuring and managing your server environment

You configure and manage the servers that comprise your IBM® API Connect on-premises cloud by using the Cloud Manager user interface.

The Cloud Manager user interface is the part of IBM API Connect that enables a Cloud Administrator to define and manage the API Connect on-premises cloud.

You can use the Cloud Manager to define the API Connect cloud by performing the following tasks:

- Create Provider organizations and invite users to serve as the owner
- Create and manage user roles and role defaults
- Create availability zones for services
- Register the relevant servers that will provide the gateway, analytics, and portal services
- Associate an analytics service with a gateway to enable reports for API Events
- Configure resources for user authentication, TLS security, and OAuth providers and make the resources visible to all or selected provider organizations
- Connect to an existing SMTP mail server and edit templates for system-generated emails
- Set the default gateway service for catalogs

- **Cloud Manager configuration checklist**
  A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM API Connect, and further supplementary tasks.
- **Activating your Cloud Manager user account**
  If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.
- **Accessing the Cloud Manager user interface**
  How to navigate to and login to the Cloud Manager user interface.
- **Defining your Cloud Manager topology**
  To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A default availability zone is provided with the installation.
- **Managing authentication and security**
  Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.
- **Configuring the cloud settings**
  Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.
- **Configuring governance in the Cloud Manager**
  How to add governance rulesets in the Cloud Manager to validate and enforce organizational governance policies and best practices across your API development process.
- **Administering provider organizations**
  Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.
- **Administering members and roles**
  Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.
- **Monitoring the cloud**
  API Connect generates events to monitor the status of your cloud.
- **Changing your Cloud Manager password and profile information**
  You can change your Cloud Manager password and update your profile information.
- **Resolving login problems by increasing HTTP header size**
  You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.
- **Onboarding a new admin for Cloud Pak for Integration**
  Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.
- **Extending the Gateway server behavior**

Cloud Manager configuration checklist

A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM® API Connect, and further supplementary tasks.

Key initial tasks

Task	Description
Log in to the Cloud Manager user interface	A default admin user account is provided for you to begin your configuration tasks.
Configure an email server for notifications	The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service.
Specify your email server as the notification server	Select the email server to be used as the notification server, and configure the sender name and email address to be included in the emails.
Register a Gateway service	A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.
Register an Analytics service	The Analytics service collects API event data from the Gateway service.
Associate the Analytics service with a Gateway service	You must associate an Analytics service with each of the Gateway services from which you want to collect API event data.
Register a Portal service	The Portal service provides a developer portal used by application developers to discover APIs and onboard consumers.
Create a provider organization	For developers to be able to publish APIs, and for API managers to be able to manage the API lifecycle, they must be a member of a provider organization. You must create a least one provider organization specifying the owner, who can add further members.

Further supplementary tasks

Task	Description
Configure authentication and security	API Connect provides default local user registries, but you can configure your own user registries, of various types, for user interface and API access control. You can also configure TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Create an Availability Zone	An Availability Zone is a logical grouping of one or more API Connect services. A default Availability Zone is provided on installation, but you can add further Availability Zones to reflect your data center topology.

Task	Description
Administer members and roles	You can add further users as members of the administration organization, and control their permissions by assigning predefined roles. You can also create your own custom roles.
Monitor your API Connect cloud	API Connect generates events to allow you to monitor the status of your cloud.

Activating your Cloud Manager user account

If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.

Before you begin

A cloud administrator invited you to join API Connect .

Procedure

1. Complete the following steps to activate your Cloud Manager account:

   If the Identity Provider uses LDAP
   : An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your LDAP user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If the Identity Provider uses a local registry
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:
     - Uppercase letters
     - Lowercase letters
     - Numbers
     - Special characters (for example: ! # $ %)

     Note:
     - The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
     - If you previously had an account that was removed, and you are being invited again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

   If the Identity Provider uses an authentication URL
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your Cloud Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

   For information on configuring user registries and making them available for Cloud Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.

2. Click Sign up to complete your registration, then click Sign in to open the Cloud Manager login page.

Results

You have created your API Connect administrator account.

What to do next

Log in to the Cloud Manager user interface and, depending on your role, start to manage the cloud topology, and work with provider organizations and cloud resources. To access the Cloud Manager login page in the future, use the following URL:

`https://host/admin`

where *host* is the fully qualified host name or IP address of the Management server.

Accessing the Cloud Manager user interface

How to navigate to and login to the Cloud Manager user interface.

Procedure

1. Open a browser and enter the URL for the cloud-admin-ui endpoint followed by /admin. Note that this is a secure connection that uses HTTPs, for example: **`https://<cloud-admin-ui>/admin`**.
   - Kubernetes, OpenShift, Cloud Pak for Integration installations: The cloud-admin-ui endpoint is specified in the Management subsystem CR, in the **`Endpoints`** section, for example:

     ```
     Endpoints:
       ...
       Name:   admin
       Type:   UI
       Uri:    https://example.com/admin
       ...
     ```

2. Enter the Cloud Administrator user name and password.
   - Kubernetes, and OpenShift individual Management subsystem install:
     If you are logging in for the first time, enter `admin` for the user name and `7iron-hide` for the password. Otherwise, enter `admin` for the user name and your own password.

   - OpenShift top-level CR install:
     The default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:

     ```
     oc get secret -n <namespace> | grep mgmt-admin-pass
     ```

     ```
     oc get secret -n <namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo
     ""
     ```

3. If your cloud contains multiple user registries, as configured on the Settings > User Registries screen, then choose the user registry that contains your login credentials. You might need to ask your administrator which user registry is appropriate for your account.
4. Click Sign In.
   Important: The first time that you access the cloud console, you must, for security reasons, enter a new password and your email address. If you forget your password and request a password reset, the notification email is sent to this email address. The email is sent by the email server that is configured in the **Notifications** section of the cloud **Settings**.

Results

The Cloud Manager user interface opens to the home page, as shown in the following screen capture:

What to do next

Configure the email server so you can reset your password if needed and send other notifications. See Tutorial: Configuring the Cloud.

Configure your topology by registering services. See Tutorial: Configuring the Cloud.

Create a Provider Organization. See Tutorial: Creating a Provider Organization.

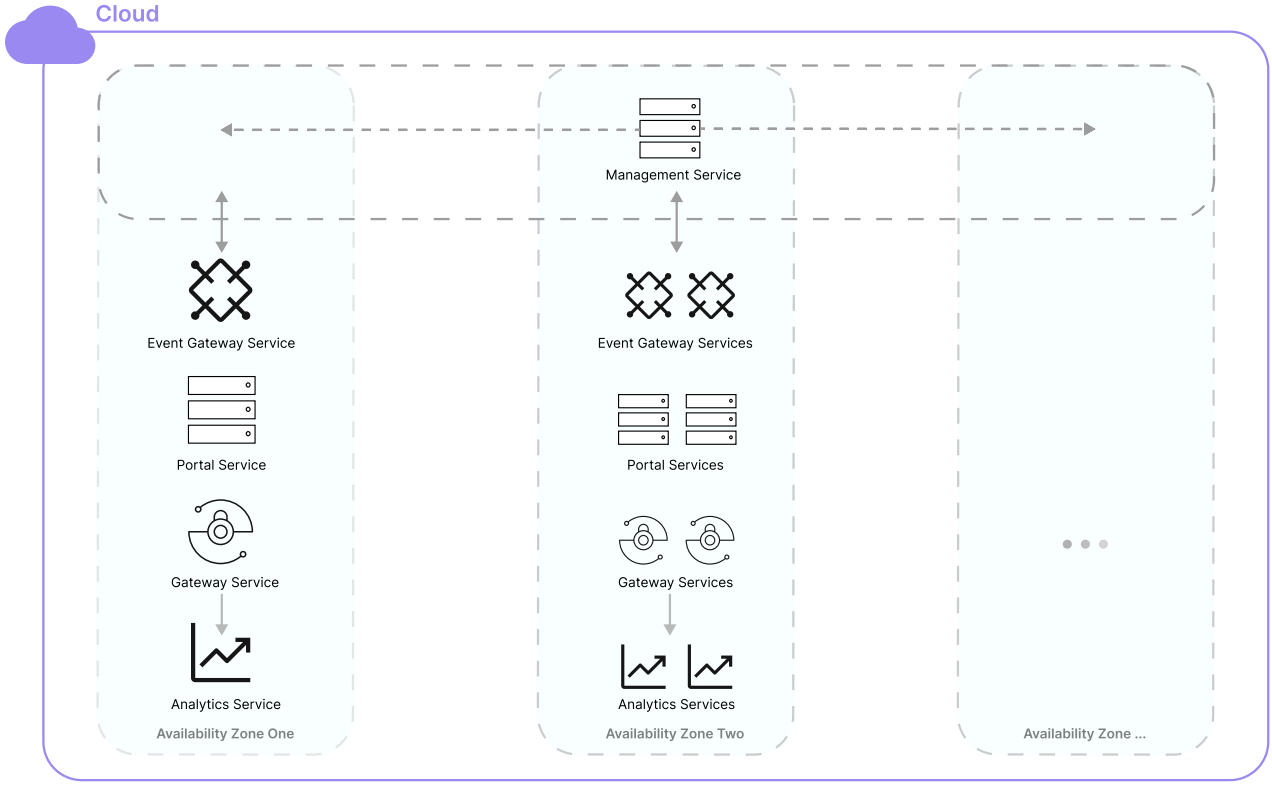
- Changing your Cloud Manager password and profile information



Defining your Cloud Manager topology

To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A default availability zone is provided with the installation.

About this task

The Cloud Manager topology consists of availability zones that contain the API Connect services. Availability zones can contain one or more DataPower® gateway services, event gateway services, analytics services, and portal services.

The following diagram illustrates the topology for services and availability zones in an API Connect network:

One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Following are the tasks that are involved in defining the API Connect topology:

- Create one or more availability zones.
- Register one or more DataPower gateway, event gateway, analytics, and portal services in each availability zone
- Associate an analytics service with each DataPower gateway service
- Set the visibility for the services

When the cloud is defined and an email server is configured, you can invite other users to access API Manager to create APIs. You then expose these APIs to the consumers (the development community) through the Developer Portal user interface.

To define the API Connect cloud, complete the following tasks:

- **Creating an availability zone**
  An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.
- **Registering a gateway service**
  A gateway service is required to handle incoming traffic for APIs.
- **Registering an event gateway service**
  Configure your IBM Event Endpoint Management instance (Manager) to be registered as an Event Gateway Service in API Connect.
- **Registering an analytics service**
  Configure at least one analytics service. The analytics service is always associated with a gateway service, from which it collects API event data.
- **Registering a portal service**
  Define one or more portal services in your API Connect on-premises cloud.
- **Associating an analytics service with a gateway service**
  To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.
- **Associating an OpenTelemetry configuration with a gateway service**
  You can associate an existing gateway service with an OpenTelemetry configuration if the service supports this feature.
- **Enabling OpenTelemetry configuration**
  Open Telemetry (OTel) is an open framework for creating and managing telemetry data, which might be traces, metrics or logs. OTel is not an alternative to monitoring tools, rather it enhances them. OTel typically supports the handling of traces, metrics, and logs.
- **Setting visibility for a service**
  The visibility setting determines which provider organizations can access a service.

Related concepts

- Configuring and managing your server environment

Creating an availability zone

An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.

About this task

Availability zones allow you to logically group API Connect services to suit your environment. For example, you can group gateway services according to the region or data center they are located in.

The Default Availability Zone is created during the installation process.

When you create an availability zone, you should provide a descriptive title; a name is generated automatically for internal identification. For example:

Table 1. Example availability zones

Title	Name
US Availability Zone	us-availability-zone
Hampshire Availability Zone	hampshire-availability-zone
Newport Availability Zone	newport-availability-zone
London South Availability Zone	london-south-availability-zone

One of the following roles is required to add and manage Availability Zones:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Follow these steps to add one or more additional Availability Zones to your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. You will see the current Availability Zones configured in your cloud. The Default Availability Zone is created at installation. To add another Availability Zone, choose Create Availability Zone.
3. Enter the following values:

Field	Description
Title (required)	Enter a descriptive title for the availability zone. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.

4. Click Create to complete the operation.

Results

The availability zone will be added on the Topology page. You can now add gateway, analytics, and portal services to the availability zone.

Related tasks

- Registering a gateway service
- Registering an analytics service
- Registering a portal service

Registering a gateway service

A gateway service is required to handle incoming traffic for APIs.

Before you begin

Before registering a DataPower® gateway service in Cloud Manager, the API Connect Gateway subsystem must be installed as a subsystem in your Kubernetes cluster, or enabled on the DataPower appliance. For a Kubernetes environment, see DataPower Gateway subsystem on Kubernetes. For appliances, see *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.

About this task

A gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.

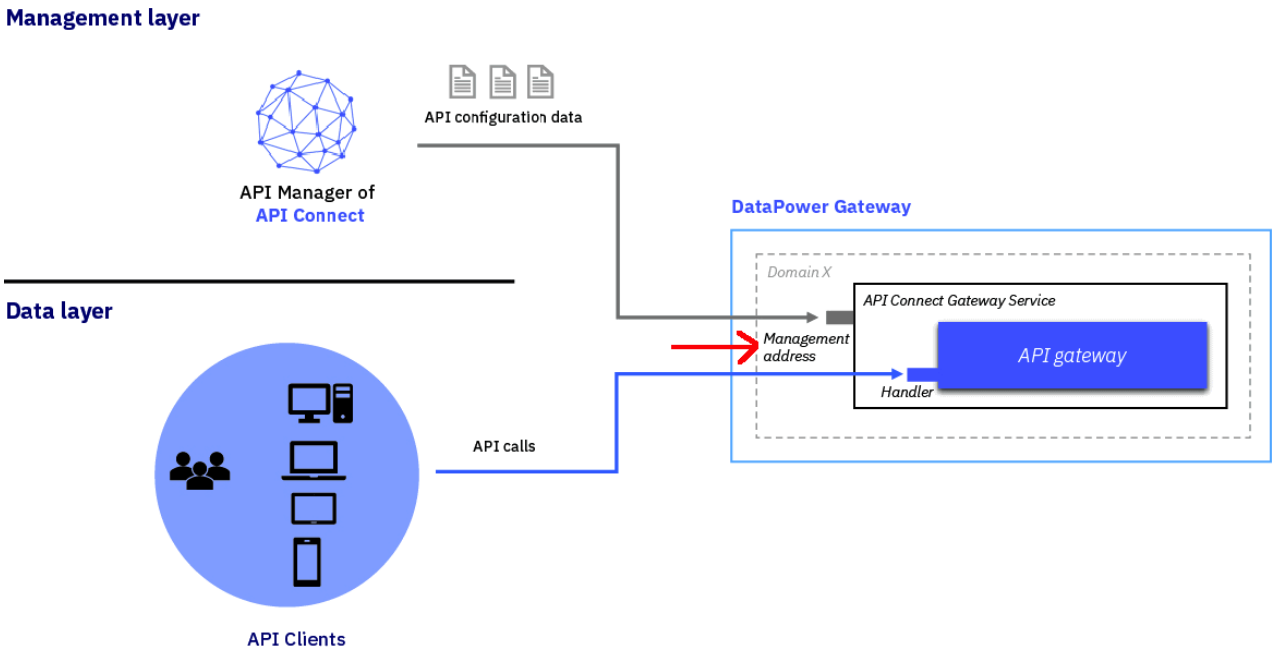
One of the following roles is required to register and manage DataPower gateway services:

- Administrator
- Topology Administrator
- Owner

- A custom role with the **`Topology:Manage`** permission

Note: You can also register, and manage, DataPower gateway services using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

Procedure



Complete the following steps to configure a DataPower gateway service for your cloud:

1. In the Cloud Manager, click Topology.
2. From the availability zone that will contain the DataPower gateway service, select Register Service.
3. On the Configure Service page, select DataPower Gateway as the service type. Select the gateway type that you want to create, either DataPower Gateway (v5 compatible) or DataPower API Gateway. For a description of the gateway types, see API Connect gateway types.
   Note: The option to enable LDAP connection pooling is only supported with the DataPower API Gateway v10.6.0.0 or later.
4. Enter the values to configure the DataPower gateway service. Obtain the endpoints from your deployment configuration. For a Kubernetes environment, the endpoints are configured by the following values in the CR (custom resource) file. For an appliance, the endpoint is configured in DataPower.

Field	Description
Title (required)	Enter a descriptive display title for the DataPower gateway service.
Name (required)	This field is populated for and is used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the gateway service: Endpoint (required)	Enter the API Connect Gateway Service endpoint. • For a Kubernetes environment, the Management Endpoint is the endpoint created in the CR (custom resource). See DataPower Gateway subsystem on Kubernetes for more information. • For an appliance, the Management Endpoint is the *Management address* to the API Connect Gateway Service shown in the gateway service connection diagram. For one gateway, this takes the form *https://<ip-address-for-gateway>:3000*. For multiple gateways, it would be the address:port of the load balancer • If you are using **`in-cluster`** communication, set this to the service endpoint URL for the gateway, which has the format: **`https://<name>.<namespace>.svc`** where: ◦ *<name>* is the **`name`** property from the gateway subsystem CR. If you are using the top-level CR this is **`<apic instance name>-gw`** ◦ *<namespace>* is the namespace that the gateway CR exists in.
Management endpoint on the gateway service: TLS client profile (required)	Specify the TLS client profile to use when the management subsystem initiates communication with the gateway. The client profile contains the TLS client certificate that is presented to the gateway when establishing a secure connection. Important: • Do not leave this property unset. You must specify a client profile for secure management to gateway communication (mTLS). If you do not want to use mTLS, then you can configure JWT instead: ◦ Use JWT instead of mTLS on Kubernetes and OpenShift. • The default profile to use is Gateway management client TLS client profile:1.0.0. On a Kubernetes or OpenShift deployment where the management and gateway subsystems are in the same namespace, the gateway service is automatically configured (during installation) to trust the Gateway management client TLS client profile:1.0.0. • If you want to use a different client certificate, do not update the Gateway management client TLS client profile:1.0.0, create a new client profile that uses the certificate you want. See Creating a TLS client profile. • If you are registering a gateway appliance, then configure your gateway to trust the client profile that you select. For more information about configuring TLS on your gateway appliance, see ◦ ../com.ibm.apic.install.doc/tapic_install_datapower_gateway_apigwy.html. ◦ ../com.ibm.apic.install.doc/tapic_install_datapower_gateway_v5compat.html. Do not configure your gateway appliances with client authentication disabled.
Management endpoint on the gateway service: Use in-cluster communucation	If you want to use **`in-cluster`** communication between the management and gateway subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems. If you are not sure, then leave this switch disabled (the default).
Management endpoint on the gateway service: Use JWT for gateway authentication to analytics service	If you plan to associate an analytics service with this gateway, and you want to use JWT authentication between the gateway and analytics service, then enable this switch. If this switch is not enabled, then mutual TLS authentication is used between the gateway and analytics service. For more information about JWT security, see Enable JWT security instead of mTLS
Use LDAP connection pool	Enable this option when you want to optimize LDAP user registry processing by enabling LDAP connection pooling. Connection pooling reduces overhead and improves performance by maintaining a pool of connections and assigning them as needed. When a connection is closed, it is returned to the connection pool for future use. Note: LDAP connection pooling is supported only with the DataPower API Gateway v10.6.0.0 or later. You cannot enable LDAP connection pooling during the initial registration of the DataPower API Gateway service. Instead, complete the registration steps and click Save; then edit the registration to enable the use of connection pools. Configure the following settings for the connection pool: • Max pool size: (Defaults to 35 connections) The maximum number of connections for an LDAP **`server:port:BindDN`** combination in the LDAP connection pool. For example, if the LDAP connection pool has six combinations and this value is 10, each combination supports 10 connections and the connection pool can have 60 connections. • Idle timeout: (Defaults to 120 seconds) The length of time, in seconds, before an idle connection is removed from the connection pool. • Document cache size: (Defaults to 0 bytes) The maximum size of the LDAP cache, in bytes. The largest supported cache size is 2147483647 bytes. Using a cache improves performance by reducing the number of times that the LDAP server must be contacted.

Field	Description
Enable AI Gateway	For the new DataPower API Gateway service, AI Gateway is enabled by default in API Connect v10.0.9.0. When AI Gateway service is enabled, it allows you to access AI Gateway policies directly on the DataPower API Gateway. For details, see Using the AI Gateway to support APIs for AI applications. Note: The AI Gateway toggle in gateway service is not supported if you already have a custom gateway extension deployed. However, you can manually enable the AI Gateway extension while retaining your existing gateway extension on the gateway service. For details, see Enabling AI Gateway on gateway service extensions. Even after following this procedure to apply AI Gateway extensions, a current limitation is that APIC UI and CLI will still show that `Enable AI Gateway` flag is not enabled on this gateway. When you disable AI Gateway, the following actions occur: • The gateway extension containing AI Gateway policies is removed from the gateway service. AI Gateway policies that were not used by any published APIs are deleted. • AI Gateway policies that were used by any published APIs remain intact.
API invocation endpoint: API endpoint base (required)	Enter the base portion of the URL that maps to the base portion of the URL for incoming API traffic. It is a public FQDN with additional paths that are specific to your API calls. For example: **https://api.mycompany.com** Note: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. If you are using the DataPower Gateway (v5 compatible), HTTP/2 is not supported on the API invocation endpoint.
API invocation endpoint: Server Name Indication (SNI) - Host name	For supporting Server Name Indication (SNI) at the API Endpoint Base. The default hostname of '*' is required to allow all hosts. Enter other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same Gateway service, using the same IP address and port, without requiring them to use the same TLS profile. Note: To allow requests from clients that don't support SNI, you **must** include a host name value of '*'.
API invocation endpoint: Server Name Indication (SNI) - TLS server profile	The TLS server profile that supports the given hostname for SNI. The server profile that is selected here contains the server certificate that is presented to callers of the APIs you publish on the gateway. By default this profile is set to Default TLS server profile. Best practice is to create your own TLS server profile that contains the certificate you want on your API invocation endpoint. For more information about configuring TLS server profiles, see TLS profiles overview. API Gateway only Restriction: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. Therefore, using a TLS server profile that supports only TLS protocol version 1.3 is not supported and will result in the gateway being unable to receive API traffic. You must use a TLS server profile that includes TLS protocol version 1.2 as one of its supported protocols. This restriction does not apply if you are using the DataPower Gateway (v5 compatible), which does not support HTTP/2.
OAuth shared secret (optional)	For sites using native OAuth providers, enter the shared secret that is used by all API calls going through the gateway. If not, a random default shared secret is automatically generated and added. Note: It is recommended to provide a custom shared secret rather than relying on the default one. Securely store this custom secret for potential future use. Note: The specified shared secret must be 64 characters (64 bytes) in length, prefixed with `0x`, and must consist only of hexadecimal characters. For example: `0xa354282f227c10250511ae9c9e8c7ed9f4f1bd0d7c04cb6d5bd178f8c62296e3` Note: If you change the shared secret, all the previously issued tokens become invalid.
Associate OpenTelemetry configuration (optional)	You can use this option to choose the OpenTelemetry configuration to be associated with the gateway service. You can set this property only after your gateway service is created, and only if the service supports this feature, See Associating an OpenTelemetry configuration with a gateway service

The following diagram illustrates the DataPower gateway service connection:

5. When you are finished, click Save.
6. If you want, you can delete the gateway service as follows;
    a. If the gateway service is already in use by any of the catalogs, you must disable the gateway service as follows:
        i. Log in to API Manager.

ii. Click Manage, then select the catalog.
iii. Click Catalog settings.
iv. Click Gateway services.
v. Click Edit.
vi. Remove the checkmark from the corresponding gateway service.
vii. Click Save.

b. Log in to the Cloud Manager user interface.
c. In the navigation list, click Topology.
d. Click the options menu icon alongside the corresponding gateway service, then select Delete.
e. Click Delete on the confirmation prompt.

Results

The DataPower gateway service is added to the appropriate availability zone for your cloud.

What to do next

Associate the DataPower gateway service with an analytics service, and set the visibility for the gateway. Add additional DataPower gateway services, or add one or more event gateway services, analytics services, or portal services.

Related tasks

- Registering a portal service
- Registering an analytics service
- Associating an analytics service with a gateway service
- Setting visibility for a service

Registering an event gateway service

Configure your IBM® Event Endpoint Management instance (Manager) to be registered as an Event Gateway Service in API Connect.

Before you begin

The Event Endpoint Management instance must be configured to trust API Connect before you register the Event Gateway Service. For instructions, see the *Retrieve the API Connect JSON Web Key Set (JWKS) endpoint*, *Configure Event Endpoint Management to trust API Connect*, and *Enabling mutual TLS* sections in the Configure an Event Endpoint Management Manager as an Event Gateway Service documentation.

About this task

Event Endpoint Management provides the capability to describe and catalog your Kafka topics as event sources, and to grant access to application developers within the organization. Application developers can discover event endpoints and configure their applications to access them through the event gateway. With Event Endpoint Management, developers can control access to the event endpoints, and also control what data can be produced to them or consumed from them.

For more information on Event Endpoint Management, see the Event Endpoint Management introduction in the IBM Event Automation documentation.

One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Create the TLS Client profile to use when contacting the Event Endpoint Management instance.

1. Create a client TLS keystore:
   a. Click > Crypto Material > Keystore > Create.
   b. Upload the manager-client-key.pem file in Step 1.
   c. Upload the manager-client.pem file in Step 2.
   d. Click Save.
2. Create a client TLS truststore:
   a. Click Truststore > Create.
   b. Upload the cluster-ca.pem file.
   c. Click Save.
3. Create a TLS client profile:
   a. Click TLS client profile > Create.
   b. Select the new keystore and truststore.
   c. Select Allow insecure server connections.
   d. Click Save.

Retrieve the Event Gateway endpoints.

4. Retrieve the Event Gateway management endpoint:
   To register an Event Endpoint Management instance with API Connect, you must provide the management endpoint on the event gateway, which defines where configuration updates from API Connect are sent. Retrieve the endpoint from Event Endpoint Management as follows:

   - OpenShift web console:
     - Log in to the OpenShift Container Platform web console using your login credentials.
     - Click Networking > Routes.
     - Click Project and select the project where the Event Endpoint Management instance is installed.
     - Use the search bar to find the route with the Name ending in **`apic`**.
     - Copy the URL for the management endpoint from the Location column.
   - CLI:
     - Log in to your Kubernetes cluster as a cluster administrator by setting your **`kubectl`** context.
     - Set the context to the namespace where your Event Endpoint Management instance is installed:

       ```
       kubectl config set-context --current --namespace=<namespace>
       ```

     - List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in **`-apic`**:

       ```
       kubectl get ingress
       ```

     - Copy the URL for the ingress resource from the **`Host`** column.
5. Retrieve the Event Gateway client endpoint:
   To register an Event Endpoint Management instance with API Connect, you must provide an endpoint which defines where clients should connect to so they can consume events. Depending where you have deployed your Event Gateway, the steps to retrieve the client endpoint will differ:

   - OpenShift web console:
     - Log in to the OpenShift Container Platform web console using your login credentials.
     - Click Networking > Routes.
     - Click Project and select the project where the Event Endpoint Management instance is installed.
     - Use the search bar to find the route with the Name ending in **`ibm-egw-rt`**.
     - Copy the URL for the client endpoint from the Location column.
     - Edit the URL to remove the **`https://`** protocol prefix, and to append the port **`:443`** as a suffix.
   - CLI:
     - Log in to your Kubernetes cluster as a cluster administrator by setting your **`kubectl`** context.
     - Set the context to the namespace where your Event Endpoint Management instance is installed:

       ```
       kubectl config set-context --current --namespace=<namespace>
       ```

     - List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in **`-ibm-egw-rt`**:

       ```
       kubectl get ingress
       ```

     - Copy the URL for the ingress resource from the **`Host`** column.
   - Stand-alone deployment:
     When deployed as a stand-alone gateway, the client endpoint value to use will be the name of the docker host running the gateway, and the **`GATEWAY_PORT`** value specified when starting the gateway container.

Register the Event Gateway Service in API Connect:

6. Log in to Cloud Manager as an administrator.
7. Click Topology.
8. On the Topology page, click Register Service.
9. On the Configure Service page, click the Event Gateway Service tile.
10. On the Configure Event Gateway Service page, configure the service by completing the following fields:

Field	Description
Title (required)	Enter a descriptive display title for the Event Gateway Service.
Name (required)	This field is populated for and is used as the internal field name.
Summary (optional)	Enter a brief description.
Service endpoint configuration: Management endpoint on the gateway service	Enter the Event Gateway management endpoint URL that you retrieved in step 4.
Service endpoint configuration: TLS client profile	Specify the TLS Client profile to use when contacting the event gateway through the management endpoint.
API invocation endpoint: API endpoint base	Enter the Event Gateway client endpoint URL that you retrieved in step 5.
API invocation endpoint: Server Name Indication (SNI) - Host	Supports SNI (Server Name Indication) at the API Endpoint Base URL. The default hostname of '*' is required to allow all hosts; add other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same event gateway service, using the same IP address and port, without requiring them to use the same TLS profile. Note: To allow requests from clients that don't support SNI, include a host name value of '*'.
API invocation endpoint: Server Name Indication (SNI) - TLS server profile	The TLS server profile that supports the specified hostname for SNI. The server profile that is selected here contains the server certificate that is presented to callers of the APIs you publish on the gateway. By default this profile is set to Default TLS server profile. Best practice is to create your own TLS server profile that contains the certificate you want on your API invocation endpoint. For more information about configuring TLS server profiles, see TLS profiles overview.

11. Click Save.
12. If you want, you can delete the event gateway service as follows;
    a. If the event gateway service is already in use by any of the catalogs, you must disable the event gateway service as follows:
       i. Log in to API Manager.

ii. Click Manage, then select the catalog.
iii. Click Catalog settings.
iv. Click Gateway services.
v. Click Edit.
vi. Remove the checkmark from the corresponding event gateway service.
vii. Click Save.

b. Log in to the Cloud Manager user interface.
c. In the navigation list, click Topology.
d. Click the options menu icon alongside the corresponding event gateway service, then select Delete.
e. Click Delete on the confirmation prompt.

Registering an analytics service

Configure at least one analytics service. The analytics service is always associated with a gateway service, from which it collects API event data.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service

About this task

The analytics service collects API event data from the gateway service. In Cloud Manager, you configure the analytics service and then associate it with one or more gateways. Multiple gateways can be associated with a single analytics service, but each gateway can be associated with only one analytics service.
One of the following roles is required to register and manage analytics services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

When you register the analytics service, you must select from one of three inter-subsystem communication methods. Before you decide which method to use, familiarize yourself with the difference between **external** and **in-cluster** communication: In-cluster or external communication between subsystems. If you are in doubt as to what communication method to use, then use the default **external** setting.

The analytics subsystem has two separate communication flows:

- Management to analytics. The management service communicates with the analytics subsystem to query for analytics data to present in the UI dashboards. This flow is known as "analytics queries".
- Gateway to analytics. The gateway sends API event data to the analytics service. This flow is known as "analytics ingestion".

What you select depends on what is most suitable for your network configuration. The options are:

Use **external** communication for both ingestion and queries
: This option is the default, and is what is used for analytics services that are upgraded from a pre-10.0.5.3 release. if your analytics subsystem is in a different environment then **external** is the only option that you can use. Both the gateway and the management service communicate with the analytics service by using the external endpoint, which is a Kubernetes **ingress** or OpenShift **route** depending on your platform.

Use **in-cluster** communication for both ingestion and queries
: You can select **in-cluster** if you have a Kubernetes or OpenShift deployment where all subsystems are within the same cluster. When this option is selected, the management, gateway, and analytics subsystems communicate with each other through internal service endpoints rather than externally accessible **ingresses** (Kubernetes) or **routes** (OpenShift).

Use **in-cluster** for ingestion and **external** for queries, or the other way around
: You can select this option if you have a Kubernetes or OpenShift deployment and you have some of your subsystems installed in the same cluster. When this option is selected, you can use different communication methods for the different analytics communication flows. For example, the management to analytics communication can use **in-cluster**, and the gateway to analytics can use **external**. You might choose this configuration if your gateway is in a different cluster to the rest of your subsystems.

Procedure

Complete the following steps to configure the analytics services for your cloud:

1. In the Cloud Manager, click Topology.
2. Select Register Services > Analytics in the Availability Zone where you have the gateways you want to associate with the analytics service.
3. Enter the values to configure the analytics service:

Field	Description
Title	Enter a descriptive title for the analytics service.
Name	This field is auto-populated by the system and used as the internal field name.
Summary	Enter a brief description.
Service endpoint configuration: Communication method.	Select your communication method, for more information on the options see, Communication types.

Field	Description

Service endpoint configuration: **External** analytics endpoint.	Enter the fully qualified domain name for the analytics ingestion endpoint that you defined during installation. To determine the endpoint, run the following command:
	• Kubernetes
	`kubectl get ingress -n <namespace>`
	The endpoint has **-ai-** in its name:
	`NAME CLASS HOSTS ADDRESS PORTS AGE`
	`def-analytics-ai-endpoint nginx a7s-in.example.com 80, 443 87d`
	• OpenShift
	`oc get routes -n <namespace>`
	The endpoint has **-ai-** in its name:
	`NAME CLASS HOSTS ADDRESS PORTS AGE`
	`def-analytics-ai-endpoint nginx a7s-in.example.com 80, 443 87d`
	Note: Kubernetes and OpenShift: This field is disabled if "Use **in-cluster** communication for both ingestion and queries" is set as the communication type.

Service endpoint configuration: TLS client profile for **external** analytics endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if "Use **in-cluster** communication for both ingestion and queries" is set as the communication type.
Service endpoint configuration: **In-cluster** analytics endpoint.	Enter the fully qualified domain name for the analytics ingestion service endpoint. The format of the service endpoint is `https://<name>.<namespace>.svc` where: • *<name>* is the **name** property from the analytics subsystem CR. If you are using the top-level CR this is **<apic instance name>-a7s**. • *<namespace>* is the namespace that the analytics CR exists in. This field is disabled if Use **external** communication for both ingestion and queries is set as the communication type.
Service endpoint configuration: TLS client profile for **in-cluster** endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the Endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if Use **external** communication for both ingestion and queries is set as the communication type.
Service endpoint configuration: Use **in-cluster** endpoint for analytics queries.	If you want the management subsystem to use the **in-cluster** service endpoint to communicate with the analytics subsystem, then select this option. If this option is not selected, then the management subsystem uses the **external** endpoint. Selection of **external** or **in-cluster** communication between the gateway and analytics subsystem is done when the gateway is associated with the analytics service, see Associating an analytics service with a gateway service. This setting is enabled when "Use **in-cluster** for ingestion and **external** for queries, or the other way around" is selected.

4. Click Save to complete the operation.
5. If you want, you can delete the analytics service as follows;
   a. If a gateway service is associated with the analytics service, you must unassociate the gateway service as follows:
      i. Log in to the Cloud Manager user interface.
      ii. In the navigation list, click Topology.
      iii. Click the options menu icon alongside the corresponding gateway service, then select Unassociate.
   b. Locate the analytics service to delete.
   c. Click the options menu icon alongside the analytics service, then select Delete.
   d. Click Delete on the confirmation prompt.

Results

The analytics service is added to your cloud settings.

What to do next

- Associate the analytics service with one or more gateway services: Associating an analytics service with a gateway service.
- Set preferred retention and rollover settings for the new analytics service: Retention and rollover.

Related tasks

- Registering a gateway service
- Registering a portal service

Registering a portal service

Define one or more portal services in your API Connect on-premises cloud.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service
- Configuring an email server for notifications
- Setting up notifications

Note:
When you create or register a Developer Portal service, the portal subsystem checks that the portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete one of the following updates depending on your platform:

On Kubernetes and OpenShift (with no apiconnectcluster)

Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

On IBM® Cloud Pak for Integration (deployed through apiconnectcluster)

Add the following section to the Apiconnectcluster custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: ptl-www
```

About this task

Each Availability Zone contains one or more portal services. The portal service provides a Developer Portal used by application developers to discover APIs and onboard consumers. An email server must be configured and set as the email server for the cloud before registering a portal service.
One of the following roles is required to register and manage portal services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Important: It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a portal site for every Catalog, for example Catalogs that are only for API Developers don't need a portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services.

Procedure

Complete the following steps to configure the portal services for your cloud:

1. In the Cloud Manager, click Topology.
2. In the Availability Zone that will contain the portal service, select Register Services > Portal.
3. Enter the values to configure the portal service.

Field	Description
Title (required)	Enter a descriptive title for the portal service. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the portal service: Endpoint (required)	Enter the IP address, fully-qualified host name, service, or ingress name. Used for communication with API Manager. • In a Kubernetes deployment, the endpoint is defined in the CR by `api.portal.$STACK_HOST`. See Developer Portal subsystem on Kubernetes. • If you are using `in-cluster` communication, set this to the service endpoint URL for the portal, which has the format: `https://<name>.<namespace>.svc` where: ◦ *<name>* is the `name` property from the portal subsystem CR. If you are using the top-level CR this is `<apic instance name>-ptl` ◦ *<namespace>* is the namespace that the portal CR exists in.

Field	Description
Management endpoint on the portal service: TLS client profile (optional)	Select the TLS Client Profile that will be used to communicate with the portal service. The profile applies to the Management Endpoint.
Management endpoint on the portal service: Use `in-cluster` communication switch	If you want to use `in-cluster` communication between the management and portal subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems. If you are not sure, then leave this switch disabled (the default).
Portal website URL (required)	The URL that will be used for public access to the portal. • In a Kubernetes deployment, the endpoint is defined in the CR by `portal.$STACK_HOST`. See Developer Portal subsystem on Kubernetes. Multiple portal-www endpoints may be configured, as described here in these topics: Defining multiple portal endpoints for a Kubernetes environment.

4. When you are finished, click Save.
5. If you want, you can delete the portal service as follows;
   a. If the portal service is already in use by any of the catalogs, you must delete the portal site as follows:
      i. Log in to API Manager.
      ii. Click Manage, then select the catalog.
      iii. Click Catalog settings.
      iv. Click Portal.
      v. Click the options menu icon alongside Portal section, next to the Edit option, then select Delete.
      vi. Click Delete on the confirmation prompt.
   b. Log in to the Cloud Manager user interface.
   c. In the navigation list, click Topology.
   d. Click the options menu icon alongside the portal service, then select Delete.
   e. Click Delete on the confirmation prompt.

Results

The portal service is configured in your cloud and can be used to publish APIs.

Associating an analytics service with a gateway service

To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.

About this task

The associated analytics service receives API event data from the gateway service.

To associate an analytics service with a gateway, you must first configure at least one analytics service and one gateway service.

One of the following roles is required to associate an analytics service with a gateway service:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Follow these steps to associate an analytics service with a gateway service:

Procedure

1. In the Cloud Manager, click Topology.
2. In the section for the Availability Zone you want to work on, locate the gateway service that requires an analytics service in the SERVICE column.
3. Locate the ASSOCIATED ANALYTICS SERVICE column.
4. If an analytics service is configured, the Associate Analytics service link is enabled for each gateway service. Click Associate Analytics Service in the same row as the gateway service that requires an analytics service.
5. In Associate Analytics Service, you see the name of the gateway service and a list of analytics services that have been configured in your cloud.
6. Select the analytics service to associate with the gateway service by adding a checkmark next to the analytics services.
7. If you specified `in-cluster` communication when you registered the analytics service, you can enable the gateway to send API event data to the internal analytics endpoint. Enable the "Use internal endpoint for ingestion of analytics data from the gateway service" switch. For more information about `in-cluster` communication, see Communication types.
8. Click Associate.
9. To remove the associated analytics service, select Unassociate analytics service from the actions menu. The gateway stops sending API event data to the analytics service.

Results

The analytics service is associated with a gateway service and starts to receive API event data from that gateway.

Associating an OpenTelemetry configuration with a gateway service

You can associate an existing gateway service with an OpenTelemetry configuration if the service supports this feature.

About this task

This topic describes how to associate an OpenTelemetry configuration with a gateway service.

Procedure

1. To register a new gateway service, see Registering a gateway service.
2. To associate an OpenTelemetry configuration with an existing gateway service, complete the following steps:
   a. In the Cloud Manager, click  Topology.
   b. Select the desired gateway service.
   c. Select the OpenTelemetry configuration to be associated.
   Note: This feature is only applicable to DataPower API Gateway.
   d. Click Save.

Results

The OpenTelemetry configuration is now associated with the desired service. If required, you can change or delete the OpenTelemetry configuration that is associated with a service by selecting a desired service.

- **Creating an OpenTelemetry configuration**
  Create an OpenTelemetry configuration as a resource in your cloud.

Creating an OpenTelemetry configuration

Create an OpenTelemetry configuration as a resource in your cloud.

About this task

After the OpenTelemetry configuration is created, you can view and edit this configuration in the Cloud Manager by selecting Resources > OpenTelemetry.

The **`Administrator`** role is required to create OpenTelemetry configuration.

Procedure

1. In the Cloud Manager, click  .
2. Select OpenTelemetry to see the list of OpenTelemetry configurations.
3. Click Create.
4. Enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name is auto-generated.
Summary	Enter a brief description.

5. Click Add in the Endpoints section.
6. Enter the following parameters:

Field	Description
Endpoint (required)	Enter the API Connect Gateway Service endpoint.
Protocol	Choose the required protocol
Signals	Choose the required signal

Field	Description
TLS client profile	Specify the TLS client profile to use when the subsystem initiates communication with the gateway. The client profile contains the TLS client certificate that is presented to the gateway when establishing a secure connection.

7. Click Add in the Headers section.
8. Enter the following parameters:

Field	Description
Name	Enter a descriptive name to use on the screen.
Value	Specify the value

9. Click Add in the Attributes section.
10. Enter the following parameters:

Field	Description
Name	Enter a descriptive name to use on the screen.
Value	Specify the value

11. If required, adjust the default values of Max queue size, Batch size, Export interval, Export timeout, and Max threads.
12. Make sure that the Parent based checkbox is deselected.
13. Choose the Sampler type.
14. If required, adjust the default values of the Sampler ratio.
15. Click Save.

Results

The OpenTelemetry configuration is saved and is available. Access this configuration in the Cloud Manager by selecting Resources > OpenTelemetry. If required, you can edit the parameters of each configuration by selecting the specific OpenTelemetry configuration.

What to do next

Associate an existing gateway service with an open telemetry configuration: Associating an OpenTelemetry configuration with a gateway service.

Enabling OpenTelemetry configuration

Open Telemetry (OTel) is an open framework for creating and managing telemetry data, which might be traces, metrics or logs. OTel is not an alternative to monitoring tools, rather it enhances them. OTel typically supports the handling of traces, metrics, and logs.

Note: OTel support is available for DataPower 10.6.0.1 and above.

Create OpenTelemetry configuration

Create the Open Telemetry configuration as follows and save it as otel.cfg. If needed, update the parameters as per the requirement. The default ports for OpenTelemetry are 4317 (grpc) or 4318 (http).
Note: Change the hostname and PORT in the following config to match your OTel Agent.

```
%if% available "otel-exporter"
otel-exporter "otel-exp"
  type http
  hostname otel-collector.cp4i.svc.cluster.local
  traces-path "/v1/traces"
  logs-path "/v1/logs"
  port 4318
  http-content-type binary
  timeout 10
  processor batch
  max-queue-size 2048
  max-export-size 512
  export-delay-interval 5000
exit
%endif%
%if% available "otel-sampler"
otel-sampler "otel-samp"
  parent-based
  type always-on
exit
%endif%
%if% available "otel"
otel "api-otel"
  exporter otel-exp
  sampler otel-samp
exit
%endif%
apigw "apiconnect"
  otel api-otel
exit
```

Create the gateway extension

1. In the same directory as `otel.cfg`, run the following command to create a `.zip` file for the `otel.cfg` file.

   ```
   zip otelgwextension.zip otel.cfg
   ```

2. Create a file that is named `manifest.json` with content specified as follow referring the newly created `.zip` file's name.

```
{
    "extension": {
        "files": [
            {
                "filename": "otelgwextension.zip",
                "deploy": "immediate",
                "type": "extension"
            }
        ]
    }
}
```

3. Create a final `.zip` file that contains both the updated `manifest.json` file and the `.zip` file created in previous step.

```
zip otel-ext.zip manifest.json otelgwextension.zip
```

Load the Gateway Extension

1. Log in to the Cloud Manager as administrator.
2. In the navigation list, click Topology.
3. From the list of gateway services, click ⋮ next to the gateway service and select Configure gateway extension.
4. Click Add.
5. Either drag and drop the .zip file of the gateway extension or click to upload the same.
6. Click Save.
7. Wait a few minutes for the extension to apply.

Setting visibility for a service

The visibility setting determines which provider organizations can access a service.

Before you begin

You must complete the following tasks:

- Create additional availability zones if needed, see Creating an availability zone
- Register at least one gateway service, see Registering a gateway service
- Register other services.

About this task

The visibility setting controls which provider organizations can use a service. The default visibility setting is Public.

One of the following roles is required to set the visibility for services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Follow these steps to set the visibility for the services in your on-premises cloud:

1. In the Cloud Manager, click Topology.
2. From the list of gateway services, click ⋮ next to the gateway service and select Edit visibility.
3. Select the visibility setting for the service. The options are:
   - Private - the service is not visible and cannot be used by any provider organization
   - Public - the service is visible and can be used by all provider organizations
   - Custom - the service is visible only to the provider organizations designated by you
4. For Custom visibility, select the provider organizations that will be able to use the service.
5. Click Save.

Results

For Private, the service cannot be used by any provider organizations. For Public, the service can be used by all provider organizations. For Custom, the service can be used by the provider organizations that you designate.

Managing authentication and security

Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.

As Cloud Administrator or Topology Administrator (or with a custom role that contains the `Settings:Manage` permission), you can configure the following authentication and security mechanisms:

- User registries to authenticate users of Cloud Manager and API Manager and of your Catalogs and APIs.
- OAuth providers to provide protection for APIs.
- TLS profiles to secure transmission of data through the Gateway to external web sites and among web servers.

The following topics describe how to configure user registries, OAuth providers, and TLS profiles:

- **User registries overview**
  API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.
- **TLS profiles overview**
  Create TLS profiles to manage the TLS communication between subsystems, external systems, and your API invocation endpoint.
- **OAuth Provider overview**
  API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

Related concepts

- OAuth Provider overview
- TLS profiles overview

User registries overview

API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.

Introduction to user registries

A user registry holds unique user account credentials, primarily usernames and passwords, which are accessed during authentication for logging into Cloud Manager, API Manager, the Developer Portal, and also for calling APIs (if the API is configured to use Basic Authentication in the Security Definition). The Cloud Administrator configures user registries to ensure that all users are successful at logging in.

User registries also provide security when calling APIs. For information on configuring Security Definitions for APIs, see Creating a basic authentication security definition.

User registries are configured as Resources. Once the user registry has been configured as a resource in Resources > User registries, the next step is indicate the active user registries for your cloud in Settings > User registries. The user registry must be made active in your cloud in order to make it available for authentication. When a user logs into Cloud Manager or API Manager, the specified user registry is queried for credentials to confirm the user's identity. To make a user registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding; for more information see Creating and configuring Catalogs.

Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access. In Cloud Manager and API Manager, a registry cannot be changed after a user is invited to be the owner of a provider organization, even if the invitation is not yet accepted.

User registries in API Connect serve the following primary functions:

- To authenticate a user at login time based upon username and password.
- To store basic profile information such as first name, last name, and email address.
- To provide secure access to Catalogs.
- To provide Basic Authentication for APIs when called by an application.

In order to log in to Cloud Manager, API Manager, the Developer Portal, or access a catalog, a user must have valid credentials (username and password) stored in a user registry that is configured in API Connect.

The Security Definition for an API can be configured to require a username and password, called the Basic Authentication method. With Basic Authentication, the username and password are included in the HTTP authorization header, and the credentials are verified through user registry.

User registries that are configured in Cloud Manager have the following characteristics:

- They are available to Cloud Manager, API Manager, the Developer Portal, and for Basic Authentication for APIs.
- They are available to provider organizations, as determined by the visibility setting.
- They can be edited and deleted only in Cloud Manager.

User registries that are configured in API Manager have the following characteristics:

- They are available to the Developer Portal (for Catalogs) and for Basic Authentication for APIs.
- They are available only to the Provider Organization that created them.

User registries supported by API Connect

API Connect integrates with several types of user registries to accommodate all security solutions. You can use your corporate LDAP registry, an Authentication URL, or an LUR to provide secure access to Cloud Manager, API Manager, the Developer Portal, and APIs. API Connect includes two internal databases that serve as local user registries, or LURs. The Providers LUR supports credentials for Provider organizations and the Admin LUR supports credentials for the Administrator organization. Multiple registries may be configured.

The following user registry types can serve as a resource in API Connect:

- Local user registry (LUR) - An internal database of usernames and passwords stored on the local server. Contains the Admin user account which may not be modified or deleted.
- LDAP - A user registry definition that points to an existing corporate LDAP directory. May be set up as case-sensitive.
- Authentication URL - Accesses a URL that points to a service for validating user credentials.
- OpenID Connect (OIDC).

- **Configuring an Authentication URL user registry**
  An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- **Configuring a shared custom user registry**
  You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.
- **Configuring an LDAP user registry in the Cloud Manager**
  You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.
- **Configuring a Local User Registry**
  A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.
- **Configuring an OIDC user registry in Cloud Manager**
  Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.
- **Setting visibility for a user registry**
  The visibility setting determines which provider organizations can access a resource, for example, user registries.
- **Deleting a user registry**
  As the Cloud Manager administrator, you can delete user registries.
- **Removing a user from a user registry**
  As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

Related tasks

- Configuring an Authentication URL user registry
- Configuring a Local User Registry
- Configuring an LDAP user registry in the Cloud Manager
- Setting visibility for a user registry

Configuring an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

About this task

This topic describes how to configure a new Authentication URL user registry as a Resource in your cloud. After the user registry is configured, you must select it for use in your cloud in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

One of the following roles is required to configure user registries.:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:
API Connect issues an HTTP **`GET`** call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as **`https://myauthurl.example.com/user/authenticate`**:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of **`200`**, the user authenticates successfully. An HTTP status code other than **`200`** indicates a failed login attempt. API Connect forwards any HTTP Header starting with **`X-`** (with the exception of **`X-Client-Certificate`**), and Cookie to the Authentication URL identity provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
 X-Forwarded-For: 8.8.9.9
 X-Custom-Header-From-Customer: special
 Cookie: MyCookie=VGhpc0lzV2lja2VkQW1hemluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- **`username`**
- **`email`**
- **`first_name`**
- **`last_name`**

If the **`username`** field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The **`Content-Type`** must be **`application/json`**.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "username":"myuser",
  "email":"myuser@example.com",
  "first_name":"My",
  "last_name":"User"
}
```

Procedure

1. In the Cloud Manager, click  .
2. Select User Registries to see the list of current user registries in your cloud.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Authentication URL User Registry and enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name that is used in CLI commands. The name is autogenerated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary (optional)	Enter a brief description.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface login, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
URL (required)	Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either `200 OK` or `401 Unauthorized` will be returned.
TLS Client Profile (optional)	Select a TLS Client Profile to allow secure authentication with a specific web server.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal .
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal , including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.

Results

The Authentication URL user registry is saved and is available to be selected as a user registry for Cloud Manager or API Manager by selecting it in Settings > User Registries. It can also be used for Basic Authentication in the Security Definition for an API.

Configuring a shared custom user registry

You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.

Before you begin

To configure a custom user registry as a resource in the Cloud Manager, the external user directory must be created and available to use with your API Connect ecosystem.

Custom user registries can be used for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal, but cannot be used to secure APIs.

One of the following roles is required to configure a custom user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create a custom user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific custom user registry can be used for authenticating Developer Portal users, while a shared custom user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared custom user registry. If you want to create an organization-specific registry, see Creating an organization-specific custom user registry for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- You can also create custom user registries by using the API Connect REST APIs (see the API Connect REST API documentation).

You can use the following instructions to create a writable or a read-only custom user registry.

API Connect provides two methods for creating a shared custom user registry in the Cloud Manager, as described in the following sections:

- Creating a shared custom user registry by using the Cloud Manager UI
- Creating a shared custom user registry by using the developer toolkit CLI

Creating a shared custom user registry by using the Cloud Manager UI

You configure a custom user registry by first creating a custom user registry type that defines your external user registry, and then creating a new custom user registry resource that references the custom user registry type that you just created. To make the registry available for user authentication, you need to add the registry to the Cloud Manager, or to the API Manager, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the custom user registry type.

Creating a custom user registry type

Use the following instructions to create a custom user registry type that defines your external user registry.

1. In the Cloud Manager, click  Resources.
2. Click Create in the User registry type section.
3. Enter the following information:

Property	Description
Title	A descriptive name of the custom user registry type to display in the UI. For example, *My custom user registry type*.
Name	The name of the user registry type. This name is auto-generated, and is used in CLI commands.
Version	The version number of the custom user registry type.
Summary	A brief description of the custom user registry type.
Properties	Enter the properties of your external user registry. Must include the property: **`remote: true`** This property must be set to **`true`** to indicate that this is an external user registry.
Secured Endpoint	Denotes the external registry secured endpoint section of the custom user registry type.
URL	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the URL and port, for example: ***`https://custom.ms.com:8888`*** API Connect will make REST calls to this endpoint for the user registry actions.
TLS Client Profile	Optionally set the TLS Client Profile URL that the custom server requires.
Headers	Optionally complete the user-defined header section to your external registry specification.
Configuration schema	Optionally complete the user-defined configuration schema section to your external registry specification.

4. Click Create. A new user registry with a Type of Custom is displayed in the User registry type list.

Creating a custom user registry resource

Use the following instructions to create a new custom user registry resource that references the custom user registry type that you just created.

1. Click Create in the User Registries section of Resources.
2. Click the Custom user registry tile.
3. Enter the following information:

Property	Description

Property	Description
Custom type	The name of the custom user registry type that you just created. For example, *my-custom-user-registry-type*. Use the drop-down arrow to select different custom user registry types.
Title	A descriptive name to display in the UI.
Name	The name of the custom user registry. This name is auto-generated, and is used in CLI commands.
Summary	A brief description of the custom user registry.
Endpoint	Optional endpoint information.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: • The Developer Portal does not support case sensitive usernames. • After at least one user has been onboarded into the registry, you cannot change this setting.
User registry managed	Determines whether API Connect manages your user registry. Valid values are: • `true` - select the checkbox • `false` - clear the checkbox
User managed	Determines whether your user registry is writable or not. Select the checkbox to set to `true` for writable. Clear the checkbox for the non-writable option.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Create. The new user registry is displayed in the User registries list.

Adding your custom user registry to the Cloud Manager or API Manager login

To make the custom user registry available for user authentication in the Cloud Manager or the API Manager, you must set it as active in the Settings > User Registries section of the Cloud Manager UI. See Selecting user registries for Cloud Manager and API Manager for more information.
If you want to make the custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Catalog settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring Catalogs.

Creating a shared custom user registry by using the developer toolkit CLI

You configure a custom user registry by first configuring an integration document that defines your external user registry, and then creating a new custom user registry resource that references the integration document that you just created. You use developer toolkit CLI commands to create the integration document, and then the custom user registry. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the integration document.

Logging in to the management server CLI

Before you can define the custom user registry, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your integration document

You define the configuration of your external user registry in an *`integration_file`*`.yaml` document, as shown in the following example.

```
integration: '1.0.0'
integration_type: 'user_registry'
```

```
info:
  name: 'custom_user_registry'
  version: '1.0.0'
  title: 'Custom External User Registry'
  summary: 'Configure External User Registry'
properties:
  remote: true
secured_endpoint:
  endpoint:  'https://custom.ms.com:8888'
  tls_client_profile_url: {$tslClientProfileUrl}
headers:
  key1: value1
  key2: value2
configuration_schema:
  option_config1:
     type: string
  option_config2:
     type: boolean
```

The integration document properties are described in the following table:

Property	Description
`integration_type`	The type of integration, which in this case is `user_registry`.
`info`	Denotes the information section for the integration document.
`name`	The name of the user registry type, for example `custom_user_registry`. This name is used in the user registry file to denote the registry type.
`version`	The version number of the integration document.
`title`	A descriptive name to display in a graphical user interface.
`summary`	A brief description of the integration document.
`properties`	Denotes the property section of the integration document.
`remote`	Indicates that this is an external user registry. Must be set to `true`.
`secured_endpoint`	Denotes the external registry endpoint section of the integration document.
`endpoint`	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the url and port, for example: `https://custom.ms.com:8888` API Connect will make REST calls to this endpoint for the user registry actions.
`tls_client_profile_url`	Optionally set the TLS Client Profile URL that the custom server requires.
`headers`	Complete the user-defined header section to your external registry specification.
`configuration_schema`	Complete the user-defined configuration schema section to your external registry specification.

Save your `integration_file.yaml` so it can be accessed by the `integrations:create` command in the following section.

Creating your custom integration

To create your custom user registry integration, run the following CLI command:

```
apic integrations:create --server mgmt_endpoint_url --subcollection user-registry integration_file.yaml
```

where:

- `mgmt_endpoint_url` is the management platform API endpoint URL.
- `integration_file` is the name of the YAML file that defines the configuration of your external user registry.

At this point API Connect makes a REST request call to the `endpoint` that is configured in the integration document, and the external platform REST API will need to return the requested information.
On completion of the integration creation, the command displays the following summary details:

```
integration_name custom_integration_url
```

The `integration_name` is derived from the `name` property in the configuration YAML file. The `custom_integration_url` is the URL with which the integration can be accessed. Both properties are needed when defining your custom user registry in the next section.
After your custom integration has completed successfully, you can continue to create the custom user registry.

Defining your custom user registry

You define the configuration of your custom user registry in a `custom_config_file.yaml` file, as shown in the following example.

```
name: 'custom_registry_name'
title: 'display_title'
registry_type: 'custom_user_registry'
integration_url: custom_integration_url
case_sensitive: true_or_false
user_managed: true_or_false
user_registry_managed: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: 'provider_title'
configuration:
  custom_config1: 'value1'
  customize: true
```

The registry properties are described in the following table:

Property	Description
`name`	The name of the custom user registry. This name is used in the CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`registry_type`	The registry type that you configured in the `name` property in the integration document, for example ***`custom_user_registry`***.
`integration_url`	The custom integration URL in your API Connect configuration. You can determine the custom integration URL by using the following CLI command: `apic integrations:list --server` ***`mgmt_endpoint_url`*** `--subcollection user-registry` Or you can copy and paste from the summary of the integration creation.
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable. Set to `false` if you don't want the registry to be writable.
`user_registry_managed`	Determines whether API Connect manages your user registry. Valid values are: • `true` • `false`
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your custom server, where: • `name` - is the name of the custom server and is the name that is used in CLI commands • `title` - is the display name of the custom server
`configuration`	The user-defined configuration based on the `configuration_schema` that is defined in the integration document.

Save your ***`custom_config_file`***`.yaml` so it can be accessed by the `user-registries:create` command in the following section.

Creating your custom user registry

To create your shared custom user registry, run the following CLI command:

`apic user-registries:create --server` ***`mgmt_endpoint_url`*** `--org admin` ***`custom_config_file`***`.yaml`

where:

- ***`mgmt_endpoint_url`*** is the platform API endpoint URL.
- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- ***`custom_config_file`*** is the name of the YAML file that defines the configuration of your custom user registry.

On completion of the registry creation, the command displays the following summary details:

`registry_name registry_url`

The ***`registry_name`*** is derived from the `name` property in the custom user registry YAML file. The ***`registry_url`*** is the URL with which the custom registry resource can be accessed.
Your shared custom user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your custom registry for Cloud Manager or API Manager login

If you want to make your custom registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   `apic user-registries:list --server` ***`mgmt_endpoint_url`*** `--org admin`

2. Determine what the current user registries are, because you will need to confirm these as well as add your new custom registry:

   `apic user-registry-settings:get --server` ***`mgmt_endpoint_url`*** `--output -`

This command outputs a list of all the current user registries in your environment, similar to the following example:

```
type: user_registry_setting
api_version: 2.0.0
name: user-registry-setting
admin_user_registry_default_url: >-
  https://server.com/api/user-registries/xxxxx/xxxxx-1234
admin_user_registry_urls:
  - >-
    https://server.com/api/user-registries/xxxxx/xxxxx-1234
provider_user_registry_default_url: >-
  https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
provider_user_registry_urls:
  - >-
    https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
created_at: '2019-09-30T12:22:19.467Z'
updated_at: '2019-10-17T10:05:37.867Z'
url: 'https://server.com/api/cloud/settings/user-registries'
```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registry-settings:update --server mgmt_endpoint_url -
   ```

   The following message is output:

   ```
   Reading USER_REGISTRY_SETTING_FILE arg from stdin
   ```

4. If you want to make your custom registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

   ```
   admin_user_registry_urls:
     - >-
       current_admin_user_registry_urls
     - new_custom_user_registry_url
   ```

   where:
   - *current_admin_user_registry_urls* are the current admin user registry URLs, as listed in Step 2 in the **admin_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_custom_user_registry_url* is the URL of your new custom user registry, as determined in Step 1.
5. If you want to make your custom registry available for authenticating API Manager users, enter the following data, followed by a new line:

   ```
   provider_user_registry_urls:
     - >-
       current_provider_user_registry_urls
     - new_custom_user_registry_url
   ```

   where:
   - *current_provider_user_registry_urls* are the current provider organization user registry URLs, as listed in Step 2 in the **provider_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_custom_user_registry_url* is the URL of your new custom user registry, as determined in Step 1.
6. Press **CTRL D** to terminate the input. A confirmation message is output, for example:

   ```
   user-registry-setting   https://server.com/api/cloud/settings/user-registries
   ```

   where *server.com* is your management server endpoint.

Configuring your custom registry in a Catalog

If you want to make your custom registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the management server as a member of a provider organization by entering the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the **apic login** command, see Logging in to a management server.
3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns:

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: custom_registry_url
   ```

   where *custom_registry_url* is the URL of your custom registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

Configuring an LDAP user registry in the Cloud Manager

You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a shared resource in the Cloud Manager, the LDAP directory must be created for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, to authenticate users to the Cloud Manager and the API Manager, or for securing a Catalog to authenticate Developer Portal users.
Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure a shared LDAP user registry that is available to all of the provider organizations in your API Connect environment. If you want to create an organization-specific registry, see Creating an LDAP user registry in API Manager for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- If you configure your LDAP user registry to be writable (by selecting the User Managed check box on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create and manage LDAP user registries by using the developer toolkit CLI (see Using the CLI to configure a shared LDAP user registry), and by using the API Connect REST APIs (see the API Connect REST API documentation).
- You can map external LDAP groups to API Connect user roles to enable greater control of user access, but this configuration can be done only by using the developer toolkit CLI; see Using the CLI to configure a shared LDAP user registry for details.

You create an LDAP user registry by configuring a set of properties in the Cloud Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. After configuring the user registry, you must set it as active in Settings > User Registries. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see LDAP authentication.

Procedure

Follow these steps to configure a new LDAP user registry as a shared resource in the Cloud Manager UI.

1. In the Cloud Manager, click Resources.
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select LDAP User Registry for the user registry type, and enter the following information:

Field	Description
Title	Enter a descriptive name to display on the screen.
Name	The name that is used in CLI commands. The name is autogenerated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface login, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Address	Enter the IP address or host name of the LDAP server.
Port	Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, `389`.
Select a TLS Client Profile (optional)	Select the TLS Client Profile that the LDAP server requires.

Field	Description
Select an LDAP protocol version	Select the version number for the LDAP protocol that you are using.
Remote directory is Microsoft Active Directory	Select this option if you use Active Directory.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** select Case sensitive if your backend LDAP server supports case-sensitivity. • Do **not** select Case sensitive if your backend LDAP server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Enable External Group Mapping	Enable this property if you want user to use this user registry to map external LDAP groups to API Connect user roles to enable more control of user authorization.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this check box if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
   - Compose DN - Select this format if you want users to login with a username that is also part of their LDAP Distinguished Name (DN). For example, using `uid` for user login where the user's LDAP DN is: `uid=<username>,ou=People,dc=company,dc=com`. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose DN is not supported with the DataPower API Gateway.
   - Compose UPN - Select this format if your LDAP directory supports binding with User Principal Names such as **`john@acme.com`**. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
     Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
   - Search DN - Select this format if you want users to login with a username that is not part of their LDAP DN. For example, if the user's LDAP DN was: `{{uid=<username>,ou=People,dc=company,dc=com but }}` you want them to login with the email. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.
     Optionally select a scope to specify which part of the directory information tree is examined:
     - Whole subtree (default)
     - Base object
     - Single level

   For all of the authentication methods:

   If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the DN that comes before the username for binding or authentication. For example, `bind_prefix: 'uid='`.
Suffix	Part of the DN that follows the username, specifying the user's location in the LDAP tree. For example, `bind_suffix: ',ou=users,dc=apic,dc=com'`. `uid=<username>,ou=People,dc=company,dc=com`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

6. For authentication method Compose UPN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Suffix	Part of the DN that follows the username for constructing the UPN. For example, `@domain.com`.
Use group authentication (optional)	Enter the Filter condition for the group.

7. For authentication method Search DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.

Field	Description
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the search filter that comes before the username. The last attribute must be the one you chose to use for login. For example, `'(&(uid='`.
Suffix	Part of the search filter that follows the username. For example, `'))(objectClass=organizationalPerson)'`. Notice how it always begins with a `'))'` which is meant to close the attribute filter for the last attribute specified in `search_dn_filter_prefix`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.
9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:
   - LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
   - API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.

   The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

LDAP ATTRIBUTE NAME	API Connect VALUE
`dn`	`uid=[username],ou=users,dc=company,dc=com`
`cn`	`[first_name] [last_name]`
`sn`	`[last_name]`
`mail`	`[email]`
`userPassword`	`[password]`

   You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
10. Click Create.
    Your new LDAP registry is shown in the list of User Registries on the Resources page.

What to do next

If you use DataPower® API Gateway, you can optionally update the service and enable LDAP connection pooling to improve performance. For instructions, see the options in step 4 of Registering a gateway service.

To make the LDAP registry available for user authentication in the Cloud Manager and the API Manager, you must set it as active in the Settings > User Registries section. See Selecting user registries for Cloud Manager and API Manager for more information.

If you want to make the LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring Catalogs.

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

- **Using the CLI to configure a shared LDAP user registry**
  You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Using the CLI to configure a shared LDAP user registry

You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in the Cloud Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users, while a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared LDAP user registry. If you want to create an organization-specific registry, see Using the CLI to create an organization-specific LDAP user registry for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- If the LDAP user registry is configured as writable (by enabling the **`user-managed`** property on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create LDAP user registries by using the Cloud Manager UI (see Configuring an LDAP user registry in the Cloud Manager), and by using the API Connect REST APIs (see the API Connect REST API documentation).
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable more control of user authorization by using the developer toolkit CLI. The following instructions explain how to set the **`external_group_mapping_enabled`** configuration on your LDAP user registry resource. For information about how to set external role mapping on your API Connect user roles, see Configuring LDAP group mappings on Cloud Manager user roles.

You configure an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see LDAP authentication.

Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **`default-idp-1`**.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your LDAP configuration

You define the configuration of your LDAP user registry in an ***`ldap_config_file`*`.yaml`** file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
```

```
user_managed: true_or_false
user_registry_managed: false
directory_type: ad
external_group_mapping_enabled: true_or_false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
configuration:
  authentication_method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
  admin_password: admin_password
  search_dn_base: "search_dn_base"
  search_dn_scope: search_dn_scope
  search_dn_filter_prefix: prefix
  search_dn_filter_suffix: suffix
  attribute_mapping:
    dn: "distinguished_name"
    cn: "common_name"
    sn: "last_name"
    mail: "email_address"
    userPassword: "password"
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the registry. This name is used in CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`integration_url`	The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable LDAP. You can change this setting to `false` if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
`user_registry_managed`	Must be set to `false` for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.
`directory`	Specify one of the of following values for the directory type: • `ad` - Indicates that the LDAP is Microsoft Active Directory • `standard` - (Default value) Indicates any other LDAP
`external_group_mapping_enabled`	Determines whether your user registry supports LDAP group mapping. Valid values are: • `true` • `false` The default value is `false`.
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your LDAP server, where: • `name` - is the name of the LDAP server and is the name that is used in CLI commands • `title` - is the display name of the LDAP server
`endpoint`	The endpoint of your LDAP server, made up of the url and port, for example: `"ldap://server.com:389"`
`tls_profile`	Optionally set the TLS Client Profile that the LDAP server requires.

Property	Description
`protocol_version`	Optionally set the version number for the LDAP protocol that you are using. Valid values are: • `2` • `3` Defaults to `3` if not explicitly set.

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- `compose_dn` - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, `compose_dn` is not supported with the DataPower API Gateway.
- `compose_upn` - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
  Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- `search_dn` - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method `compose_dn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`
`bind_prefix`	Set the prefix to the DN, for example: `(uid=`
`bind_suffix`	Set the suffix to the DN, for example: `)`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name-value pair, specified as follows:
	`ldap_registry_attribute_name``: "`*`apic_ldap_attribute_value`*`"`
	Where:
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect populates the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

For authentication method `compose_upn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_upn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example, `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`bind_suffix`	Enter the domain part of the user principal name. For example: `@acme.com`

Properties	Description
attribute_mapping	If **user_managed** is set to **true**, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name-value pair, specified as follows: ***ldap_registry_attribute_name*: "*apic_ldap_attribute_value*"** Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect populates the LDAP attribute with, by replacing the content contained in **[ ]** with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are **username**, **first_name**, **last_name**, **email**, and **password**. The following extract shows an example of an attribute mapping: **attribute_mapping:** **dn: "uid=[username],ou=users,dc=company,dc=com"** **cn: "[first_name] [last_name]"** **sn: "[last_name]"** **mail: "[email]"** **userPassword: "[password]"**

For authentication method **search_dn**, set the following configuration properties:

Property	Description
authentication_method	**search_dn**
authenticated_bind	The bind method. Valid values are: • **"true"** - authenticated bind • **"false"** - anonymous bind If specific permissions are not needed to search the registry, select **"false"**. If specific permissions are necessary, select **"true"**.
admin_dn	If **authenticated_bind** is set to **"true"**, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example, **"cn=admin,dc=company,dc=com"**
admin_password	If **authenticated_bind** is set to **"true"**, enter the user password for the **admin_dn**.
search_dn_base	Optionally set a base DN, for example: **"dc=company,dc=com"**
search_dn_scope	Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are: • **base** • **one** • **sub** (default value)
search_dn_filter_prefix	Set the prefix to the DN, for example: **(uid=**
search_dn_filter_suffix	Set the suffix to the DN, for example: **)**
attribute_mapping	If **user_managed** is set to **true**, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name-value pair, specified as follows: ***ldap_registry_attribute_name*: "*apic_ldap_attribute_value*"** Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect populates the LDAP attribute with, by replacing the content contained in **[ ]** with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are **username**, **first_name**, **last_name**, **email**, and **password**. The following extract shows an example of an attribute mapping: **attribute_mapping:** **dn: "uid=[username],ou=users,dc=company,dc=com"** **cn: "[first_name] [last_name]"** **sn: "[last_name]"** **mail: "[email]"** **userPassword: "[password]"**

Save your ***ldap_config_file*.yaml** so it can be accessed by the **user-registries:create** command in the following section. See the Example section for an example configuration file.

Creating your LDAP user registry

To create your shared LDAP user registry, run the following CLI command:

apic user-registries:create --server *mgmt_endpoint_url* --org admin *ldap_config_file*.yaml

where:

- ***mgmt_endpoint_url*** is the platform API endpoint URL.
- **--org admin** means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- ***ldap_config_file*** is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The *registry_name* is derived from the **name** property in the configuration YAML file. The *registry_url* is the URL with which the registry resource can be accessed. Your shared LDAP user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your LDAP registry for Cloud Manager or API Manager login

If you want to make your LDAP registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Determine what the current user registries are, because you will need to confirm these as well as add your new LDAP registry:

   ```
   apic user-registry-settings:get --server mgmt_endpoint_url --output -
   ```

   This command outputs a list of all the current user registries in your environment, similar to the following example:

   ```
   type: user_registry_setting
   api_version: 2.0.0
   name: user-registry-setting
   admin_user_registry_default_url: >-
     https://server.com/api/user-registries/xxxxx/xxxxx-1234
   admin_user_registry_urls:
     - >-
       https://server.com/api/user-registries/xxxxx/xxxxx-1234
   provider_user_registry_default_url: >-
     https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   provider_user_registry_urls:
     - >-
       https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   created_at: '2019-09-30T12:22:19.467Z'
   updated_at: '2019-10-17T10:05:37.867Z'
   url: 'https://server.com/api/cloud/settings/user-registries'
   ```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registry-settings:update --server mgmt_endpoint_url -
   ```

   The following message is output:

   ```
   Reading USER_REGISTRY_SETTING_FILE arg from stdin
   ```

4. If you want to make your LDAP registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

   ```
   admin_user_registry_urls:
     - >-
       current_admin_user_registry_urls
     - new_ldap_user_registry_url
   ```

   where:
   - *current_admin_user_registry_urls* are the current admin user registry URLs, as listed in Step 2 in the **admin_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_ldap_user_registry_url* is the URL of your new LDAP user registry, as determined in Step 1.

5. If you want to make your LDAP registry available for authenticating API Manager users, enter the following data, followed by a new line:

   ```
   provider_user_registry_urls:
     - >-
       current_provider_user_registry_urls
     - new_ldap_user_registry_url
   ```

   where:
   - *current_provider_user_registry_urls* are the current provider organization user registry URLs, as listed in Step 2 in the **provider_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_ldap_user_registry_url* is the URL of your new LDAP user registry, as determined in Step 1.

6. Press **CTRL D** to terminate the input. A confirmation message is output, for example:

   ```
   user-registry-setting   https://server.com/api/cloud/settings/user-registries
   ```

   where *server.com* is your management server endpoint.

Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the management server as a member of a provider organization by entering the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the **apic login** command, see Logging in to a management server.

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where *catalog_name* is the value of the `name` property of the required Catalog. The command returns:

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: ldap_registry_url
   ```

   where *ldap_registry_url* is the URL of your LDAP registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the **user_managed** property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

   The command returns a list of all the user registries on that server, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example **https://company.com/api/user-registries/x-x-x-x-x/*registry_id***.
2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registries:update --server mgmt_endpoint_url --org admin registry_name_or_id -
   ```

   where ***registry_name_or_id*** is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

   ```
   Reading USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_managed: true_or_false
   ```

   where **true** makes the registry writable, and **false** makes the registry read-only.
4. Press **CTRL D** to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the **attribute_mapping** configuration, as described in the previous registry property tables.

Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

For more information about the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
directory_type: standard
case_sensitive: false
identity_providers:
  - name: ldap
    title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

Configuring a Local User Registry

A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.

About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can create and configure a new LUR. After you create it, you must set it as active in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

One of the following roles is required to configure user registries:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

Procedure

Follow these steps to configure a new LUR:

1. In the Cloud Manager, click  .
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal , or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select Local User Registry as the type for the user registry and enter the following information:

Field	Description
Title (required)	Enter a descriptive name for use on the screen.
Name (required)	The name that is used in CLI commands. The name is autogenerated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface login, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Case sensitive	Select this setting if user names are case-sensitive. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited. Note: Every account in the Developer Portal , including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Save.

Results

The user registry is saved and is available to be configured for user authentication in Cloud Manager or API Manager by selecting it in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

Configuring an OIDC user registry in Cloud Manager

Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create a shared registry. For information on how to create an organization-specific registry, see Creating an OIDC user registry in API Manager.

Important: If you are using X (formerly known as Twitter) as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your X application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.
API Connect provides two methods for creating an OIDC user registry in Cloud Manager, as described in the following sections:

- Using the UI to configure an OIDC user registry
- Using the CLI to configure an OIDC user registry

Using the UI to configure an OIDC user registry

Use the Cloud Manager application's user interface to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

1. In the Cloud Manager navigation pane, click Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create.
   Many of the registry settings are preconfigured to simplify the configuration steps.

   Provider Type
   Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

Field	Description
Provider Type	OIDC provider. Select one of the following supported OIDC providers: • Facebook • GitHub • Google • LinkedIn • Slack • X (formerly known as Twitter) • Windows Live • Standard OIDC (default value allows you to specify another provider)
Title	Provide a descriptive name for display purposes.
Name	Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary	Provide a brief description of the new registry.
Email required	Select this option if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the Developer Portal.
Unique email address	Select this option if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

   Provider Endpoint
   Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.
   Token Endpoint
   Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.
TLS	Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

   UserInfo Endpoint
   Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint. For LinkedIn, the endpoint changed and now uses the following value: `https://api.linkedin.com/v2/me` If you previously configure the OIDC registry using the legacy LinkedIn OIDC protocol, you do not need to specify this endpoint.

Field	Description
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Email Endpoint

Required for the legacy LinkedIn OIDC protocol.
Due to changes in LinkedIn, the configuration settings for the OIDC registry in API Connect also changed. If you are configuring a new OIDC registry for LinkedIn, you can leave the Email Endpoint field blank.

If you previously configured an OIDC registry for use with the legacy LinkedIn OIDC protocol, update your configuration by providing the Email endpoint settings as described in Table 4. The new setting is required for the legacy LinkedIn OIDC protocol.

Table 4. Email Endpoint settings

Field	Description
URL	For the legacy LinkedIn OIDC protocol, this field defaults to the following value: `https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))` You can override the setting by typing in a new value.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

JWKS Endpoint

Fill in the settings as described in Table 5.

Table 5. JWKS Endpoint settings

Field	Description
URL	Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Logout

You can configure either of the following types of logout support, but not both:

- Logout redirect:
  Allows you to specify what the user sees after logging out of API Connect; for example, you might want to "redirect" the user to the OIDC provider's logout endpoint, or to another address. When the user logs out of API Connect, the browser is redirected to the specified URL for further processing by the specified URL.

- RP-initiated logout:
  Provides a more secure form according to the OpenID Connect RP-Initiated Logout 1.0 Profile. When the user logs out of API Connect, API Connect issues a POST request to the specified endpoint URL to clear the user's session. With this option, you can optionally provide an RP logout redirect endpoint URL as well.

Fill in the settings as described in Table 6.

Table 6. Logout options

Field	Description
Logout redirect URL	Optional. Provide a URL to redirect the browser when the user logs out of API Connect. If you use this option, do not enable the OIDC RP logout.
Enable OIDC RP logout	Select this option to use the RP-initiated logout instead of the conventional logout redirect. If you use this option, do not provide a Logout redirect URL. With the RP-initiated logout, you can optionally specify an RP-logout redirect URL.
URL endpoint that the RP will issue a POST request	Provide the URL to the endpoint where the POST request will be executed; for example, the authorization endpoint of the OpenID provider.
TLS	Select the TLS profile to use when sending the POST request to the OpenID provider endpoint.
RP logout redirect endpoint URL	Optional. Provide a URL where the OIDC provider can redirect after the logout operation. The URL functions as the `post_logout_redirect_uri`, as described in the OpenID Connect RP-Initiated Logout 1.0 Profile.
Include refresh_token in logout	Optional. Allow the refresh_token to be included, in addition to the id_token_hint, per the OpenID Connect RP-Initiated Logout 1.0 Profile.

Client Information

Fill in the settings as described in Table 7.

Table 7. Client Information settings

Field	Description
Client ID	Provide the client ID of the application that is registered with the selected OIDC provider.
Client Secret	Provide the client secret of the application that is registered with the selected OIDC provider. This field is optional when you create an OIDC directory of type Standard and set the Client Authentication Method to Data encoded form body. If you are not using the Client Secret, ensure that mutual TLS is configured with the OIDC provider. To enable mutual TLS, create a TLS profile and include it in the OIDC user registry setup.
Response Type	Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.
Scopes	Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.
Client Authentication Method	Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: • HTTP Basic authentication schema • Data encoded form body

Additional Support

Optional. Select the additional security parameters described in Table 8.

Table 8. Additional security options

Security parameter	Setting name for CLI	Description
NONCE	`nonce`	Enable the NONCE extension to prevent compromised requests from being used again (replayed).

Security parameter	Setting name for CLI	Description
Proof Key for Code Exchange (PKCE)	`pkce`	Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted.

Advanced Features

Optional. Select the advanced features described in Table 9.

Table 9. Advanced features

Feature / UI Label	Setting name for CLI	Description
Auto onboard	`auto_onboard`	Allow users to executes calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. Note: Does not apply to consumer organizations.
Always use the userinfo endpoint	`userinfo`	Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.
Use Portal as Endpoint for external OIDC provider traffic	`proxy_redirect`	When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager. When enabled, the redirect URI for the Developer Portal should be set to `/ibm_apim/oidcredirect`. For details, see the Redirect URI.
Return third-party access token	`proxy_access_token`	Include the third-party OIDC access token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party id_token	`proxy_id_token`	Include the third-party OIDC id_token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party access_token and id_token as separate claims	`proxied_token_as_separate_claim`	Include the third-party OIDC tokens (the `proxy_access_token` and `proxy_id_token`) in the response as separate claims instead of adding them to the access_token issued by API Connect. To use this feature, you must enable at least one of the Return third-party access token and Return third-party id_token options. Separating the third-party tokens prevents them from affecting the size of the access_token issued by API Connect.
Token Relay	`token_relay`	Allow `access_token/refresh_token` to send in 302 redirect for logout
Userinfo POST	`post_userinfo`	If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint. Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.
Use IBM® APIC token expiration setting from cloud	`override_provider_ttl`	Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see Configuring timeouts for access tokens and refresh tokens.
Disable hash verification (CLI only)	`disable_hash_verification`	Disable `at_hash`, `c_hash`

User Mapping

Fill in the settings as described in Table 10.

Note: The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 10. User mapping settings

Field	Description
Username	The name of the field in the response token that contains the user's user name. Note: The Username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed.
Email	The name of the field in the response token that contains the user's email address.
First name	The name of the field in the response token that contains the user's given name.
Last name	The name of the field in the response token that contains the user's surname.

Redirect URI

The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.

Note: If the Developer Portal is publicly accessible and you select the `proxy_redirect` option, you must configure your OIDC provider to use the following redirect URI:

- URI path: `/ibm_apim/oidcredirect`
- Full URL example: `https://<your-developer-portal-domain>/ibm_apim/oidcredirect`

Where:

`<your-developer-portal-domain>` is the actual hostname of your public-facing Developer Portal; for example, `developer.example.com`.

This configuration ensures that the OIDC provider can correctly redirect authenticated users back to the Developer Portal as part of the login flow.

Enabling the OIDC user registry

Complete the following steps to enable the new user registry for Cloud Manager, API Designer, or both.

1. On the navigation pane, click Settings.
2. Click User Registries > Edit.
3. Click Edit in the section that corresponds to the application for which you are enabling the new user registry.
4. Select the new OIDC user registry.
5. When you have finished enabling the registry, click Save.

Using the CLI to configure an OIDC user registry

Use the developer toolkit CLI to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

Configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated catalog.
Note:

- An OIDC registry cannot be used to secure APIs on the gateway.
- If you are using an OIDC user registry for login, The Management server handles the interaction with the third-party OIDC provider. The management server is considered the application from the perspective of the third-party OIDC provider. Therefore, your OIDC redirect endpoint on the management server, which the third-party authorization server uses to send the token, must be accessible to the OIDC provider. To ensure login functions, you must allow access if your API Connect environment is secured behind a firewall. This is true for user login on both API Manager and Cloud Manager.
- If OIDC user registry is used for consumer login at the Developer Portal and Developer Portal is in the DMZ, you can use the `proxy_redirect` property. This allows the Developer Portal to act as the endpoint for proxying communication between the OIDC provider and API Connect.
- When you register your application with the third-party OIDC provider, you are required to supply the associated OIDC redirect URI, https://consumer.mycompany.com/consumer-api/oauth2/redirect for example. However, you cannot access this information until you create your OIDC user registry in API Connect. First, register your application without this information and then update it later, as detailed in the instructions on this page.

Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
For full details of the `apic login` command, see Logging in to a management server.

Defining your OIDC registry configuration

Define the configuration of your OIDC user registry in a YAML file. At a minimum, the YAML file must include the settings from the following list. For additional settings, see the tables provided with the UI version of the procedure in this topic.

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type
```

where:

- *registry_title* is your chosen descriptive title for the user registry.
- *oidc_integration_url* is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

  ```
  apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
  ```

- *case_sensitivity_setting* determines whether your user registry is case-sensitive. Valid values are:
  - `true`
  - `false`

  To ensure proper handling of user name capitalization, ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:
  - Only set `case_sensitive` to `true` if the backend OIDC provider supports case-sensitivity.
  - Set `case_sensitive` to `false` if the backend OIDC provider does not support case-sensitivity.

  Note: After at least one user has been added to the registry, you cannot change this setting.
- *email_required* determines whether an email address is required as part of the user onboarding process. Valid values are:
  - `true`
  - `false`

  If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding.
  Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.

- *email_unique_if_exist* determines whether email addresses must be unique within the user registry. Valid values are:
  - `true`
  - `false`

  Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
- *app_client_id* is the client ID of the application that is registered with the OIDC server, and must be in string format.
- *my-client-secret* is the client secret of the application that is registered with the OIDC server, and must be in string format.
- *oidc_provider_type* is the type of OIDC provider; specify one of the following values:
  - `facebook`
  - `github`
  - `google`
  - `linkedin`
  - `slack`
  - `twitter`
  - `windows_live`
  - `standard`

  Note:
  - Use the `twitter` provider type if your OIDC provider is X (formerly known as Twitter).
  - Use the `standard` provider type for any OIDC provider that is compliant with the OIDC standard.
    If the provider type is `standard`, you must include the following additional properties in the `configuration` section of your YAML file:

    ```
    authorization_endpoint: 'oidc_auth_endpoint'
    token_endpoint:
      endpoint: 'oidc_token_endpoint'
    ```

    where:
    - *oidc_auth_endpoint* is the authorization endpoint on the OIDC server, and must be in string format.
    - *oidc_token_endpoint* is the token endpoint on the OIDC server, and must be in string format.

Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file.

Note: Endpoints are subject to change; when you create a registry you must verify the default endpoint provided by API Connect.
API Connect makes the best effort to update endpoints for the known OIDC user registry types. However the OIDC provider can change the endpoint at any time. It is the customer's responsibility to confirm that the endpoints provided by API Connect are supported by the OIDC provider and to update the OIDC configuration as needed.

The default configurations are as follows:

- Facebook

  ```
  authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
  token_endpoint:
    endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
  userinfo_endpoint:
    endpoint: 'https://graph.facebook.com/me'
  scope: email public_profile
  field_mapping:
    username: email
    email: email
    last_name: last_name
    first_name: first_name
  ```

- GitHub

  ```
  authorization_endpoint: 'https://github.com/login/oauth/authorize'
  token_endpoint:
    endpoint: 'https://github.com/login/oauth/access_token'
  userinfo_endpoint:
    endpoint: 'https://api.github.com/user'
  scope: 'read:user user:email'
  field_mapping:
    username: login
    email: email
    last_name: name
    first_name: name
  ```

- Google

  ```
  authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'
  token_endpoint:
    endpoint: 'https://www.googleapis.com/oauth2/v4/token'
  scope: openid profile email
  field_mapping:
    username: email
    email: email
    last_name: family_name
    first_name: given_name
  ```

- LinkedIn
  Some settings differ between the legacy configuration and the newer configuration. Be sure to use the correct settings for the LinkedIn protocol that you are using.

  - New OIDC protocol:

    ```
    authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
      credential_location: form_body
      field_mapping:
        email: email
        username: name
        first_name: given_name
    ```

```
    last_name: family_name
  scope: openid profile email
  token_endpoint:
    endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
  userinfo_endpoint:
    endpoint: 'https://api.linkedin.com/v2/me'
```

- Legacy OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
token_endpoint:
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
userinfo_endpoint:
  endpoint: 'https://api.linkedin.com/v2/me'
email_endpoint:
  endpoint: 'https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))'
scope: r_liteprofile r_emailaddress
field_mapping:
  username: emailAddress
  email: emailAddress
  last_name: localoizedLastName
  first_name: localizedFirstName
credential_location: form_body
```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'
token_endpoint:
  endpoint: 'https://slack.com/api/oauth.access'
userinfo_endpoint:
  endpoint: 'https://slack.com/api/users.identity'
scope: identity.basic identity.email
field_mapping:
  username: user.email
  email: user.email
  last_name: user.name
  first_name: user.name
```

- X (formerly known as Twitter)

```
request_endpoint: https://api.x.com/oauth/request_token'
authorization_endpoint: https://api.x.com/oauth/authenticate'
token_endpoint:
    endpoint: 'https://api.x.com/oauth/access_token'
userinfo_endpoint:
    endpoint: 'https://api.x.com/1.1/account/verify_credentials.json'
oauth_signature_method: 'HMAC-SHA1'
field_mapping:
    email: email
    first_name: name
    last_name: name
    username: screen_name
```

- Windows Live

```
authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
  endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
scope: openid offline_access profile email
field_mapping:
  email: email
  username: preferred_username
  first_name: name
  last_name: name
```

- Standard

```
response_type: code
scope: openid
field_mapping:
  username: sub
  email: email
  last_name: family_name
  first_name: given_name
credential_location: auth_header
```

  Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin oidc_config_file
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the **name** property of your provider organization.
- *oidc_config_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the *registry_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry_url* is an internal URL that API Connect assigns to the registry.
After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc_redirect_uri** value is in the **consumer:** section; for example:

```
consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect
```

Enabling your OIDC registry in a Catalog

If you want to make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the Management server as a member of a provider organization; enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the **apic login** command, see Logging in to a management server.
3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: oidc_registry_url
   ```

   where *oidc_registry_url* is the URL of your OIDC registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Setting visibility for a user registry

The visibility setting determines which provider organizations can access a resource, for example, user registries.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service

About this task

The user registry visibility setting controls which provider organizations are able to use that registry for authenticating Developer Portal users, or for securing APIs. For details on how to specify the user registries that can be used for authenticating users of the Cloud Manager and API Manager user interfaces, see Selecting user registries for Cloud Manager and API Manager.

Procedure

Follow these steps to set the visibility for the resources (user registries) in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select User Registries as the resource to view.
3. From the list of user registries, choose Edit visibility from the actions menu next to the name of the user registry you are working with.
4. Select the visibility setting for the user registry. The options are:
   - Private - the user registry is not visible and cannot be used by any provider organization
   - Public - the user registry is visible and can be used by all provider organizations
   - Custom - the user registry is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the user registry.
6. Click Make visible to complete the operation.

Results

For Private, the user registry cannot be used by any provider organizations. For Public, the user registry can be used by all provider organizations. For Custom, the user registry can be used by the provider organizations that you designate.

Deleting a user registry

As the Cloud Manager administrator, you can delete user registries.

About this task

Complete the following steps to delete a user registry. All users within the user registry will be deleted. The pre-configured user registries (API Manager Local User Registry and Cloud Manager Local User Registry) may not be deleted. Any user registry marked as the Default in Settings > User Registries also may not be deleted.

One of the following roles is required to delete a user registry:

- Administrator
- Owner

Procedure

1. In the Cloud Manager, click  .
2. Select User Registries to see the list of current user registries in your cloud.
3. Choose Delete from the overflow menu that is adjacent to the user registry you want to delete.
4. Optionally, you can delete multiple user registries by marking the checkboxes and selecting Delete Selected User Registries from the overflow menu for the list.
5. Confirm the deletion.

Results

The user registry is deleted and removed from the User Registries list in Cloud Manager. All user accounts contained in the user registry are deleted.

Removing a user from a user registry

As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

For details on how to remove a user from a user registry, see the following subtopics:

- **Removing yourself from a user registry**
  As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.
- **Removing another user from a user registry**
  You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Removing yourself from a user registry

As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.

Before you begin

You cannot remove yourself from a user registry if you are a member of a provider organization. Before removing yourself from a user registry, ensure that you have been deleted from any provider organizations. For more information, see Removing a user from an organization.

Procedure

1. Log in to the management server as the user that you want to remove.
   The format of the login command depends on whether you are a user in the Cloud Manager admin organization, or you are a user in a provider organization.

   If you are a Cloud Manager admin user, enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   If you are a provider organization user, enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
   ```

   where *scope* has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**, and the default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and you have access to both, when you remove yourself from the user registry you will lose access to both user interfaces regardless of which organization you log in to.

2. Remove yourself from the user registry. Enter the following command:

```
apic me:delete --server mgmt_endpoint_url
```

For example:

```
apic me:delete --server platform-api.myserver.com.com
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1    [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

Removing another user from a user registry

You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Before you begin

To complete this task, you must have Administrator access to your API Connect cloud, or be the owner of a provider organization, depending on the scope of the user registry.

You cannot remove a user from a user registry if that user is a member of the Cloud Manager admin organization, a provider organization, or a consumer organization, and that user registry is used for the associated login. Before removing a user from a user registry, ensure that they have been deleted from any organizations for which that user registry is used for login. For more information, see Deleting a member or Removing a user from an organization.

Procedure

1. Log in to the management server.
   - If the user registry is defined at the cloud administration level, and therefore available to all provider organizations, you must log in as a member of the Cloud Manager admin organization.
   - If the user registry is defined at a provider organization level, and therefore specific to that provider organization, you must log in as the organization owner.

   For full details of the **apic login** command, see Logging in to a management server.

   Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and the user has access to both, when you remove them from the user registry they will lose access to both even though you are logging in to the admin organization.
2. Identify the name of the user registry from which you want to remove the user. Enter the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org organization_name
```

where *organization_name* has the value **admin** if you are logged in as a member of the Cloud Manager admin organization, or is the name of the provider organization if you are logged in as an organization owner.
For example:

```
apic user-registries:list --server platform-api.myserver.com.com --org admin
```

The command returns a list of all user registries, with the registry name displayed first; for example:

```
api-manager-lur     https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245
cloud-manager-lur   https://platform-api.myserver.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/3adbf524-
cd74-4051-99c0-89ce5ffcc9c0
my-ldap             https://platform-api.myserver.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/29eae413-
cd74-4051-99c0-89ce5ffcc9c0
```

3. Identify the name of the user, from the required user registry, that you want to remove. Enter the following command:

```
apic users:list --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
```

For example:

```
apic users:list --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command returns a list of all users in the user registry, with the user name displayed first; for example:

```
user1     [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
user2     [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/12f1aa82-d9f0-4670-99f1-7500d1fb6583
```

4. Remove the required user from the user registry. Enter the following command:

   ```
   apic users:delete user_name --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
   ```

   For example:

   ```
   apic users:delete user1 --server platform-api.myserver.com.com --org admin --user-registry my-ldap
   ```

   The command confirms successful removal by returning the details of the deleted user; for example:

   ```
   user1    [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
   0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
   ```

TLS profiles overview

Create TLS profiles to manage the TLS communication between subsystems, external systems, and your API invocation endpoint.

Mutual TLS is used to secure communication between API Connect subsystems, and TLS is used for communication with external systems such as email servers.

If you do not want to use mTLS for inter-subsystem communication, you can use JWT instead:

- Use JWT instead of mTLS on Kubernetes and OpenShift.

Some of the API Connect TLS configuration is managed in the Cloud Manager UI, and is covered by this topic. The rest of the API Connect TLS configuration, which includes the management REST API endpoints and portal site certificates, are managed at the infrastructure level. For more information, see:

- Kubernetes and OpenShift: API Connect certificates

The API Connect TLS configuration that is managed in the Cloud Manager UI covers the following areas:

- Client certificates for inter-subsystem communication: Communication from your management subsystem to your portal, analytics, and gateway services.
- API invocation endpoint. The certificates that callers of your published APIs see.
- TLS profiles that you create for use in API definitions.
- Communication with third-party systems.

When you install API Connect, default TLS profiles are created. If all of your API Connect subsystems are in the same environment (same Kubernetes or OpenShift namespace and project directory), then you can use these default TLS profiles to register your portal, gateway, and analytics services with your management subsystem.
Note: If you do not want to use the default TLS profiles, it is recommended to create new TLS profiles to use instead. Do not edit the default TLS profiles.
Two types of TLS profile can be configured in the Cloud Manager UI:

- Client profiles are used to define the client certificate and ciphers that are used for making client connections to other systems.
- Server profiles are used to define the server certificate and ciphers that are used for securing server endpoints. The only server profile that is created automatically (during installation) is the **`Default TLS server profile`**, which is used to secure the API invocation endpoint.

The components of a TLS Profile are:

- TLS version indicates the version of the Transport Layer Security Protocol that is used by the profile. Options are TLS versions 1.0, 1.1, 1.2, and 1.3.
- Support for mutual authentication and renegotiation for server profiles.
- Support for weak server connections and Server Name Indication for client profiles.
- Supported cipher suites.
- Keystores, which contain the TLS keys that are used for initiating client connections.
- Truststores, which contain the public keys to validate your analytics, portal, and gateway subsystems, and for trusted third-party services that you integrate with.

Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

TLS profiles created during installation

The following table shows the TLS profiles that API Connect creates during installation. You can use these profiles when you register your portal, gateway, and analytics services if your deployment is:

- On OpenShift or Kubernetes, and all subsystems are installed in the same environment and namespace.

Table 1. TLS profiles

TLS profile name	Description
Default TLS server profile	For testing and demonstration purposes, you can specify this profile as the TLS server profile when you register your gateway service. For production deployments, best practice is to create your own TLS server profiles and not use the **`Default TLS server profile`**.
Default TLS client profile	You can use this profile as a client profile for communication between the management subsystem and any other system. This profile is set to trust everything (**`insecure server connections`** is set to **`true`**), and has no keystore or truststore. Use this profile only for testing and demonstrations.
Analytics ingestion TLS client profile	Default client profile for use when the management or gateway subsystem communicates with the analytics service: • From the management subsystem to the analytics subsystem, when you register the analytics service and when querying for analytics data. • From the gateway to the analytics subsystem, when the gateway sends API event data to the analytics subsystem. Select this profile when you register the analytics service. Note: If you want to use a different client certificate for your analytics service, do not edit this client profile, create a new profile instead.

TLS profile name	Description
Portal Director TLS client profile	Default client profile when the management subsystem communicates with the developer portal subsystem. Select this profile when you register the portal service. Note: If you want to use a different client certificate for your portal service, do not edit this client profile, create a new profile instead.
Gateway management client TLS client profile	Default client profile when the management subsystem communicates with the gateway subsystem. Select this profile when you register the gateway service. Note: If you want to use a different client certificate for your gateway service, do not edit this client profile, create a new profile instead.

Keystores created during installation

The following table shows the keystores that API Connect creates during installation:

Table 2. Keystores

Keystore name	Description
Analytics ingestion	Used by the **`Analytics ingestion TLS client profile`**, this keystore contains the client certificate that is used for connecting to the analytics subsystem's ingestion endpoint. This certificate is used by the management subsystem when it initiates communication with the analytics subsystem, and by the gateway when it sends API event data to the analytics subsystem. Kubernetes and OpenShift installations: The default client certificate in this keystore is set from the Kubernetes certificate analytics-ingestion-client. Do not edit this keystore. If you want to use a different client certificate for analytics ingestion, then create a new client profile and keystore for it.
Portal director	Used by the **`Portal Director TLS client profile`**, this keystore contains the client certificate that is used when the management subsystem initiates communication with the portal subsystem. Kubernetes and OpenShift installations: The default client certificate in this keystore is set from the Kubernetes certificate portal-admin-client.
Gateway mgmt	Used in the **`Gateway management client TLS client profile`**, this keystore contains the client certificate that is used when the management subsystem initiates communication with the gateway. Kubernetes and OpenShift installations: The default client certificate in this keystore is set from the Kubernetes certificate gateway-client-client or gw-dr-client.
Default TLS server keystore	Used in the **`Default TLS server profile`**, this keystore contains the server certificate that secures the API invocation endpoint on your gateway. Note: It is recommended to use the **`Default TLS server profile`** only for testing and demonstrations. Best practice is to create a new keystore and server profile for your API invocation certificate.
Default keystore for id_token signing key	Used for signing ID tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.
Default keystore for self signed token signing key	Used for signing self-signed tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.
Default keystore for temporary token signing key	Used for signing temporary tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.
Default keystore for access_token signing key	Used for signing access tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.

Truststores created during installation

The following table shows the truststores that API Connect creates during installation:

Table 3. Truststores

Truststore name	Description
Analytics ingestion	Used by the **`Analytics ingestion TLS client profile`**, this truststore contains the **`root-ca`** and **`ingress-ca`**, with which the management subsystem validates the certificate that the analytics subsystem presents.
Portal director	Used by the **`Portal Director TLS client profile`**, this truststore contains the **`root-ca`** and **`ingress-ca`**, with which the management subsystem validates the certificate that the portal subsystem presents.
Gateway management client truststore	Used by the **`Gateway management client TLS client profile`**, this truststore contains the **`ingress-ca`** on Kubernetes and OpenShift, with which the management subsystem validates the certificate that the gateway subsystem presents.

- **Creating a TLS server profile**
  Create a TLS server profile in the Cloud Manager UI to secure the API invocation endpoint on your registered gateways.
- **Creating a TLS client profile**
  Create TLS client profiles in the Cloud Manager UI to secure client connections in your API Connect environment.
- **Creating a keystore**
  Create a keystore by uploading a public and private key pair.
- **Creating a truststore**
  Create a truststore that contains a list of certificates that your TLS profile trusts.
- **Managing TLS profiles, keystores, and truststores**
  TLS profiles, keystores, and truststores can be created, updated, and deleted in the Cloud Manager UI.
- **Using OpenSSL to generate and format certificates**
  Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.

Creating a TLS server profile

Create a TLS server profile in the Cloud Manager UI to secure the API invocation endpoint on your registered gateways.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

Create the keystores and truststores for your TLS server profile.

One of the following roles is required to configure TLS server profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

About this task

When you register a gateway service, you select a TLS server profile that contains the TLS certificate that is used to secure the API invocation endpoint on the gateway. It is recommended to create your own TLS server profile to secure your API invocation endpoints. The procedure in this topic covers how to create this TLS server profile.

Procedure

Complete the following steps to create a TLS server profile:

1. In the Cloud Manager, click  Resources.
2. Select Crypto Material.
3. Click Create in the TLS server profile table.
4. Enter the fields to configure the TLS server profile:

Field	Description
Title	Enter a title for the profile.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Version	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, **`MyProfile 1.0`** and **`MyProfile 1.1`**.
Summary	Enter a description of the profile.
Protocols	Select one or more supported TLS protocol versions. The default is 1.2 and 1.3.
Mutual Authentication	Determines the level of two-way authentication for the server profile. In two-way authentication, the server responds to a client by sending a request for the client certificate. • None (default) No support for mutual authentication. • Request Enable this option to request client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the certificate is not checked on the gateway. • Require Enable this option to require client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the TLS handshake fails and the request is blocked.
Limit Renegotiation	Client-initiated renegotiation allows the connection to be retried. The default is to prevent renegotiation. Remove the checkmark to allow renegotiation.
Keystore	A keystore is a repository that contains a public and private key pair that are used to secure the endpoint. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Truststore	A truststore is a repository that contains TLS certificates which the endpoint secured by your TLS server profile trusts. When a client connects to your endpoint, it must present a certificate that is signed by a certificate in your truststore. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Ciphers	Cipher suites are encryption algorithms that are used to secure the TLS communication. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

5. Click Save.

Creating a TLS client profile

Create TLS client profiles in the Cloud Manager UI to secure client connections in your API Connect environment.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

One of the following roles is required to configure TLS client profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

A TLS client profile defines the TLS version, keystore, truststore, and ciphers used when making a client connection to a TLS secured endpoint.

Procedure

Complete the following steps to create a TLS client profile:

1. In the Cloud Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the TLS client profile table.
4. Enter the fields to configure the TLS Client Profile:

Field	Description
Title	Enter a title for the profile.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Version	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, **`MyProfile 1.0`** and **`MyProfile 1.1`**.
Summary	Enter a description of the profile.
Protocols	Select one or more supported TLS protocol versions. The default is 1.2 and 1.3.
Server Connection	Specify whether to support weak or insecure credentials. • Allow insecure server connections - Insecure server connections can mean connections that use certificates that are self-signed, expired, corrupted, or from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections. • Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates presented on the same IP address using different hostnames. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.
Keystore	A keystore is a repository that contains public and private key pairs. The keystore has the public key that the client presents when it initiates communication with a TLS secured endpoint. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Truststore	A truststore is a repository that contains verified public keys. Truststores contain the list of certificates that your TLS client profile trusts. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Ciphers	Cipher suites are encryption algorithms that are used to secure the TLS communication. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include **elliptic_curve_auto_negotiation** and **elliptic_curve** properties in a YAML file definition for the TLS client profile. The **elliptic_curve** property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When **elliptic_curve_auto_negotiation** is set to **true**, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any **elliptic_curve** property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The **elliptic_curve_auto_negotiation** option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

  Table 1.

API enforcement on the gateway	API Connect server access security
secp192r1	prime192v1
secp256r1	prime256v1

  Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
       .
       .
       .
  - secp256r1
  - prime256v1
       .
       .
       .
```

Procedure

Complete the following steps to create a TLS client profile with elliptic curve cryptographic schemes defined:

1. Create a YAML file definition for your TLS client profile, with the required **elliptic_curve** property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see Logging in to a management server.
3. Create the TLS client profile by using the following command:

   ```
   apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
   ```

   where:
   - *mgmt_endpoint_url* is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
   - *organization_name* is either **admin**, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
   - *tls_client_profile_yaml_file* is the name of the YAML file that contains the definition for your TLS client profile.

   Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.

For reference details of all the **`apic tls-client-profiles`** commands, see the toolkit CLI reference documentation.

You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Creating a keystore

Create a keystore by uploading a public and private key pair.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

Your private and public keys must be in PEM or P12 formatted files.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure keystores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

API Connect provides pre-configured keystores that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new keystores that contain your own TLS certificates.
Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Procedure

Complete the following steps to create a TLS client profile:

1. In the Cloud Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the keystore table.

Field	Description
Title	Enter a title for the keystore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Private key & public key: Step 1: Upload private key	Upload the file that contains the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).
Private key password	If the private key has a password, then enter it here.
Private key & public key: Step 2: Upload public key	If the public key is contained in a separate file, upload it in Step 2. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).

4. Click Save.
   Note: Uploaded keys and certificates cannot be download from API Connect.

Creating a truststore

Create a truststore that contains a list of certificates that your TLS profile trusts.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

Your public keys must be in PEM or P12 formatted files.

Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

API Connect provides pre-configured truststores that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new truststores with your own TLS certificates.
Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Procedure

1. In the Cloud Manager, click  Resources.
2. Select Crypto Material.
3. Click Create in the truststore table.

Field	
Title	Enter a title for the truststore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Upload truststore certificates	Upload the file that contains the public key certificate.

4. Click Save.

Managing TLS profiles, keystores, and truststores

TLS profiles, keystores, and truststores can be created, updated, and deleted in the Cloud Manager UI.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

To view TLS server profiles, keystores, and truststores, one of the following roles is required:

- Viewer
- Custom role with the `Settings: view` permissions

To view, create, edit, or delete TLS server profiles, keystores, and truststores, one of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

The Crypto Material section in the Cloud Manager UI contains the TLS profiles, keystores, and truststores configured for your cloud.

API Connect provides pre-configured keystores and truststores that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new keystores and truststores with your own TLS certificates.
Important: Do not modify the default keystores and truststores that are created at installation.
If you create your own TLS profiles, keystores, and truststores, API Connect verifies all certificates you upload, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expiry. Certificate expiration dates are displayed in the keystores and truststores that contain them.

Certificate files that you upload must be in PEM or P12 format.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.

Procedure

1. In the Cloud Manager, click Resources.
2. Select Crypto Material.
3. From the Crypto Material section you can add, edit, and delete your TLS profiles, keystores, and truststores.
    - TLS server profiles. Configure the TLS profiles used to secure the API invocation endpoints on your gateways. If you want to update keys and certificates, then view the TLS server profile to identify the keystore and truststore that contains them.
    - TLS client profiles. Configure the TLS profiles used to initiate client connections to other systems. If you want to update keys and certificates, then view the TLS client profile to identify the keystore and truststore that contains them.

      You can manage the visibility of TLS client profiles for provider organization members. Select Edit visibility from the ⋮ options menu next to the name of the profile. The following visibility settings are available:
        - Private - the profile is visible only in the Cloud Manager UI and cannot be used by any provider organization.
        - Public - the profile can be used by all provider organizations.
        - Custom - the profile can be used by the provider organizations you specify.
    - Keystores. Upload the private and public key pairs that your TLS profiles use.

      The certificate's subject, finger print, and expiration date are displayed. Click > to view more certificate details.

      Note: You cannot download your uploaded keys and certificates from API Connect.
    - Truststores. Upload the certificates that your TLS profiles trust.
    - JWK sets. The JWK sets in the Crypto Material section are not related to TLS profiles. See the Config sync feature.

Using OpenSSL to generate and format certificates

Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.

OpenSSL is an open source toolkit that can be used for generating and validating TLS certificates.

This topic covers how to generate a self-signed TLS certificate by using the OpenSSL toolkit, and how to convert certificates in PEM format to P12 format.

Creating a self-signed certificate with OpenSSL

Use the following command to create a private key and public certificate with OpenSSL:

```
openssl req -newkey rsa:2048 -nodes -keyout private_key.pem -x509 -days 365 -out public_certificate.pem
```

The OpenSSL command asks for the following information to create your private key and public certificate (example values shown):

- Country Name (2 letter code) []: US
- State or Province Name (full name) []: California
- Locality Name (eg, city) []: Sacramento
- Organization Name (eg, company) []: exampleorganization
- Organizational Unit Name (eg, section) []:
- Common Name (eg, fully qualified host name) []: gateway.exampleorganization.com
- Email Address []:

Common Name must be set to the fully qualified domain name of the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example. `192.16.183.131` or `gateway.exampleorganization.com`).

To review the generated public certificate run:

```
openssl x509 -text -noout -in public_certificate.pem
```

To combine the generated private_key and public_certificate PEM files into a password protected P12 file, run:

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12
```

To validate a P12 file, run:

```
openssl pkcs12 -in certificate.p12 -noout -info
```

Creating PKCS#12 (P12) certificate from PEM files

PKCS#12 (P12) defines an archive file format for storing cryptographic objects as a single file. Use OpenSSL to create a password protected P12 file from your PEM files.

Prerequisites:

- Private key file. For example: private_key.pem.
- CA signed certificate. For example: public_certificate.pem.
- If you have intermediate certificates from your CA, concatenate them into a single .pem file to create a ca_chain.pem file:

  ```
  cat ca1.pem ca2.pem ca3.pem > ca_chain.pem
  ```

  the ca_chain.pem file should look like this:

  ```
  -----BEGIN CERTIFICATE-----
  MIIEpjCCA46gAwIBAgIQEOd26KZabjd+BQMG1Dwl6jANBgkqhkiG9w0BAQUFADCB
  ...
  lQX7CkTJn6lAJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
  -----END CERTIFICATE-----
  -----BEGIN CERTIFICATE-----
  MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NUmXJTANBgkqhkiG9w0BAQUFADBv
  ...
  -----END CERTIFICATE-----
  -----BEGIN CERTIFICATE-----
  MIIENjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQQGEwJTRTEU
  ...
  -----END CERTIFICATE-----
  ```

- If you have multiple end-entity (leaf) certificates in one file, then split them into separate files and create separate P12 files for each certificate.

Create the P12 file with the following OpenSSL command (if you don't have CA certificates to include, then omit `-CAfile <filename> -chain`):

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

OAuth Provider overview

API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

Introduction to OAuth

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information. In API Connect, you can secure an API with OAuth.

In Cloud Manager, you configure both Native and Third party OAuth providers that can be made visible to selected Provider organizations. The OAuth Provider configuration is based on the OAuth 2.0 Specification, which is available at https://tools.ietf.org/html/rfc6749. Knowledge of the OAuth 2.0 specification is required to implement an OAuth Provider in API Connect.

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: In a multinode cluster, OAuth operation fails if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **Configuring a native OAuth provider**
  Native OAuth providers are configured and managed by you within your cloud.
- **Configuring a third-party OAuth provider**
  Enter the secure endpoints to provide OAuth authentication from a third party.
- **Setting the visibility for OAuth providers**
  The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.
- **OAuth concepts for API Connect**

Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example,

- If you change the name of autogenerated assembly actions in the source code, the assembly is prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client_id checks:
If you are calling an OAuth endpoint, the sequence of `client_id` checks in the token request is as follows:

1. Check both body and query.
   - If found in only the body, validate and return a `200` or appropriate return code.
   - If found in only the query, return a `wrong location` error.
   - If found in both the body and the query, return a `more than one location` error.
2. When not found in the body or the query, check the `Authorization` header.
   - If found in this header, validate and return a `200` or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the `client_id` is in the request body.
One of the following roles is required to configure a native OAuth provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

- The OAuth provider logs analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

Procedure

OAuth provider configuration uses a series of screens. The first set of screens controls a basic OAuth provider configuration. Perform the following steps to configure a native OAuth Provider for your cloud:

1. In the Cloud Manager, click Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
   a. Complete the following parameters for the first screen, then click Next.

Field	Description
Title	Enter a title for the native OAuth provider.
Name	The system autopopulates this field.
Description (optional)	Enter a brief description.
Base path (optional)	The API shares a base path, which is the URL segment common to all operations. It does not include the hostname or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For more information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. In the next screen, enter the following additional configuration parameters, then click Next.

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to log in to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." does not require user security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The client exchanges the user's username and password directly for an access token, and only first-party clients can use this flow.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

d. Enter the parameters for user security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User security is not required for the Application grant type. Click Next when done.

Field	Description

Identity extraction	Determines how the user credential is extracted:
	• Basic Authentication - HTTP basic authentication (requires no additional configuration)
	• Default HTML Form - Use default login form for username and password
	• API Gateway only Context variable - Specify which variable contains the username and password. API Connect OAuth context variables as listed here API Connect context variables
	Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible).
	• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security.
	• Redirect - If you select Redirect , enter the following parameters:
	  ◦ End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL
	  ◦ Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark symbol (?), usually consisting of key-value pairs separated by ampersand symbol (&).
	  Note: To ensure the query parameter that you entered is applied to the gateway, republish your OAuth provider.
	  ◦ Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements.
	• API Gateway only Disabled - do not collect the user credential
	Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.

Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL user registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.
Authorization	The following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use the default HTML form to authorize. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML authorization form for user security. • API Gateway only Disabled - Disable authorization.

3. Review the Summary for the native OAuth provider configuration.
4. Click Back to make changes.
5. Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.
   If you want to specify the native OAuth Provider in your Catalog, see Specifying the OAuth Providers.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

- **Configuring basic settings for a native OAuth provider**
  You can update the identification details and basic configuration settings for a native OAuth provider.
- **Configuring scopes for a native OAuth provider**
  Access tokens contain authorization for specific scopes.
- **Configuring user security for a native OAuth provider**
  Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- **Configuring tokens for a native OAuth provider**
  Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- **Configuring token management and revocation for a native OAuth provider**
  Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.
- **Configuring introspection for a native OAuth provider**
  Define an introspection path to allow the metadata for an access token to be examined.
- **Configuring metadata for a native OAuth provider**
  Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Configuring the OIDC parameters for a native OAuth provider**
  Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.
- **Editing a native OAuth provider by using the API Editor**
  You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. To modify the identification details, click information in the sidebar menu, then update the following fields as required:

Field	Description
Title	Enter a title for the native OAuth provider.
Name	The system autopopulates this field.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the hostname or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to log in to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client credentials." does not require user security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The client exchanges the user's username and password directly for an access token, and only first-party clients can use this flow.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
	
	Tip: If you plan to configure OpenID Connect (OIDC) for a Native OAuth provider, include at least one of the following grant types: Implicit, Access code.

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:
   a. Click User Security in the sidebar menu, then click Edit.
   b. Update the user security settings as required; for more details, see Configuring user security for a native OAuth provider.
   c. Click Save when done.
3. Click Save when done.

Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see The OAuth 2.0 Authorization Framework.

One of the following roles is required to configure scopes for a native OAuth Provider:

- Administrator

- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure the scopes for the access token:

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

   In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.
   If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

2. Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are started after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and overwrite any previous scopes.

Field	Description
Application scope check	Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS profile to use for an application scope check.
Owner scope check	Further refine the scope with an additional check. Enter the endpoint and an optional TLS profile to use for an owner scope check.

   For more information about scope, see Scope
3. Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

Field	Description
Enabled	Select the checkbox to enable the advanced scope check after token validation. Enter an optional default validator endpoint.
Use endpoint from API	Select the checkbox to use the endpoint from the API, or clear the checkbox to override the endpoint from the API.

   For more information about scope, see Scope
4. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure the user security settings for the OAuth Provider:

1. Click User Security in the sidebar menu.
2. Specify the following parameters for user security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

Field	Description

Identity extraction	Determines how the user credential is extracted:
	• Basic Authentication - HTTP basic authentication (requires no additional configuration)
	• Default HTML Form - Use default login form for username and password
	• API Gateway only Context variable - Specify which variable contains the username and password. API Connect OAuth context variables as listed here API Connect context variables
	• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security.
	• Redirect - If you select Redirect , enter the following parameters:
	  • End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL
	  • Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark (?) symbol, usually consisting of key-value pairs separated by ampersand symbol (&).
	  Note: To ensure the query parameter that you entered is applied to the gateway, republish your OAuth provider.
	  • Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements.
	• API Gateway only Disabled - do not collect the user credential
	Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the **`state_nonce`** query parameter, otherwise the authorization fails.

Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL user Registry.
Authorization	Various methods can be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use the default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. • API Gateway only Disabled - Disable authorization.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure tokens for the native OAuth provider:

1. Click Tokens in the sidebar menu.
2. Define the settings to configure tokens.

Field	Description
Access tokens time to live	Enter the expiration time period in seconds for access tokens.
API Gateway only One-time use access token	Click the checkbox to enable one-time use for the access token. Access tokens are multiple use by default, which allows them to be used for multiple requests. When one-time use is enabled, the access token will be consumed after one use. The OAuth flow needs to be repeated to obtain another access token. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Refresh tokens	Click the checkbox to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.
One-time use refresh token	Clear the checkbox to disable one-time use for the refresh tokens. Refresh tokens are one time use by default, which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one-time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Maximum consent	Click the checkbox to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.
API Gateway only Token secret	Click the checkbox to select the Shared Secret, which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter a key name and key value to use as the token secret.
API Gateway only Proof Key for code Exchange	Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. You can enable this extension when deploying with the DataPower® API Gateway. For more information, see RFC 7636. Select the options for your OAuth Providers: • Enable proof key for code exchange If selected, enforces PKCE when submitted in Authorization Code grant requests. • Always required If selected, requires PKCE in all Authorization Code grant requests. • Allow plain Select this checkbox to allow the plain challenge method in Authorization Code grant requests.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

- Refresh tokens

Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third-party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 OAuth 2.0 Token Revocation.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure revocation settings for tokens:

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the checkbox.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.
   Note: If you are using the API Manager user interface, then for the External option to be available, you must be using DataPower® API Gateway version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see Creating and configuring Catalogs
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
   - Resource owner revocation path-Uses the standard OAuth revocation path to allow the resource owner (user) to revoke the application permission.
   - Client revocation path-Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.

   For more information about managing tokens with the Native DataPower Gateway, see Token management with the native DataPower Gateway.
5. For External, the settings depend on the gateway type, as follows:
   DataPower API Gateway:
   - Endpoint-the URL of the external management endpoint.
   - TLS client profile (optional)-the TLS client profile to secure connections.
   - Security-how to secure connections. The only supported method is basic authentication.
   - Basic authentication username (optional)-the username for authentication.
   - Basic authentication password (optional)-the password for authentication.
   - Basic authentication request header name (optional)-the request header that contains the authentication string, if you supply both a request header name and username or password, the request header authentication method is used.
   - Custom header pattern (optional)-the name pattern of the headers to use for sending additional information to the external management service.
   - Cache type-the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
   - Fail on error-if selected, processing is stopped if the connection to the external management service fails.

   Note: For more information about the JSON format that is required when exchanging messages with the external management service, see JSON format to exchange messages with the external management service.
   DataPower Gateway (v5 compatible):
   - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine whether the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see Token revocation.
   - TLS client profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

Results

Depending on the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

About this task

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See OAuth 2.0 Token Introspection.

One of the following roles is required to enable introspection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to enable introspection:

1. Click Introspection in the sidebar menu.
2. Select the checkbox to enable Introspection. The OAuth standard path for introspection /oauth2/introspect is automatically entered. This path is used when another entity inspects the token contents.
3. Click Save when done.

Results

Tokens will be queried using the /oauth2/introspect path. Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

About this task

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see OAuth external URL and authentication URL.

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure metadata collection:

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see Authentication URL user registry.
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5. API Gateway only If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as **`metadata`**.
6. API Gateway only If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as **`miscinfo`**.
7. Save the OAuth Provider.
8. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see Configuring basic settings for a native OAuth provider.
You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure an OIDC template:

1. Click OpenID Connect.
2. Select Enable OIDC and then enter the following parameters as appropriate:

Field	Description
Support hybrid response types	Optional: The administrator selects the response types that this OAuth provider supports for the OpenID Connect hybrid flow.
Auto Generate OIDC API Assembly	Optional. Select this option to generate the full OIDC assembly. Leave this option unselected to simply enable OIDC support in the OAuth provider, and allow developers to implement their own assemblies.
ID token issuer	Descriptive text to indicate the source of the key.
ID token signing crypto object	The cryptographic object to use to sign the token.
ID token signing key	The JSON Web Key (JWK) to be used to sign the ID token.
ID token signing key identifier	The key ID used for signing the token.
ID token signing algorithm	The algorithm used to sign the token.
OpenIDConnect Discovery path	A URL that is exposed by the provider and allows a client to send a request for information about the provider's publicly visible configuration.

3. Click Save when done. You can edit the policies by using the API Editor.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example,

- If you change the name of autogenerated assembly actions in the source code, the assembly is prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the **`oauth-provider-settings-ref`** field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to edit the OAuth configuration:

1. Click API Editor.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag editor to add additional policies to the OIDC behavior.
   Note: If you add a policy that references a TLS profile, an **invoke** policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For more details about how to enable a TLS profile in a Catalog, see Creating and configuring Catalogs.
4. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Complete the following steps to configure a third party OAuth provider:

1. In the Cloud Manager, click Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
   a. Complete the following parameters for the first screen and click Next.

Field	Description
Title	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name	This field is auto-populated by the system and used as the internal field name.

Supported grant types	Select from the following options:
	• Implicit: An access token is returned immediately without an extra authorization code exchange step.
	• Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require user security.
	• Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code.
	• Resource owner - Password: The client exchanges the user's username and password directly for an access token, and only first-party clients can use this flow.
	• API Gateway only Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).

Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. Specify configuration settings for the endpoints, and then click Next.

Field	Description
Authorization URL	An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example: **`https://example.com/oauth2/authorize`**
Token URL	A token request URL where the client application exchanges an authorization grant for an access token. Example: **`https://example.com/oauth2/token`**
Introspect URL	The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example: **`https://example.com/oauth2/introspect`** For more information on integrating third party OAuth providers for introspection, see OAuth introspection for third-party OAuth providers.
API Gateway only Introspect cache type	The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: • No cache (default): Responses are not cached. • Protocol: Defined by the **`cache-control`** header in the provider response. • Time to live: Defined by the provider.

Field	Description
API Gateway only Cache Time to Live	The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.
TLS Profile (optional)	Select an optional TLS profile for communicating with the third party provider.
Security	Default is Basic Authentication.
Basic authentication request header name	The `x-introspect-basic-authorization-header` is available to provide a user-configured HTTP Basic authorization header.
API Gateway only Basic authentication username (optional)	The default username for HTTP Basic authentication.
API Gateway only Basic authentication password (optional)	The default password for HTTP Basic authentication.
API Gateway only Token validation	Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: • Connected: The query is successful if the status return code is **`200`**. • Active (default): The query is successful if the status return code is **`200`** and the response JSON body includes the property **`active: true`**.
API Gateway only Custom header pattern (optional)	A regular expression for request headers that are to be passed to the third-party provider; for example, `x-Introspect-*`.
API Gateway only Authorization header pass through	Select this checkbox if you want to retain the **`Authorization`** header for a bearer token. The default behavior is to remove this header.

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
sample_scope_2	Scope for token
additional scopes	Scope for token

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.
   If you want to specify the third party OAuth Provider in your Catalog, see Specifying the OAuth Providers.

- **Configuring scopes for a third-party OAuth provider**
  Access tokens contain authorization for specific scopes.

Configuring scopes for a third-party OAuth provider

Access tokens contain authorization for specific scopes.

About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth-protected API is called, the gateway checks the access token's scopes against the allowed scopes in the API's security definition to decide whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The access token grants the final scope permission based on the results of all scope checks.

One of the following roles is required to configure scopes for a third-party OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

When you create a third-party OAuth provider, you can add scopes immediately. For more information, see Configuring a third-party OAuth provider or you can update the scope settings for an existing third-party OAuth provider. The Advanced scope check after token generation option is not available during creating a third-party OAuth provider. To edit Scopes and enable the Advanced scope check after token generation settings for an existing third-party OAuth provider, complete the following steps:

1. Click Resources > OAuth Providers.
2. Select the third-party OAuth provider that you want to edit the scope.
3. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.
4. To add new Scopes, complete the following steps:
   - Click Add.
   - Enter the Name and Description for new scope.
   - Click Save.
   - To delete existing scopes, click Delete.
5. To Implement an extra scope check at the API consumer level to ensure the compliance with the API's scope requirements, complete the following steps:
   - Select the Enabled checkbox to enable the advanced scope check after token validation.

- Enter the Default validator endpoint.
- **Optional:** Select the TLS client profile to use for an owner scope check. For more information about TLS client profile, See TLS profiles overview.
- Select the Use endpoint from API checkbox to use the endpoint from the API. If you selected Use endpoint from API, the Default validator endpoint is optional.
- If you want to enable basic authentication, select Enable security checkbox and fill the following parameters:

Table 1.

Field	Description
Mode	Select Basic authentication.
Optional: Basic authentication request header name	A default header name is provided, which you can modify to meet your specific requirements.
Optional: Basic authentication username and password	Enter the `username` and `password`.
Optional: Request headers and Response context variables	Enter `Request headers` and `Response context variables`. Make sure that it is in **`Perl Compatible Regular Expressions`** format. For more information about PCRE format, see PCRE.

- Click Save when done. For more information about scope, see Scope.

Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

- Scope

Setting the visibility for OAuth providers

The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Follow these steps to set the visibility for the OAuth providers in your on-premises cloud:

1. In the Cloud Manager, click Resources.
2. Select OAuth Providers.
3. Choose Edit visibility from the actions menu next to the name of the OAuth provider that requires a visibility setting.
4. Select the visibility setting for the OAuth provider. The options are:
   - Private - the OAuth provider is not visible and cannot be used by any provider organization. It is accessible only to the admin organization in Cloud Manager.
   - Public - the OAuth provider is visible and can be used by all provider organizations
   - Custom - the OAuth provider is visible only to the provider organizations that you designate
5. For Custom visibility, select the provider organizations that you want to have access to the OAuth provider.
6. Click Save to complete the operation.

Results

For Private, the OAuth provider is not visible and cannot be used by any provider organizations. For Public, the OAuth provider is visible and can be used by all provider organizations. For Custom, the OAuth provider is visible only to the provider organizations designated by you.

OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multinode cluster, OAuth operation fails if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **OAuth user scenario**
  Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- **OAuth introspection for third-party OAuth providers**
  OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients

can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.

- **OAuth external URL and authentication URL**
  You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Scope**
  Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- **Tokens**
  Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- **Authentication URL user registry**
  You can use an authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides extra metadata to be embedded in the token.
- **Custom forms for user security**
  You can create custom forms for the authorization and identity extraction phase of OAuth.
- **Securing an API with a JSON Web Token**
  There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM API Connect.
- **Troubleshooting OAuth**
  You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

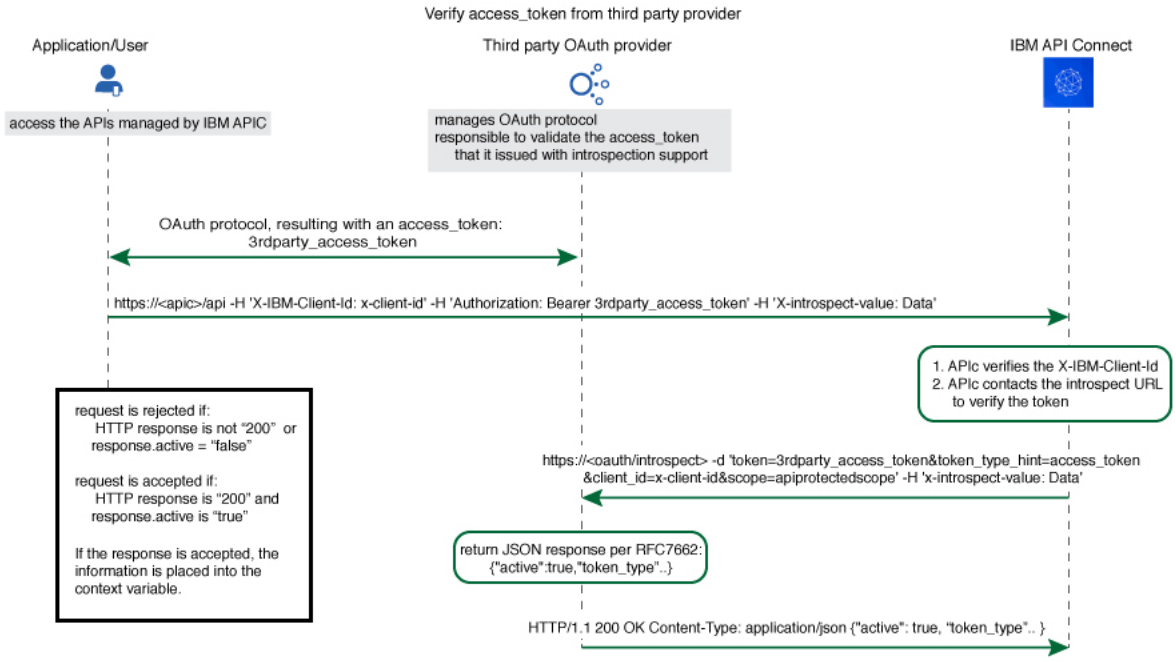
In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.



OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in RFC 7662. In addition to the specification, the **`x-Introspect-`** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.

The Introspect URL is configured in the Third Party OAuth provider configuration. See Configuring a third-party OAuth provider.

When an API is protected by a third-party OAuth provider, API Connect extracts the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as **`x-introspect-*`**.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider. The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be **`x-Introspect-`**.

API Connect issues this POST request to the introspection endpoint specified in **`x-tokenIntrospect`**, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider responds with `HTTP 200` indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
 Content-Type: application/json;charset=UTF-8
 Cache-Control: no-store
 Pragma: no-cache
```

```
{ "active":true,
   "token_type":"bearer",
   "client_id":"xxx-xxx",
   "username":"John Smith",
   ...
}
```

If the value of the active claim is `false`, the token is treated as invalid.

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
```

```
{
  "active":false
}
```

A response code other than **HTTP 200** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see API Connect context variables.

When contacting the introspection endpoint, API Connect uses **client_id**/**appId** and **client_secret**/**appSecret** to construct the HTTP Basic authorization header.

By default, if **x-introspect-basic-authorization-header** exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcnR5LWNsaWVudF9pZDozcmQtcGFydHlfY2xpZW50X3NlY3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format ***user*:*password***, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and username and password details are not supplied in the third party OAuth provider configuration, but **client_id** and **client_secret** values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider.
If either, or both, of scope and **scope validate url** are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect further enforces the scope validation in the following order:

1. If **scope** is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If **scope validation url** is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see Creating an OAuth security definition.

For more information, see Scope.
DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a **suppress-parameters** header as follows:

  suppress-parameters: client_id

  suppress-parameters: scope

  or

  suppress-parameters: client_id scope

  depending on which parameters you want to suppress.
- Define an API property called **suppress-parameters** in the API definition itself, with one of the following string values:

  client_id

  scope

  or

  client_id scope

  depending on which parameters you want to suppress. For information on how to define API properties, see Setting API properties.

OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL- when you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL-When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.
  See: Authentication URL.

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

  `X-API-OAUTH-METADATA-FOR-PAYLOAD`

  `X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`

  Note: The headers before this are the default header names for the DataPower API Gateway but you can override them, see Configuring metadata for a native OAuth provider.
- DataPower Gateway (v5 compatible):

  `API-OAUTH-METADATA-FOR-PAYLOAD`

  `API-OAUTH-METADATA-FOR-ACCESSTOKEN`

The response header value from **`X-API-OAUTH-METADATA-FOR-PAYLOAD`** or **`API-OAUTH-METADATA-FOR-PAYLOAD`** is placed in the response payload and indicated as **`metadata`**.

The response header value from **`X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`** or **`API-OAUTH-METADATA-FOR-ACCESSTOKEN`** is placed within the access token and indicated as **`miscinfo`**.

The two metadata response headers are case-insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
"token_type":  "bearer",
"access_token":  "AAEkNzhjDHYyyYy...cL0Mv6ctl37w7ZU",
"metadata":  "m:metadata-for-payload_content"
"expires_in":  3600,
"scope":  "read",
"refresh_token":  "AAEnj5SynCMybF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with **`"miscinfo"`** containing the metadata information.

```
{
"active":  true,
"token_type":  "bearer",
"client_id":  "78c2f10f-799a-4e1f-8e0a-098634997a35",
"username":  "Fred Smith",
"sub":  "fred",
"exp":  1479850049,
"expstr":  "2016-11-22T21:27:29Z",
"iat":  1479846449,
"nbf":  1479846449,
"nbfstr":  2016-11-22T20:27:29Z",
"scope":  "read",
"miscinfo":  "m:metadata-for-accesstoken_content",
"client_name":  "MobileApp"
}
```

Input to the External URL

The following request headers are sent to the External URL.
Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **`x-existing-metadata-for-payload`** and **`x-existing-metadata-for-access-token`**. The Metadata URL can use this information to create a new set of metadata values.
The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload     payload-from-auth-url
X-existing-metadata-for-access-token     token-from-auth-url
X-URI-in     /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in     POST
X-POST-Body-in     client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP     IP_address
X-X-Global-Transaction-ID     ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **`X-POST-Body-in`** header is not supported.

Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **miscinfo** field can be accessed in the Assembly with the **oauth.miscinfo** context variable, as in the example.

```
apim.setvariable('message.body',apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

Refresh tokens and metadata

The Authentication URL (if configured for authentication) is started first, during authentication of the resource owner. The External URL is started as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not started. The metadata from the refresh token is retained and then copied into the newly generated access token.

Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with **m:**
- Metadata from the Authentication URL is prefixed with **a:**

Note: When revocation is enabled, some internal details are also stored in the **miscinfo** field, in brackets within the access token as shown in the following example:

```
"miscinfo": "[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in the following sections.

Certain characters are not allowed in metadata

Metadata from the authentication URL is stored temporarily when using Authorization code or implicit grant with consent.

API Connect internally uses two prefixes - **!ma** and **!mp** to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - **!ma** and **!mp** should not be used as the metadata itself.

Grant types and metadata

The OAuth grant types described in the following sections include **authorization code (access code)**, **implicit**, and **client credentials (application)**.

Authorization code grant type

- In a three-legged Authorization code flow, metadata from the Authentication URL is stored in **dp-state** and carried over to the authorization code and access token. Around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the **dp-state**. In addition, if revocation is enabled, it is also part of the token metadata. The combined size of the token metadata, the payload metadata (including internal data), and internal revocation details cannot exceed 512 bytes in total.

  If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "`metadata too large`" as shown in the example.

  ```
  "metadata":"m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
  "miscinfo":"[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
  ```

  The size restriction does not apply when metadata is sent from the Metadata URL and not from the Authentication URL because the metadata is not stored in **dp-state** or in the authorization code.

  Example of the **authorization code (access code)** grant type:

  ```
   $ curl -k -d
  "grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
  https://9.70.153.90/fei/sb/introspectp1/oauth2/token
  { "token_type":"bearer",
  "access_token":"AAEkOThlZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ20ZN5Tl_TqYFeIfB7BFf6HFgibEoOjWXXEA84oFsWuE4NY-
  RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_1YKm3ahrfhR5kI3sPO0uADEoseIP5-O9anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
  PHBialoRkBD5qca6kO0fV2M", "metadata":"a:[Authorization Code-Test-auth-url-payload]", "expires_in":3600,
  "scope":"scope_introspect", "refresh_token":"AAFAg1EVMbwicr_L0fTZ4q6HZ-
  RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNGl5C1GbIe3dwhXJdiWA0Go-
  dduhVtCbG26sJRRXyYrMeRxWnJsylBETPI8HQEN4a_D7fmxKcTVRZBvq86byg95qe1ZKyERi0Lhxdd_O4Nvss" }
  ```

  ```
  $ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
  "token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
  { "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746", "username":"anyuser",
  "sub":"anyuser", "exp":1484766368, "expstr":"2017-01-18T19:06:08Z", "iat":1484762768, "nbf":1484762768,
  "nbfstr":"2017-01-18T18:06:08Z", "scope":"scope_introspect", "miscinfo":"[r:gateway]a:[Authorization Code-Test-auth-
  url-token]", "client_name":"oauth_app" }
  ```

Implicit grant type

- When implicit grant type is used, the access token and the metadata are returned in the **location** header as a fragment, as you see in the example.

```
< Location:
 https://localhost#access_token=AAEkOTh1ZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ2buS2KfWdq-
nYBJSi4nmPxQBtLae17tKBPRMzwP5BC386nlxpoOTE1G748ZVH6Mq_TJL3GeV3PtXTVIkWOLBJi_7tljiQfpnVfrNkovvZkhUexYmFkcDsmLSdaWxZ6Pc
IMPAC4ojT8qV1sYV-
ChTk36yqOx_NiKimZaDikDk7WTg&expires_in=3600&scope=scope_introspect&token_type=bearer&metadata=a%3A[Implicit-Test-
auth-url-payload]

$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
             { "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746",
"username":"anyuser", "sub":"anyuser", "exp":1484768365, "expstr":"2017-01-18T19:39:25Z", "iat":1484764765,
"nbf":1484764765, "nbfstr":"2017-01-18T18:39:25Z", "scope":"scope_introspect", "miscinfo":"[r:gateway]a:[Implicit-
Test-auth-url-token]", "client_name":"oauth_app" }
```

Client credentials grant type

Authentication URL cannot start when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL is included as metadata.

Behavior when retrieving metadata with both an external URL and an authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "`error on metadata url`" is written for metadata in both the payload and the access token.

If the remote server does not send specified HTTP response headers, blank values are written for metadata.
Attention: An External URL overwrites existing values from Authentication URL including blank values.
If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

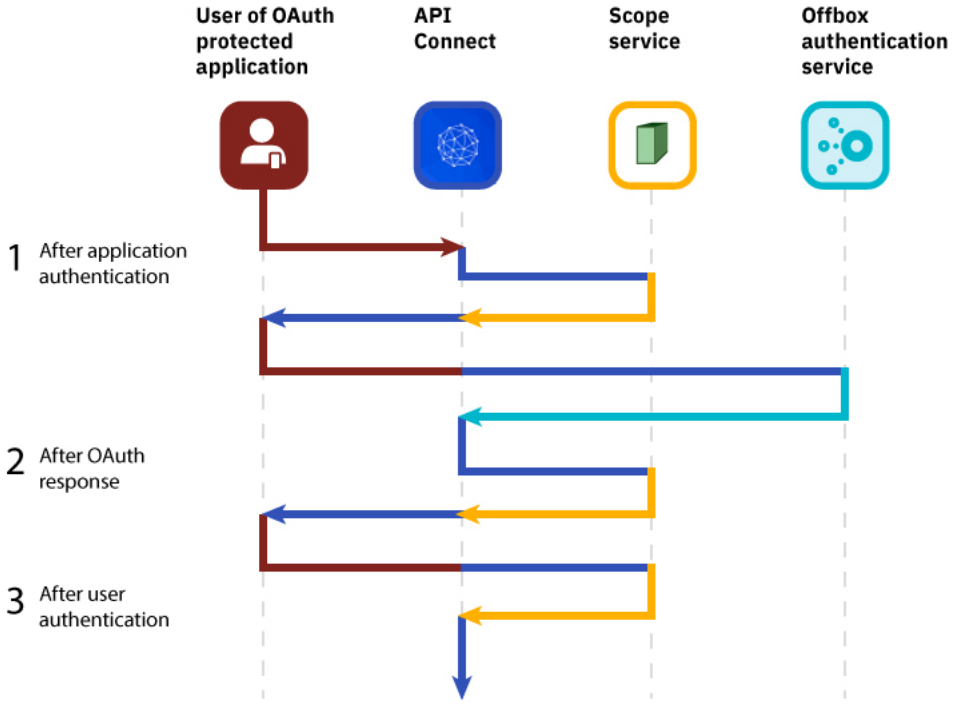
Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.
Note:

- An OAuth Provider must have at least one scope.
- An OAuth token will not be granted unless a default scope is configured at the provider, or one or more predefined scopes are included in the grant request.
- If no default scope is defined, and the request does not contain a scope, an invalid scope error is returned for the request.

OAuth provider



To provide more refined support for the OAuth scope handling, API Connect allows the Authentication URL user registry extension to modify the scope value.

When you define an OAuth provider, the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.

1. After the application successfully authenticates, and if OAuth Native provider > Advanced scope check > Application scope check is configured, API Connect makes a call to allow extra verification and uses the contents of **x-selected-scope** to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header **x-selected-scope** must be present, or the call fails.
2. If OAuth Native provider > User Security > Authentication is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in Authentication URL user registry. When the response code is `HTTP 200`, and the response header **x-selected-scope** is present, the value that is configured in **x-selected-scope** is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, **x-selected-scope** is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider > Advanced scope check > Owner scope check is enabled and configured with a valid URL, API Connect makes a call to allow the content of **x-selected-scope** to refine the scope value. When Owner scope check is enabled, the HTTP response header **x-selected-scope** must be present, or the call fails.

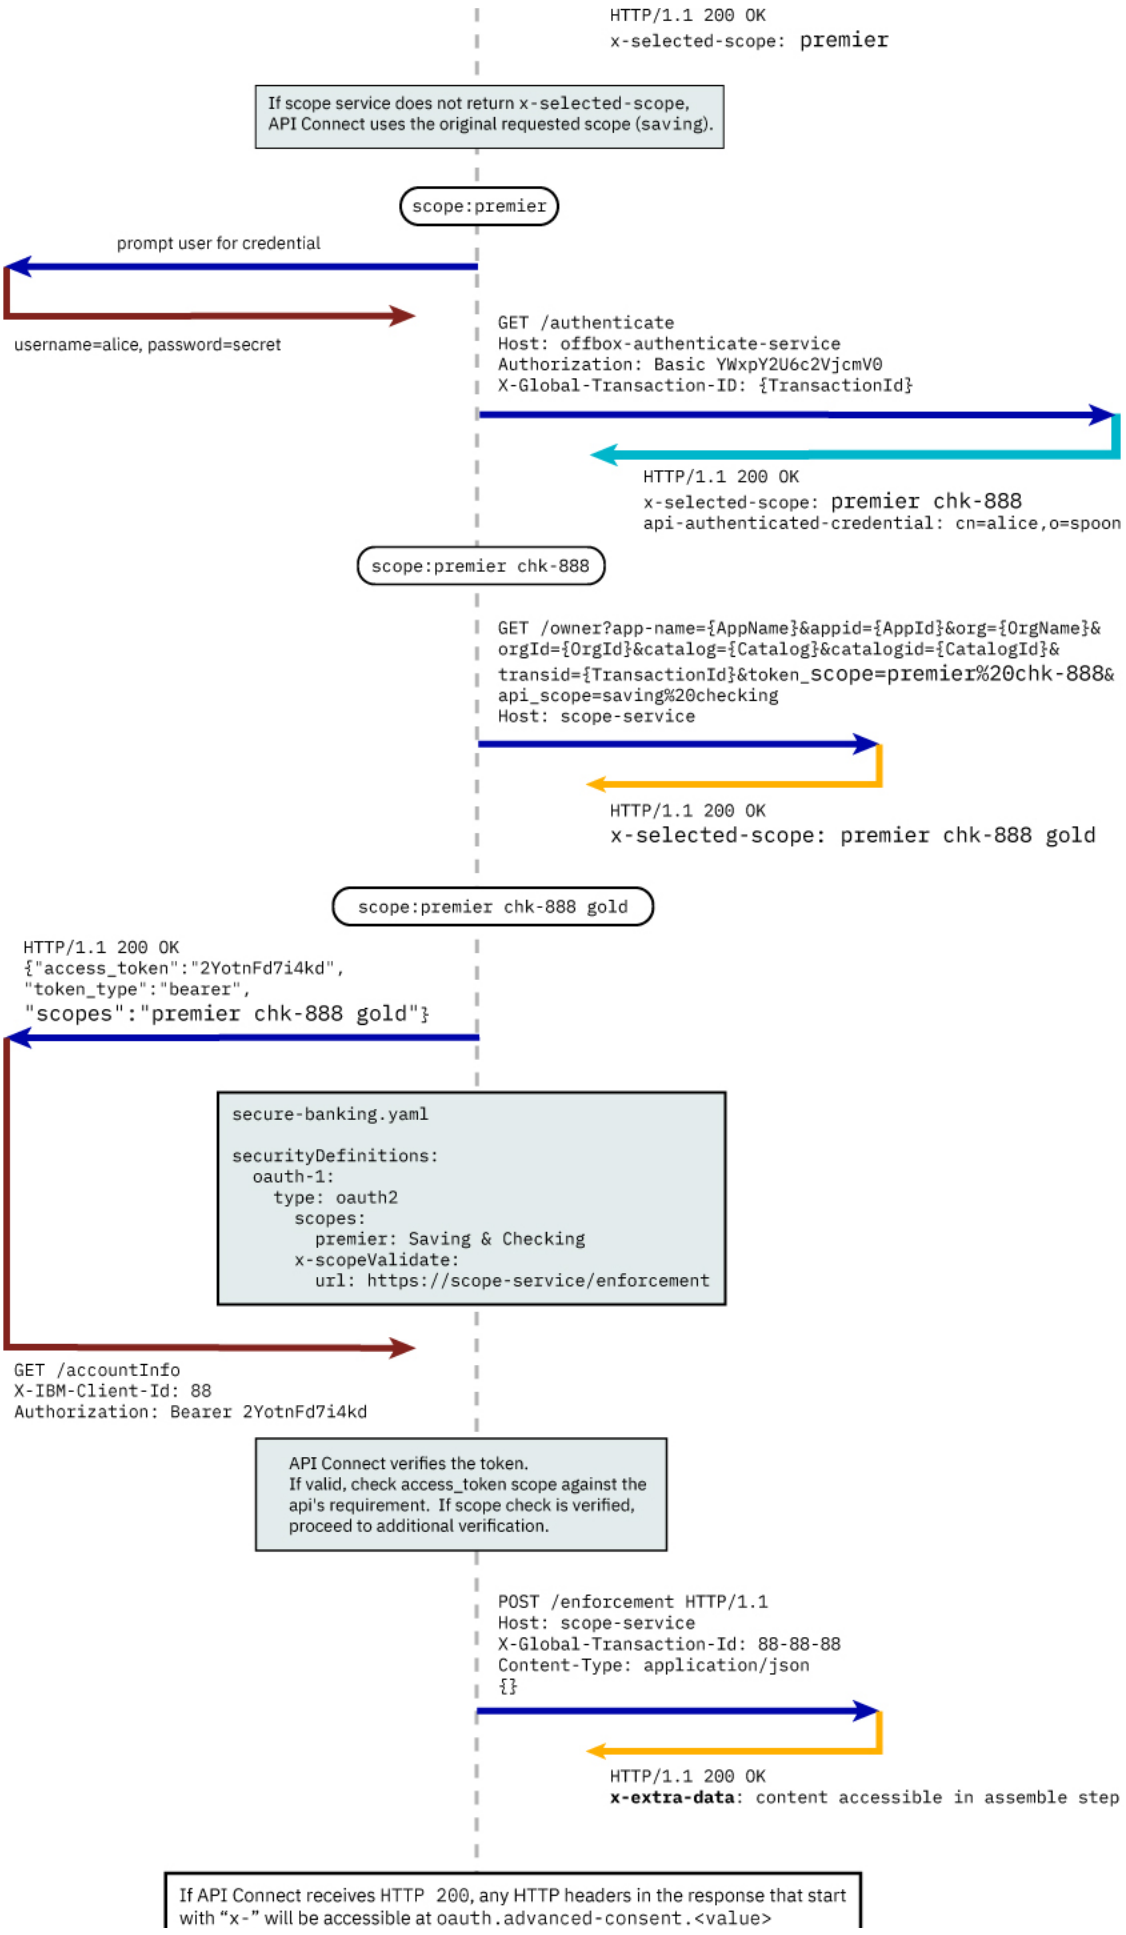


Figure 1. OAuth advanced scope overview

The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. Figure 2 shows a more detailed view of the transaction flow with examples that show when **`x-selected-scope`** provides a new scope value.

Figure 2. OAuth advanced scope detail

HTTP/1.1 200 OK
x-selected-scope: premier
If scope service does not return x-selected-scope, API Connect uses the original requested scope (saving).
scope:premier
prompt user for credential
username=alice, password=secret
GET /authenticate
Host: offbox-authenticate-service
Authorization: Basic YWxpY2U6c2VjcmV0
X-Global-Transaction-ID: {TransactionId}
HTTP/1.1 200 OK
x-selected-scope: premier chk-888
api-authenticated-credential: cn=alice,o=spoon
scope:premier chk-888
GET /owner?app-name={AppName}&appid={AppId}&org={OrgName}&
orgId={OrgId}&catalog={Catalog}&catalogid={CatalogId}&
transid={TransactionId}&token_scope=premier%20chk-888&
api_scope=saving%20checking
Host: scope-service
HTTP/1.1 200 OK
x-selected-scope: premier chk-888 gold
scope:premier chk-888 gold
HTTP/1.1 200 OK
{"access_token":"2YotnFd7i4kd",
"token_type":"bearer",
"scopes":"premier chk-888 gold"}
secure-banking.yaml
securityDefinitions:
oauth-1:
type: oauth2
scopes:
premier: Saving & Checking
x-scopeValidate:
url: https://scope-service/enforcement
GET /accountInfo
X-IBM-Client-Id: 88
Authorization: Bearer 2YotnFd7i4kd
API Connect verifies the token.
If valid, check access_token scope against the api's requirement. If scope check is verified, proceed to additional verification.
POST /enforcement HTTP/1.1
Host: scope-service
X-Global-Transaction-Id: 88-88-88
Content-Type: application/json
{}
HTTP/1.1 200 OK
x-extra-data: content accessible in assemble step
If API Connect receives HTTP 200, any HTTP headers in the response that start with "x-" will be accessible at oauth.advanced-consent.<value>

For the above example, `x-extra-data` is accessible at `oauth.advanced-consent.x-extra-data`.
If other than `HTTP 200` is returned, it has the same effect as if the access token does not contain neccesary permissions to access the resource.

Consumer API enforcement

Standard scope validation
To access the API /getaccount the application must send a **GET** request with an access token that contains the scope, or scopes, defined in the OAuth provider. If the request doesn't contain a scope, you must specify a default scope to use. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file secure-banking.yaml defines the scope, or scopes, that must exist in the token to be granted access to the API /getaccount.

```
secure-banking.yaml

securityDefinitions:
   scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
security:
  - scope-only:
      - checking
  - scope-only:
      - saving
      - mutual
```

In the examples, the access token **AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ** is able to access the API because it contains one, or a combination of **scope-only** that is defined in secure-banking.yaml such as:

- **checking**
- **saving mutual**
- **checking saving mutual**

Advanced Scope Check
Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes **x-scopeValidate** as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
    x-scopeValidate:
      url: 'https://advanced-scope-check.bk.com/validate-scope'
      tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an **HTTP POST** request to the **x-scopeValidate** endpoint similar to the following example. Response code `HTTP 200` from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
     POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
     Host: advanced-scope-check.bk.com
     Content-Type: application/json

   {"context-root" : checking,
    "resource" : accountinfo,
    "method" : GET,
    "api-scope-required" : [jointaccount],
    "access_token" : {"client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
                      "not_after" : 174364070,
                      "not_after_text" : "2017-07-11T02:27:50Z",
                      "not_before" : 174360470,
                      "not_before_text" : "2017-07-11T01:27:50Z",
                      "grant_type" : "code",
                      "consented_on" : 1499736470,
                      "consented_on_text" : "2059-07-11T01:27:50Z",
                      "resource_owner" : "cn=spoon,email=spoon@poon.com",
                      "scope" : "jointaccount mutual",
                      "miscinfo" : "[r:gateway]"
                     }
}
```

An example of successful response follows.

```
HTTP/1.1 200 OK
Cache-Control: no-store
Pragma: no-cache
X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "**x-**" is kept as the context variable **oauth.advanced-consent**. Based on the example successful response, **X-Custom-For-Assemble-Process: audit** becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options
You can optionally use additional fields for validation:

Request Header
: Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable
: Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format **oauth.advanced-consent.***.

- IETF RFC 6749

Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- **Refresh tokens**
  If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- **Token revocation**
  In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- **Authenticating and authorizing through a redirect URL**
  You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- **Token management with the DataPower Gateway (v5 compatible)**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- **Token management with the DataPower API Gateway**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the expires_in property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYy1hbGxlhdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens > Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see Configuring a native OAuth provider.

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management > Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted.

The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml

<?xmlversion="1.0" encoding="UTF-8"?>
<token>
   <token_type>bearer</token_type>
   <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
   <expires_in>3600</expires_in>
   <scope>3600</scope>
   <resource-owner>alice</resource-owner>
   <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

Provide token information on revocation request

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET  <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET  <revocationURL>GET  HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
```

```
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a `200 OK` response to the Gateway.

Revoking tokens issued to Alice up to and including a specific date

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Revoking all tokens issued up to and including a specific date

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
<oauth-revocation>
```

Putting it all together

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
HTTP/1.1 200 OK
Content-Type: application/xml
Cache-Control: public, max-age=120
Date: Fri, 08 May 2015 21:49:03 GMT

<?xml version-"1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

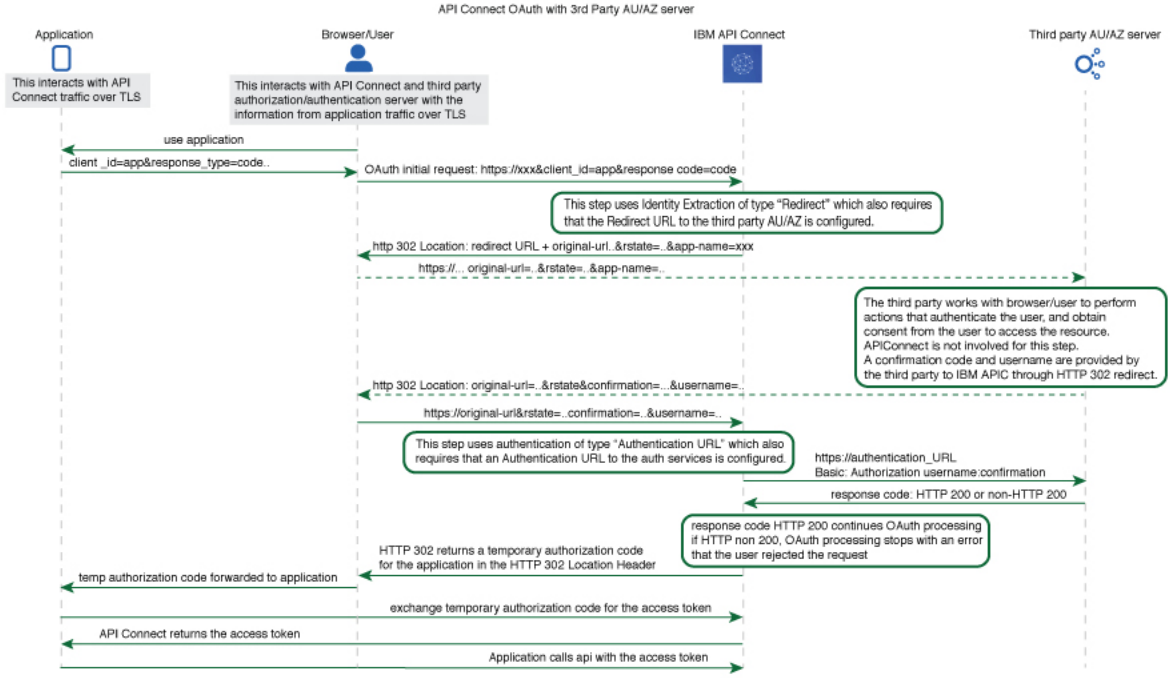
Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The `before` attribute uses the `xs:dateTime` syntax.

Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

Before you begin



To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see Creating an OAuth security definition.

About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow

1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an **`HTTP 302`** redirect based on **`identity extraction -> redirect -> redirect-url`**, for user authentication (and optional authorization).
2. The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an **`HTTP 302`** redirect that uses the **`original-url`** from the request, with the username and confirmation code appended.
3. API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on **`authentication -> x-ibm-authentication-url`**, to confirm user identity before the request is completed.
4. An **`HTTP 200`** response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the **`grants`** type.
   - **`- accessCode`** returns a temporary code to the application.
   - **`- implicit`** returns the access token to the application.

   For any response other than HTTP 200, the request fails with a statement added to the error log.

Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

1. Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
   a. To include elements in your form that are provided by API Connect, use the following query parameters from the URL that your user is redirected to.
   Note: With the exception of **`original-url`**, none of these parameters are included in the URL automatically; you must add them as required.

   app-name
   : The name of the application requesting access, as provided through the Developer Portal.

   appid
   : The id of the application requesting access.

   catalog
   : The name of the catalog where the product is being used by the application.

   catalogid
   : The id of the catalog where the product is being used by the application.

   catalogtitle
   : User-friendly display name for the catalog.

   org
   : The name of the consumer organization that hosts the application.

   orgid
   : The id of the consumer organization that hosts the application.

   orgtitle
   : User-friendly display name for the organization.

   original-url

The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the state_nonce is appended. The state_nonce is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the **`state_nonce`** should remain unchanged.

provider
: The name of the API provider organization.

providerid
: The id of the API provider organization.

providertitle
: User-friendly display name for the provider organization.

requested-scope
: [optional] If Application Scope check is enabled and replaces the **`scope`** from the initial application request, this field holds the **`scope`** value from the initial application request, and the new replacement scope value is put into **`original-url`**.

transid
: transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

```
Redirect_URL?original-url=Original_URL&state_nonce=R_State&app-name=Application_Name
```

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

b. Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the *Original_URL* and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect.
Original URL requires the following form:

```
Original_URL&username=User_Name&confirmation=Confirmation_Code
```

where all variables are as described previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=spoon&confirmation=12345678
```

c. To send your own error responses after the authentication and authorization service, redirect the user to the *Original_URL* and append an error code. You can also append a user name. Use the following form:

```
Original_URL&username=User_Name&error=Error_Response
```

where *Error_Response* is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as `200 OK` if you want to allow access, or non-`200 HTTP` response code, such as `401 Unauthorized` to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2.
For more information on configuring an OAuth Provider, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See Quota enforcement.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:
If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.
- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure

DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see Configuring the quota enforcement server.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com
```

```
x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Note: The steps described in this topic are required if you are using the appliance version of the gateway. For the API Connect supplied Kubernetes deployment, the API Security Token Manager is preconfigured provided that, in the gateway service custom resource file, v5 compatibility mode is disabled and the token management service is enabled:

```
      .
      .
      .
spec:
      .

```

For more information, see Installing the DataPower Gateway subsystem.
Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

In order to manage tokens with the DataPower® API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Note: This setting is also required when you use a third-party OAuth provider and **`Introspect cache type`** is set to **`protocol`** or **`Time to live`**.
For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.
6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see Defining the API security token manager and Creating a gateway peering instance.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user **`cn=spoon,o=ibm`** with username **`spoon`** and password **`spoon`** using a registered administration application of **`5287fe53-8747-438a-8262-681ec75b79c5`**.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request

"owner": "cn=spoon,o=ibm",

"clientName": "PetStore Application",

"scope": "listpet",

"issuedAt": 1503327054,

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Authentication URL user registry

You can use an authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides extra metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs in with username: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **`cn=spoon,o=eatery`**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **`access_token`**.
- Overriding the **`scope`** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the authentication URL endpoint can replace the **`scope`** value that the application receives. For example, you can provide a specific resource owner an account number within the **`scope`** header response for use in future processing steps.

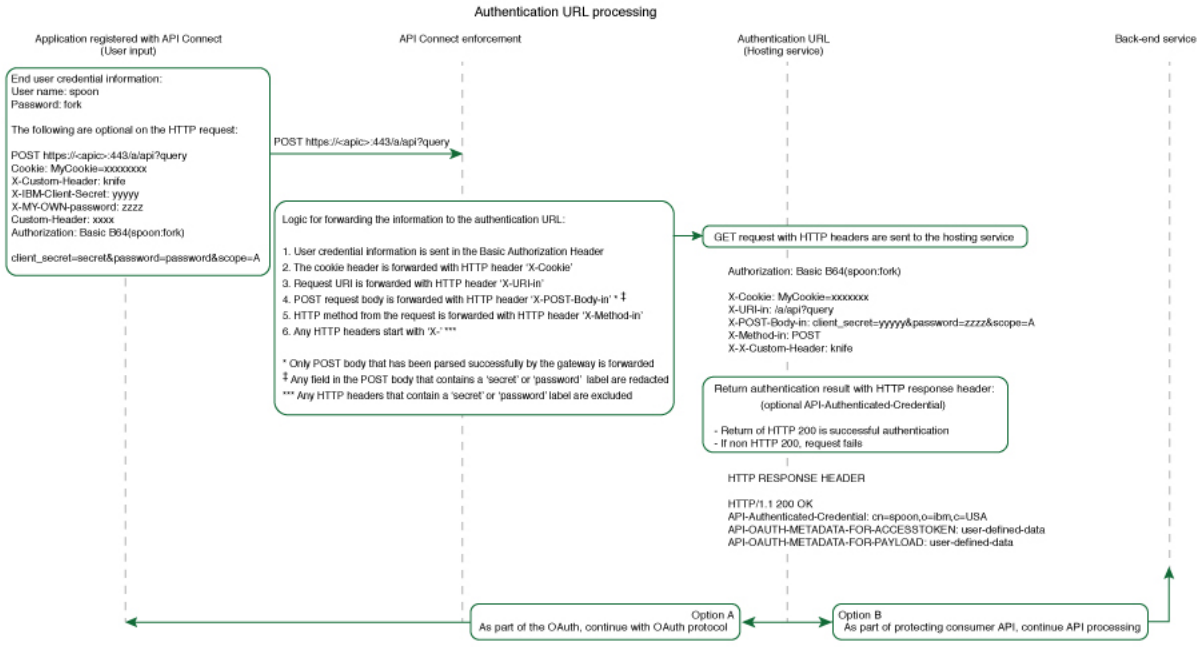
When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect uses **`cn=spoon,o=eatery`** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.



API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested **`scope`** from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

About this task

The Native OAuth provider configuration provides the capability for requiring another authentication and authorization steps for user security. Custom HTML forms can be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- **Creating a custom HTML login form for user security**
  Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- **Creating a custom HTML authorization form for user security**
  Custom HTML forms can be created for user security during the authorization stage in OAuth.

Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. For more information, see Configuring a native OAuth provider. This topic describes how to create the Custom HTML form for identity extraction.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. API Connect parses a well-formed XHTML document to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example,

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.
   For example,

   ```
   <button
   id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_bu
   tton" type="submit" name="login" value="true">Log in</button>
   ```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing steps 1 through to 8 results in a form similar to the following example:

    ```
    <html lang="en" xml:lang="en">
      <head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>
      <body>
        <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
          <h1>Please sign in</h1>
          <p>Username </p>
          <p ><input type="text" name="username" required="required" /> </p>
          <p>Password </p>
          <p ><input type="password" name="password" required="required" /> </p>
          <EI-INJECT-HIDDEN-INPUT-FIELDS/>
          <p > <button
    id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_bu
    tton" type="submit" name="login" value="true">Log in</button> </p>

          <EI-LOGINFIRSTTIME>
            <p>If you have forgotten your user name or password, contact your system administrator.</p>
    ```

```
      </EI-LOGINFIRSTTIME>

      <EI-LOGINFAILED>
        <p >At least one of your entries does not match our records.
          If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFAILED>

      <EI-INTERNAL-CUSTOM-FORM-ERROR/>

    </form>
  </body>
</html>
```

11. Make your form available at a URL of your choice.
12. If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Related tasks

- Creating a custom HTML authorization form for user security

Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You can select how to authorize application users and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. This topic describes how to create the custom HTML form for authorization.

About this task

In three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user grants permission to an application to access their data through an authorization form. You can present a custom form or a default form. Your custom form must fulfill certain requirements.
Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

1. Create a well-formed XHTML document. This is parsed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example,

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Add the line `<AZ-INJECT-HIDDEN-INPUT-FIELDS/>`. This line is a placeholder that API Connect replaces with input fields necessary for the completion of the OAuth process.
4. Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

   ```
   <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
   <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
   ```

5. Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<AZ-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the user.
6. Optional: You can add to the form HTML elements that load features from external sources, such as images or JavaScript.
   For example, `<script src="http://www.example.com/example.js" />`
7. Insert spacing and extra elements as you require. Completing steps 1 through to 6 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><title>Request for permission</title></head>
  <body class="customconsent">
    <div>
      <div>
        <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
          <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
          <p>Greeting..</p><DISPLAY-RESOURCE-OWNER/>
          <p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
          <div>
            <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
            <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
          </div>
        </form>
      </div>
      <AZ-INTERNAL-CUSTOM-FORM-ERROR/>
    </div>
  </body>
</html>
```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a custom HTML form for authorization for user security. Provide the URL as the endpoint at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Related tasks

- Creating a custom HTML login form for user security

Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM® API Connect.

About this task

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the **jwt-generate** command, and then augment the response payload with your generated token replacing the `id` token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

Procedure

Create a **jwt-generate** policy in the assembly.

a. In API Manager, open the Assembly tab.
b. Add a jwt-generate policy to the assembly for the API.

Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

You can use the following links to go to the topics:

- OAuth 2.0 support in the Developer Portal test tool
- OAuth requires quorum in a multi-node cluster

OAuth 2.0 support in the Developer Portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see Testing an API using the Developer Portal test tool.

OAuth requires quorum in a multi-node cluster

In a multinode cluster, OAuth operation fails if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

Configuring the cloud settings

Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.

The cloud settings let you define basic configuration for your deployment. To view the current settings, log in to Cloud Manager and click  in the navigation pane.

Tip: When you are familiar with the cloud settings, you can modify them using the Toolkit command-line interface instead of the user interface.
Visit the following pages to configure settings:

Overview
: Provide a title and description for your cloud administrator organization. For more information, see Change the name of your cloud.

Onboarding
: Specify time-out settings for onboarding invitations, password resets, access tokens, and refresh tokens. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
For more information on setting timeouts, see the following topics:

  - Configuring invitation timeouts
  - Configuring the password-reset notification and timeout
  - Configuring timeouts for access tokens and refresh tokens

User Registries

Configure one or more user registries to authenticate users of Cloud Manager or API Manager. The user credentials for all users who login to each applications must be stored in the specified registries. For more information on configuring user registries, see Selecting user registries for Cloud Manager and API Manager.

Roles
: Create roles and assign them to members of the Admin organization to specify which tasks members are authorized to perform. For more information on assigning roles, see Administering members and roles.

Role Defaults
: The Role Defaults for the Admin organization are not configurable, but you can customize the base roles for provider organizations and consumer organizations. For more information on customizing base roles, see Role Defaults overview.

Endpoints
: View the list of endpoints configured for API Manager, provider APIs, and consumer APIs during the installation process.

Notifications
: Select the email server for your on-premises cloud notifications, configure notification settings, and specify the sender name and email address to be included in the emails. You can also preview and customize email templates used for notifications. For more information on setting up notifications, see Setting up notifications. Note: Be sure to configure the email server, because it is needed for sending invitations and other notifications to users.

Catalog Defaults
: Specify one or more gateway services to be provided to every Catalog by default, so that Products (which contain APIs) can be made available to users. When a new Catalog is created in a provider organization, it is assigned to the default gateway service. Any changes you make to these settings do not affect existing Catalogs. For more information on selecting gateway services, see Configuring the default gateway services for Catalogs.

Audit Setting
: Configure auditing settings to monitor API calls and log information about the calling users, the time of each call, and the activity involved in each event. The audit focuses on "who" did "what" and "when", including the request payload and the result of the operation. All create, update, and delete operations are audited. Generally, read operations are only audited if the calling user logged in with an OIDC Provider user registry. For more information about configuring the use of auditing, see Configuring audit logging to monitor user operations.

Use the following list to locate instructions for using specific cloud settings:

- **Change the name of your cloud**
  You can change the name of your cloud.
- **Configuring an email server for notifications**
  Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.
- **Setting up notifications**
  Select an email server and set up the "sent from" information for notifications.
- **Configuring invitation timeouts**
  You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.
- **Configuring API key settings**
  You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.
- **Using the CLI to modify cloud settings**
  Use the toolkit CLI to edit the cloud settings.
- **Configuring Base64 encoding for temporary tokens**
  How to enable and disable Base64 encoding for temporary tokens.
- **Configuring the password-reset notification and timeout**
  Configure the time allowed for a user to reset a password, and customize the notification that the user receives.
- **Selecting user registries for Cloud Manager and API Manager**
  Select the user registries to authenticate users for Cloud Manager and API Manager.
- **Configuring timeouts for access tokens and refresh tokens**
  Configure timeout values for the access tokens and refresh tokens for user registries.
- **Viewing platform and UI endpoints**
  A view-only list of platform and UI endpoints is provided.
- **Configuring the default gateway services for Catalogs**
  Configure the list of default gateway services that are available to new Catalogs.
- **Managing the public/private key pairs for signing tokens**
  Manage the public/private key pairs that are used for signing tokens in API Connects.

Change the name of your cloud

You can change the name of your cloud.

About this task

You can change the name of your cloud using the Overview page.

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage`

Procedure

Follow these steps to change the name of your cloud:

1. In the Cloud Manager, click  Settings.
2. Select Overview..
3. Click Edit to change the name of your cloud.
4. Enter a Title and the name is auto-generated. Enter a brief Summary and click Save.

Configuring an email server for notifications

Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.

Before you begin

You must complete the tasks in the following section:

1. Defining your Cloud Manager topology

About this task

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Topology Administrator
- Custom role with `Settings:Manage` permission

The email server sends invitation emails with activation links and other system messages. More than one email server may be configured in Cloud Manager, but only one email server may be selected as the active server to send notifications at any one time. For instructions on how to select the active email server and to view a list of the email messages that are sent, see Setting up notifications.
Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

To configure one or more email servers to use for email notifications in Cloud Manager, complete the following steps:

1. In the Cloud Manager, click Resources.
2. Choose Notifications.
3. Enter the values to configure the email server.

Field	Description
Title (required)	Enter a descriptive title for the email server. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Address (required)	IP address for the email server
Port (required)	Port that the email server runs on
Authenticate User	Enter a user name to use for authorization with the SMTP server. The user name is required if the SMTP server requires authentication.
Authenticate Password	Enter the password for the Authenticate User. This password is used for authorization with the SMTP server. The password is required if the SMTP server requires authentication.
TLS Client Profile (optional)	Select an optional TLS Client Profile that will be used to communicate with the email server if the Secure Connection option is selected.
Secure Connection	Select this option to specify that TLS security is used. The following conditions apply: • If this option is not selected then TLS security is not used even if the email server is configured to use the STARTTLS protocol. • If this option is selected and a TLS Client Profile is selected, that profile is used and the STARTTLS protocol configuration on the email server is honored. • If this option is selected and no TLS Client Profile is selected, the Default TLS client profile is used and the STARTTLS protocol configuration on the email server is honored.

4. You can send a test email to confirm that the email server is properly configured. Click Test email in the Test Connection page to open a dialog window. Enter one or more valid email addresses in the Recipients field. Separate multiple recipients with commas. Click Send test email. Check that the test email was received by the recipients.
5. If the test email is successful, click Save to save the email server configuration. If the test is unsuccessful, check the configuration values and update as needed.
   Note: In order to send emails, you must select an email server as your active server in Settings > Notifications.

Results

The email server is configured.

What to do next

You must now select the email server to use as your active email server in Cloud Settings > Notifications. You can enter the sender information, and customize the email templates. For more information, see Setting up notifications.
Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Setting up notifications

Select an email server and set up the "sent from" information for notifications.

Before you begin

You must configure an email server to use for your notifications in Resources > Notifications, before you can set up the notification configuration in Settings > Notifications. See Configuring an email server for notifications for more information.

About this task

In Settings > Notifications, you select the email server that you want to use as the active server to send notification emails. An active email server is required to send email notifications. More than one email server may be configured in Cloud Manager, but only one email server may be selected to send notifications at any one time. The email server must be configured and selected for notifications before adding a Portal Service to your cloud.

You also configure the sender information to be included on all the emails and optionally, edit the standard text for the email templates.

One of the following roles is required to add roles to select the email server, enter the sender information, and edit the email templates:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Notifications.
3. To configure the active email server:
   a. Click Edit in the Sender & Email Server section.
   b. Select an email server in the list; a check mark is displayed next to the currently selected server.
   c. Click Save.
4. To delete an email server from the list, click the options menu next to the server name and select Delete.
5. To change the sender name and email address for notifications:
   a. Click Edit in the Sender & Email Server section.
   b. Fill in the Name and Email address that notifications will be sent from.
   c. Click Save.
6. To preview and edit the notification email templates, see Customizing email notification templates

What to do next

You can now create a provider organization.

- **Customizing email notification templates**
  API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

Customizing email notification templates

API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

About this task

The API Connect emails are sent automatically when certain system events occur. The email templates are organized by scope, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
admin	Admin organization activities such as invitations, portal sign up, and password reset.
catalog	Activities related to Catalogs; for example: such as application life cycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations
space	Invitations

Email notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see Configuring sender details for email notifications in the Managing your APIs section.

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: You can also customize notifications by using the developer toolkit CLI, or by using the API Connect REST APIs. See Using the CLI to modify cloud settings, or API Connect REST APIs, for more information.
If you want to configure the notifications at the Provider Organization level, see Configuring notifications in the Managing your APIs section.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Notifications.
   On the Notifications page, templates display in a list, sorted by scope. When selecting a template to modify, be sure to select the version that applies to the appropriate scope.

3. To preview the text for a template, select Preview from the actions menu next to the template name.
4. To edit the text for the template, either click the template name, or select Edit in the action menu.
   When a template is opened, an attempt is made to get the language from the browser setting, but if this isn't possible the template defaults to English.

   The text includes variables; for example, **{{catalog}}**. The notification text is based on Handlebars syntax. Most variables are enclosed in double curly braces **{{ }}**, but can be enclosed in triple curly braces **{{{ }}}** to disable HTML escaping, when the variable is a URL link for example. For more information on Handlebars, see https://handlebarsjs.com/.

   To obtain the complete list of variables that are available for a particular notification template, complete the following steps:
   a. Log in to the management server from the command line as a member of the cloud administration organization; for details, see Logging in to a management server. You can use the same management server URL, user name, and password in the login command that you use to log in to the Cloud Manager user interface.
   b. Enter the following command:

   ```
   apic notification-templates:get template_name --server mgmt_endpoint_url --scope cloud --subcollection template_scope
   --fields variables --output -
   ```

   where:
   - *template_name* is the name of the required notification template, as displayed in the Template column in the user interface.
   - *template_scope* is the scope name displayed in the Scope column alongside that template.

   For example:

   ```
   apic notification-templates:get member-invitation --server https://myserver.com --scope cloud --subcollection catalog
   --fields variables --output -
   ```

   The variables that are available for the template are displayed, for example:

   ```
   variables:
     - org
     - catalog
     - activationLink
     - expiresAt
     - originator
     - originatorFirstName
     - originatorLastName
     - originatorEmail
     - username
     - email
     - firstName
     - lastName
   ```

   The **--output -** parameter causes the command output to be written to the command line. You can specify **--output** ***filepath*** to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.

5. To view and edit the notification template in a different language, select one of the following supported languages from the View template in drop-down list:
   - Chinese (Simplified)
   - Chinese (Traditional)
   - Czech
   - Dutch
   - English (US English)
   - French
   - German
   - Italian
   - Japanese
   - Korean
   - Polish
   - Portuguese
   - Russian
   - Spanish
   - Turkish
6. Edit the Subject as required.
7. Select the Content type that you want to use for the template, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
8. Edit the body of the template as required.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 2. List of allowed HTML tags and their attributes

HTML tag	Attribute
<a>	"class", "href", "hreflang", "style"
	"class", "style"
	"class", "style"
<cite>	"class", "style"
<blockquote>	"class", "cite", "style"

HTML tag	Attribute
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **`<img src="https://path/to/image.png"/>`** tag in the template. The **`src`** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

9. Click Save when done.
   Note: Edits made to a template are saved only for the specific language version that is edited.

Related information

- Configuring notifications

Configuring invitation timeouts

You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.

About this task

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

Follow these steps to set the invitation timeout:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the invitation timeout setting that you want to change:
   - Cloud Settings Invitation Timeout
   - Admin Organization Invitation Timeout
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
5. Click Save.

Results

Invitations contain a link, which expires after the specified the timeout. If the user does not register before the expiration, you can send a new invitation.

Configuring API key settings

You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.

About this task

Applications exchange the API key exchange the API key for an access token.

Procedure

Follow these steps to set the API key timeout:

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the API Key timeout setting.
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   Note: The default timeout value is 5 minutes.
5. Select Multiple use of apikey to allow applications to exchange the API key for an access token multiple times.
   By default, this option is enabled.

   Note: For the toolkit, the API key is a single-use key, regardless of the settings Multiple use of apikey .
   To enable this setting with the CLI, set the **`api_key_multiple_uses`** field to **`true`**.

6. Click Save.

Results

API Key times out based on the set timeout value.

Using the CLI to modify cloud settings

Use the toolkit CLI to edit the cloud settings.

About this task

Some cloud settings can be modified in the Cloud Manager UI, but all settings can be modified with the toolkit CLI. You can modify the cloud settings configuration file and upload the changes, or issue commands to modify individual settings directly. If multiple people modify the cloud settings, any newer settings overwrite older settings regardless of the method used to update the settings.

For more information about working with the toolkit CLI, see the toolkit CLI reference documentation.

Procedure

1. Run the following command to log in to a management server as a member of the cloud administration organization:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **`default-idp-1`**.
   For more information on logging in, see Logging in to a management server.

2. Optionally retrieve the current list of cloud settings with the following command:

   ```
   apic cloud-settings:get --server mgmt_endpoint_url --output -
   ```

   where *mgmt_endpoint_url* is the URL of the server where the cloud settings are stored.

3. Add or modify settings using one of the following methods:
   - Issue each setting from the command line.
     For simple changes, you can issue commands to modify settings without editing the configuration file.

     - Issue the following command to start the update process:

       ```
       apic cloud-settings:update --server mgmt_endpoint_url -
       ```

       where *mgmt_endpoint_url* is the URL of the server where the cloud settings are stored. Include the hyphen at the end of the command to indicate that input follows on the next command line.

     - Type the information for a single setting on one line, and press ENTER to submit it.
       Specify each setting on a single line and use the following format to specify the setting's name and value:

```
setting_name: setting_value
```

For example, the following command updates a single setting:

```
apic cloud-settings:update --server mgmt_endpoint_url -
refresh_expires_in: expiration time
Ctrl+D
```

- Type Ctrl+D to indicate that the data entry is complete, as shown in the example.

- Upload a file containing the settings.
  If you have multiple settings or lengthy values to add or modify, you might prefer to make all of the changes at once by creating or modifying the configuration file and then uploading it.

  - Create a .yaml file with your settings.
    You can choose the file name but must use YAML format. The file can contain as few or as many settings as needed.

    Settings use the following format; notice that the setting's name must be enclosed in quotation marks as shown in the example. The last setting in the file does not end with a comma.

    ```
    "setting_name": setting_value,
    ```

  - Upload the file with the following command:

    ```
    apic cloud-settings:update --server mgmt_endpoint_url my_cloud_settings.yaml
    ```

  For information on using input files with the toolkit CLI, see ../com.ibm.apic.toolkit.doc/rapic_cli_command_line_input.html.

4. When you are ready to log out of the management server, use the following command:

   ```
   apic logout --server mgmt_endpoint_url
   ```

Results

The settings are cached for a maximum of five minutes, so you might experience a delay before your changes take effect.

Configuring Base64 encoding for temporary tokens

How to enable and disable Base64 encoding for temporary tokens.

About this task

You can enable or disable Base64 encoding for temporary tokens. Temporary tokens are invitations, and password reset tokens. When Base64 encoding is enabled, the temporary token is encoded in Base64 format. When Base64 encoding is disabled, the temporary token remains in the JSON Web Token (JWT) format, and means that the length of the URL that the user receives is reduced.

Base64 encoding is enabled by default.

One of the following roles is required to configure Base64 encoding:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

Follow these steps to configure Base64 encoding for temporary tokens:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the Base64 encoding setting.
4. Select Enable to enable Base64 encoding, or Disable to keep temporary tokens in the JSON Web Token (JWT) format.
5. Click Save.

Results

You have successfully enabled or disabled Base64 encoding for temporary tokens.

Configuring the password-reset notification and timeout

Configure the time allowed for a user to reset a password, and customize the notification that the user receives.

Before you begin

Configure an email server that can be used for mailing notifications to users. If you do not configure an email server, a link cannot be send to a user who wants to reset a password. For information on configuring the email server, see Setting up notifications.

About this task

When a user clicks Forgot Password? and provides an email address on the sign-in page, an email is generated with a link where the user can reset the password. When you deploy API Connect, the password-reset settings are configured with default values. You can optionally modify the time-out setting to set a new expiration for resets as well as the notification that is emailed to users.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Configure the password reset timeout:
   a. In the Settings navigation list, click Onboarding.
   b. Click Edit next to Reset Password Time to Live.
   c. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   d. Click Save.
4. Customize the notification template for password resets:
   a. In the Settings navigation list, click Notifications.
   b. In the Notifications Templates list, select the appropriate version of the "password-reset" template by clicking the name.
   You can create different versions of the template for different user roles.
   c. Customize the template as explained in Customizing email notification templates.
   d. Click Save.

Results

Password reset notifications contain a link, which expires after the specified the timeout. If the user does not reset the password before the link expires, they can request a new link.

Selecting user registries for Cloud Manager and API Manager

Select the user registries to authenticate users for Cloud Manager and API Manager.

About this task

In Settings > User registries, you select one or more user registries to authenticate users of Cloud Manager and API Manager. The user credentials for all users who login to the applications must be stored in the selected registries.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

For details on how to control which user registries can be used by provider organizations for authenticating Developer Portal users, or for securing APIs, see Setting visibility for a user registry.

Procedure

To select the user registries for Cloud Manager and API Manager, follow these steps:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click User Registries.
3. The current list of user registries is displayed for Cloud Manager and for API Manager. To add user registries, click Edit in either the Cloud Manager or API Manager panel.
   Note: The list of user registries is derived from the user registries that were previously configured as a Resource in Resources > User Registries. For more information, see User registries overview
4. Select the user registry by placing a check mark next to the name in the list. Remove a user registry by removing the check mark.
5. Click Save.

Results

The user registry list is updated to reflect the selected user registries available for authenticating users.

What to do next

To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.

- **Setting a default user registry for Cloud Manager and API Manager**
  You can select a default user registry for Cloud Manager and and for API Manager.

Related tasks

- Configuring an LDAP user registry in the Cloud Manager

- Configuring an Authentication URL user registry
- Configuring a Local User Registry

Setting a default user registry for Cloud Manager and API Manager

You can select a default user registry for Cloud Manager and and for API Manager.

About this task

In Settings > User registries, you can set a user registry as the default user registry.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click User Registries.
3. To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.
   Note: The list of user registries is derived from the user registries that were previously configured as resources in Resources > User Registries. For more information, see User registries overview

Results

The user registry list is updated to reflect the default user registry.

Related tasks

- Configuring an LDAP user registry in the Cloud Manager
- Configuring an Authentication URL user registry
- Configuring a Local User Registry

Configuring timeouts for access tokens and refresh tokens

Configure timeout values for the access tokens and refresh tokens for user registries.

About this task

IBM® API Connect supports the use of access tokens and refresh tokens for user registries that authenticate users of the Cloud Manager, the API Manager, and the Developer Portal.

Access tokens allow users to sign in and remain logged in for a specified amount of time (the timeout period). Refresh tokens allow the access token to be renewed automatically without requiring the user to sign in again. Access tokens are configured by default, and you can modify the timeout setting. Refresh tokens are disabled by default but are configured with a default timeout when you enable them.

Refresh tokens, when enabled, are generated every time an access token is created. Refresh tokens can be used to obtain a new access token without having to prompt a user to re-login. If you enable the use of refresh tokens, then when the token expires it is refreshed automatically in the background so that the user can continue working without interruption. When the user logs out, the refresh token is revoked and the application can no longer use it.

Note: If users log in with non-OIDC user registries, the use of refresh tokens is supported in API Manager, API Designer, the Developer Portal, and the CLI Toolkit. When the refresh token expires, the user is always redirected to the login page.
If users log in with OIDC user registries:

- If the OIDC providers do not support refresh tokens, API Connect will not issue a refresh_token, regardless of the setting of `refresh_token_enabled` in the cloud settings.
- For more information about OIDC configuration, see Configuring an OIDC user registry in Cloud Manager.

You can configure access tokens and refresh tokens using the Cloud Manager UI, or the Toolkit CLI.

Using the UI to configure tokens

Configure timeout settings for access tokens and refresh tokens in the Cloud Manager Settings pages.

Procedure

1. Click in the navigation pane.
2. Configure the timeout for access tokens:
   a. On the Onboarding page, click Edit next to Access Token Time to Live.
   b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.

c. Click Save.

3. Configure the timeout for refresh tokens:
   a. On the Onboarding page, click Edit next to Refresh Token Time to Live.
   b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   c. Click Save.

Using the CLI to configure tokens

Use the Toolkit CLI to configure timeout settings for access tokens and refresh tokens.

About this task

Use the following properties to specify refresh tokens for cloud settings:

- **`access_token_expires_in`**
  Integer. Represents the expiration time, in seconds, for access tokens issued by API Connect.
- **`refresh_expires_in`**
  Integer. Represents the expiration time, in seconds, for refresh tokens issued by API Connect. Must be greater than **`access_token_expires_in`**.
- **`refresh_token_enabled`**
  Boolean. Disabled by default. To enable, set to **`true`**. When enabled, generates a **`refresh_token`** field in the response to the **`/token`** API call.

The following extract from a cloud settings file shows example settings for these properties:

```
"type": "cloud_setting",
"api_version": "2.0.0",
"name": "cloud-setting",
"access_token_expires_in": 28800,
.
.
.
"refresh_expires_in": 57600,
"refresh_token_enabled": false,
.
.
.
```

Use the toolkit CLI (**`apic`**) to update the cloud settings with new values for the properties. You can either specify values as command line arguments, or enter them manually in a configuration file as explained in Using the CLI to modify cloud settings.

Viewing platform and UI endpoints

A view-only list of platform and UI endpoints is provided.

About this task

You can view the list of endpoints configured during the installation process. Included in this view-only list are the following endpoints:

- API Manager URL - the URL for opening the API Manager UI
- Platform REST API endpoint for the Admin and Provider REST APIs - this endpoint handles the REST APIs for Admin and Provider functions.
- Platform REST API endpoint for consumer REST APIs - this endpoint handles the REST APIs for consumer (Portal) functions.

One of the following roles is required to view endpoints:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` or `cloud-settings: view` permissions

Procedure

To view the endpoints, follow these steps:

1. In the Cloud Manager, click  Settings.
2. Select Endpoints.
3. View the list of endpoints.

Configuring the default gateway services for Catalogs

Configure the list of default gateway services that are available to new Catalogs.

About this task

One of the following roles is required to configure Catalog Defaults:

- Administrator
- Owner

- A custom role with the `cloud settings:manage` permission

You publish APIs by adding them to a product and then publishing the product to a catalog. To be able to publish products to a catalog, the catalog must be assigned to at least one gateway service so that the APIs in the product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a catalog, and they can be of mixed types, DataPower® API Gateway and DataPower Gateway (v5 compatible).

A product is gateway type specific, either DataPower API Gateway or DataPower Gateway (v5 compatible). By default, when you publish a product to a catalog, it is published to all the assigned gateway services of the same gateway type as the product, but you can choose to publish the product only to selected gateway services, of that type, at publish time; see Publishing a draft product for more information. The APIs in the product are available to be called at all the specified gateway service endpoints.

The procedure described in this topic specifies the gateway services that are assigned by default to newly created catalogs, but you can change the assigned gateway services for a specific catalog; see Creating and configuring catalogs.

Procedure

To configure the gateway services that are assigned to new Catalogs by default, complete the following steps:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Catalog Defaults.
3. Click Edit to change the list of default gateway services.
4. Select the required gateway services, then click Save.

Results

When a new Catalog is created in a provider organization, the default gateway services are automatically assigned to it. Any changes you make to the list of default services affects only the Catalogs that are created after you save your changes. Existing Catalogs are not affected.

Managing the public/private key pairs for signing tokens

Manage the public/private key pairs that are used for signing tokens in API Connects.

API Connect uses public-key cryptography to secure tokens. By default, an API Connect deployment receives one public/private key pair, which is used for signing and verifying tokens. When a token is created, API Connect signs it with the deployment's private key. Any third-party can verify that digital signature with the deployment's public key.

The public/private key pair is generated for you by API Connect on the first start-up after installation, upgrade, or migration. The keys are stored in a keystore object.

Why do you need public/private key pairs?

API Connect uses a public/private key pair to sign and verify the following tokens:

- access_token: Verifies that the user has permission to access resources.
- id_token: Stored within the access token to specifies the user's ID.***Confirm?***
- temporary_token: Provides for short-lived access so that the user can log in and receive an access token. For example, when the user receives a link for resetting a password or to register for an account.

How does APIC use the public/private key pair?

Each API Connect deployment is assigned a public key, which is made openly available, plus a corresponding private key, which can only be accessed by that deployment. To verify a user's access to resources for a transaction, API Connect signs every token with the private key. Any other party can use the openly available public key to verify the signature. Because the private key is not shared, it can be used repeatedly instead of generating a new value for each signature.

When your app accesses an API endpoint, the access_token is in JWT format and includes a 'kid" value that is the new key.

Note: The signature for public/private key schema is larger than for shared secrets, so the access_token that is returned will also be larger. If you encounter issues with headers becoming too large, refer to the following topic: Resolving login problems by increasing HTTP header size.

How can you manage public/private key pairs?

By default, your deployment is assigned one key pair, which is stored in a keystore and never expires. The same key pair is used for signing and verify all tokens. The key pair consists of a public key and a private key:

- key_signing: The private key that API Connect uses for signing tokens
- key_verify: The public key that anyone can access and use for verifying token signatures

API Connect uses the following cloud settings to determine which public/private keystores are used for each type of token:

- access_token_keystore_urls: [*keystore_url_0, keystore_url_n*]
- id_token _keystore_urls: [*keystore_url_0, keystore_url_n*]
- temporary_token _keystore_urls: [*keystore_url_0, keystore_url_n*]

Each setting specifies an array of URLs where the keystores are hosted, with the keystore at position 0 representing the current key pair. You can optionally generate additional key pairs, store them in new keystores, and use them with the tokens to enhance security. Each key pair is stored in its own keystore and can be set to expire at a different time. Providing a different key pair for each type of token is a good practice because it limits the damage if a token is compromised.

If you specify one keystore for a token, that key pair is used for every new token of the same type, and it never expires. If you specify multiple keystores, you can assign a lifetime to each and when the keys in the first keystore expire, the keys are obtained from the next keystore in the list, and so on.

You can use the public/private key pairs and keystores to perform the following operations with tokens:

Sign a token
: The first keystore in the array is the current keystore; use its key_signing key to sign tokens.

Verify a token's signature
: To verify a token's signature, start with the current keystore (the first in the array). If the token doesn't match the key_verify key, move to the older keystores and compare the token with the key_verify value in each.

Add key pairs
: When you create a new key pair, add the keys to a separate keystore, and then add that keystore's URL to the end of the token's keystore array. The first keystore in the array is the "current" keystore, and subsequent keystores in the array are used in turn.

Revoke key pairs
: If you suspect that a token is compromised, you can revoke they keys for signing and verifying it. To revoke a key pair, delete the corresponding keystore from the token's keystore array. Removing a keystore removes the keys that were used for signing and verifying tokens, and invalidates all of the tokens that were issued with that key pair.
: Attention: You must always retain at least one key pair for signing and verifying tokens.

Rotate through keystores to periodically change the key pairs in use
: To rotate through key pairs for a token, configure at least two keystores for the token. Specify the "current" keystore first in the array, followed by the "next" keystores. Make sure that the each keystore's lifetime overlaps that of the next keystore so that keys from the current keystore don't expire before the new key pair takes effect.
: Before you configure the lifetime for a keystore, you can refer to the Onboarding section of the Cloud Settings page to quickly see the lifetime that is configured for each type of token. Then make sure you specify enough keystores, with long enough lifetimes, to span each token's lifetime. For example, if the temporary_token lives for 72 hours and the key used for signing it lives for 24 hours, you need to provide at least 3 sets of keys to span the token's lifetime:

: temporary_token: [keystore1, keystore2, keystore3]

- **Configuring public/private key pairs for tokens**
  Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

Configuring public/private key pairs for tokens

Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

About this task

By default, an API Connect deployment receives one public/private key pair, which is used repeatedly. The public/private key pair is generated for you the first time you start API Connect after installing or upgrading it. The keys are stored in a keystore object. You can add and revoke keys, and configure a rotation through keys for enhanced security.

You can configure key pairs for tokens in the Cloud Manager user interface, or by using the Toolkit CLI.

Using the Cloud Manager UI to configure public/private key pairs

Use the Cloud Manager user interface to configure key pairs for signing and verifying tokens.

About this task

Manage Keystore assignment and Keystore history for tokens

Procedure

1. In the Cloud Manager, click  .
2. In the Settings navigation list, click Signed Token.
   The Signed Token page displays the list of supported tokens for signing.
3. Review the current token settings:
   - Click Payload to display the payload code for the set of tokens.
   - Click History log next to a token to view its previous keystore assignments (this history never includes the current keystore assignment). The most recent assignment displays at the top of the list. You can remove any keystore assignment from the history by clicking  .
4. To add or change a keystore assignment for a token, complete the following steps:
   a. On the Signed Token page, click Edit.
   b. On the Edit signed token page, select a keystore for the token you want to modify.
   c. Click Save to save your changes and update the keystore history.
      Changes take effect immediately.

      The previously selected keystore is added to the history for the token that you just updated. The history never includes the current keystore assignment.

Using the Toolkit CLI to configure public/private key pairs

Use the Toolkit CLI to configure key pairs for signing and verifying tokens.

About this task

Use the following properties to the keystore URLs that contain the public/private key pair for each type of token. For each setting, the list of keystores is an array of strings, with each string representing the complete URL of a keystore. The first keystore in the array (*keystore_url_0*) is the one that is currently in use.

- access_token:

  ```
  access_token_keystore_urls: [keystore_url_0, keystore_url_n]
  ```

- id_token:

  ```
  id_token_keystore_urls: [keystore_url_0, keystore_url_n]
  ```

- temporary_token:

  ```
  temporary_token_keystore_urls: [keystore_url_0, keystore_url_n]
  ```

The keystore URLs can be lengthy. You can avoid errors by writing the settings in a file and uploading that file. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example configures a different keystore for each type of token:

```
access_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/de5298dd-a00b-45a0-9d08-96c5d93e1273
id_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/85a21745-8ac3-499d-929a-2d017bade815
temporary_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/63d6462f-c93d-439b-b422-0e604381e97a
```

Procedure

1. Create a YAML file with the keystore settings for each type of token as shown in the example.
   For information on using input files with the toolkit CLI, see Reading input from the command line.

2. Run the following command to log in to a management server as a member of the cloud administration organization:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For more information on logging in, see Logging in to a management server.

3. Upload the YAML file with the new settings by running the following command:

   ```
   apic cloud-settings:update --server mgmt_endpoint_url my_token_keystore_settings.yaml
   ```

4. Run the following command to log out of the management server:

   ```
   apic logout --server mgmt_endpoint_url
   ```

Configuring governance in the Cloud Manager

How to add governance rulesets in the Cloud Manager to validate and enforce organizational governance policies and best practices across your API development process.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. For more information, see Enabling governance on Kubernetes for more information. If governance is enabled in your deployment, the Governance icon  is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

The governance service is available to all user roles.

About this task

The governance service is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. You configure governance by creating one or more custom rulesets that contain a collection of rules that can then be used to check Swagger, OpenAPI, and AsyncAPI documents, as well as product documents. The governance service contains the following types of rulesets:

API

- Global rulesets - these are custom rulesets that you can keep private, or you can make available to some or all of your provider organizations for validating APIs.
- Default rulesets - these are default rulesets that are built-in to API Connect, and contain pre-configured rules that are available to all of your provider organizations for validating APIs, and cannot be edited.

Product

- Global rulesets - these are custom rulesets that you can keep private, or you can make available to some or all of your provider organizations for validating products.

The governance service is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Tags can be added to API rulesets that, when matched with the same tag in an API, help ensure that the appropriate rulesets are preselected for your validation scans. In this way, the governance process can be run more quickly and effectively. These preselected rulesets can be deselected from the scan if required.

Note:

- Governance in API Connect supports the creation of custom rulesets that contain rules that use only the built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions. The use of custom functions, for example rules that use functions that you created yourself in JavaScript files, is not supported. Also note that the following Spectral OpenAPI rules aren't supported as they might identify false positives:
  - `oas2-unused-definition`
  - `oas3-unused-component`
- Some of the Spectral rules within the Default rulesets contain the property `recommended: false`, which means that those rules are ignored during validation. However, if you create a new ruleset from one of these rulesets by using the Save as new ruleset option, the `recommended` property isn't transferred to the new ruleset. Therefore, all the rules are used in the validation, unless you delete those rules from the ruleset. The Spectral ruleset names are prefixed with spectral-.
- Dereferencing, which means not introspecting a referenced definition within an API, is not supported in the governance service. Instead, a referenced object can be explicitly validated by using custom rules.
- You can also configure governance rulesets directly in a provider organization. For more information, see Configuring governance in the API Manager.

You can configure both API and product rulesets by using the following methods:

- Create a new ruleset by using the UI
- Import a ruleset
- Create a ruleset by using the CLI

Procedure

- To create a new API or product ruleset by using the Cloud Manager UI, complete the following steps.

1. In the side menu bar, click  Governance.
   The Governance page is displayed.
2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
   The manage rulesets page is displayed.
3. In the Global rulesets section, click Add > Create from scratch.
   The Create ruleset wizard opens.
4. Provide the following Ruleset info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the ruleset. This name is displayed in the list of global rulesets.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Version	Yes	The version number defaults to 1.0.0, but can be edited. You can have rulesets with the same name, but with different version numbers. The version number must be in the format `major.minor.patch`.	String
Description	No	An optional description of the ruleset.	String

5. Optional: For API rulesets, you can add one or more tags to your ruleset by clicking Add, and completing the tag Name and Description.
   Adding matching tags to your rulesets and APIs, means that validation scans can preselect which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For more information about how to add tags to APIs, see Adding tags to an API.
6. Click Next, and add an initial rule to your ruleset.
7. Provide the following Rule info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the rule.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Description	Yes	A description of the rule.	String
Message	No	Provide a message to help users understand what the goal of the rule is. If no message is provided, the value of the Description property is used for the message output of the validation scan.	String
Severity	Yes	Select a severity level from the following options: • error • warn • info • hint • off error is selected by default.	String

8. In the Given section, specify one or more values for the parts of the API or product document to target. To add more values, click Add. Values must be written in JSONPath.
9. In the Then section, specify the function type and options that will be used to evaluate the target values in the API or product document. Write this section in YAML syntax.
   In the following API rule example, for a Given value of **$** (which means root level of the document), the Then section uses the Spectral core **truthy** function to check that the **info.contact** property value is not **false**, **""**, **0**, **null**, or **undefined**.

   ```
   - field: info.contact
     function: truthy
   ```

   The Then section can also contain a list of functions to be applied to the Given part of the document. In the following API rule example, for a Given value of **$.info.version** (which refers to the **version** property inside the **info** property at the root level of the document), the Then section uses both the **truthy** function, and the Spectral core **pattern** function that checks that the **info.value** matches the regex expression that is given by **functionOptions.match**.

   ```
   - function: truthy
   - function: pattern
     functionOptions:
       match: "^[0-9]+.[0-9]+.[0-9]+(-[a-z0-9+.-]+)?"
   ```

   For a complete list of the Spectral core functions that you can use in your custom API rules, along with examples of these functions, see https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
10. Click Create to create your draft ruleset.
    Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon .
11. You now have the following options:
    - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon alongside Rules in the navigation pane. Remember to click Save when you finish editing.
    - If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the Governance overview page.

- To import an existing API or product ruleset, complete the following steps. Remember that for API rulesets, the rules in your imported ruleset can contain only built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.

  1. In the side menu bar, click Governance.
     The Governance page is displayed.
  2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
     The manage rulesets page is displayed.
  3. In the Global rulesets section, click Add > Import.
     The Import ruleset wizard opens.
  4. Drag a file into the Upload file box, or click in the Upload file box to select a file to upload. The maximum file size is 100 kb, and the supported file types are YAML, YML, and JSON.
  5. Click Next.
  6. Edit the Ruleset info details as required, and click Import.
     Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon .
  7. You now have the following options:
     - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon alongside Rules in the navigation pane. Remember to click Save when you finish editing.
     - If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the Governance overview page.

- To create an API or product ruleset by using the toolkit CLI, complete the following steps.
  1. Create a JSON file that contains the new ruleset.
     The following JSON shows the contents of an example API document ruleset file:

     ```
     {
         "name": "short-draft-ootb",
         "title": "short-draft-ootb",
         "description": "short ruleset",
         "ruleset_type": "global-custom",
         "tags": [
           {
             "name": "general",
             "description": "general work"
           }
         ]
         "rules": [
           {
             "name": "sec-array-boundaries-2",
             "description": "Array size should be limited to mitigate resource exhaustion attacks.\nThis can be done using
