    - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- General settings; select the required options:
  - Required: A property associated with this schema is required.
  - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
  - URL (required): The URL for the target documentation.
  - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
  - Name: Replaces the name of the element or attribute used for the described schema property.
  - Namespace: The URL of the namespace definition.
  - Prefix: The prefix to be used for the Name.
  - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
  - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/><book/></books>`) or unwrapped (`<book/> <book/>`).
- Click Save when done.

Example

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining response components

Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a response component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more response components defined, expand Responses.
3. You can create a new response component, or edit any existing response component.
   - To create a response component, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response component, click the response component name in the navigation pane, then refer to Editing a response.

- **Creating a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
- **Editing a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.
- **Creating a content definition**
  A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.
- **Editing a content definition**
  A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.
- **Creating an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information.
- **Editing an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the response; you can either create a response from scratch, or you can reference a response that is defined in a response component.
   - To create the response from scratch, provide the following information on the Definition tab:
     - Response name: A name for the response.
       If you are creating an operation response, this name is the HTTP status code.

       If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/responses/Name`

     - Description (required): A description of the response. You can use CommonMark syntax for rich text representation.
   - To reference a response that is defined in a response component, provide the following information on the Reference tab:
     - Response name: A name for the response.
       If you are creating an operation response, this name is the HTTP status code.

       If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/responses/Name`

- Reference from: Select a reference to a response component.

2. Click Create.
   The response details are displayed for further editing; see Editing a response.

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Response name: A name for the response.
     If you are editing an operation response, this name is the HTTP status code.

     If you are editing a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/responses/Name`

     To change the name, click Update, then click Save when done.

   - Description: A description of the response. You can use CommonMark syntax for rich text representation.
   - Headers: Headers define information that can be returned in the response.
     To define a new header for the response, click Add, then refer to Creating a header.

     To edit an existing header, click the header name, then refer to Editing a header.

   - Content: A content definition describes the content of the response.
     To define a new content definition for the response, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

   - Links: Links describe how various values returned by one operation can be used as input for other operations.
     To define a new link for the response, click Add, then refer to Creating a link.

     To edit an existing link, click the link name, then refer to Editing a link.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating a content definition

A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.

Before you begin

Launch the content definition creation window. For details of the areas in your API definition from where you can create a content definition, see the following topics:

- Editing a header

- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
2. Click Create.
   The content definition details are displayed for further editing; see Editing a content definition.

Editing a content definition

A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.

Before you begin

Open the details form for a content definition. For details of the areas in your API definition from where you can edit a content definition, see the following topics:

- Editing a header
- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
   - Schema:
     To define a schema for the content definition, click Create, then refer to Creating a schema component.

     If the content definition already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
   - Examples:
     To add an example of the content, click Add, then refer to Creating an example.

     To edit an existing example, click the example name, then refer to Editing an example.

- Encoding: An encoding definition describes how a specific schema property is encoded.
  To add an encoding definition, click Add, then refer to Creating an encoding definition.

  To edit an existing encoding definition, click the name, then refer to Editing an encoding definition.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information.

Before you begin

Launch the encoding definition creation window when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property.
   - Content Type: The Content-Type for encoding the property; for example, `application/xml; charset=utf-8`, `image/png, image/jpeg`.
   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type `array` or `object` generate separate properties for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
2. Click Create.
   The encoding definition details are displayed for further editing; see Editing an encoding definition.

Editing an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information

Before you begin

Open the details form for an encoding definition when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property. To change the name, click Update, then click Save when done.
   - Content Type: The Content-Type for encoding the property; for example:
     - `application/xml; charset=utf-8`
     - `image/png, image/jpeg`.
   - Headers: A map allowing additional information to be provided as headers.
     To add a new header, click Add, then refer to Creating a header.

     To edit an existing header, click the header name, then refer to Editing a header.

   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type `array` or `object` generate separate properties for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameter components

Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a parameter component, you must reference it from elsewhere in your API definition.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to `header`.
- A parameter can have various format styles, the style of a header is always `simple`.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more parameter components defined, expand Parameters.
3. You can create a new parameter component, or edit any existing parameter component.
   - To create a parameter component, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter component, click the parameter component name in the navigation pane, then refer to Editing a parameter.

- **Creating a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
- **Editing a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- Defining parameters for a Path

- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the parameter; you can either create a parameter from scratch, or you can reference a parameter that is defined in a parameter component.
   - To create the parameter from scratch, provide the following information on the Definition tab:
     - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/parameters/`*`Name`*

       Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
     - Parameter name (required): The name of the parameter.
     - Located In (required): The location of the parameter. Select one of the following options:
       - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
       - header: Custom headers that are expected as part of the request.
       - path: The parameter value is part of the operation's URL, enclosed in {}.
       - cookie: Used to pass a specific cookie value to the API.
     - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
     - Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
       - matrix: Path-style parameters defined by RFC 6570.
       - label: Label style parameters defined by RFC 6570.
       - simple: Simple style parameters defined by RFC 6570.
       - form: Form style parameters defined by RFC 6570.
       - spaceDelimited: Space separated array values.
       - pipeDelimited: Pipe separated array values.
       - deepObject: Provides a simple way of rendering nested objects using form parameters.
     - Select the following options as required:
       - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
       - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
       - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
       - Explode: When selected, parameter values of type **`array`** or **`object`** generate separate parameters for each value of the array or key-value pair of the map.
       - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC 3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding. This property applies only if the Located In property is set to query.
   - To reference a parameter that is defined in a parameter component, provide the following information on the Reference tab:
     - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/parameters/`*`Name`*

       Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
     - Parameter name (required, available if you are creating a path or operation parameter): The name of the parameter.
     - Reference from: Select a reference to a parameter component.
2. Click Create.
   The parameter details are displayed for further editing; see Editing a parameter.

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- Defining parameters for a Path
- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: Available if you are editing a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/parameters/`*`Name`*

     To change the name, click Update, then click Save when done.
   - Parameter name (required): The name of the parameter.
   - Located In (required): The location of the parameter. Select one of the following options:
     - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
     - header: Custom headers that are expected as part of the request.
     - path: The parameter value is part of the operation's URL, enclosed in {}.
     - cookie: Used to pass a specific cookie value to the API.
   - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
   - Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
     - matrix: Path-style parameters defined by RFC6570.
     - label: Label style parameters defined by RFC6570.
     - simple: Simple style parameters defined by RFC6570.
     - form: Form style parameters defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form parameters.
   - Select the following options as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
     - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
     - Explode: When selected, parameter values of type **`array`** or **`object`** generate separate parameters for each value of the array or key-value pair of the map.
     - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding. This property applies only if the Located In property is set to query.
   - Schema:
     To define a schema for the parameter, click Create, then refer to Creating a schema component.

     If the parameter already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining example components

An example component is a reusable example that you can add to an API to make the specification of your API clearer.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an example component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more example components defined, expand Examples.
3. You can create a new example component, or edit any existing example component.
   - To create an example component, click the add icon ⊕ alongside Examples, then refer to Creating an example.
   - To edit an existing example component, click the example component name in the navigation pane, then refer to Editing an example.

- **Creating an example**
  You add examples to an API to make the specification of your API clearer.
- **Editing an example**
  You add examples to an API to make the specification of your API clearer.

Creating an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Launch the example creation window. For details of the areas in your API definition from where you can create an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the example; you can either create an example from scratch, or you can reference an example that is defined in an example component.
   - To create the example from scratch, provide the following information on the Definition tab:
     - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.
   - To reference an example that is defined in an example component, provide the following information on the Reference tab:
     - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

     - Reference from: Select a reference to an example component.
2. Click Create.
   The example details are displayed for further editing; see Editing an example.

Editing an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Open the details form for an example. For details of the areas in your API definition from where you can edit an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   -
     - Example Name: If you are editing an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/`*`Name`*

       To change the name, click Update, then click Save when done.
     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - Example Value: A literal example.
     - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining request body components

A request body component is a reusable definition of the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more request body components defined, expand Request Bodies.
3. You can create a new request body component, or edit any existing request body component.
   - To create a request body component, click the add icon ⊕ alongside Request Bodies, then refer to Creating a request body.
   - To edit an existing request body component, click the request body component name in the navigation pane, then refer to Editing a request body.

- **Creating a request body**
  A request body defines the structure of the body of an API request.

- **Editing a request body**
  A request body defines the structure of the body of an API request.

Creating a request body

A request body defines the structure of the body of an API request.

Before you begin

Launch the request body creation window; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the request body; you can either create a request body from scratch, or you can reference a request body that is defined in a request body component.
   - To create the request body from scratch, provide the following information on the Definition tab:
     - Name: A name for the request body.
       If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/requestBodies/Name`

     - Description: A description of the request body. You can use CommonMark syntax for rich text representation.
     - Required: Determines if the request body is required in the request.
   - To reference a request body that is defined in a request body component, provide the following information on the Reference tab:
     - Name: A name for the request body.
       If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/requestBodies/Name`

     - Reference from: Select a reference to a request body component.
2. Click Create.
   The request body details are displayed for further editing; see Editing a request body.

Editing a request body

A request body defines the structure of the body of an API request.

Before you begin

Open the details form for a request body; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: A name for the request body.

Available if you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/requestBodies/Name`

- Description: A description of the request body. You can use CommonMark syntax for rich text representation.
- Content: A content definition describes the content of the request body.
  To define a new content definition for the request body, click Add, then refer to Creating a content definition.

  To edit an existing content definition, click the content definition name, then refer to Editing a content definition.
- Required: Determines if the request body is required in the request.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining header components

A header component defines a reusable custom header that can be sent in an API request or returned in an API response.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a header component, you must reference it from elsewhere in your API definition.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more header components defined, expand Headers.
3. You can create a new header component, or edit any existing header component.
   - To create a header component, click the add icon ⊕ alongside Headers, then refer to Creating a header.
   - To edit an existing header component, click the header component name in the navigation pane, then refer to Editing a header.

- **Creating a header**
  A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.
- **Editing a header**
  A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Creating a header

A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.

Before you begin

Launch the header creation window. For details of the areas in your API definition from where you can create a header, see the following topics:

- Editing a response
- Editing an encoding definition
- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the header; you can either create a header from scratch, or you can reference a header that is defined in a header component.
   - To create the header from scratch, provide the following information on the Definition tab:
     - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/headers/`*`Name`*

     - Description: A description of the header. You can use CommonMark syntax for rich text representation.
     - Required: Determines whether this header is mandatory.
     - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
     - Allow Empty Value: The header can be sent with an empty value.
     - Explode: When selected, header values of type **`array`** or **`object`** generate separate headers for each value of the array or key-value pair of the map.
     - Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding.
   - To reference a header that is defined in a header component, provide the following information on the Reference tab:.
     - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/headers/`*`Name`*

     - Reference from: Select a reference to a header component.
2. Click Create.
   The header details are displayed for further editing; see Editing a header.

Editing a header

A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Before you begin

Open the details form for a header. For details of the areas in your API definition from where you can edit a header, see the following topics:

- Editing a response
- Editing an encoding definition
- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Header name: If you are editing a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/components/headers/Name`

  To change the name, click Update, then click Save when done.
- Description: A description of the header. You can use CommonMark syntax for rich text representation.
- Required: Determines whether this header is mandatory.
- Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
- Allow Empty Value: The header can be sent with an empty value.
- Explode: When selected, header values of type **array** or **object** generate separate headers for each value of the array or key-value pair of the map.
- Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
- Schema:
  To define a schema for the header, click Create, then refer to Creating a schema component.

  If the header already has a schema defined, click View to edit the schema.

  For full details on editing a schema, see Editing a schema component.
  Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
- Content: A content definition describes the content of the header.
  To define a new content definition for the header, click Add, then refer to Creating a content definition.

  To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining security scheme components

A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.
HTTP Bearer	Use an HTTP Bearer definition to specify how to validate the Bearer token that is required to call an API.

- **Defining basic authentication security scheme components**
  A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.
- **Defining API key security scheme components**
  An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- **Defining OAuth2 security scheme components**
  An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.
- **Defining OIDC security scheme components**
  An OIDC (OpenID Connect) security scheme defines settings for using your OIDC provider to control access to the API.
- **Defining an HTTP bearer security scheme**
  An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

Defining basic authentication security scheme components

A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see Working with user registries.

To create a user registry with Cloud Manager, see User registries overview.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM API Connect expects an authentication URL to return an HTTP `200 OK` response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see LDAP authentication.

For information about using an Authentication URL, see Authentication URL user registry.

To make use of a basic authentication security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create a basic authentication security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an existing basic authentication security scheme component, click the component name in the navigation pane.
4. If you are creating a new basic authentication security scheme component, you can either create it from scratch or you can reference another basic authentication security scheme component.
   To create a basic authentication security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/`*`Security_Scheme_Name`*

   - Security Scheme Type (required): Select http.
   - Scheme (required): The name of the HTTP Authorization scheme to be used in the Authorization header as defined in RFC7235.
   - Authenticate using User Registry: The name of the user registry to be used for authentication. This is the value of the **`name`** field that was auto-generated when the user registry was created.
   - Bearer format: A hint to the client to identify how the bearer token is formatted. Bearer tokens are usually generated by an authorization server, so this information is primarily for documentation purposes.
   - Description: An optional description of the basic authentication security scheme. You can use CommonMark syntax for rich text representation.

   To reference another basic authentication security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/`*`Security_Scheme_Name`*

   - Reference from: Select a reference to another basic authentication security scheme component.
5. If you are creating a new basic authentication security scheme component, click Create.
   The security scheme component details are displayed for further editing.
6. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Fore more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

Defining API key security scheme components

An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme component to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security scheme components, one for each type of credentials.

To make use of an API key security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an API key security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an API key existing security scheme component, click the component name in the navigation pane.
4. If you are creating a new API key security scheme component, you can either create it from scratch or you can reference another API key security scheme component.
   To create an API key security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/`***`Security_Scheme_Name`***

   - Security Scheme Type: Select apiKey.
   - Name: The name of the header, query or cookie parameter to be used. For a key of type client secret you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
     Note: The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a **`set-variable`** policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:
     - In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

       Table 1.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	$(request.headers.X-IBM-Client-Secret)

       For more information on configuring a Set Variable policy, see Set Variable.
     - In the Source tab, add a **`set-variable`** policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-IBM-Client-Id
            value: $(request.headers.X-IBM-Client-Id)
            type: string
          - set: message.headers.X-IBM-Client-Secret
            value: $(request.headers.X-IBM-Client-Secret)
            type: string
```

       For more information on defining a **`set-variable`** policy in your OpenAPI source, see set-variable.
     You should position the **`set-variable`** before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.
   - Key Type: Select client_id or client_secret.
     Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.
     If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

     If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

   - Located In: Select one of the following options, to specify how the credentials are sent:
     - header: The credentials are sent in the request header.
     - query: The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

     Note: If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see Client ID behavior in API key security definitions.

- Description: An optional description of the API key security scheme. You can use CommonMark syntax for rich text representation.

5. To reference another API key security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another API key security scheme component.
6. If you are creating a new API key security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

- **Client ID behavior in API key security definitions**
  How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.
Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	• When Return V5 Responses compatibility option is off: 401 client ID is missing. • When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. For information about setting compatibility options, see Configuring v5 compatibility options.

Defining OAuth2 security scheme components

An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme component, you must:

1. Create an OAuth provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the OAuth instructions step in Creating and configuring Catalogs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an OAuth2 security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an existing OAuth2 security scheme component, click the component name in the navigation pane.
4. If you are creating a new OAuth2 security scheme component, you can either create it from scratch or you can reference another OAuth2 security scheme component.
   To create an OAuth2 security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Definition Type: Select oauth2.
   - Flow: Select one or more of the following options:
     - Implicit
     - Resource Owner - Password
     - Application
     - Access Code

     Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
     If you selected Resource owner - JWT as the supported grant type when you created the OAuth provider, you must select Resource owner - Password as the Flow for this security scheme.
   - OAuth Provider: The name of the OAuth provider to be used. This is the value of the `name` field that was auto-generated when the OAuth provider was created.
   - Description: An optional description of the OAuth2 security scheme. You can use CommonMark syntax for rich text representation.

   To reference another OAuth2 security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another OAuth2 security scheme component.
5. If you are editing an existing OAuth2 security scheme component, provide the following information:
   - The URL endpoints (the applicable endpoints depend on the flow type):
     - Authorization URL
     - Refresh URL
     - Token URL

     Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.
   - Scopes:
     - To add a new scope, click Add. To edit an existing scope, click the options icon ⋮ alongside the required scope, then click Edit.
     - Provide the following information:
       - Scope: The scope identifier.
       - Description: An optional description of the scope. You can use CommonMark syntax for rich text representation.
6. If you are creating a new OAuth2 security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Defining OIDC security scheme components

An OIDC (OpenID Connect) security scheme defines settings for using your OIDC provider to control access to the API.

Before you begin

Before you can create an OIDC security scheme component, you must create a native OAuth provider and configure the OIDC settings for it.

1. Create an OIDC provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Configure the OIDC parameters for your native OAuth provider.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components > Security Schemes and then click ⊕ to add a new security scheme.
3. In the Add schema dialog box, provide the following settings before clicking Add:
   - Security Scheme Name (Key): provide a name for the new scheme.
   - Security Scheme Type: select openIdConnect
   - OpenID Connect URL: type the authorization endpoint URL for the OIDC provider.
4. On the OpenId Connect Security Scheme page, add information about the OIDC provider:
   - Type: select your OIDC provider from the list.
     The list only displays the native OAuth providers that are configured for OIDC with a discovery URL provided in the OpenIDConnect Discovery path field, and are enabled for the catalog that the API is configured to use.
   - OpenID Connect URL: When you select your provider, the URL is filled in for you with the discovery URL that was configured for the native OAuth provider.
5. Click Save.

Defining an HTTP bearer security scheme

An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

About this task

For information on the use of bearer tokens with OpenAPI 3 APIs, see Bearer Authentication in the OpenAPI 3 specification.

If an HTTP bearer token is found in the request, its value is stored within the context as **`api->security->bearer_token`**. If an external URL validation is invoked, any response with a status code of 200 is stored within the context as **`api->security->bearer_validation_response`**.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components > Security Schemes.
3. Click Add.
4. In the Add Object dialog box, provide the following information:
   - Security Scheme Name (Key) - Provide a descriptive name for the new scheme.
   - Security Scheme Type - Select http.
   - Scheme - Select Bearer.
   - Bearer Format - Select JWT.
   - Validation Method - Select a method. If you select external-url, provide the following additional information:
     - Validation Endpoint - Provide the URL of the server used for validation. To ensure a secure connect, the URL should use the **`https`** protocol.
     - TLS Profile name - If the validation endpoint uses the **`https`** protocol, select the name of the TLS client profile to use for a secure connection.
   - Description - Provide a description of the JWT scheme.
5. Click Create to create the new scheme.
6. Click Save in the page header.

Defining link components

A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a link component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more link components defined, expand Links.
3. You can create a new link component, or edit any existing link component.
   - To create a link component, click the add icon ⊕ alongside Links, then refer to Creating a link.
   - To edit an existing link component, click the link component name in the navigation pane, then refer to Editing a link.

- **Creating a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.
- **Editing a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Creating a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Launch the link creation window. For details of the areas in your API definition from where you can create a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the link; you can either create a link from scratch, or you can reference a link that is defined in a link component.
   - To create the link from scratch, provide the following information on the Definition tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/links/Name`

     - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
     - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
     - Description: A description of the link. You can use CommonMark syntax for rich text representation.
   - To reference a link that is defined in a link component, provide the following information on the Reference tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/links/Name`

- Reference from: Select a reference to a link component.

2. Click Create.
   The link details are displayed for further editing; see Editing a link.

Editing a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Open the details form for a link. For details of the areas in your API definition from where you can edit a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: If you are editing a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/links/Name`

     To change the name, click Update, then click Save when done.
   - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
   - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
   - Parameters: A map representing parameters to pass to an operation as specified with Operation ID or identified via Operation Ref. The key is the parameter name to be used, whereas the value can be a constant or an expression to be evaluated and passed to the linked operation.
   - Request Body: The request body to use when calling the target operation.
   - Description: A description of the link. You can use CommonMark syntax for rich text representation.
   - Server: A server to be used by the target operation. Provide the following information:
     - Server URL The specified URL is used to determine the full URL endpoint for the calling the API, according to any vanity endpoint configuration in the Catalog in which the API is published. For full details, see Configuring vanity endpoints for a Catalog.
     - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
     - Server Variables A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
       - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
       - Provide the following information:
         - Server Variable Name (required).
         - Default value (required).
         - An optional rich text description. You can use CommonMark syntax for rich text representation.
         - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
       - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
   - Phase: The phase of the lifecycle that your API is in; select one of the following options:
     - Realized (default) - The API is in the implementation phase.
     - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
     - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
   - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
     Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
   - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see Enabling CORS support for an API.
   - Target Services: Define web services that you want to use in your API definition. For details, see Defining target services for an API.
   - Enforced: Select this option to enforce the API by using the DataPower API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
   - Properties: Add properties that can be referenced in your API definition. For details, see Setting API properties.
   - Catalog Properties: Define property values that are specific to a particular Catalog. For details, see Defining Catalog specific property values.
   - Activity Log: Configure your logging preferences for the API activity that is stored in analytics. For details, see Configuring activity logging.
   - Exxtensions: Extensions added to the API to extend the OpenAPI specification. For details, see Adding an OpenAPI extension to an API.

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
   a. Click the add icon ⊕ alongside Target Services in the navigation pane.
   b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.
4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see API properties.
Note: Once defined, an API property is read only.
For information on how to reference a property in an API definition, see Variable references in API Connect.

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see Creating and configuring Catalogs. Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
   - To define a new API property, complete the following steps:
     - Click the add icon ⊕ alongside Properties in the navigation pane.
     - Provide the following information:
       - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the Name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
       - Value: A default value for the property. Leave blank if the property is to have a null vale by default.
       - Description: An optional description of the property. You can use CommonMark syntax for rich text representation.
       - Select Encoded if you want to hide the property values, or protect user passwords from casual observance.
         Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
     - Click Create.
   - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
4. Click Save to save your changes.

What to do next

Optionally, define a value for the property that is specific to a particular Catalog; see Defining Catalog specific property values.

- **Defining Catalog specific property values**
  For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see Setting API properties.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
   - To define a new Catalog specific property value, complete the following steps:
     - Click the add icon ⊕ alongside Catalog Properties in the navigation pane.
     - Type the Catalog Name exactly as it displays in the **name** field for the selected Catalog.
       Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
     - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
     - Alongside Property Overrides, click Add.
     - Provide the following information:
       - Property Name: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see Setting API properties.
       - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
     - Click Create.
   - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring application authentication for an API

Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.

About this task

Note: This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Enable application authentication, as follows:
   Note: To identify the application, you must enable a security requirement of type **clientID**.
   a. Select the Gateway tab, expand Gateway and portal settings, then click Application Authentication.
   b. Select Certificate.
3. Specify how the client certificate is sent to the gateway, as follows:
   a. In the navigation pane, click Application Authentication Source.
      Any existing application authentication source definitions are listed.
   b. Alongside Application Authentication Source, click Add.
   c. Select the required option, header or tls-cert.
      You can separately add one or both of the options.
      When the API is called, an X509 client certificate must be supplied, either in the specified HTTP header, or as a TLS client certificate from TLS mutual authentication. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see Registering an application.

      The Gateway service to which the API is published can be configured to use TLS mutual authentication to secure API calls made to that Gateway service; for details, see Configuring the initial Gateway service. If you select this option, continue to sub-step d.

      If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

   d. If you select the tls-cert option, enable mTLS at the Gateway level.
      Enable mTLS by setting "Mutual authentication: Required" (or "Requested" if not all APIs use mTLS) in the TLS Server Profile that is specified for the API invocation endpoint in your gateway service configuration. The gateway service is configured in the Cloud Manager UI (requires cloud administrator permissions). For more information, see Registering a gateway service and TLS profiles overview.

      You can create a truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

      The following example cURL command uses a client-cert during SSL:

      ```
      **curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id:
      1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
      ```

      Note: This feature is intended for the scenario where different applications are registered with different end certificates in the Developer Portal, which have the same intermediate or root CA issuer. The certificate passes Gateway-level mTLS if it matches the issuer available in the truststore, but allows access only to the API that matches the correct end certificate.

4. Click Create.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the `log` context variable, which populates the API event record on completion of the API execution; for more information, see API activity logging context variables.

Note:
Activity logging that calls for logging of analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description
Success Content	Defines the type of content to be logged when the operation is successful. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is activity.
Error Content	Indicates what content to log when an error occurs. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is payload.

4. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

In the Policies view of IBM API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
  The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.
- **Adding elements to your assembly**
  Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.
- **Handling errors in the assembly**
  Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM API Connect.

You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes the following options:

- Palette - lists the available elements in the assembly flow.
- Canvas - used to arrange and visualize the elements in the assembly.
- Property sheet - used to configure the elements in the assembly.

The palette

The palette is a list of different elements that you can include in your assembly. To view the palette, click the plus icon ⊕ on the canvas. You can use the Rotate icon ↻ to rotate the palette as you prefer. To maximize and minimize the palette view, click the Maximize and Minimize icons.

You can release the palette by clicking the Close icon ✕.

The canvas

You can use the canvas to create a graphical representation of the assembly flow. To add an element to the assembly flow from the palette, click the plus icon ⊕ at the appropriate location on the canvas and select the required element from the available list. To delete an element from the canvas, hover over the element and click the Delete icon 🗑.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.
API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon ⛶.

The property sheet

When you select an element that is in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon ✕.

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can be branched, thrown, and caught according to the policies available. The message context flows through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting
: Before the assembly is executed, security and then rate limits are enforced.
First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

: If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence
: The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when **`if`** and **`operation-switch`** logic constructs are used, or for the remaining assembly to be ignored when a **`throw`** policy is executed.
The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and, at the end of the API call, the message is used as the response.

: The request context contains the information that is sent by the API caller and varies with the type of operation called and the configuration of that operation. For example, a GET operation can never have a populated **`request.body`**, and you can configure an operation to have **`request.parameters`** (query parameters).
The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts
: Because the message can be overwritten, it is useful to create and reference new contexts where possible so that they are saved and reused during the API call.

  - Use the **`map`** policy to overwrite the message context when you need to execute a policy that only acts on the message.
  - Use the request context when you want to use the original request made to the API.
  - Use the **`map`**, **`invoke`**, and **`proxy`** policies to create new contexts when you want to save your message.
    Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

For example, **invoke** is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a **validate** policy, and a **map** policy then saves the message as a new context, ready for a second **invoke** policy to overwrite the message without losing the first **invoke** policy's output.

You can also access contexts outside of the message or your custom contexts, but these contexts cannot be written to. For a list of contexts, see API Connect context variables.

Branches and catches

Using logic constructs, such as **operation-switch** or **if**, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.

When a catch is triggered, either by an error occurring during the execution of a policy, or because a **throw** policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

Related concepts

- Variable references in API Connect

Related tasks

- Adding elements to your assembly

Related reference

- API Connect context variables

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see execute OpenAPI extension for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see The assembly editor.

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.
   Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version that is present on the gateway.
   a. Select the Gateway tab, then click Policies in the navigation pane.
   b. Click the plus icon ⊕ at the appropriate location on the canvas to view the palette that lists the available elements.
   c. Select the element that you want to add from the palette to the canvas by clicking it.
      Note:
      - Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
      - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
   d. Add and edit properties of the element by clicking the element and using the property sheet.
      For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see API policies and logic constructs. For information about the properties of logic constructs, see Logic Constructs.
   e. Specify a version for the policy.
      To add a version, click the Source icon </>, and complete the **version** section of the policy YAML. For example:

```
execute:
  - invoke:
      version: 2.2.0
```

```
      title: invoke
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see execute OpenAPI extension.

4. Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a **throw** element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon if one is displayed.
   The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
   Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, use the Select errors field to select the appropriate error.
9. Optional: To remove an error case from a catch, clear the corresponding checkbox from the Select errors drop-down. To clear all the error cases from a catch, click the cross corresponding to the total number of error cases in the Select errors field.
10. Optional: To change the precedence of your catches, use the Move up ↑ or Move down ↓ icons.
    If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch from the palette, click the plus icon ⊕ at the appropriate location in the assembly flow. Select an element that you want to apply to the catch by clicking it.
12. Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the **Invoke** policy in your assembly. Otherwise, if the error occurs during the execution of the **Invoke** policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an **Invoke** policy, see Invoke.

For details of all the errors that can be returned by the assembly and are available to the catch function, see Error cases supported by assembly catches.

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.

About this task

When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate > With specifications. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.

Note:

- OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see Staging an API or Publishing an API.
- You can also validate your API document by using governance rulesets. For more information, see Validating an API or product document by using the governance service.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.

1. Open the required API for editing, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
2. Click Validate > With specifications from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

   For example,

   .
4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

   For example, 
   .

Validating an API or product document by using the governance service

How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. See Enabling governance on Kubernetes, and Enabling governance on VMware for more information. If governance is enabled in your deployment, the Governance icon is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

The governance service is available to all user roles.

The governance service has the following limitations:

- It does not support de-referencing, which means it does not automatically introspect referenced definitions within an API. However, you can explicitly validate referenced objects using custom rules as needed to ensure compliance with your API standards.
- The following OpenAPI Specification (OAS) rules are not enabled in governance service to prevent false positive errors:
  - oas2-unused-definition
  - oas3-unused-component

Tip: Before using the governance service to validate any API documents, you should first run Validate > With specifications to validate the OpenAPI YAML source. For more information, see Validating the OpenAPI YAML source.

About this task

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API and product development process. The service contains the following types of rulesets:

API
: Rulesets to validate your API documents.

  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
  - Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's

available in Spectral.

Product
: Rulesets to validate your product documents. Note that the validation scan of products looks only at the product yaml; it does not include the scanning of any API documents that the product refers to.

  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
  - Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

You can create your own provider organization rulesets to validate your Swagger, OpenAPI, AsyncAPI, and product documents against, or use the global rulesets that are provided for your organization. For more information about configuring rulesets, see Configuring governance in the API Manager.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

You can complete the instructions that are in this task by using the API Manager UI, or by using API Designer when the UI is online, and is connected to a cloud instance that has the governance microservice enabled on it. You can also use the toolkit CLI; for details see Validating an API or product document by using the toolkit CLI.

The following validation scan methods are available:

- Validate an API document from within an API
- Validate a product document from within a product
- Validate one or more API or product documents from within the Governance section
- Validate one or more published API or product documents from within a catalog or space

Procedure

- To validate an API document from within the API, complete the following steps.
  1. Open the required API for validating, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
  2. Click Validate > With rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your API document against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The API can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The API Design page is displayed.
     If validation errors were found during the scan, the ruleset status icon in the header menu bar displays the number of errors found, for example:

     
     You can click on the ruleset status icon to see a detailed list of the errors, and their location in the YAML. You can also then click on an individual error to navigate directly to the relevant section in the API.
- To validate a product document from within the product, complete the following steps.
  1. Open the required product for validating, by clicking on the title of the product in the Products tab of the Develop page.
  2. Click Validate with rulesets from the menu bar in the header.

     
  3. Select the rulesets that you want to validate your product document against, and click Next.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The product can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The product Design page is displayed.
- To validate one or more draft API or product documents from within the Governance section, complete the following steps.
  1. In the side menu bar, click Governance.
     The Governance page is displayed.
  2. Click the Rulesets tab.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.

7. Select the APIs or products that you want to validate, and click Validate.
   If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
8. Optional: You can click Download to download the results of the validation into a .csv file.
9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
10. Click Done when finished.

- To validate one or more published API or product documents from within a catalog or space, complete the following steps.
  1. Select the catalog or space that you want to run the validation in, and then select Governance from the menu bar.
  2. Select Rulesets.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.

Results

Your API or product document is validated against one or more rulesets.

What to do next

You can use the results of the validation to help you improve your API or product document. You can also use the results to help you edit the rulesets, and create new rulesets; see Configuring governance in the API Manager for more information.
You can also run validation scans on a catalog or space, to check one or more of the API documents that it contains. For more information, see Scanning your catalogs and spaces.

- **Validating an API or product document by using the toolkit CLI**
  How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

Related information

- The governance ruleset lifecycle

Validating an API or product document by using the toolkit CLI

How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

About

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your API or product documents. You can also validate an API or product document by using the API Manager and the API Designer UIs. For more information about validation scanning, see Validating an API or product document by using the governance service.

The following validation scan methods are available by using the toolkit CLI:

- Validate a single API or product document that is stored locally
- Validate one or more API or product documents that are stored on the management server

Validate a single API or product document that is stored locally

To run a validation scan on a single API or product document against one or more rulesets, complete the following steps. The document must be stored locally.

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server platform_api_host_name --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. Run the **compliance:validate** toolkit command in **governance** mode.

```
apic --mode governance compliance:validate --org <target_org> --server <platform_api_host_name> --rulesets
<ruleset_name_1>,<ruleset_name_2> API_OR_PRODUCT_FILE
```

where:

- ***<target_org>*** is the name of the provider organization that owns the APIs to be validated.
- ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "platform server").
  Tip: To determine the correct server for API Connect Governance, use the Platform API endpoint. You can find the Platform API endpoint by logging to API Manager > Download clients > Download toolkit credentials. The downloaded credentials file will contain the platform endpoint.
  <platform_api_host_name> is the hostname portion URL of the platform API endpoint.
  For example, if your server URL is **https://mybackend.example.com/api**, then the hostname is **mybackend.example.com**
- ***<ruleset_name_1>,<ruleset_name_2>*** is a comma-delimited list specifying the names of the rulesets to be applied to the API or product. (Specify each ruleset name; do not use the ruleset IDs.)
- **API_OR_PRODUCT_FILE** is the path and filename of the document to be validated.

Validate one or more APIs or products that are stored on the management server

This operation runs a validation scan on all of the draft APIs, or all of the products, that are listed in the **COMPLIANCE_REQUEST_FILE**. You can scan only APIs, or only products, at any one time. The APIs must be stored as draft APIs in your provider organization.

1. Create a JSON **COMPLIANCE_REQUEST_FILE** that specifies the rulesets to use during validation, and the location of either the draft APIs or the products that you want to scan. The file can contain URLs only for APIs, or only for products; you cannot list both API and product URLs in the same file.
   The following example shows a configuration file that specifies two draft APIs, and two rulesets. In the **spectral-oas** ruleset, the **info-contact** rule is disabled and will be ignored during validation.

```
{
  "apiUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/a08898fe-b422-41d3-
b058-c3280d632e93","https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/26692eab-f43b-
4af3-985c-2deaa401eb7f"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "spectral-oas",
        "disabled": ["info-contact"]
      },
      {
        "rulesetName": "spectral-owasp",
        "disabled": []
      }
      ]
 }
}
```

   The following example shows a configuration file that specifies one product document.

```
{
  "productUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-product/a07968fe-b422-
41d3-b058-c3280d632e93"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "product-info",
        "disabled": ["subscribe"]
      },
      {
        "rulesetName": "product-rate",
        "disabled": []
      }
      ]
 }
}
```

   Where:

   - **apiUrls** is a comma-delimited list of API URLs. Each URL specifies the location of the draft APIs in a particular provider organization.
   - **productUrls** is a comma-delimited list of product URLs. Each URL specifies the location of the product document in a particular provider organization.
   - **rulesetName** is a list of rulesets to be applied to the APIs or products during validation.
     For each ruleset in the list, you can optionally add the **disabled** property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization. See Step 1 for details.
3. Run the **compliance:validate_all** toolkit command in **governance** mode.

```
apic --mode governance compliance:validate_all --org <target_org> --server <platform_api_host_name>
COMPLIANCE_REQUEST_FILE
```

where:

- ***<target_org>*** is the name of the provider organization that owns catalog containing the APIs to be validated.
- ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
- ***COMPLIANCE_REQUEST_FILE*** is the path and filename of the configuration file that lists the API or product documents, and the rulesets to be used during the validation (for example, validate-apis.json).

LDAP authentication

The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.

Programming guidelines

When authenticating with LDAP, observe the following guidelines:

- Use only a LDAP interface -- Users can only be authenticated via a connection to an LDAP server.
- Active Directory -- Use of an Active Directory interface is prohibited, however, LDAP authentication with Active Directory is supported.
- Administrator properties -- The LDAP administrator must have access to all user's LDAP properties.

LDAP attributes read by IBM® API Connect are as follows:

Attribute	Definition
`mail`	User's SMTP email address.
`cn`	Used internally to determine user's common name.
`sn`	Used internally to determine user's last name or surname.
`givenname`	Used internally to determine user's first name.
Prefix from `Search dn`	Used as username.

Using an LDAP Server for User Authentication

Every entry in an LDAP directory server has a distinguished name (DN). The DN is the name that uniquely identifies an entry in the directory. A DN is made up of `attribute=value` pairs, separated by commas. For example:

```
cn=Ben Gray,ou=editing,o=New York Times,c=US
cn=Lucille White,ou=editing,o=New York Times,c=US
cn=Tom Brown,ou=reporting,o=New York Times,c=US
```

Any of the attributes defined in the directory schema can be used to make up a DN. The order of the component attribute value pairs is important. The DN contains one component for each level of the directory hierarchy from the root down to the level where the entry resides. LDAP DNs begin with the most specific attribute (usually some sort of name) and continue with progressively broader attributes, often ending with a country attribute. The first component of the DN is referred to as the Relative Distinguished Name (RDN). It identifies an entry distinctly from any other entries that have the same parent. In the previous examples, the RDN "cn=Ben Gray" separates the first entry from the second entry, (with RDN "cn=Lucille White"). These two example DNs are otherwise equivalent. The attribute=value pair making up the RDN for an entry must also be present in the entry. (This is not true of the other components of the DN.)

Examples

In the following examples, a user search is performed from Base DN. The search is done anonymously, or if authenticated bind is used, an authenticated user is used. Search DN appends the prefix, the given user name, and the suffix. If the prefix used is (`uid=` and the suffix used is "`)`", `uid` becomes the user name attribute. The default search filter used is: `(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}))` and attributes used for prefix are also added to the search filter. In this case, where '(`uid=`' is the prefix, when searching for users, the search filter becomes:

```
  (|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*)(uid={filter}*))
```

where `{filter}` is replaced by actual text.
The authenticated bind DN is a user on the external LDAP server permitted to get base DNs and search the LDAP directory within the defined search base. It should also be able to read other user properties and be used if anonymous access to LDAP to get base DNs and to search and get access to user attributes is not allowed. When a search is performed for *Steve*, the LDAP query filter shown in the following example is used and search is done from base DN specified in UI. When the user's DN is returned, the DN and password are used to authenticate the user:

```
(|(cn=Steve*)(sn=Steve*)(mail=Steve*)(givenName=Steve*)(uid=Steve*)).
```

For bind during login calls, the search string used is the prefix. For example, if the prefix is '(`uid=`', the search string used to search for a user during log in becomes: (`uid=Steve`).

Using the mail attribute as the user name

When you want to use an email address as the user name, (for example *steve@company.com*), you typically use the mail attribute as the prefix '(`mail=`'. In this case, use the following search string to perform the search internally (assuming '(`mail=`' as prefix):

```
(|(cn=steve@company.com*)(sn=steve@company.com*)(mail=steve@company.com*)
(givenName=steve@company.com*)(mail=steve@company.com*))
```

In the previous example, if DN is found, the password is used with the DN to perform a bind. The first result is taken, so be sure to use a unique attribute for username. Next, the LDAP properties for the user are read (`cn`, `sn`, `mail`, `givenName`). If LDAP properties cannot be read using the logged-in user, they are read from the user's DN using authenticated bind credentials. If the user name attribute differs, it is also queried for. For example, if the prefix is '(`uid=`', the `uid` attribute is also read from the user's DN object:

```
(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*))
```

Note: The prefix and suffix cannot be used to get a user's DN directly. For example, the following attempt to directly get a user's DN fails:

```
Prefix: "uid="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_con_ldap_requirements_,
Suffix: ",ou=users,dc=company,dc=com"
```

LDAP referrals

LDAP referrals allow a directory tree to be partitioned and distributed between multiple LDAP servers. An LDAP referral is a domain controller's way of indicating to a client application that it does not have a copy of a requested object, while giving the client a location that is more likely to hold the object. The client then uses the object as the basis for a DNS search for a domain controller.

API Connect support for LDAP referral includes:

- Searching for users that are part of multiple Active Directory trees and forests.
- Authenticating users in the Cloud Manager, API Manager and the Developer Portal.

Note: API Connect LDAP referral support is dependent on the following conditions:

- A single LDAP host/port is configured with administrator credentials and all users are referred to from the tree/server's base DN.
- As part of the user search following the LDAP referral , the same administrator credentials are used in the downstream trees/forests.
- LDAP API authentication does not support external LDAP referral. Internal LDAP referral is supported.

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **`cn=spoon,o=eatery`**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **`access_token`**.
- Overriding the **`scope`** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the **`scope`** value that the application receives. For example, you can provide a specific resource owner an account number within the **`scope`** header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use **`cn=spoon,o=eatery`** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.

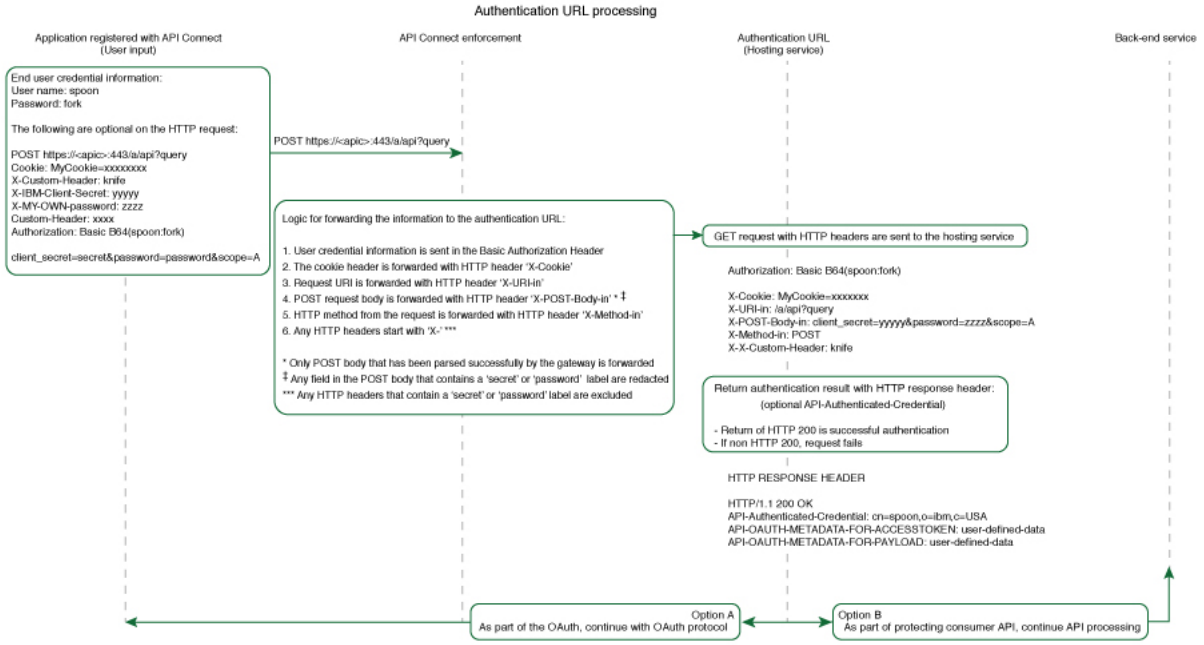
API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested **`scope`** from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```



If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Activating an API

After you have created an API definition you can activate it to auto-publish your API document and make it available for testing.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you activate an API, API Connect automatically completes the following actions:

- Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. Note that if you later want to delete the draft Product, you cannot delete it directly; instead, delete the API and the draft Product is deleted together with the API; see Deleting an API definition. If you want to remove the Product from any Catalogs to which it is published, you must do this separately; see Removing a Product from a Catalog
- Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.

To activate an API, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Note:

- The API activation will not complete successfully if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to activate an API they must be disabled; for information on lifecycle approval settings, see Creating and configuring Catalogs.
- To activate an API from the API Designer user interface, you must be connected to a Management server; API activation is not available with API Designer in offline mode. For more information, see Logging in from API Designer.
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,
col: 0)
400
```

Procedure

To activate an API and auto-publish your API document, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Under Testtab, click Target Configuration. The Preferences page opens.
4. Set the Auto-publish toggle to the On position: 
Results

On successful completion, the API is shown as On: 
You can stop the API by moving the activation slider control to the Off position:

If you stop an API, the application subscription is deleted, and the auto Product is removed from the Sandbox Catalog.
Note: You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting **Use the default built-in Sandbox Catalog**. For more information, see Specifying the testing preferences for an API.
If you make a change to the API, it is republished automatically, You can also republish a running API manually by stopping it and then re-activating it.

The error indicator shows whether there are validation errors in the OpenAPI source for the API definition. If there are errors, click the icon for more details:

You can also activate an API during the creation process, and on the API test page; see Creating an API definition and Testing an API.

Note: If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.

Testing an API

Select a test tool and verify that your API works as you intended.

Before you publish an API where customers can access it, you need to test it and ensure that it is defined and implemented correctly. API Connect offers tools for running both simple and complex tests, in different environments. Use the following list of options to choose the test tool that best meets your needs:

- Execute and debug the API in the Test tab
  On the Test tab, you can quickly invoke your API from the API Connect UI with minimal preparation. The Test tab offers full control over the API call through a simple set of fields where you can define your request. The response includes both a visual flow diagram and a code trace that shows how the API's process flow is executed. Note: the Test tab tool is only available to APIs that use the DataPower API Gateway.
- Call the API externally from the Automated API behavior testing application as explained in Testing an API with Automated API behavior testing
  Automated API behavior testing provides a simple set of fields where you can quickly invoke your API. You can automate tests and define schedules for running them. You can even set up API monitoring and receive alerts on your API health before issues occur.
- Call the API from a local test environment
  The Local Test Environment is a lightweight API Manager, running on your computer, that allows you to rapidly test APIs without connecting to an API Connect management server.
- Run a simple test in the Policies editor
  Note: The Test panel is deprecated and might be removed without warning.
- Use the Try it tool in the Explorer tab to run simple tests
  You can use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and review any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note: Due to CORS, when a test call is made with a browser-based API test tool, an HTTP OPTIONS call is made to the API first. The OPTIONS call:

- Does not use any credentials, so is not attributed to any consumer organization.
- Is logged as an API event in the analytics data. Because the OPTIONS call does not use credentials, the API events are only visible in analytics data in the Cloud Manager and API Manager UIs. The OPTIONS events are not visible in the developer portal analytics view, which includes only analytics data for a single consumer organization.
- Is not included in consumer rate limits.
- Is included in consumption-based licensing (if used).

- **Locating API information on the Endpoints tab**
  The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).
- **Using the Test tab to debug your API**
  Use the Test tab to execute calls and trace the API's actions in API Connect.
- **Testing an API with Automated API behavior testing**
  Use the IBM Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.
- **Testing an API with the Policies editor**
  IBM API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.
- **Testing an API with the Local Test Environment**
  Use the Local Test Environment (LTE) to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.
- **Testing an API with the Explorer tab**
  Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can also use the Try it tool to test the behavior of the API.

Locating API information on the Endpoints tab

The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).

Use the Endpoints tab to retrieve information that you can use when you call the API from an application.

Note: The fields in the Sandbox Sample Application Credentials section apply to the assembly tool's built-in client application and not to any application that you created. The credentials that display here are the default credentials that display in the assembly tool Test panel's "Identification" section.

To copy information from the Endpoints tab, click next to a field.

The following values for the API are displayed in the Endpoints tab so that you can copy them and paste them into calls:

Base API Endpoint
: The URL representing the endpoint of the API that you are editing and testing. To invoke the API, append one of its supported queries (path and parameters) to this URL.

Client ID and Client Secret
: The values of the built-in test application's client ID and client secret. You can invoke APIs externally by providing the application's credentials in the request header.

OAuth Token URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can obtain an access token for calling the API.

OAuth Auth URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can submit an access token and receive an authorization token in exchange. You then use the authorization token when calling the API.

Rate Limit
: If you specified a rate limit on the Security panel when you created the API, the limit is displayed here for reference. If you did not specify a rate limit, the default rate limit displays.

Using the Test tab to debug your API

Use the Test tab to execute calls and trace the API's actions in API Connect.

The Test tab not only lets you quickly invoke an API with any needed headers and parameters, but lets you view the content of the response in both parsed and raw format. Additionally, you can view a trace of the actions execute as the API's process flow operates to complete the call. Viewing the trace can help you debug problems with the API's execution.

Note: The Test tab tool is only available to APIs that use the DataPower API Gateway.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Complete the following tasks to prepare your API for testing, execute requests, and debug responses.

1. Preparing an API for debugging with the Test tab
   Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.
2. Specifying the testing preferences for an API
   By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.
3. Sending the API request
   Fill in fields to set up the request for an API that you want to debug on the Test tab.
4. Reviewing the API response and trace
   Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.
5. Testing a GraphQL API with the Test tab
   For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

Preparing an API for debugging with the Test tab

Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To invoke your API in the Test tab, the following requirements must be satisfied:

The DataPower API Gateway is configured to support the API probe
: To enable the Test tab's trace feature, the DataPower API Gateway must be configured to support gateway peering and the gateway probe. In a gateway service running in Kubernetes, the API probe is automatically enabled. In a gateway service running external to Kubernetes, the DataPower configuration must be added to the application domain supporting API Connect. Check with your administrator to confirm that gateway peering and the gateway probe are enabled as explained in Configuring DataPower API Gateway.

The API uses the DataPower API Gateway
: A gateway exposes APIs to calling applications, and provides processing actions that enable the APIs to integrate with various endpoints. API Connect supports two versions of the DataPower Gateway, but you can only debug APIs that use the DataPower API Gateway. The v5-compatible gateway is not supported. If your API definition has CORS enabled but you cannot see the Test tab, the API is probably configured to use the wrong version of the gateway.
  You can determine which gateway your API uses by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop, then select the APIs tab.
3. Click the title of the API you want to test.
4. On the API's Design page, locate the Gateway field and note which option is selected.

You can change the gateway selection for an API on the Design page, but you must ensure that the policies used in the API's process flow are compatible with the new selection. For information on changing the gateway for an API, see Specifying the gateway type for an API definition.

CORS is enabled in the API definition

Cross-Origin Resource Sharing support ensures that the API can be accessed from another domain. CORS support must be enabled for your API to be properly invoked and traced. If your API uses the API Gateway but you cannot open the Test tab, it's possible that CORS was not enabled in the API definition.
You can enable CORS for you API by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop.
3. On the Develop page, click the name of the API you want to test. The API's Design page appears.
4. Under the Gateway tab, locate the CORS field and select it to enable support.
5. Click Save in the page header.

The API is published in the Sandbox catalog with the default Product/Plan, or a specified catalog and Product/Plan

By default, when you test an API with the Test tab, a default Product/Plan is generated for the API and published to the built-in Sandbox Catalog. However, you can optionally specify a range of API testing preferences including an alternative Product/Plan, and target Catalog; for more information, see Specifying the testing preferences for an API. When you publish (activate) an API, the API is enabled online and becomes available for use. You cannot execute an offline API, even for testing purposes. You can set an API online by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop.
3. On the Develop page, click the name of the API you want to test.
4. In the Design page header, click the settings icon . The **Preferences** page appears.
5. Set the Auto-publish toggle to On position.

Next topic: Specifying the testing preferences for an API

Specifying the testing preferences for an API

By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: This feature is not available if you are using the Local Test Environment.

Procedure

1. Open the required API for editing, in either of the following ways:
   - During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
   - To open an existing API for editing, complete the following steps:
     - In the navigation pane, click Develop, then select the APIs tab.
     - Click the title of the API version that you want to work with.
2. Under the Test tab, click Target Configuration.
   The Preferences page opens.
3. Use the Edit links to configure the following testing preferences, as required:

   Auto-publish
   : In order to execute an API for testing purposes, you must make it online. To make the API online and auto-publish your API document, set the Auto-publish toggle to the On position.

   Target catalog
   : The Catalog to which you want to publish the Product that contains the API. The selected Catalog is used as the scope for the other preference settings. You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting Use the default built-in Sandbox Catalog.

   Target Gateway service
   : The gateway service to which you want to publish the Product that contains the API.

   Target product
   : The Product that will contain the API; you can select any of the Products from the selected Target catalog, or you can opt to use an automatically generated Product by selecting Generate Product on Save. The auto-generated Product has the title *api_title* auto product.

   Target product rate limit
   : If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the Target product rate limit option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied.

   Target Plan
   : The Plan in the selected Product that you want the test application to subscribe to. If you opted to use an automatically generated Product, the Target Plan option is not available; instead, the application is subscribed to the Default Plan in the automatically generated Product.

   Test application

The application that you want to subscribe to the selected Plan. You can select an application of your choice or, if you opted to use the Sandbox Catalog, you can instead use the pre-supplied test application by selecting Use the built-in Test Application.

Test Consumer Org
The consumer organization that you want to subscribe to the selected Plan. If you selected your own application, the consumer organization is preset to that which contains the application, and cannot be changed. If you opted to use the pre-supplied test application you can, if required, select a consumer organization of your choice.
Click Reset to reset preferences to the default values.

4. Click Save Preferences when done.
   The Test page header displays the following details:
   - The target catalog.
   - The target gateway services.
   - The target product associated with the current API.
   - If the current status of API is Online or Offline. You can configure this in the API's Design page header.

Results

The next time you bring the API online, the API is published as specified by the preference settings, ready for testing.
Note: These settings are stored in your browser's local storage and will be used for your API testing in subsequent sessions. The following settings are specific to each individual API:

- Target product
- Target product rate limit
- Target Plan

The remaining settings will be applied to all your APIs.
Previous topic: Preparing an API for debugging with the Test tab
Next topic: Sending the API request

Sending the API request

Fill in fields to set up the request for an API that you want to debug on the Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Open the Test tab

1. Log in to API Manager or API Designer.
2. In the navigation list, click Develop, then select the APIs tab.
3. Click the title of the API that you want to test.
4. On the API Design page, click the Test tab in the page header.

Fill in the Request section

Use the Request section of the page to set up the request URL, the authentication mechanism, and the request parameters. Complete the following steps to fill in the fields that are needed for configuring the request.

Note: The Test tab does not support vanity endpoints; you must specify the gateway endpoint at which the API is invoked. The **Request** field uses the gateway endpoint by default.

1. To fill the Security scheme, complete the following steps:
   a. Click Authorizations and select the security definition that you want. The available security definitions depend on the security schemes that are already configured in the API. To know how to configure security schemes, see Defining security schemes. The available security definitions are:
      - API key
      - Basic
      - OAuth
   b. If your API definition uses API key authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:

      Name
      The variable name that is auto-populated from security scheme.
      Located In
      Location is auto-populated from the security scheme.
      Value
      The user can enter the value based on the auto-populated name. For example, if the name is X-IBM-Client-Id, the user can enter the same name in the value field.

      For more information on API key security schemes, see Defining API key security schemes.
   c. If your API definition uses Basic authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:

      Username and Password
      Enter the username and Password that is needed for authenticating with the user registry.

      For more information on basic security schemes, see Defining basic authentication security schemes.
   d. If your API definition uses OAuth authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:
      Note:

- The OAuth authorization supports only the native OAuth provider. For more information on native OAuth provider, see Configuring a native OAuth provider
- The available flow options for OAuth authorization are:
  - Implicit
  - Access Code
  - Resource Owner - Password
  - Application

  The fields on the Authorize page are based on the configured flow. For example, in password flow, the Authorization URL field is not available.

Authorization URL
: This URL is used to redirect users for authentication and authorization. The URL is auto-populated from the OAuth Provider that you created in the Resources page.

Name
: The name of the OAuth provider is auto-populated.

Client ID
: This ID is used to authenticate and authorize the client's access to the resources. It is auto-populated based on the application that you selected under Target configuration. For more information, see Specifying the testing preferences for an API.

Client secret
: Enter the secret key corresponding to the Client ID. The client secret is displayed only once when you create the application. Note down the secret key for OAuth authorization.

Flow
: Flow in API authorization refers to the OAuth flow types that determine the process of obtaining authorization. It depends on the flow type that you select when you create the security scheme for the authorization. This field is auto-populated by default.

Scopes
: Select the check boxes of scopes that you want to add. The scopes are included in the access tokens that are generated from the OAuth provider. When an OAuth protected API is invoked, the gateway checks the scopes that are carried in the access tokens. Then it compares them against the list of allowed scopes in the security definition to determine whether to grant access.

Token URL
: This URL is used for obtaining OAuth tokens during the authentication process. The Token URL is auto-populated based on the URL that you add when creating the corresponding OAuth provider on the Resources page.

Redirect URIs
: Select the redirect URIs from the list.

Username and Password
: Enter the username and password of the user registry that is selected under the corresponding OAuth providers on the Resources page.

Click Get Token to create the access token.

The system automatically updates the access token in the Parameter tab when you apply authorization.

For more information on OAuth security schemes, see Defining OAuth2 security schemes.

e. Click Apply.
When you invoke the API, API Connect populates a header using the provided information.

2. Select an operation and request a URL from the list provided.
3. On the Parameters tab, define header, query, and path parameters.
An empty row is provided for you to define parameters, enter the parameter name in the Key field, select query, header, or path in the Located in field as appropriate, and supply a string value in the Value field. As you begin to define a new parameter, a further empty row is added automatically.

   Default header parameters and values are provided. For example, if the API has client ID or client secret definitions applied, the corresponding keys are added as header parameters, with the values preset; for details on configuring client ID and client security definitions, see Creating an API key security definition.

   The following table lists some common header definitions that are used in a request:

Table 1. Common request headers

Key	Value	Comments
Accepts	*media_type/subtype*	Specify the type of content that the response headers should use. The default is **`application/json`**.
X-IBM-Client-Id	*client_ID_val*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client ID of your application.
X-IBM-Client-Secret	*client_secret_value*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client secret of your application..
Authorization	Bearer *access_token*	Encode the token in base64. API Connect cannot encode the token for you.
Content-Type	*media_type/subtype*	Specify the type of content that the response body should use; for example, **`application/json`** or **`image/png`**.

   If the API has path or query parameters defined, these are added to the parameters list, ready for you to supply values; for details on configuring path and query parameters, see Defining Paths for a REST API and Configuring an operation.

4. If the operation is POST or PUT, set up the request body.
   a. Click the Body tab.
   b. Type the information for the body of the request.

Send the request

When your API request is configured, click Send to execute the call.

If a message displays indicating "No Response", the API call cannot be completed. Possible causes of this problem are as follows:

- CORS is not enabled in the API's definition

Edit the API's definition and enable CORS. Then, save the change and publish the API. If you are using your own client app, remember to subscribe it to the API again after publishing.

- The gateway service URL has an invalid certificate
  Follow the instructions to accept the certificate and continue testing.
- The browser cannot connect to the gateway service

Previous topic: Specifying the testing preferences for an API
Next topic: Reviewing the API response and trace

Reviewing the API response and trace

Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When the API request is invoked, the response displays in the "Response" section of the Test tab. The response always includes the HTTP status code the amount of time it took to receive a response. If the call completes (even if it returns an error), the response also includes headers and a body.

Click the Body tab to see the body of the response. When you review the body of the response, click the Parsed tab to view the response using the format that you specified in the "Accepts" request header. Click the Raw tab to view the unformatted response body.

Click the Headers tab to see the content of request headers and response headers.
Attention: If the assembly or back-end API returns a Cache-Control header, add the `Cache-Control: no-store` request header to prevent the browser from caching the request. Depending on your server, you might want to use the `Cache-Control: no-cache` header instead.
Click the Trace tab to display a record of the API execution so you can see what actions were triggered and the code that we executed for each action.

Examine the trace

Use the Trace tab to see exactly how the API call was executed. This is helpful when the call returned an error and you don't know why. You can debug the API by reviewing the trace to see each step of the API's execution.

Note: The Trace works only with the default Gateway's URL. You cannot select a different Gateway for the trace.
The Trace tab contains the following components to help you debug the API:

Process flow diagram
: In the diagram, the policies (actions) that were executed during the call are highlighted while the rest of the process flow is dimmed. The highlights make it easy to see where the executed actions occurred in the overall flow while clarifying the actual flow of execution for the call. For example, if the process flow includes a switch with three options, only the option that was selected during the call is highlighted.

Policies list
: A list of the highlighted policies lets you select a policy to examine its trace.

Advanced toggle
: The Advanced toggle that lets you control the level of detail in the trace. A basic trace shows the code for the input and output of the selected policy. An advanced trace shows the full code for the policy's execution.

Code box
: The selected level of code for the current policy displays in the code box, where you can review it in detail to see exactly how that policy was executed. By default, a minimal version of the response displays (the endpoint, the request, and the response, and the status message), with sections collapsed. You can expand individual sections by clicking the expand icon next to each. To see the complete response, click the Advanced toggle.

Previous topic: Sending the API request
Next topic: Testing a GraphQL API with the Test tab

Testing a GraphQL API with the Test tab

For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

You can test a GraphQL query in either of the following ways:

- Use a `POST` operation, in which case the query is sent in the body of the operation request.
- Use a `GET` operation, in which case the query is sent as a query parameter.

For each operation type, you can test the query against either the GraphQL API endpoint itself, or against the cost endpoint that returns details of the cost of a request to the GraphQL API endpoint.

Whichever method and endpoint you use, you can either supply the query directly, or you can use the GraphiQL editor to help construct the query; the editor provides type ahead assistance based on the schema that is defined for the API, and highlights errors along with correction suggestions. The schema was initially uploaded when the GraphQL API definition was created, but might have been modified subsequently. For details on creating a GraphQL API definition, see Creating a GraphQL proxy API. For details on modifying the schema, see Using the GraphQL schema editor.

Before you begin

See Preparing an API for debugging with the Test tab for the requirements that your API definition must meet for you to test it with the Test tab.

Procedure

1. In the Request section, select the required operation type and endpoint; for example:
   - `POST https://myserver.com/myorg/sandbox/mybasepath/graphql`
   - `GET https://myserver.com/myorg/sandbox/mybasepath/graphql/cost`
2. On the GraphiQL tab, in the left hand pane of the editor, supply the query; for example:

```
{
  accounts(limit: 100) {
    name {
      first
      last
    }
  }
}
```

3. If required, you can supply additional request headers on the Parameters tab.
4. If your query includes variables, you can supply values for the variables in the Query Variables pane. For example, if the query is as follows:

```
query MyQuery($Query__accounts__limit: Int)
{
  accounts(limit: $Query__accounts__limit) {
    name {
      first
      last
    }
  }
}
```

   you can set a value for the `Query__accounts__limit` by entering the following in the Query Variables pane:

```
{
  "Query__accounts__limit": variable_value
}
```

   where *variable_value* is the required value.
5. Click either Send, or the Execute Query icon ▶ in the editor. The response is displayed in the GraphiQL editor, and the Trace section shows you how the API call was executed. For details on the trace information, see Examine the trace.

Previous topic: Reviewing the API response and trace

Testing an API with Automated API behavior testing

Use the IBM® Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.

Automated API behavior testing provides a simple set of fields where you can quickly invoke your API through automation.

Automated API behavior testing is an optional add-on to API Connect, and must be deployed by your administrator. If Automated API behavior testing is available in your deployment, a Test API displays on the Home page in API Manager.

If you want to use Automated API behavior testing for validating an API, complete the following steps to get started.

1. Log in to API Manager.
2. Activate your API to make sure that it's available online.
3. Create a client application and copy its client ID and client secret.
4. Subscribe the client app to the API.
5. Click API Manager in the banner to return to the Home page, and then click the Test API tile.

- **Testing an API with the Policies editor**
  IBM API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.

Testing an API with the Policies editor

IBM® API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note:

- If you are testing an OpenAPI 2.0 API, you can use either the Policies editor test tool described here, or you can use the Test tab. If you are testing an OpenAPI 3.0 API, only the Test tab is available; see Using the Test tab to debug your API.
- If you are testing an API that contains references to API properties, only those references that are defined inside the API assembly are resolved and replaced with their corresponding values when you invoke the API in the assembly test tool; property references that are defined outside of the API assembly are not resolved. For more information on API properties, see Setting API properties (OpenAPI 2.0) or Setting API properties (OpenAPI 3.0).
- Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.

Procedure

To test an API, complete the following steps.

1. If you are using API Designer, set the mode to Online using the Options menu ⋮ on the main page.
2. In the navigation pane, click Develop, then select the APIs tab.
3. Click the title of the API that you want to work with.
4. Click the Gateway tab then, in the navigation pane, click Policies.
5. If you are testing the API for the first time and, when you created the API definition, you selected the Activate API option, your test setup will already be configured and you can proceed immediately to the next step to test your API. Otherwise, click Offline to toggle the API to the Online state. If you are retesting your API after making changes, the modified API will have been republished automatically on saving.
6. Click the Test icon.
   Note:
   - The Test icon is active only if you have toggled your API to the Online state, as described in step 5.
   - The Catalog, Product, Plan, and application details displayed in the Setup pane reflect your configured API testing preferences; see Specifying the testing preferences for an API,
7. In the Operation section, select the API operation that you want to test, then click Invoke.
   The API response is displayed in the Response section.
   Note: If you receive a message relating to an untrusted certificate, click the link provided, accept the certificate, then return to the test environment and click Invoke again. The message also mentions a lack of CORS support on the server, but this is just one possible cause for the connection failing.

Testing an API with the Local Test Environment

Use the Local Test Environment (LTE) to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.

API Connect provides the following methods for testing an API on your local machine:

- Invoke the API from the API Designer UI application running in Online mode as described in Testing an API.
- Call the API in the Local Test Environment with a cURL command, as described in the following sections.

Prerequisites

- The API Connect developer toolkit, including the API Designer user interface, installed. For installation and running instructions, see Installing the toolkit.
- The Local Test Environment and the API Designer must be from the same API Connect fix pack release in order for them to work together.
- Docker installed.
  Note: The Local Test Environment is not supported with Docker Version 18.09.x.
- A minimum of 4 GB of RAM available to Docker if a single gateway type is used, or 6 GB if both the DataPower® API Gateway and DataPower Gateway (v5 compatible) are used.
  Note: As you increase the number of APIs that are published to your gateways, you will need to allocate further memory to Docker. You will also need to start the Local Test Environment with a larger database; see **`apic-lte start`**.
- If you are using Windows, ensure that your C: drive (or the drive on which your HOME directory is located, if different), is enabled as a shared drive so that the Local Test Environment files are accessible to the Docker containers.

Installing the Local Test Environment

There are two options for installing the Local Test Environment:

- Each user downloads the Local Test Environment images to their local machine and installs the Local Test Environment from there.
- One user downloads the Local Test Environment images and uploads them to a private Docker registry, from where any user can install the Local Test Environment.

To install the Local Test Environment from your local machine, complete the following steps:

1. Open a browser and visit the API Connect announcement page, search for your product version, and locate the "Downloads" table on the product announcement page. In the table, click the link to download each of the following files:
   - apic-lte-images-*version*.tar.gz, which contains all required Docker images.
     Example: apic-lte-images-10.0.2.tar.gz
   - apic-lte-*platform*-*version*, which are binary files for the macOS, Linux®, and Windows platforms.
     Examples:
     - macOS: apic-lte-osx-10.0.2
     - Linux: apic-lte-linux-10.0.2
     - Windows: apic-lte-win-10.0.2
2. On the macOS or Linux platform, use the **`chmod`** command to make the binary file executable; for example:

   ```
   chmod +x linux-apic-lte
   ```

3. Load the Docker images into your local Docker image repository by entering the following command:

   ```
   docker load < apic-lte-images.tar.gz
   ```

Note: In all Local Test Environment commands that are used on the remainder of this page, replace *platform* with **`macOS`**, **`linux`**, or **`windows`**, depending on your platform, as follows:

- macOS: replace ***`platform`*`-apic-lte`** with **`osx-apic-lte`**
- Linux: replace ***`platform`*`-apic-lte`** with **`linux-apic-lte`**

- Windows: replace ***platform*-apic-lte** with **win-apic-lte**

To upload the Local Test Environment images to a private Docker registry, complete the following steps:

1. Download the **IBM_API_CONNECT_LOCAL_TEST_ENVIRO.zip** file as described in step 1.
2. Distribute the appropriate binary file to all users, according to the platform.
3. Upload the Local Test Environment to your private Docker registry; enter the following command:

   platform*-apic-lte registry-upload apic-lte-images.tar.gz *registry_host

   where *registry_host* is the host name or IP address of your private Docker registry. Now, any user can install and run the Local Test Environment as follows:
   a. If the private Docker registry requires authentication, log in by entering the following command:

      docker login *registry_host*

   b. Load the Docker images into your local Docker image repository by entering the following command:

      platform*-apic-lte init *registry_host

Starting the Local Test Environment

1. Start the Docker images by running the following command:

   ***platform*-apic-lte start**

   Note:
   - By default, the ***platform*-apic-lte start** command starts only a DataPower API Gateway. To also start a DataPower Gateway (v5 compatible), enter the following command:

     ***platform*-apic-lte start --datapower-gateway-enabled --datapower-api-gateway-enabled**

   - The Local Test Environment might fail to start with an error message that includes the strings **Error: certificate is not yet valid** and **CERT_NOT_YET_VALID**. The most likely cause is that the date and time setting is incorrect on the machine that is the running the Local Test Environment. Ensure that the date and time setting is correct, before attempting the start command again. If you are using Docker for Windows, the clock in the Docker containers can become out of sync with the system clock, especially after a machine has been put in sleep mode. In this case, restarting Docker should fix the clock discrepancy; for more information, see https://github.com/docker/for-win/issues/4526.
   - By default, the LTE starts with an empty backend database that does not contain the APIs and Products that might have been published during an earlier run of the LTE. To start the LTE with the backend database that was used during the previous run, use the flag **--keep-config**, for example, **platform-apic-lte start --keep-config**. When you use **--keep-config** any other flag that is specified for the start is ignored. Instead the same flags that were used during the earlier start are used, in particular the same gateways are enabled.
2. Verify that the Local Test Environment is installed and running correctly by running the following commands:
   a. Check the status of the LTE components:

      ***platform*-apic-lte status**

      This output from this command shows the status of all components, and provides endpoint and authentication details, and should be similar to the following:

      ```
      Container                       Status
      ---------                       ------
      apic-lte-apim                   Up 3 minutes
      apic-lte-datapower-gateway      Not Running
      apic-lte-datapower-api-gateway  Up 2 minutes
      apic-lte-db                     Up 3 minutes
      apic-lte-juhu                   Up 3 minutes
      apic-lte-lur                    Up 3 minutes

      - Platform API url: https://localhost:2000
      - Admin user: username=admin, password=7iron-hide
      - 'localtest' org owner: username=shavon, password=7iron-hide
      - 'localtest' org sandbox test app credentials client id: 80963e74076afe50d346d76401c3c08a
      - Datapower API Gateway API base url: https://localhost:9444/localtest/sandbox/
      ```

   b. Log in to the management server:

      apic login --server localhost:2000 --username shavon --password 7iron-hide --realm provider/default-idp-2

      This command confirms that you can log in to the management server, and the response should be as follows:

      Logged into localhost:2000 successfully

      Known issue: If you receive an error during the login, stop and then restart the LTE; then log in again.

Note: To configure the toolkit credentials for Local Test Environment, use the following command:

apic client-creds:set ~/.apic-lte/credentials.json

Preparing an API for testing in the Local Test Environment

To prepare an API for testing in the Local Test Environment, you must publish it to the Sandbox Catalog in the Local Test Environment. If you want to test an API that you already published, proceed to Testing an API in the Local Test Environment., otherwise, complete the following steps:

1. Launch the API Designer user interface with the following command:

   APIC_DESIGNER_CREDENTIALS=~/.apic-lte/credentials.json <path-to-designer>

2. Open the required local directory; this is the directory in which your API and Product definition files will be stored.
3. Connect to the Local Test Environment. If you haven't previously connected to the Local Test Environment, click Add Another Cloud, then complete the following steps:

a. In the HOST URL field, enter `https://localhost:2000`, then click Next.
b. In the Username field, enter `shavon`, in the Password field enter `7iron-hide`, then click Sign in.
Note:
- If you are not able to connect to the Local Test Environment using `https://localhost:2000`, enter `https://127.0.0.1:2000` instead in the HOST URL field.
- If you receive an error during the login, stop and then restart the LTE; then log in with API Designer again.

If you have previously connected to the Local Test Environment, click the existing tile to log in immediately.

The API Designer welcome page opens.

4. Click Develop APIs and Products, then click the API that you want to test. For details on how to configure an API definition, see Developing your APIs and applications.
5. You must publish your API before testing. For instructions on how to publish an API, See Publishing a draft Product
Note: Whenever you make any changes to an API, you must republish it before retesting.

Testing an API in the Local Test Environment.

To test an API in the Local Test Environment, issue a REST API call to the following URL:

**`https://localhost:9444/localtest/sandbox/`*`basepath/operation_path`*`?client_id=`*`lte_client_id`*

where:

- *basepath* is the base path that is configured in the API definition.
- *operation_path* is the path for the operation that you want to invoke, as configured in the API definition.
- *lte_client_id* is the client ID for the test application in the local test environment, as returned by the ***`platform`*`-apic-lte status`** command in step 2.

The following example show how to test the API that is created in the tutorial Creating a proxy REST API definition, by using the **`curl`** utility; the API returns the details of bank branches:

```
curl -k https://localhost:9444/localtest/sandbox/branches/details?client_id=80963e74076afe50d346d76401c3c08a

```

Local Test Environment commands

The following table summarizes the Local Test Environment commands; use the **`help`** command to get full usage details for any command.

Table 1. Local Test Environment command summary

Command	Description
***`platform`*`-apic-lte help `*`command`**	Display help information for any command.
***`platform`*`-apic-lte init`**	Download the Local Test Environment Docker images.
***`platform`*`-apic-lte start`**	Start the Local Test Environment Docker images. Use the **`--database-max-heap-size`** parameter to set the size of the Local Test Environment database, in bytes; for example: **`linux-apic-lte start --database-max-heap-size 4096M`** **`linux-apic-lte start --database-max-heap-size 1G`** **`linux-apic-lte start --database-max-heap-size 1048576K`** **`linux-apic-lte start --database-max-heap-size 1073741824`** The default value is **`1024M`**. Tip: By default, the ***`platform`*`-apic-lte start`** command deletes all previous data and re-initializes the Local Test Environment configuration, so all your previous configuration, including published Products, is deleted. To retain the previous configuration, and to apply the same command parameters that were used in the previous ***`platform`*`-apic-lte start`** command, supply the **`--keep-config`** parameter.
***`platform`*`-apic-lte status`**	Display status information for the Local Test Environment components, and endpoint and authentication details.
***`platform`*`-apic-lte stop`**	Stop the Local Test Environment Docker images.
***`platform`*`-apic-lte version`**	Display Local Test Environment version information.

Troubleshooting the Local Test Environment

You can consult the log file for each Local Test Environment microservice or database by using the following command:

`docker logs container-name`

where *container-name* is one of the following:

- `apic-lte-juhu`: the authentication gateway
- `apic-lte-apim`: the API Management service
- `apic-lte-lur`: the Local User Registry
- `apic-lte-db`: the Postgres database of the API Management service
- `apic-lte-datapower-api-gateway`: the DataPower API Gateway
- `apic-lte-datapower-gateway`: the DataPower Gateway (v5 compatible)

You can access the gateway logs in either of the following ways:

- Use the gateway administration web UI:
  1. Open the page `https://localhost:web_ui_port` in a browser; for details of the required port value, see Local Test Environment port values.
  2. Select the apiconnect domain and the WebGUI interface, and log in with user name `admin` and password `admin`.
  3. Click View Logs.
- Use the gateway administration CLI:
  1. Open an SSH connection by using the following command:

     ```
     ssh -p gateway-ssh-port localhost
     ```

     For details of the required port value, see Local Test Environment port values. The user name is `admin` and the password is `admin`.
  2. Enter the command **switch domain apiconnect**.
  3. To view the gateway log, enter the command **show log**.
  4. To view the log for the communication between the gateway and the API management system, enter the command **show logging gwd-log**.

Local Test Environment port values

If any of the default port values for the Local Test Environment components conflict with ports already in use on your system, you can change them when you start the Local Test Environment by passing one or more `--component port_value` parameters to the `platform-apic-lte start` command, where:

- *component* is the Local Test Environment component whose port value you want to change.
- *port_value* is the required value.

For example:

```
platform-apic-lte start --datapower-api-gateway-api-port 9445
```

The following table lists the components, together with the corresponding *component* parameters, and the default port values:

Component	*component* parameter	Default port value
DataPower API Gateway API port	`datapower-api-gateway-api-port`	9444
DataPower API Gateway API Connect service port	`datapower-api-gateway-apic-service-port`	3001
DataPower API Gateway REST management port	`datapower-api-gateway-rest-management-port`	5555
DataPower API Gateway SSH port	`datapower-api-gateway-ssh-port`	9023
DataPower API Gateway administration web UI	`datapower-api-gateway-web-gui-port`	9091
DataPower API Gateway XML management port	`datapower-api-gateway-xml-management-port`	5551
DataPower Gateway (v5 compatible) API port	`datapower-gateway-api-port`	9443
DataPower Gateway (v5 compatible) API Connect service port	`datapower-gateway-apic-service-port`	3000
DataPower Gateway (v5 compatible) REST management port	`datapower-gateway-rest-management-port`	5554
DataPower Gateway (v5 compatible) SSH port	`datapower-gateway-ssh-port`	9022
DataPower Gateway (v5 compatible) administration web UI	`datapower-gateway-web-gui-port`	9090
DataPower Gateway (v5 compatible) XML management port	`datapower-gateway-xml-management-port`	5550
Platform API port	`platform-api-port`	2000

Testing an API with the Explorer tab

Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can also use the Try it tool to test the behavior of the API.

Before you begin

To test an API in the Try it test tool, the API must be auto-published. If the API is not auto-published, the Try it tool isn't enabled in the Explorer.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

About this task

The Explorer tab in the API editor of the API Designer UI and API Manager UI enables you to view how your APIs look to an API consumer in the Developer Portal. You can check the descriptions of the different artifacts, and as well as any schemas or examples, and you can also test the behavior of the API by using the Try it tool.

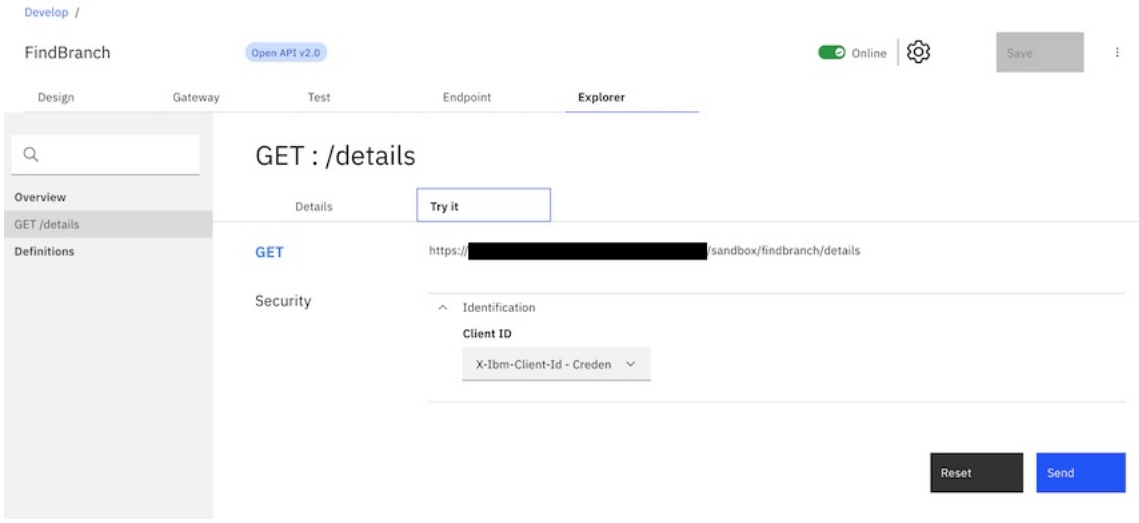
Note:

- You cannot use the Try it tool to test non-enforced APIs.

Procedure

To test an API by using the Try it tool, complete the following steps.

1. If you are using API Designer, set the mode to Online using the Options menu ⋮ on the main page.
2. In the navigation pane, click Develop, then select the APIs tab.
3. Click the title of the API that you want to work with.
   The API editor is displayed.
4. Click the Explorer tab.
   An Overview of the API is displayed.
5. Click the API artifacts in the side menu bar to explore the operations and definitions that are available in the API, including reviewing any examples and schemas.
6. To test API behavior, click an operation in the side menu bar, and click the Try it tab.
   The test pane for the operation is displayed, as shown in the following example:



7. Provide any required API parameters, and click Send.
   The API response is displayed in the Response section.
   Note: If you receive a message relating to an untrusted certificate, click the link provided, accept the certificate, then return to the test environment and click Send again.

What to do next

When you are happy with the look and behavior of your API, you can stage the API to a Product in a Catalog. For more information, see Staging an API.

Staging an API

The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Staging is not available when working offline in API Designer.

A Catalog is a staging target, and behaves as a logical partition between the DataPower® Gateway and Developer Portal.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **`X-IBM-Client-Id`** or **`X-IBM-Client-Secret`**.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of **`$ref`** properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **`$ref`** field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can stage an API either from the Develop listing page, or from within the API definition itself.
   a. To stage an API from the Develop listing page, click the options menu icon alongside the required API, and then select Stage.
   b. To stage an API from within the API definition, complete the following steps:
      i. Click the title of the API that you want to work with.
      ii. Click the options menu icon:

      iii. Click Stage.
4. Choose one of the following actions:
   - To stage the API by adding it to a new Product:
     - Select New Product - Publish using a new product.
     - When prompted, enter a Title and Version.
     - The Product Name is automatically entered. The Name is the used to refer to the product in CLI commands. See the toolkit CLI reference documentation.
     - Click Next.
   - To stage the API by adding it to an existing Product:
     - Select Existing Product - Publish using an existing product
     - Select the Product you want to use.
     - Click Next.
5. On the Stage To page, select the Catalog to which you want to stage the Product.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.
6. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
7. Click Stage.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Publishing an API

The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Manage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **`X-IBM-Client-Id`** or **`X-IBM-Client-Secret`**.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of **`$ref`** properties), and ensuring these are valid JSON Pointers within the file.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "**`(?`**" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **`$ref`** field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can publish an API either from the Develop listing page, or from within the API definition itself.
   a. To publish an API from the Develop listing page, click the options menu icon ⋮ alongside the required API, and then select Publish.
   b. To publish an API from withing the API definition, complete the following steps:
      i. Click the title of the API that you want to work with.
      ii. On the Develop page, click the Menu icon (three dots), adjacent to the API that you want to edit, and then click Edit API.
      iii. Click the Test tab and then select Target Configuration.
      The Preferences dialog box is displayed.
      iv. Set the Auto-publish option to On.
   Remember: The auto publish setting is not associated with individual APIs. If you activate the auto publish setting for one API, it applies to all other APIs, regardless of the catalogue or the gateway. Therefore, it is highly recommended that you select a single set of settings for all the APIs instead of changing the settings individually for each API.
4. Choose one of the following actions:
   - To publish the API by adding it to a new Product:
     - Select New Product - Publish using a new product.
     - When prompted, enter a Title and Version.
     - The Product Name is automatically entered. The Name is the used to refer to the product in CLI commands. See toolkit CLI reference documentation.
     - Click Next.
   - To publish the API by adding it to an existing Product:
     - Select Existing Product - Publish using an existing product
     - Select the Product you want to use.
     - Click Next.
5. Select the Catalog to which you want to publish the Product.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.

7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. Click Publish.

Results

Your Product is published to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the Pending state; the Product is published in the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see Publishing a Product.
For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Notes:

- If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.
- If the Product contains an API that includes a user-defined policy that has not been imported into this Catalog, the publish will fail. The user-defined policy must be available in the required Catalog for the Product to be published successfully. For detailed instructions on how to import a user-defined policy into a Catalog, see Importing a user-defined policy into a Catalog.

Creating a new version of an API definition

You can create multiple versions of an API definition and edit the versions independently by using IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: If you want to publish a modified API to a production Catalog, you **must** create a new version of the API. You cannot publish an API to a production Catalog if there is already a published API with the same name and version.

Procedure

To create a new version of an API definition, complete the following instructions:

1. In the navigation pane, click Develop, then select the APIs tab.
2. You can create a new version of an API definition either from the Develop page, or from within the API definition itself.
   a. To create a new version of an API definition from the Develop page, complete the following steps:
      i. Alongside the API version that you want to work with, click the options icon, then click Save as a new version. The Save API as a new version window opens.
      ii. Enter your new version number, then click Save.
   b. To create a new version of an API definition from within the API definition itself, complete the following steps:
      i. Click the title of the API definition that you want to create a new version of.
      ii. Click the options menu icon:

      iii. Click New Version, enter your new version number, then click Submit.

Note: The version corresponds to the **`info.version`** property value of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended, for example `1.0.0`.

Results

You have created a new version of your API definition, which you can now edit independently of other versions. Each version of the API definition is listed separately on the APIs and Products page.

Related tasks

- Creating an API definition

Updating an API definition from a file

You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The update operation completely replaces the previous API definition.

Procedure

To update an API from a file, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to update.
3. Click the options menu icon:

4. Click Update, then either drag and drop the file or click the link to select the file from your local file system.
5. Click Submit, then click Save.

Updating a SOAP API

You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.

About this task

You complete this task by using the browser based API Manager UI.

You can also use the API Connect developer toolkit CLI to update a SOAP API; for more information see API development and management commands.

When you initiate the update action, the specified WSDL is parsed to find a service that matches the name of the API that you are updating. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed.

Only those sections of the API that are affected by the new WSDL are replaced, the other sections are unchanged.

Procedure

To update a SOAP API from a WSDL file or a .zip archive, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the SOAP API that you want to update.
3. Click the options menu icon:

4. Then click Update WSDL, and either drag and drop the file or click the link to select the file from your local file system.
   The format of the WSDL file is validated. If the format is invalid, an error message is displayed.
5. Click Next.
   The services in the selected API are displayed. If no match is found, an error message is displayed.
6. Click Upload.
   The SOAP API is updated from the specified WSDL definition.
7. Click Save to save the updates.
8. If you updated a previously published API, you must publish it again for the change to take effect:
   a. Click the Online/Offline toggle (shown in step 3) to set the API as Offline.
   b. Click the toggle again to set the API back to Online, which publishes the API again.

Related tasks

- Creating an API definition

Renaming an API definition

By renaming an API definition, you change the **name** property that, together with the version, is used to uniquely identify the API definition in API Connect. The **name** property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Click the options menu icon:

4. To rename the API, select Rename.
   Only this version of the API is renamed.
5. Enter the new name, then click Submit.
   Note: If you previously added the API to a Product, it will no longer be recognized by that Product. You must open the Product and modify the **`apis:`** section on the Source tab as appropriate; for example:

```
apis:
  newname1.0.0:
    name: 'newname:1.0.0'
```

Changing an API rate limit

When you activate an API to make it available for testing, as described in Activating an API, no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Note:

- For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.
- If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the **Target product rate limit** option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied. for more information, see Defining rate limits for an API operation.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Select Test tab and click Target Configuration.
4. On the Preferences page, locate the Target product rate limit and click Edit.
5. Select Unlimited to allow unrestricted calls to the API, or select Custom to define the required rate limit; use the supplied fields to define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute.
   Note:
   The system clock determines the start time for rate, and burst limits. The intervals are configured as follows:
   - 1 second interval starts at each new second.
   - 1 minute interval starts at the beginning of each minute.
   - 1 hour interval starts at the beginning of each hour.
   - 1 day interval starts at midnight UTC.
   - 1 week interval starts on Thursday at 00:00:00 UTC.
6. Click Choose Rate Limit when done.
7. Click Save Preferences.

Results

You have successfully updated the rate limit period for the API.

Adding an OpenAPI extension to an API

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.

Before you begin

Import the OpenAPI extension into the Sandbox Catalog, or into any Catalog to which the API that you are adding the extension to will be published; see Importing an OpenAPI extension into a Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Select the Gateway tab, expand Gateway and portal settings, then click Extensions.
4. Select the OpenAPI extensions that you want to use with this API, then click Save.
   Note: The OpenAPI extensions listed are those that have been imported into the Catalog and gateway service defined in the testing preferences for the API; see Importing an OpenAPI extension into a Catalog and Specifying the testing preferences for an API. You will also need to import the OpenAPI extension into any Catalog to which the API will be published.
5. Update the OpenAPI source for the API definition with the values for the fields as defined in your selected OpenAPI extension schema files, as follows:
   a. Click the Source icon </>.
   b. Add a property whose name must begin with **`x-`** and references the name of the OpenAPI extension that you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file.
   For an example, see Referring to an extension in an API definition
   c. Click Save when done.

Downloading an API definition

You can download the details of your API definitions so that you can store them for later recovery.

Before you begin

To complete this task, you must have created an API definition. For more information, see Creating an API definition.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Drafts:View`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

You can download REST APIs that were created by using Creating a REST proxy API from a target service for example. This download creates a .yaml file that defines the API.

You can download SOAP APIs that were created by using Creating a REST proxy API from an existing WSDL service , or Creating a SOAP proxy API from an existing WSDL service for example. This download creates a .zip file that contains the WSDL definition and the YAML file that defines the API.

You can use the downloaded .yaml and .zip files to re-create your API. For information about creating an API from a .yaml file, see Adding a REST API by importing an OpenAPI definition file. For information about creating an API from a .zip file, see Adding a SOAP API by importing a zip file.

Procedure

To download a .yaml, or .zip file that contains the details of your API, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Alongside the API version that you want to work with, click the options icon ⋮ and then click Download.
3. Save the file to the required location.

Results

You downloaded a .yaml, or .zip file with a representation of your API.

Deleting an API definition

You can delete an API definition that is no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. You can delete an API either from the Develop listing page, or from within the API definition itself.
   a. To delete an API from the Develop listing page, click the options menu icon ⋮ alongside the required API, and then select Delete.
   b. To delete an API from within the API definition, complete the following steps:
      i. Click the title of the API definition that you want to work with.
      ii. Click the options menu icon:

      iii. To delete just this version of the API, select Delete. To delete all versions of this API, select Delete API.

   Note: If a Product was previously generated automatically from the API, by using the Activate API option, that Product will be deleted together with the API; such Products have the title *api_title* auto product.
3. Click Delete to confirm.

Using an options file when importing a WSDL service

When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.

You can use an options file when importing a .zip file while performing any of the following tasks:

- Creating a REST proxy API; see Creating a REST proxy API from an existing WSDL service.
- Creating a SOAP proxy API; see Creating a SOAP proxy API from an existing WSDL service.
- Adding a target WSDL service to an API definition; see Editing an API definition.

The options file is a YAML file, and must have the file name apiconnect.yaml.

You can include the following fields in the file:

Table 1. Fields that can be included in the apiconnect.yaml file

Field name	Value	Default	Description
`suppressExamples`	**`true`** or **`false`**	**`false`**	Suppress auto-generation of examples.
`wssecurity`	**`true`** or **`false`**	**`true`**	Enable generation of definitions for WS-Security headers.
`implicitHeaderFiles`	Array of XSD file locations		Additional schema files, not referenced in the WSDL, that are used to define additional SOAP headers.
`port`	The **`name`** attribute for a **`wsdl:port`** in a **`wsdl:service`** definition.		Create the API by using the information for the specified port. If the specified port does not exist, or refers to a REST/XML port rather than a SOAP port, the API creation fails. If no **`port`** field is present in the options file, API Connect creates the API by using the first SOAP port that it finds in the **`wsdl:service`** definition.

Example

```
suppressExamples: true
wssecurity: false
implicitHeaderFiles:
  - xsdDir/schema1.xsd
  - xsdDir/schema2.xsd
```

Variable references in API Connect

In API Connect you can reference different variables in your API definition.

When defining an API, creating a custom policy, or configuring another policy or logic construct, you can include references to context variables and properties.

Variable references are resolved either when the API is staged in a Product, for static variables that are fixed upon staging, or when the API is called, for variables that can change with each API call.

Types of variables

Context variables

A context variable is a variable relevant during an API call, for example, the input of the call, the path of the call, or the message during the call. A context variable is one of the variables that makes up that particular context.
Context variables can consist of more than one part, for example, `request.headers`.

For a list of available context variables, see API Connect context variables.

API properties

An API property is a variable in an API where its value depends upon the Catalog in which the API is staged or published. By referencing an API property, you can use the same API definition in different Catalogs where there are small differences between the instances of the API between the Catalogs. For example, an assembly could contain an **if** construct that executes its case when a particular Catalog is used, determined from the value of the API property. API properties can also be used to hide a value such as a password by encoding the value.
API properties are referenced by name.

For a list of API properties, see API properties

For more information, see Setting API properties (OpenAPI 2.0) or Setting API properties (OpenAPI 3.0).

Note: Once defined, an API property is read only.

Catalog properties

A Catalog property is specific to a Catalog. and can be referenced in any of the API definitions in that Catalog. For more information, see Creating and configuring Catalogs.

Notes:

- If you change the value of a Catalog property, any API that references that property must be republished for it use the new value.
- Catalog properties and API properties are not supported with global policies. Therefore, if you use such properties in a global policy, they are not replaced with the values specified in the Catalog or API property definitions.

Methods of referencing variables

You can get, or set, the value for a referenced variable.

- Get the value for a variable in either of the following ways:
  - Through the GatewayScript policy, run the **apim.getvariable()** API.
  - API Gateway only Through the GatewayScript policy, use the **context.get()** function; for more information, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.
  - Through the XSLT policy, run a stylesheet that uses the **apim:getVariable** extension function.
  - In an assembly policy field that supports variable references, use the following syntax:

    $(*variable*)

- Set the value for a variable in either of the following ways:
  - Through the Set Variable policy.
  - Through the GatewayScript policy, use the **apim.setvariable()** API.
  - API Gateway only Through the GatewayScript policy, use the **context.set()** function; for more information, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.
  - Through the XSLT policy, run a stylesheet that uses the **apim:setVariable** extension element.

GatewayScript references

When you want to reference a variable in a GatewayScript context, use one of the following methods:

```
apim.getvariable(variable)
```

where *variable* is the name of the context variable or API property that you want to reference.

```
apim.setvariable(variable, value, action)
```

where

- *variable* is the name of the context variable or API property that you want to reference.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, use the following code:

  ```
  var contentType = apim.getvariable('request.headers.content-type');
  apim.setvariable(variable, contentType, 'set');
  ```

  This property is required only when **set** or **add** is specified as the action.
- *action* is the action that you want to apply to the variable. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

Use the **getvariable** method to retrieve the value of a context variable or API property, and the **setvariable** method to change one.

Some of the situations where you would use this type of reference are:

- GatewayScript policies. -For more information, see GatewayScript.
- **if** logic constructs. For more information, see if.
- User-defined policies. For more information, see Authoring policies.

Stylesheet references

You can reference a variable by using functions and elements in an XSLT policy with the following syntax:

```
<xsl:variable name="variable_name" select="apim:getVariable(variable)" />
```

where *variable* is a literal value, another variable, or a valid XSLT XPath statement.

```
<xsl:call-template name="apim:setVariable">
    <xsl:with-param name="varName" select="variable"/>
    <xsl:with-param name="value" select="value"/>
```

```
    <xsl:with-param name="action" select="action"/>
</xsl:call-template>
```

where

- *variable* is the name of the context variable or API property that you want to reference. This can be a literal value, another variable, or a valid XSLT XPath statement.
- *value* is the string value that you want to set the variable to. This can be a literal value, another variable, or a valid XSLT XPath statement. This property is required only when **set** or **add** is specified as the action.
- *action* is the action that you want to apply to the variable. This can be a literal value, another variable, or a valid XSLT XPath statement. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

The following example sets a named variable to the value of the Content-Type header in a request:

```
<xsl:variable name="contentType" select="apim:getVariable('request.headers.content-type')" />
<xsl:call-template name="apim:setVariable">
    <xsl:with-param name="varName" select="'variable'"/>
    <xsl:with-param name="value" select="$contentType"/>
    <xsl:with-param name="action" select="'set'"/>
</xsl:call-template>
```

Inline references

In many situations you can make a simpler reference, by using the following syntax:

```
$(variable)
```

where *variable* is the name of the context variable or API property that you want to reference.
Some of the situations where you would use this type of reference are:

- The URL called by an Invoke or Proxy policy. For more information about the policies, see Invoke or Proxy.
- A Map policy. For more information, see Map.

Notes: The map policy can reference the following variables inline:

- Variables that are defined as inputs to the map policy and specified in the from field of a mapping.
- Context variable or API properties, provided that the **x-ibm-gateway-map-resolve-apic-variables** API property is not set to **false**. If an inline reference in a map policy resolves to a context variable or API property, it is immediately replaced by the corresponding value. For more information on the **x-ibm-gateway-map-resolve-apic-variables** API property, see Properties controlling the map policy.

For more information on the use of inline references, and examples, see the following About inline references section.

About inline references

When you use an inline reference for a property value in an assembly policy, the variable reference is replaced with the corresponding string value at run time, before the property is evaluated. For example, consider the following incoming request, which has two headers and two query parameters (a **curl** command is used to illustrate the request):

```
curl --data-binary @request.json \
   -H 'Content-Type: application/json' \
   -H 'X-Environment: test' \
   http://apiserver/org/catalog/petstore/getPetDetails?petid=285&storeid=z03
```

If an **invoke** policy is configured as follows:

```
 invoke:
    target-url: https://backend/GetPetInfo/$(request.parameters.storeid)/$(request.parameters.petid)
```

then the value of the **target-url** property is evaluated as **https://backend/GetPetInfo/z03/285**, and this is therefore the URL to which the **invoke** policy sends its request.

DataPower Gateway (v5 compatible) only You can also use an inline reference in the **condition** property of a **switch** policy. Consider the following example:

```
- switch:
    case:
        - condition: "$(request.headers.X-Environment)" == "production"
          execute:
              - invoke:
                  http://www.finance.com/base/stockquote
        - condition: "$(request.headers.X-Environment)" == "test"
          execute:
              - invoke:
                  http://testserver1.finance.com/stockquote
```

Using the incoming request referred to previously, the value of the **X-Environment** header is **"test"**. The inline references are first evaluated, then the conditions are evaluated as JavaScript. Therefore, the first condition is evaluated as **"test" == "production"**, returning **false**, and the second condition is evaluated as **"test" == "test"**, returning **true**, so the **invoke** policy sends its request to **http://testserver1.finance.com/stockquote**.
Important: This example, which encloses the inline references inside double quotes, assumes that the API is deployed to the DataPower API Gateway. If you deploy the API to the DataPower Gateway (v5 compatible), then the double quotes are added implicitly when the inline references are evaluated, and you must therefore omit them from the **condition** property; the two conditions in this example would therefore be

```
condition: $(request.headers.X-Environment) == "production"
```

and

```
condition: $(request.headers.X-Environment) == "test"
```

However, as an alternative to using an inline reference in a `condition`, you can instead use pure JavaScript, as follows:

```
- switch:
    case:
        - condition: request.headers["X-Environment"] == "production"
          execute:
              - invoke:
                  http://www.finance.com/base/stockquote
        - condition: request.headers["X-Environment"] == "test"
          execute:
              - invoke:
                  http://testserver1.finance.com/stockquote
```

in which case the policy configuration will work correctly as-is in both types of gateway.
For more information on the types of gateway, see API Connect gateway types.

In addition to single strings, you can use an inline reference for a complete object. Consider the following example, which uses an inline reference in a `set-variable` policy:

```
- set-variable:
    actions:
        - set: saved.reqHdrs
          value: $(request.headers)
          type: string
```

Here, the `request.headers` structured JSON object is substituted with its corresponding string representation, and a variable named `reqHdrs` is therefore created, under the `saved` object, with a string value of `{"Content-Type":"application/json","X-Environment":"test",...}`. However, if you are using the DataPower API Gateway, you can specify `type: any`, in which case the `set-variable` policy copies the value as-is, and `saved.reqHdrs` is created as a JSON object rather than a string:

```
- set-variable:
    actions:
        - set: saved.reqHdrs
          value: $(request.headers)
          type: any
```

You can reference a property in a JSON or XML request directly by name, by using the following syntax:

`$(request.body.property_name)`

For example, if the request contains `{ "account-number": 123 }` or `<account-number>123</account-number>` you can retrieve the value `123` by using the following inline reference:

`$(request.body.account-number)`

If the property value is within a nested property structure, you can reference it by concatenating the property names. For example, if the request contains `{ "account": { "balance": 123 } }` or `<account><balance>123</balance></account>` you can retrieve the value `123` by using the following inline reference:

`$(request.body.account.balance)`

Similarly, you can reference a property in a JSON or XML response by using the following syntax:

`$(message.body.property_name)`

Restriction: If you are using the DataPower API Gateway, you can reference properties in this way only if the format of the request or response is JSON; the mechanism is not supported with XML request or response formats. If the you are using the DataPower Gateway (v5 compatible) the mechanism is supported with both JSON and XML formats.

API properties

Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.

In IBM® API Connect, you can create API properties that consist of Catalog-specific values to eliminate the need for source code modifications. You can then reference the properties elsewhere in your API definition.

Pre-supplied API properties

Pre-supplied API properties for various policies are shown in the tables.

A list of invoke related API properties that control the behavior of the invoke policy.

Table 1. Properties controlling the invoke policy

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-decode-request-params	No	If set to a value of `true`, any request parameters that are referenced by a variable definition on an invoke target-url are URL-decoded. The default behavior is to not decode any parameters, thereby sending them to the target URL without alteration.	Boolean

Property	Required	Description	Data type

DataPower Gateway (v5 compatible) only
x-ibm-gateway-invoke-suppress-clientid
	No	When set with a value of **true**, or not specified, the X-IBM-Client-Id HTTP header (if specified on the API request) is suppressed from being sent to the invoke target URL. When set with a value of **false**, the X-IBM-Client-Id HTTP header is no longer suppressed from being sent to the invoke target URL.
		This property is supported only by the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a **header-control** property to the **invoke** policy configuration in the OpenAPI definition for your API, as in the following examples.
		
		Suppress the **X-Client-ID** header as follows:
		
		`- invoke:`
		`  target-url: http://myhostname/mypath`
		`  header-control:`
		`  type: blacklist`
		`  values:`
		`  - ^X-Client-ID$`
		
		Suppress the **userId** query parameter as follows:
		
		`- invoke:`
		`  target-url: http://myhostname/mypath`
		`  parameter-control:`
		`  type: blacklist`
		`  values:`
		`  - ^userId$`
			Boolean

DataPower Gateway (v5 compatible) only x-ibm-gateway-optimize-invoke	No	If set to `false`, prevents the replacement of the last invoke in a policy with proxy. Any value other than `false` (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-queryparam-encode-plus-char	No	If set to a value of **true**, all "+" characters in the query parameter values of the target-url of the Invoke and Proxy policies are encoded to "%2F". The default value is **false**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-api-enforce-response-limits	No	If set to a value of **true**, allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned. Note: The x-ibm-gateway-api-enforce-response-limits property is supported by the DataPower Gateway (v5 compatible) but not by the DataPower API Gateway. However, if you are using the DataPower API Gateway, consider using a Parse policy in your API assembly to enforce these limits. For information on the different types of gateway, see API Connect gateway types.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-emulate-v4-soap-error	No	IBM API Management Version 4.0 initiates a DataPower error when a SOAP fault is returned from a web service. IBM API Connect provides a mechanism to catch SOAP errors and does not initiate a DataPower error. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to **true** only in the case where a gateway extension is expecting to handle a SOAP error in a post error rule. The default value is **false**. Note: This property is deprecated in favor of x-ibm-gateway-invoke-emulate-v4-invoke-error.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-keep-payload	No	If set to a value of **true**, the invoke policy sends a payload on an HTTP DELETE method. This property is available for use with IBM DataPower Gateway version 7.7.1.1 and later. The default value is **false**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-emulate-v4-invoke-error	No	IBM API Management Version 4.0 initiates a DataPower error when a backend server error is returned, either a SOAP fault returned from a web service or a JSON or XML (non-SOAP) error from a restful service. IBM API Connect provides a mechanism to catch SOAP errors and operation errors and does not initiate a DataPower error when they occur. If no catch policy is configured, a generic error message is generated. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to **true** only in the case where a gateway extension is expecting to handle a backend server error in a gateway extension post error rule or if the client of the API is expecting the backend server error to be returned. The default value is **false**.	Boolean

A list of map-related API properties that control the behavior of the map policy.

Table 2. Properties controlling the map policy

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-array-first-element-value	No	In IBM API Management Version 4.0, if a mapping source value is from an array then only the first value is output. In API Connect, the default behavior is to return an array of all array element values. To maintain compatibility with IBM API Management Version 4.0, set this API property to **true** to only return the first array element value.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-resolve-apic-variables	No	By default, any API Connect variable that is found in the map configuration is resolved. For example, **$(request.headers.content-type)** resolves to the request's content type header. Because searching for variables in every map property can be CPU intensive, you can choose not to resolve variables by setting this API property to `false`. If this property is not configured or is set to any other value, the existing behavior to search for these variables continues. Note that variable usage within a map value JavaScript snippet is not changed provided that the variables that are referenced come from a configured map input.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-create-empty-array	No	This property controls how the map policy handles the output of an empty array; it can have the following values: • **all**: Output all empty arrays, including empty children arrays. This is the default value if the property is not configured or has an invalid value. • **parent**: Output only the current property's empty array value. Children map actions of this property are not attempted. • **none**: Prevent any empty output array values from being produced.	String

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-optimize-schema-definition	No	Set the value of this property to **`true`** to provide a performance improvement to the map policy when a very complex schema definition is referenced by a policy output definition; for example, some very complex schemas that are generated by importing a very complex WSDL schema. The map policy builds a schema from an API definition when a referenced definition is provided as the value of the schema. If the schema does not have references that generate a circular reference, setting this property to **`true`** might provide a performance benefit while generating the same schema as would otherwise have been generated. However, in cases where the schema is very complex, with many potentially circular references, the generated schema could be different because the enhanced schema handling processes circular references differently. In such cases therefore, you should examine the resulting output to determine if the performance benefit gained is not at the expense of a change in the map policy output. The default value of this property, is **`false`**, maintaining the existing behavior and performance.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-null-value	No	Set the value of this API property to **`true`** to allow a property from a map policy's input data with a value of **`null`** to be mapped to the output document. By default, a property from a map policy's input data with a value of **`null`** is not mapped to the output document.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-resolve-xmlinput-datatypes	No	XML input elements with numeric or boolean data have no metadata to indicate whether this data should be mapped as a string value or as the specific data type. If you set the value of this property to **`false`**, XML input elements are always mapped as a string. If you set the value to **`true`**, numeric or boolean XML input elements are mapped as the corresponding data type from the input schema. The default value is **`false`**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-xml-empty-element	No	This property controls how the map policy handles XML input empty elements and impacts JSON output when the input document is XML; it can have the following values: • **`string`**: The value for an empty XML element is considered to be an empty string. This is the default value if the property is not configured or has an invalid value. • **`null`**: The value for an empty XML element is considered to be null. A mapping of this element to a JSON output property does not occur unless the API property x-ibm-gateway-map-null-value is also specified with a value of **`true`**. • **`none`**: The empty XML element is ignored. • **`string-badgerfish`**: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. • **`null-badgerfish`**: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the API property **`x-ibm-gateway-map-null-value`** is also specified with a value of **`true`**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-schema-definition-reference-limit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String

Property	Required	Description	Data type

DataPower Gateway (v5 compatible) only
x-ibm-gateway-map-emulate-v4-default-required-properties
	No	Set this property to true to have default values generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
		• An array consists of objects that contain one or more required properties.
		• An object which is optional has one or more child properties that are required.
		By default, these required properties are not present in the output. If you set the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property to **true**, these required properties will be present in the output. If the output schema defines a **default** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:
		• String: empty string ("")
		• Number: 0
		• Boolean: false
		• Object: empty object
		• Array: empty array
		Example 1
		The input data has the following array of objects:
		`[{"a": "value1"}, {"a": "value2", "b": "value3"}]`
		The output schema defines the output object as having two properties, **a** and **b**, of which **b** is required. The map policy defines the following mappings:
		• `input.array.a` to `output.array.a`
		• `input.array.b` to `output.array.b`
		If the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property is set to **true**, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:
		`[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]`
		Example 2
		The output schema defines the following structure:
		`{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }`
		Property **b** is optional but property **d** within **b** is required.
		The map policy defines a mapping to `output.a.b.c`.
		If the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property is set to **true**, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:
		`{"a" : {"b" : {"c" : "value1", "d" : ""} } }`
		If the **x-ibm-gateway-map-emulate-v4-default-required-properties** API property is not specified or does not have a value of **true**, these required properties are **not** created in the output with their default values.
			Boolean

DataPower Gateway (v5 compatible) only x-ibm-gateway-map-post-process-json-output	No	Set the value of this property to **true** to enable post processing of mapped JSON output. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set the value to **false** for no post processing of mapped JSON output. The default value is **false**.	Boolean

DataPower Gateway (v5 compatible) only
x-ibm-gateway-map-emulate-v4-empty-json-object
	No	If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set the value of this property to **true** to create an empty object for the parent of the target mapping, emulating the behavior of IBM API Management Version 4.0.
		Example
		The map policy defines a mapping to `output.a.b.c`.
		If input data is present, the output is as follows:
		`{ "a": { "b": { "c": "inputvalue" } } }`
		If there is no input data, and the **x-ibm-gateway-map-emulate-v4-empty-json-object** API property is set to **true**, the output is as follows:
		`{ "a": { "b": { } } }`
		Properties **a** and **b** are created but the value of **b** is an empty object.
		The default value is **false**.
			Boolean

DataPower Gateway (v5 compatible) only A list of proxy-related API properties that control the behavior of the proxy policy.

Table 3. Properties controlling the proxy policy

Property	Required	Description	Data type

x-ibm-gateway-proxy-suppress-clientid	No	A setting of `false` activates the injection of the X-IBM-Client-Id HTTP header (if it is specified on the API request), or the **`client_id`** query parameter in the request URL, to the proxy target-url. If not specified, or set with a value of `true`, suppresses the sending of this parameter to the proxy target-url.
		This property is supported only by the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a **`header-control`** property to the **`invoke`** policy configuration in the OpenAPI definition for your API, as in the following examples.
		
		Suppress the **`X-Client-ID`** header as follows:
		
		`- proxy:`
		`  target-url: http://myhostname/mypath`
		`  header-control:`
		`  type: blacklist`
		`  values:`
		`  - ^X-Client-ID$`
		
		Suppress the **`userId`** query parameter as follows:
		
		`- proxy:`
		`  target-url: http://myhostname/mypath`
		`  parameter-control:`
		`  type: blacklist`
		`  values:`
		`  - ^userId$`
			Boolean

x-ibm-gateway-optimize-invoke	No	If set to `false`, prevents the replacement of the last invoke in a policy with proxy. Any value other than `false` (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean
x-ibm-gateway-queryparam-encode-plus-char	No	If set to a value of **`true`**, all "+" characters in the query parameter values of the target-url of Invoke and Proxy policies are encoded to "%2F". The default value is **`false`**.	Boolean
x-ibm-gateway-api-enforce-response-limits	No	If set to a value of **`true`**, allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned.	Boolean

A list of API properties that control the behavior of the rate limit policy.

Table 4. Properties controlling the rate limit policy

Property	Required	Description	Data type
x-ibm-gateway-emulate-v4-plan-rate-limit	No	By default in IBM API Connect Version 10, if you configure a rate limit only for a Plan and not for the API operations within the Plan then a single rate limit threshold is set for the API as a whole, regardless of which operation in the API is requested. This behavior differs from IBM API Management Version 4.0 where the rate limit is set **individually** for **each** operation in the API. To change the Version 10 behavior to emulate the Version 4.0 behavior, set this API property to a value of **`true`**.	Boolean

A list of API properties that control the behavior of multiple policies.

Table 5. Properties controlling multiple policies

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-sourcecode-resolve-apic-variables	No	If set to **`true`**, API Connect variable references are resolved. Set to **`false`** if you want the policy to ignore API Connect variable references. The default value is **`true`**. This property applies to the following policies: • Map • GatewayScript • XSLT • if • switch Note: This property setting is overridden by the x-ibm-gateway-map-resolve-apic-variables API property setting for the Map policy.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-api-json-parse-error-handling	No	If an API request or response payload includes valid JSON content that contains characters that cannot be represented in the JSONX XML internal syntax that is used by the DataPower Gateway, set this property to **`escape-unicode`** to allow the payload to be accepted without parsing errors. If this property is not configured or is set to any other value, the payload is rejected as invalid JSON. This property applies to the API request payload, and to the API response payload when **`x-ibm-gateway-api-enforce-response-limits`** is enabled.	String
DataPower Gateway (v5 compatible) only x-ibm-gateway-framework-preserve-escaped-reverse-solidus	No	By default, the string `\\` in a policy property is converted to a single `\` character. Set this property to **`true`** to preserve the string `\\`.	Boolean

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-inspect-request-headers	No	Causes an inspection of the HTTP headers in the API request to check for characters in the header values that are illegal XML characters; it can have the following values: • **`default`**: There is no inspection for these characters in the header values. If one is present, the API request fails with an HTTP 500 Internal Server Error. • **`sanitize`**: Any illegal XML characters in header values are replaced with a **`?`** character. The API processing will continue. Any API that attempts to read **`request.headers.<headername>`** will see the **`?`** character in the value. However, the original protocol headers representing **`message.headers`** will still have the original character, which will be sent to an invoke or proxy backend server. • **`bad-request`**: There will be an inspection for these characters in the header values. If one is present, the API request fails with an HTTP 400 Bad Request. The default value is **`default`**.	Boolean

API policies and logic constructs

Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.

Policies are the building blocks of assembly flows, and they provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

Logic constructs behave in a similar way to policies, but they affect how and which parts of the assembly are implemented without modifying the data flow of the assembly.

IBM® API Connect provides the following ways that you can create, configure, and apply policies and logic constructs:

Policies associated with a Plan
: A Plan provides a mechanism for grouping API operations or subsets of operations from one or more APIs. You can set rate limiting policies on a Plan to specify how many requests an application is allowed to make during a specified time interval. You can also configure a policy for each operation that is included in a Plan. For more information, see Working with Products.

Registration policies
: This section provides details about the out-of-the-box (OOTB) policies that are automatically deployed to the DataPower® API Gateway. It outlines the policies included in the registration process and is updated as needed to reflect changes in each release.

Built-in policies
: A built-in policy enables you to apply a pre-configured policy statement to an assembly to control processing capabilities in the Gateway server. Built-in policies are applied by using the API Designer assembly editor to add a built-in policy to your assembly and to configure the properties for that policy. For more information, see Built-in policies.
Note: You can also apply built-in policies to your APIs by adding an **`assembly`** extension to your OpenAPI definition file. For more information, see IBM extensions to the OpenAPI specification.

Logic constructs
: A logic construct enables you to control the flow of data through your assembly during an API call. Like policies, logic constructs are applied to an API by using the API Designer assembly editor to add a logic construct to your assembly and to configure the behavior of the construct. For more information, see Logic Constructs.
Note: You can also apply logic constructs to your APIs by adding an **`assembly`** extension to your OpenAPI definition file. For more information, see IBM extensions to the OpenAPI specification.

User-defined policies
: A user-defined policy enables you to create your own policies to control extra processing features in the Gateway server, such as security, or routing of requests. User-defined policies are created outside of API Connect and then imported into one or more Catalogs, so they can be applied to an operation in the same way as built-in policies. For more information, see Authoring policies.

- **Built-in policies**
  IBM API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing in the Gateway server when an API is invoked.
- **Logic Constructs**
  IBM API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.
- **Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway**
  In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.
- **User-defined policies**
  Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

Built-in policies

IBM® API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing in the Gateway server when an API is invoked.

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

- DataPower Gateway Indicates that the policy can be run on the DataPower Gateway (v5 compatible).
- API Gateway Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see API Connect gateway types.

Built-in policies are configured in the context of an API. You can use the API Designer assembly editor to add a built-in policy to an API and to configure the properties for that policy.

You can also add built-in policies to an API by creating an OpenAPI definition file. For more information, see Creating an OpenAPI definition file.

The following table shows the list of built-in policies that are available. The table contains links to configuration information for both the built-in policy definitions, and the OpenAPI policy definitions. The policies are the same, but they are created in different ways.

Table 1. Built-in policies

Built-in policy	OpenAPI policy	Description	DataPower Gateway	API Gateway
Activity Log	activity-log	Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity. Note: The Activity Log policy is not supported in the assembly for an API whose gateway type is DataPower API Gateway. Instead, you configure activity logging in the API design settings. For details, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).	✓	✓ Functionality provided in the API design; see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0)
Client Security	client-security	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	✗	✓
Extract	extract	Use the Extract policy to extract and transform data from fields in your API.	✗	✓
GatewayScript	gatewayscript	Use the gatewayscript policy to execute a specified DataPower GatewayScript program.	✓	✓
Generate JWT	jwt-generate	Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).	✓	✓
GraphQL Cost Analysis	graphql-cost-analysis	Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.	✗	✓
GraphQL Execute	graphql-execute	Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.	✗	✓
GraphQL Introspect	graphql-introspect	Use the GraphQL Introspect policy to introspect a GraphQL schema.	✗	✓
if	if	Use the if policy to apply a section of the assembly when a condition is fulfilled.	✓	✓ Functionality provided by switch
Invoke	invoke	Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.	✓	✓
JSON to XML	json-to-xml	Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.	✓	✓
Log	log	Use the Log policy to customize or override the default activity logging configuration for an API.	✗	✓
Map	map	Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.	✓	✓
OAuth	oauth	Use the OAuth policy to policy to perform OAuth processing based on defined OAuth provider settings.	✗	✓
operation-switch	operation-switch	Use the operation-switch policy to apply a section of the assembly to a specific operation.	✓	✓
Parse	parse	Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	✗	✓
Proxy	proxy	Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the `message.body` and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.	✓	✓ Functionality provided by Invoke
Rate Limit	ratelimit	Use the Rate Limit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	✗	✓
Rate Limit Info	ratelimitinfo	Use the Rate Limit Info policy to return information about your rate limits.	✗	✓
Redaction Redaction - DataPower API Gateway Redaction - DataPower Gateway (v5 compatible)	redact - DataPower API Gateway redact - DataPower Gateway (v5 compatible)	Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	✓	✓
Set Variable	set-variable	Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.	✓	✓

Built-in policy	OpenAPI policy	Description	DataPower Gateway	API Gateway
switch	switch	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	✓	✓
throw	throw	Use the throw policy to throw an error when it is reached during the execution of an assembly flow.	✓	✓
User Security	user-security	Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	✗	✓
Validate Validate - DataPower API Gateway Validate - DataPower Gateway (v5 compatible)	validate - DataPower API Gateway validate - DataPower Gateway (v5 compatible)	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	✓	✓
Validate JWT	jwt-validate	Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.	✓	✓
Validate Username Token	validate-usernametoken	Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.	✓	✗
XML to JSON	xml-to-json	Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).	✓	✓
XSLT	xslt	Use the XSLT policy to apply an XSLT transform to the payload of the API definition.	✓	✓

Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 3.0 API assembly

- **Activity Log**
  Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.
- **Client Security**
  The Client Security policy can be used to extend client authentication access for your APIs.
- **Extract**
  Use the Extract policy to extract and transform data from fields in the API context.
- **GatewayScript**
  Use the gatewayscript policy to execute a specified DataPower GatewayScript program.
- **Gemini invoke**
  Use the Gemini invoke policy to invoke Gemini operations.
- **Generate JWT**
  Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).
- **GraphQL Cost Analysis**
  Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.
- **GraphQL Execute**
  Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.
- **GraphQL Introspect**
  Use the GraphQL Introspect policy to introspect a GraphQL schema.
- **IBM Cloud Authentication**
  Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.
- **Invoke**
  Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.
- **JSON to XML**
  Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.
- **Lambda**
  Use the Lambda policy to directly trigger AWS Lambda functions from API without using the Amazon API Gateway.
- **Log**
  Use the Log policy to customize or override the default activity logging configuration for an API.
- **Map**
  Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.
- **OAuth**
  An OAuth policy performs the requested OAuth processing based on the defined OAuth provider settings.
- **Azure openai invoke**
  Use the Azure OpenAI invoke policy to invoke Azure OpenAI operations.
- **openai invoke**
  Use the OpenAI invoke policy to invoke OpenAI operations.
- **Parse**
  Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.
- **Proxy**
  Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the `message.body` and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.
- **Rate Limit**
  Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.
- **Rate Limit Info**
  Use the Rate Limit Info policy to return information about rate limits, burst limits, and count limits. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

- **Redaction - DataPower API Gateway**
  Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.
- **Redaction - DataPower Gateway (v5 compatible)**
  Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.
- **Set Variable**
  Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.
- **Token Mediation**
  The Token Mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.
- **User Security**
  Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.
- **Validate - DataPower API Gateway**
  Use the Validate policy to validate the payload in an assembly flow against a schema.
- **Validate - DataPower Gateway (v5 compatible)**
  Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.
- **Validate JWT**
  Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.
- **Validate Username Token**
  Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.
- **watsonx.ai invoke**
  Use the watsonx.ai invoke policy to invoke watsonx.ai operations.
- **Websocket Upgrade**
  Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.
- **XML to JSON**
  Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).
- **XSLT**
  Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Activity Log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see activity-log.

Note that if you are using the DataPower API Gateway, you can configure your logging preferences by using the API design editor. For more information, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).

About

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is `activity` for when API execution completes successfully, and `payload` for when API execution completes with an error code. Apply the Activity Log policy to your assembly to change the type of content to log in these API event records. For more information about API event records, see API event record field reference.
Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled. Enable buffering as follows in the API YAML:

```
x-ibm-configuration:
  ...
  activity-log:
    enabled: true
    error-content: payload
    success-content: payload
  ...
  buffering: true
```

Note:
Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but does not log successful cases.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Activity Log policy properties

Property label	Required	Description	Data type
Title	Yes	A title for the policy is required, but a default value, `activity-log` is provided.	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
Content	Yes	Defines the type of content to be logged when the operation is successful. Valid values: • **`none`**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **`activity`**: Logs invocation only (only the resource URI is recorded). • **`header`**: Logs activity and header. • **`payload`**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **`activity`**.	string
Error content	No	Indicates what content to log if an error occurs. Valid values: • **`none`**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **`activity`**: Logs invocation only (only the resource URI is recorded). • **`header`**: Logs activity and header. • **`payload`**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **`payload`**.	string

Client Security

The Client Security policy can be used to extend client authentication access for your APIs.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see client-security.

About

You use the Client Security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
  - For all methods except HTTP, use the ID Name and the Secret Name properties to specify the location that contains the ID and the location that contains the secret.
    - When Cookie, specify which cookie.
    - When Context Variable, specify which runtime context variable.
    - When Form, specify the form data.
    - When Header, specify which header.
    - When Query, specify which query parameter.
  - For the HTTP method, use the HTTP Type property to specify the format of the authorization header, which expects the Basic form in the **`basic base64_id:secret`** format.
- Define the method to authenticate the extracted client credentials. The supported methods are Native (this means by using IBM® API Connect), or by using a specified Third party user registry.
  - If Third party, use the User Registry Name property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Client Security policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`client-security`**.	string

Property label	Required	Description	Data type
Description	No	A description of the policy.	string
Stop on Error	Yes	If this setting is enabled, assembly processing stops if client security fails, and an error is returned. The check box is selected by default.	boolean
Secret Required	Yes	If this setting is enabled, the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID. The check box is selected by default.	boolean
Credential Extraction Method	Yes	Select one of the following options to define how the calling application authenticates: • Header: client ID and client secret credentials must be supplied in the request header. • Query: client ID and client secret credentials must be supplied as query parameters in the request URL. • Form: client ID and client secret credentials must be supplied as form data sent in a POST request. • Cookie: client ID and client secret credentials must be supplied in a header called `Cookie`. • HTTP: the calling application must authenticate by using basic authentication. • Context Variable: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a GatewayScript policy for example. The names of these context variables are determined by the values that you supply in the ID Name and Secret Name properties of the Client Security policy. The default value is Header.	string
ID Name	Yes, unless the selected value of Credential Extraction Method is HTTP	The name of the parameter whose value specifies the client ID. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
Secret Name	Yes, if Secret Required is enabled and the selected value of Credential Extraction Method is other than HTTP	The name of the parameter whose value specifies the client secret. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
HTTP Type	Yes, if the selected value of Credential Extraction Method is HTTP	The authentication type. Currently, the only available option is Basic.	
Authenticate Client Method	Yes	Select one of the following options: • Native: only client ID and client secret are used to authenticate the client. If the selected value of Credential Extraction Method is HTTP then the calling application must supply the client ID for the user name, and the client secret for the password. • Third party: a user registry is used to authenticate the client. If the selected value of Credential Extraction Method is other than HTTP then the calling application must supply the user name for the client ID, and the password for the client secret. The default value is Native.	string
User Registry Name	Yes, if the selected value of Authenticate Client Method is Third party	Select the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

API Gateway only

Extract

Use the Extract policy to extract and transform data from fields in the API context.

Before you begin

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly editor. For details about how to configure the policy in your OpenAPI source, see extract.

About this task

The Extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see Constructing JSONata expressions to extract and transform data.

The input to the Extract policy must be parsed data. One way to produce parsed data is to add a Parse policy before the Extract policy in your assembly.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Extract policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 2. Extract policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **extract**.	string
Description	No	A description of the policy.	string
Root	Yes	The data source that contains the content to transform. The default value is **message.body**.	string
Capture	Yes	The path expression that identifies the field. The default setting is **$**, which indicates the entire input.	string
Transform	Yes	The expression that defines how to transform the content.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - extract:
      version: 2.0.0
      title: extract
...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

Transform the contents of the **account** field to include only the last 4 characters.

```
- extract:
    version: 2.0.0
    title: extract
    root: message.body
    extracts:
      - capture: $.members.policy.**.account
        transform: $substring($,-4)
    description: Include only the last 4 characters of the account field.
```

- **Constructing JSONata expressions to extract and transform data**
  To extract and transform data from fields in the API context when using the Extract policy with the DataPower API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

API Gateway only

Constructing JSONata expressions to extract and transform data

To extract and transform data from fields in the API context when using the Extract policy with the DataPower® API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - **$eval()**
  - **$sift()**
  - **$each()**
  - **$error()**
  - **$assert()**
  - **$fromMillis()** is supported with the following restrictions:
    - The **$fromMillis()** parameter supports numbers in the range -5364662400000 - 2903299199000.
      - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
      - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- **$now()** is supported with the following restrictions:
  - The following component specifiers are not supported:
    - **W** = Week in year
    - **w** = Week in month
    - **X** = ISO week-numbering year
    - **x** = ISO week-numbering month

- Representing numbers as words are not supported, so the following presentation modifiers are not supported:
  - **W** = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
  - **w** = Lowercase word (for example: [Yw] => two thousand and twenty-four)
  - **Ww** = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
- Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
$apiCtx()	Generic access to an API context	The **$apiCtx()** extension gives generic access to an API context. • Sample transform field in an extract action: **"$apiCtx().request.uri"** • Sample condition of a case in a switch action: **"$apiCtx().request.path = '/simple/apictx-function'"**
$header(name)	**message.headers.name**	Message header
$httpVerb()	**request.verb**	HTTP method of the request
$operationID()	**api.operation.id**	ID of the operation
$operationPath()	**api.operation.path**	Path of the operation
$queryParameter('name')	• **request.parameters.*name*.locations** The supported keyword is **query**. • **request.parameters.*name*.values**	Searches for the index of **query** in **request.parameters.*name*.locations** and returns **request.parameters.*name*.values[index]**, where **[index]** is the value for **query** in locations. Parameter values are not URL decoded.
$statusCode()	**message.status.code**	Status code
$storageType([arg])	***variable*.body** You can specify any variable in the API context. When no variable is specified, the default variable **message.body** is used.	Storage type of the message. The supported values are **binary**, **empty**, **graphql**, **json**, **stream**, or **xml**.
$urlParameter('name')	• **request.parameters.*name*.locations** The supported keywords are **path** and **query** • **request.parameters.*name*.values**	Searches for the index of **path** and **query** in **request.parameters.*name*.locations** and returns a single array that contains both **path** and **query** values from **request.parameters.*name*.values**. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. **http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese** The **$urlParameter('breed')** URL returns the following array of values. **[cats, adopt, Sphynx, Siamese]** In this example, the URL includes an API path that is configured as **/petstore/{breed}/{breed}**, where **breed** is configured to be a path parameter of the API path. As a result, **cats** and **adopt** are included in the output.
$xpath(path, xpathExpression)	You can specify any writable variable in the API context. The **xpathExpression** must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. **$xpath($, '//price')**

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
$gqlActiveOperation([graphql_message])	**message.body**	Gets the active operation found in the specified GraphQL message. The **operationName** must be the same as the name of the active operation.
$gqlAlias(graphql_field_node)	**message.body**	Gets the alias of a GraphQL field node.
$gqlFragments([graphql_message])	**message.body**	Gets the fragments found in the specified GraphQL message.
$gqlName([graphql_node])	**message.body**	Gets the node name. For operations, the node name is the **operationName**. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the **operationName** of **message.body** is retrieved.
$gqlOperations([graphql_message])	**message.body**	Gets the operations found in the specified GraphQL message.
$gqlType([graphql_node])	**message.body**	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the **&** (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- **`query`**
  The entire GraphQL query including operations and fragments.

- ***`operationName`***
  For an anonymous operation, ***`operationName`*** can be empty.

- ***`~fragmentSpreadName`***
- ***`on~typeCondition`***
- ***`~~fragmentDefinitionName`***

GatewayScript

Use the gatewayscript policy to execute a specified DataPower® GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see gatewayscript.

About

The gatewayscript policy gives you built-in access to the DataPower Gateway module via variable **`apim`**.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. gatewayscript policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`gatewayscript`**.	string
Description	No	A description of the policy.	string

Source	Yes	The GatewayScript source code to execute. For example:
		
		`var message = [ 'Hello', 'World!' ];`
		`console.debug(message.join(' '));`
			string

Examples

The following examples show how the full OpenAPI for the policy looks in the source code.

Example one:

```
gatewayscript:
  title: writes message to DataPower log
  source: console.debug('Hello World!');
```

Example two:

```
gatewayscript:
  title: script written in multiple lines
  source: |
    var message = [ 'Hello', 'World!' ];
    console.debug(message.join(' '));
```

For more code examples, see GatewayScript code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- GatewayScript APIs for API management
- Accessing and manipulating a variable in the API context
- OAuth context variables

Errors

The following error can be thrown while the policy is being executed:

- **`JavaScriptError`** - a generic error that captures all errors that occur during the execution of the policy.
- **GatewayScript code examples**
  Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Related tasks

- Creating a new REST OpenAPI definition

GatewayScript code examples

Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing a GatewayScript policy or user-defined policy for a new API Gateway API, use the mechanisms described in Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The GatewayScript functions that are listed here use the common name **`apim`** to call the methods. However, you can change the common name to one of your choice by using one or other of the following function calls depending on your gateway type:

  DataPower Gateway (v5 compatible)
  ```
  var name = require('local:///isp/policy/apim.custom.js');   // v5-Compatible Gateway
  ```
  API Gateway
  ```
  var name = require('apim');                                 // DataPower API Gateway
  ```

  where *name* is your chosen name; for example:

  ```
  var apim = require('apim');
  ```

Access the assembly context

The following code snippets show examples of how to access the assembly context.
Example one returns the **`request`** context:

```
apim.getvariable('request');
```

Example two returns the header named **`myheader`**:

```
apim.getvariable('request.headers.myheader');
```

Example three shows how to set, add, or clear a context variable, in this case a message header:

```
apim.setvariable('message.headers.name', value, action)
```

where

- *name* is the name of the message header that you want to set, add, or clear.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the *value* as **`request.headers.content-type`**. This property is only required when **`set`** or **`add`** is specified as the action.
- *action* is the action that you want to apply to the variable. Valid options are:
  - **`set`**
  - **`add`**
  - **`clear`**

  If no option is set, the default option of **`set`** is applied.

For a complete list of context variables, see API Gateway context variables, and for more information about how to reference context variables in IBM API Connect see Variable references in API Connect. If you are using the DataPower® API Gateway, see also Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Read input synchronously

The following code snippets show examples of how to read input synchronously by using the `apim.getvariable` function to read data direct from a context. JSON input is returned as a JavaScript object. XML data is returned as a NodeList object (DOM).
Example one returns a synchronous read of the original request body into the variable that is called *json*:

```
var json = apim.getvariable('request.body');
```

Example two returns a synchronous read of the current message into the variable that is called *xml*:

```
var xml = apim.getvariable('message.body');
```

Note: If the content type of the data is neither XML nor JSON, the `apim.getvariable()` function returns a NodeList object consisting of one binary node, which must be converted to a string. If the content really is XML or JSON, you must then parse this string, as illustrated in the following example:

```
var data = apim.getvariable('request.body');

// if a nodelist was returned and the type is 13 (BLOB/Binary Node), convert it
// to a Buffer, which can then be converted to a string
if ((data.item && data.length > 0 && data.item(0).nodeType === 13)) {
  data = data.item(0).toBuffer().toString();
}

// if the string really is XML or JSON, then now add code to parse it with
// the appropriate XML or JSON parse function
      .
      .
      .
```

Read input asynchronously

The following code snippets show the `apim.readInput()` calls that you can use to perform a JavaScript callback function to read input data asynchronously into a variable. JSON input is returned as a JavaScript object. XML data is returned as a NodeList object (DOM). Other types of input are returned as a Buffer object.

```
apim.readInput(callback(err,input) {});
apim.readInputAsJSON(callback(err,json) {});
apim.readInputAsXML(callback(err,nodelist) {});
apim.readInputAsBuffer(callback(err,buffer) {});
```

Note: The `apim.readInput()` function attempts to determine the input data type and call the appropriate `apim.readInputAs`*`type`*`()` function in order to return the data in the correct format. However, to ensure that the correct data type is returned, use the `apim.readInputAs`*`type`*`()` function.
The `apim.readInputAs`*`type`*`()` function reads the data from either the INPUT context (for example `session.INPUT`), or from a policy output context (for example `policy.output`), depending on whether a previous policy had been called that had written output to a policy output context. This function then calls the underlying IBM DataPower GatewayScript `readAs`*`type`* method on the relevant context to read the data, and then use JavaScript callbacks to return the data to a variable. For more information about DataPower methods, see Gateway programming model and GatewayScript.

The following is an example of how to use the `apim.readInputAsJSON()` callback function to get data into a variable that is called *json*:

```
apim.readInputAsJSON(function (error, json) {
if (error)
{
// handle error
}
else
{
// the json parameter will contain the json data that has been read
// process the json object in some way and write to the output context
if (json.test=='true')
{
// if json data contains a variable called test that is set to true, then also add some test data
json.data = 'This is my test data'
}
session.output.write(json);
// write to the output context
}
});
```

Configure error information

The following code block shows an example of how to configure the policy implementation to produce error information by using the `apim.error()` function. In this example, `MyError` is thrown to the assembly flow. If there is a catch handler it catches this error, otherwise the assembly skips the execution of the flow and sends a `500 Internal Error` response.

```
apim.error('MyError', 500, 'Internal Error', 'Some error message');
```

where:

- `MyError` is the name of the error.
- `500` is the HTTP code of the required error message.
- `Internal Error` is the HTTP reason phrase for the error.
- `Some error message` is the suggested action for the user.

Accessing the caught exception in a catch block

The following example shows how, in the `catch` block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

```
let exception = apim.getError();
```

The function returns a JSON object; for example:

```
{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}
```

Write output

The following example shows how to write data into the output, in this case the JSON data `'{ "status": "created" }'`, by using the `session.output.write` variable:

```
session.output.write('{ "status": "created" }');
```

The `session.output.write` variable is a standard GatewayScript method that writes data to the output context. For more information, see Contexts and sessions.
Use the following function to set the format of the content that is written to the `session.output` variable:

```
apim.output('application/type');
```

For example, if you were creating a policy that called:

```
session.output.write('<test>this is some xml data</test>');
```

the policy would write XML data to the output context. You would need to configure the policy to also call

```
apim.output('application/xml');
```

to tell the system that the output is XML. It can cause issues in the processing of the policy if the actual output context format, and the format that is specified in `apim.output`, are different.
Note: If you use `apim.setvariable` to manipulate `message.body`, you must immediately follow the `apim.setvariable` function call with an `apim.output` function call that specifies the content type of the payload that was written to `message.body` by `apim.setvariable`.

API Gateway only

Gemini invoke

Use the Gemini invoke policy to invoke Gemini operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see gemini-invoke.

About

The Gemini invoke policy provides access to six Gemini operations:

- `POST models/[model]:generateContent`
- `POST models/[model]:countTokens`
- `POST models/[model]:embedContent`
- `POST models/[model]:batchEmbedContents`
- `GET models/[model]`
- `GET models`

The Gemini invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Gemini invoke policy properties

Property label	Required	Description	Data type
Title	No	Gemini invoke chat completions	string
Description	No	A description of the policy.	string
Gemini Operation	Yes	The Gemini operation to invoke; must be one of the following operations: • **`POST models/[model]:generateContent`** An HTTP POST operation for **`generateContent`**. See Generating Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:countTokens`** An HTTP POST operation for **`/countTokens`**. See Counting tokens in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:embedContent`** An HTTP POST operation for **`embedContent`**. See Embed Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:batchEmbedContents`** An HTTP POST operation for **`batchEmbedContents`**. See Batch Embed Content in the Gemini API documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the Gemini API documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the Gemini API documentation for sample response examples.	string
Gemini API Key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Gemini requests.	string
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the Gemini service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the Gemini service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
Gemini Operation Path Parameters	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
Gemini Operation Query Parameters	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the Gemini response. By default, this property uses message as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Generate JWT

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see jwt-generate.

About

JSON Web Token (JWT) is a compact, URL-safe way of representing claims that are to be transferred between two parties. The Generate JWT policy enables you to generate claims and configure whether they are to be used as the payload of a JSON Web Signature (JWS) structure, or as the plain text of a JSON Web Encryption (JWE) structure. Specifying the cryptographic material for both the JWS and the JWE produces a nested JWT that is both digitally signed and encrypted. The JWT is then assigned to the Authorization header as a Bearer token (the default option), or to the runtime variable in the JSON Web Token (JWT) property, if specified.

Note:

- For algorithm types HS256, HS384, and HS512 the cryptographic objects referenced must be a Shared Secret Key.
- For algorithm types RS256, RS384, RS512, ES256, ES384, ES512, PS256, PS384, PS512 the cryptographic objects referenced must be a Crypto Key (private key).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to sign the JWT.

Prerequisites

The following prerequisites apply:

- If you are using one or more cryptographic objects (crypto objects), they must be located in the API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or certificate that is needed to encrypt or sign the JWT contents.
- If a JSON Web Key (JWK) is being used, it must be referenced by a runtime variable.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Generate JWT policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`jwt-generate`**.	string
Description	No	A description of the policy.	string
JSON Web Token (JWT)	No	Runtime variable in which to place the JWT that is generated. The default value is: **`generated.jwt`**. However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
JWT ID Claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to **`true`**, and a UUID is generated and set as the JTI claim value.	boolean
Issuer Claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: **`iss.claim`**	string
Subject Claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string
Audience Claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
Validity Period	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is **`3600`**.	integer
Private Claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
Sign JWK variable name	No	Runtime variable that contains the JWK that is used to sign the JWT.[1]	string
Cryptographic Algorithm	No	The cryptographic algorithm to use. Valid values are: • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512	string
Sign Crypto Object	No	The cryptographic object to use to sign the JWT.[1]	string
Sign KID value	No	The customized **`kid`** value for JWT signing.	string
Encryption Algorithm	No	The encryption algorithm to use. Valid values are: • A128CBC-HS256 • A192CBC-HS384 • A256CBC-HS512	string
Encrypt JWK variable name	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string

Property label	Required	Description	Data type
Key Encryption Algorithm	No	The key encryption algorithm to use. Valid values are: • RSA1_5 • RSA-OAEP • RSA-OAEP-256 • dir • A128KW • A192KW • A256KW	string
Encrypt Crypto Object	No	The cryptographic object to use to encrypt the claim.	string
Encrypt KID value	No	The customized **kid** value for JWT encryption.	string

Example

```
    - jwt-generate:
        version: 2.1.0
        title: jwt-generate
        description: New jwt-generate v2.1.0 policy.
        jwt: generated.jwt
        jti-claim: true
        iss-claim: iss.claim
        sub-claim: sub.claim
        aud-claim: aud.claim
        exp-claim: 3600
        private-claims: private.claims
        jws-jwk: jws.jwk
        jws-alg: HS256
        jws-crypto: jwsCryptoObjectName
        custom-kid-value-jws: jws.kid
        jwe-enc: A128CBC-HS256
        jwe-jwk: jwe.jwk
        jwe-alg: RSA1_5
        jwe-crypto: jweCryptoObjectName
        custom-kid-value-jwe: jwe.kid
```

Errors

The following error can be thrown while the policy is being executed:

- **RuntimeError** - a generic error that captures all errors that occur during the execution of the policy. Upon failure, the detailed error message that is received from the underlying JOSE module is written to the default system log as an error message. This detailed error message is also assigned to the runtime variable jwt-generate.error-message, so it can be retrieved via catch.

If a catch is not configured, in the case of a failure the Generate JWT policy returns an HTTP code 500 **Invalid-JWT-Generate** failure. The detailed error message from the underlying JOSE module can be found in the system log.
Attention: If you are an API developer who is troubleshooting a failure that one of your customers had with your API, consider the security risks before sending a customer the exact content of the log message. You can avoid the possibility of someone launching an attack based on the information that they receive from the log message by sending the customer only general information about the message.

Related information

- Introduction to JSON Web Tokens

[1] A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used. If you are using one or more cryptographic objects (crypto objects), they must be located in the API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or certificate that is needed to encrypt or sign the JWT contents.

GraphQL Cost Analysis

Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-cost-analysis.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Cost Analysis policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **graphql-introspect**.	string
Description	No	A description of the policy.	string
Input	No	A variable in the API context that contains the input to the GraphQL cost analysis. The content of the body field of the variable is the GraphQL cost query. By default, the variable name is **message**. The query should be in the format as specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.	string
Output	No	A variable in the API context where the results of the GraphQL cost analysis are stored. The content of the body field of the variable is the result of GraphQL cost analysis. The default variable name is the same as that of the variable specified for the input field. Therefore, by default, the input of the GraphQL cost analysis is overwritten by the output.	string
Target	No	A variable in the API context that contains the target for the GraphQL cost analysis. The content of the body field of the variable is the GraphQL context. By default, the variable name is **graphql_execute_args**. The target context specifies the query to analyze and, optionally, the result of the query execution.	string

GraphQL Execute

Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 (DataPower API Gateway Version 10.0.4.0 and later) 2.1.0 (DataPower API Gateway Version 10.5.2.0 and later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-execute.

About

The GraphQL Execute policy executes a GraphQL query by using sub-queries. The policy splits up the original GraphQL query into different sub-queries that can then be processed in different ways. The GraphQL Execute policy supports the following four different sub-queries as targets:

1. **root**; contains the core GraphQL query that you want to invoke on the backend.
2. **__introspection**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend.
3. **__rateLimit**; contains the **__rateLimit** query that specifies the different rate limit data that you want to receive.
4. **__cost**; contains the **__cost** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.

The **root**, **__rateLimit**, and **__introspection** targets can be executed in any order, or at the same time. The **__cost** target can be executed at any time if no response data is expected. If response data is expected, then the **__cost** target is executed after the **root** target in order to accurately return correct response cost data. After all the targets are executed, the GraphQL Execute policy combines all of the responses together. To enable the responses of the individual targets to be correctly merged with each other into a final, single response, the GraphQL Execute policy must include all of the introspection types that are associated with each level of the response data.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Execute policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **graphql-execute**.	string
Description	No	A description of the policy.	string
Target	No	The target for the sub-queries. Valid values are: • **root**; contains the core GraphQL query that you want to invoke on the backend. • **__introspection**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend. • **__rateLimit**; contains the **__rateLimit** query that specifies the different rate limit data that you want to receive. • **__cost**; contains the **__cost** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.	string

GraphQL Introspect

Use the GraphQL Introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-introspect.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Introspect policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is `graphql-introspect`.	string
Description	No	A description of the policy.	string
Input	No	A variable in the API context that contains the input to introspect. The content of the `body` field of the variable is the input to introspect. By default, the variable name is `message`.	string
Output	No	A variable in the API context where the results of the introspection are stored. The content of the `body` field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified in the Input field. Therefore, by default, the input of the introspection is overwritten by the output.	string

API Gateway only

IBM Cloud Authentication

Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ibm-cloud-authentication.

About

The IBM Cloud Authentication policy provides an API key to the IBM Access Manager and, if successfully authenticated, returns a Bearer token to be used by all subsequent watsonx.ai operation requests. The Bearer token is cached and will be valid for approximately 60 minutes. A new token is retrieved when a response for the API key was not cached. or expired.

The IBM Cloud Authentication policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. IBM Cloud Authentication policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy; the default value is `ibm-cloud-authentication`. The title displays in the API assembly editor in the UI.	string
Description	No	A description of the policy.	string
API key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate subsequent watsonx.ai requests.	string

Invoke

Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable **`message.body`** or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.

Note: The Invoke policy does not support responses with multipart form data, that is, when the response is set to `Content-Type: multipart/related`.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.1 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

API Gateway only

Configuring the Invoke policy for DataPower API Gateway

Follow these steps to configure the Invoke policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Invoke policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Invoke policy for DataPower Gateway (v5 compatible). For information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see invoke.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Invoke policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Invoke policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`invoke`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Invoke URL value is pre-supplied from information that is defined in the imported WSDL.	string

Property label	Required	Description	Data type
Backend type	No	Select one of the following options to determine how the payload is sent to the backend. Detect Detect the message type and send the payload to the backend accordingly. XML Package the payload as XML and send. If the message type is not XML, the operation fails. JSON Package the payload as JSON and send. If the message type is not JSON, the operation fails. Binary Package the payload as binary and send, regardless of the message type. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. The default value is Detect.	string
GraphQL send type(policy version 2.2.0 and later)	Yes, if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep	Select one of the following values to determine how the GraphQL payload is sent to the back end. Detect Detect the message type and send the payload to the back end accordingly. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. JSON Package the payload as JSON and send. If the message type is not GraphQL, the operation fails. Note: GraphQL send type is supported only if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply from the endpoint (in seconds). The default value is **60**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **301 Moved Permanently**. If you select this checkbox, the **invoke** policy follows the URL redirection by making a further call to the URL specified in the **Location** header in the response. If you clear this checkbox, the **invoke** saves the **301** status code and the API call is considered to be complete. Note: The **follow-redirect** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **invoke** always follows the URL redirection; the **proxy** policy (not supported by the DataPower API Gateway) saves the **301** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the Invoke. The following values are valid. • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **GET**. However, if set to **Keep**, or the property is removed from the source, the HTTP method from the incoming request is used.	string
HTTP Version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Select one of the following values. • HTTP/1.0 • HTTP/1.1 • HTTP/2 The default value is HTTP/1.1.	string
HTTP/2 Required (policy version 2.1.0 and later)	No	Select this checkbox to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non-TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if HTTP Version is set to HTTP/2.	boolean
Compression	No	Select this checkbox to enable Content-Encoding compression on upload. The checkbox is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are: Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL. Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option. No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings. Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached. The default value is Protocol.	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to **`Time to Live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Allow WebSocket Upgrade (policy version 2.1.0 and later)	No	Select this checkbox to allow an HTTP or HTTPS connection to be upgraded to the WebSocket protocol if the request received by the corresponding HTTP or HTTPS handler on the DataPower API Gateway uses WebSocket (ws) or WebSocket Secure (wss). Note: • This setting is available only for GraphQL APIs. • The Allow WebSocket Upgrade setting is deprecated. To allow WebSocket upgrade requests that can manage API processing data, define an assembly WebSocket upgrade policy. For more information, see Websocket Upgrade.	boolean
Inject proxy headers	No	If you select this checkbox, the **`invoke`** policy injects the **`X-Forwarded-For`**, **`X-Forwarded-To`**, **`X-Forwarded-Host`**, and **`X-Forwarded-Proto`** headers to the request that is sent to the target URL. The checkbox is cleared by default.	boolean
Decode Request Params	No	If you select this checkbox, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The checkbox is cleared by default.	boolean
Queryparam Encode	No	If you select this checkbox, all "+" characters in the query parameter values of the target URL are encoded to %2F. The checkbox is cleared by default.	boolean
Keep Payload	No	If you select this checkbox, the invoke policy sends a payload on an **`HTTP DELETE`** method. The checkbox is cleared by default.	boolean
Restrict to HTTP 1.0 (policy version 2.0.0 only)	No	If you select this checkbox, HTTP transactions are restricted to version 1.0. The check box is cleared by default.	boolean
Allow chunked uploads	No	If you select this checkbox, chunked-encoded documents are sent to the server. When the HTTP 1.1 protocol is used, the body of the document can be delimited by either **`Content-Length`** or chunked encoding. While all servers can interpret **`Content-Length`**, many applications fail to understand chunked-encoded documents. For this reason, **`Content-Length`** is the standard method. The use of **`Content-Length`** interferes with the ability of the DataPower Gateway to fully stream. If you must stream full documents to the target server, enable this property. When enabled, the server must be RFC 2616 compatible. Unlike all other HTTP 1.1 features that can be negotiated down at run time, you must know beforehand that the target server is RFC 2616 compatible. The check box is selected by default. Note: Chunked encoding is not supported by the HTTP 1.0 protocol.	boolean

Property label	Required	Description	Data type
Persistent Connection (policy version 2.3.0 and later)	No	Select this checkbox to enable HTTP persistent connections, allowing connection re-use. The checkbox is selected by default.	boolean
Header control	No	Specifies the headers in **`message.headers`** that you want to copy to the target URL. To prevent headers from being copied, complete the following steps. a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. To specify headers that you want to be copied, complete the following steps. a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. The values that you specify are in regular expression format. For example, to specify the Content-Type header, enter **`^Content-Type$`** By default, Blocklist is selected, with no blocklist entries, meaning that **all** headers are copied.	string
Parameter control	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. To prevent parameters from being copied, complete the following steps. a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. To specify parameters that you want to be copied, complete the following steps. a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. The values that you specify are in regular expression format. For example, if the incoming request is **`http://apigw/org/sandbox/petstore/base?petid=100&display=detailed`** and you specify a white list entry of **`^petid$`**, the target URL at run time will be **`http://myhost/mypath?storeid=3&petid=100`** By default, Allowlist is selected, with no allowlist entries, meaning that **no** parameters are copied.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a **`catch`** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable *message*. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as Map. Note: If you want the response to be saved in *message*, leave the Response object variable property blank, do **not** supply the value `message`.	string
Buffering	No	Select Buffering to specify whether to buffer the payload. If Buffering is selected, the payload is buffered, and the Invoke policy can check the type of the payload. If Buffering is not selected, the payload is streamed, and the Invoke policy cannot check the payload type. Note: If you enable Buffering, you must also configure a Parse policy to interpret the payload. Without a Parse policy, the payload remains an uninterpreted buffer, and the Invoke policy succeeds if the backend service accepts payloads of type **`binary`** or **`detect`**. If a Parse policy is configured, it implicitly disables streaming, even if buffering is off, because parsing requires the full payload to be buffered. For more information, see Parse.	boolean

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - invoke:
      version: 2.0.0
      title: invoke
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

```
- invoke:
    version: 2.0.0
    title: get the account status
    target-url: https://example.com/accounts/{id}?status={status}
    cache-response: time-to-live
    cache-putpost-response: true
    tls-profile: MyTLSProfile:1.0.0
    verb: POST
```

```
    timeout: 60
    compression: false
    username: MyUser
    password: MyPassword
    stop-on-error:
      - ConnectionError
      - OperationError
```

DataPower Gateway (v5 compatible) only

Configuring the Invoke policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Invoke policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Invoke policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Invoke policy for DataPower API Gateway. For information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see invoke.

You might notice that the last invoke in their policy is replaced by a proxy. The replacement is sometimes done automatically by the IBM® API Connect DataPower Gateway to improve performance. The proxy is functionally equivalent to the invoke, but the API caller might notice the following differences when proxy is used.

- If the HTTP request made by the invoke or proxy gets a redirect (`3xx`) response:
  - invoke returns the response from following the redirect response.
  - proxy does not follow `3xx` responses, and the redirect response is returned.
- The IBM API Connect test tool shows that proxy was used, but invoke appears in the analytics latency records.
- The response from the proxy can contain different whitespace or escaping than a response from invoke. Despite the differences in the response, it is still valid.

If you want to prevent replacement of the last invoke in the assembly with proxy, you can set the API property api.properties.x-ibm-gateway-optimize-invoke to `false`.
For more information, see API properties.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Invoke policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Invoke policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`invoke`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Invoke URL value is pre-supplied from information that is defined in the imported WSDL.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply from the endpoint (in seconds). The default value is **`60`**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this checkbox, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this checkbox, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the Invoke. The following values are valid. • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **`GET`**. However, if set to **`Keep`**, or the property is removed from the source, the HTTP method from the incoming request is used.	string
Compression	No	Select this checkbox to enable Content-Encoding compression on upload. The checkbox is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are: Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL. Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option. No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings. Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached. The default value is Protocol.	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to **`Time to Live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a **`catch`** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable *message*. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as Map. Note: If you want the response to be saved in *message*, leave the Response object variable property blank, do **not** supply the value `message`.	string
Buffering	No	Select Buffering to specify whether to buffer the payload. If Buffering is selected, the payload is buffered, and the Invoke policy can check the type of the payload. If Buffering is not selected, the payload is streamed, and the Invoke policy cannot check the payload type. Note: If you enable Buffering, you must also configure a Parse policy to interpret the payload. Without a Parse policy, the payload remains an uninterpreted buffer, and the Invoke policy succeeds if the backend service accepts payloads of type **`binary`** or **`detect`**. If a Parse policy is configured, it implicitly disables streaming,even if buffering is off, because parsing requires the full payload to be buffered. For more information, see Parse.	boolean

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - invoke:
      version: 1.0.0
      title: invoke
    ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

```
- invoke:
          version: 1.0.0
          title: get the account status
          timeout: 60
          verb: POST
          cache-response: time-to-live
          cache-ttl: 900
          stop-on-error:
            - ConnectionError
            - OperationError
```

```
        tls-profile: MyTLSProfile
        target-url: https://example.com/accounts/{id}?status={status}
        username: MyUser
        password: MyPassword
```

JSON to XML

Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

The JSON to XML policy uses a simple convention, based on BadgerFish, to convert your API context payload from JSON to XML. The policy expects the JSON input to be in the same format as the BadgerFish convention, so the structure can be rebuilt in XML. No additional configuration is required. For more information about the BadgerFish convention, see BadgerFish.
Note: The JSON to XML policy does convert the JSON structure `{ "a" : "hello" }` (which is not BadgerFish convention) into `<a>hello</a>`.
Use the IBM® API Connect API Designer assembly view when you are creating your API definition to add a built-in policy to the flow.

The policy must be attached to the flow at the point at which you require the conversion to be performed. For example, if you need to convert a JSON-formatted request into an XML-formatted request, the policy must be attached to the request flow.

The policy reads input from the **`message.body`**, if that context exists, otherwise from the **`request.body`**, and then writes the output to the **`message.body`**.

Note: If you are using the DataPower API Gateway, the input to the JSON to XML policy must be parsed data. One way to produce parsed data is to use a Parse policy before a JSON to XML policy in your assembly flow, which provides explicit control of the parse action.

- **Configuring the JSON to XML policy for DataPower API Gateway**
  Follow these steps to configure the JSON to XML policy for DataPower API Gateway in the assembly user interface.
- **Configuring the JSON to XML policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the JSON to XML policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the JSON to XML policy for DataPower API Gateway

Follow these steps to configure the JSON to XML policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the JSON to XML policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the JSON to XML policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. For information about how to configure the policy in your OpenAPI source, see json-to-xml.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the JSON to XML policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`json-to-xml`**.	string
Description	No	A description of the policy.	string
Input	No	The input message to convert. Specify the name of a variable in the API context. ***`variableName`*`.body`**, the message payload, represents the JSON input to convert. The default value of the variable is **`message`** and **`message.body`** is the default input.	string
Output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***`variableName`*`.body`** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **`message.body`**. Otherwise, when the input message is the variable **`my-message-variable`**, for example, the default output is **`my-message-variable.body`**. The variable cannot be any read-only in the API context.	string

Property label	Required	Description	Data type
Conversion type	No	The conversion type that determines the target format of the output. The following options are available: • None: No conversion of the output takes place. • badgerFish: BadgerFish convention is used to determine the target conversion format of the output.	string
Root XML Element Name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the Always output the root element checkbox is selected. The default value is **`json`**.	string
Always output the root element	Yes	Select this checkbox if you always want the policy to output the root element, even if it is not required to make the XML document well formed. The default value is **`false`**.	boolean
Element name for JSON array elements	No	The XML element name to be used for JSON array elements.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - json-to-xml:
      version: 2.0.0
      title: json-to-xml
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For example, the following simple JSON object

```
{ "a": { "$" : "hello" } }
```

becomes

```
<a>hello</a>
```

The following JSON object with an attribute

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

becomes

```
<a type="world">hello</a>
```

DataPower Gateway (v5 compatible) only

Configuring the JSON to XML policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the JSON to XML policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the JSON to XML policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the JSON to XML policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see json-to-xml.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the JSON to XML policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`json-to-xml`**.	string
Description	No	A description of the policy.	string
Root XML Element Name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the Always output the root element checkbox is selected. The default value is **`json`**.	string

Property label	Required	Description	Data type
Always output the root element	Yes	Select this checkbox if you always want the policy to output the root element, even if it is not required to make the XML document well formed. The default value is **`false`**.	boolean
Element name for JSON array elements	No	The XML element name to be used for JSON array elements.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - json-to-xml:
      version: 1.0.0
      title: json-to-xml
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For example, the following simple JSON object

```
{ "a": { "$" : "hello" } }
```

becomes

```
<a>hello</a>
```

The following JSON object with an attribute

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

becomes

```
<a type="world">hello</a>
```

API Gateway only

Lambda

Use the Lambda policy to directly trigger AWS Lambda functions from API without using the Amazon API Gateway.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	1.3.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see Lambda.

About

The Lambda policy lets you trigger AWS Lambda functions from within an API's assembly without requiring you to use the Amazon API Gateway. When you add the policy to an API assembly, you can specify the Lambda function to invoke and provide credentials for using it. The credentials can be either an AWS IAM role, or an Access Key ID/Secret Access Key pair. You can download the lambda policy from Lambda policy fix pack.

To enable API Connect to invoke a Lambda function, complete the following tasks:

1. Configure access to the Lambda function in AWS as explained in the Setting up permissions and trust in AWS section of this topic.
2. Define an API policy in API Connect using the policy properties in the Properties section of this topic.

Note:

- The Lambda policy uses VPC endpoints to ensure that the communication from the gateway to the Lambda service is over the AWS private backbone.
- For information about Lambda and instructions for using the Lambda features, see the AWS Lambda documentation.

Setting up permissions and trust in AWS

To use a Lambda policy, you must set up a role in your AWS account, specifying a permissions policy and a trust relationship, so that API Connect can invoke the AWS Lambda function. There is one authentication option when using the AWS Lambda policy:

- Access Key ID/Secret Access Key

Use the instructions for the option that best suits your needs.

Access Key ID/Secret Access Key

Provide the AWS Access Key ID/AWS Secret Access Key pair of an account with permission to invoke one or more Lambda functions. The permissions of this account should be as narrowly-scoped as possible; the account should be a service account with no other permissions other than the ability to invoke one or more Lambda functions. For more information, see the Identity-Based IAM Policies for Lambda documentation.
To use the Access Key ID/Secret Access Key authentication option, complete the following steps to use your account's IAM service and create an IAM service account with appropriate permissions to facilitate limited communication with API Connect:

1. Sign in to the AWS Management Console and open the IAM console.
2. On the AWS IAM console, click Users in the navigation list, and then click Add users.
3. When prompted to "Set user details", provide a User name (unique within your AWS account) and select Access key - Programmatic access.
   You can select the Password - AWS Management Console access option, but it is not required for interaction with API Connect.

   There are a variety of options for defining permissions for the new user account. See the AWS Identity and Access Management User Guide for information on adding the user to a user group, or attaching a policy directly to the user.

   A straightforward method of defining user permissions that adheres to the least-privilege principle is to create an IAM user with no permissions, and then add that user to the permissions configuration of a specific Lambda function, as demonstrated in the following steps.

4. On the "Set user details" page, click Next: Tags without making any changes to the new User account.
5. Create the desired Tags and then click Next: Review.
6. Review your settings and click Create user.
   Ignore the warning that **`This user has no permissions`** because you will assign permissions in the remaining steps.

7. Click Download .csv to save the new user's Access key ID and Secret access key, and store them in a safe place. These values will be used as the AWS Access Key ID and AWS Secret Access Key when configuring the Lambda policy of your API in API Connect.
8. Update the Lambda function to provide permissions for the new user:
   a. In the Lambda console, open the Functions page.
   b. Select the function that API Connect will invoke.
   c. Click Configuration.
   d. In the Resource-based policy statements section, click Add permissions.
   e. Select AWS account and add a unique Statement ID.
   f. Set Principal to the ARN of the new user.
      `arn:aws:iam::<AWS_account_ID>:user/<username>`, available on the Users > *<username>* page.

   g. Set the Action to **`lambda:InvokeFunction`**.
   h. Click Save.

   Repeat this step for every Lambda function that the user account will invoke.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`lambda`**.	string
Description	No	A description of the policy.	string
AWS Access Key ID	Yes	AWS Access keys are long-term credentials for an AWS IAM user. Required if the AWS Assume Role ARN is not provided instead. For instructions on creating the access key pair in AWS, see Access Key ID/Secret Access Key in this topic.	string
AWS Secret Access Key	Yes	The secret access key that corresponds to the specified AWS Access Key ID.	string
Function	Yes	The name or Amazon Resource Name (ARN) of the AWS Lambda function to execute, using one of the following formats: • Function name; for example: **`my-function`** • Function ARN; for example: **`arn:aws:lambda:us-east-a:123456789012:function:my-function`** • Partial ARN – **`123456789012:function:my-function`** For more information, see **`FunctionName`** in the AWS Lambda Developer Guide.	string
Region	Yes	The AWS region where the Lambda function is hosted.	string
Qualifier	No	The alias or version of the Lambda function that you want to execute. For more information, see **`Qualifier`** in the AWS Lambda Developer Guide.	string

API Gateway only

Log

Use the Log policy to customize or override the default activity logging configuration for an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see log.

About

By default, the logging of activity when an API is called, and the sending of the log data to the analytics server, is determined by the settings in the API definition, as described in Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0). However, you can customize activity logging by adding a Log policy to the API assembly flow.

The Log policy enables you to gather all API analytics data for processing in your assembly, and to control what activity log data is sent to the analytics server. Here are some examples of the ways in which you can use the Log policy to customize API activity logging:

- Gather activity log data, use a Redaction policy to redact sensitive fields in the data, then send to the analytics server.
- Send different levels of analytics data depending on certain conditions; for example, the API operation that was called.
- Configure custom activity logging in a global policy that is applied to every API in a Catalog. For more information on global policies, see Working with global policies.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Log policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`log`**.	string
Description	No	A description of the policy.	string

Mode	Yes	Select one of the following options:
		• Gather-only: gather all analytics data and write it to the **`log`** context variable, which populates the API event record on completion of the API execution. For more information on the fields in the **`log`** context variable, and the consequent API event record, see API event record field reference.
		• Send-only: perform the following actions:
		  ◦ Read the data from the **`log`** context variable.
		  ◦ Truncate all message payloads and convert to a textual representation.
		  ◦ Send the data to the analytics server.
		• Gather-and-send: perform a **`gather-only`** operation, immediately followed by a **`send-only`** operation.
		If you use the Send-only or Gather-and-send option, data is buffered and sent to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information, see Configuring an analytics endpoint in the DataPower knowledge center.
		Note: If you are offloading to a third party analytics server, you can redact any aspect of the event data. If you are using API Connect analytics, you can redact only request and response payloads.
			string

API Gateway only Log Level	No	The type of content to log. Enter one of the following values: • `none`: Indicates no logging. • `activity`; Logs the invocation only, which is only the resource URI. • `header`: Logs activity and header. • `payload`:Logs activity, header, and payload. • `default`; Use the log level setting defined in the API definition; for more information, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0). This is the default value. • `$(value)`: An inline parameter in the format **`$(value)`** to retrieve a value from the API context.	

Map

Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.5.0.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see map.

About

Be aware that MAP decodes all parameter values to an ASCII character equivalent. If a MAP parameter contains entries such as %nn, the MAP output contains decoded values.

For information about the structure of a Map policy and its behavior, see The Map policy structure.

For information about configuring a Map policy by using the user interface, see Configuring the Map policy in the user interface.

For examples of YAML representations of different Map policy configurations, see Map policy examples.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Map policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The field is visible when editing inputs. The default value is **map**.	string
Description	No	A description of the policy. The field is visible when editing inputs.	string
Inputs	Yes	A list of variables that are inputs of the policy.	array (string)
Outputs	Yes	A list of variables that are outputs of the policy.	array (string)
Value	Yes	A GatewayScript program to be performed by the policy in order to map its inputs to its outputs, or to set the value of outputs.	string

Note: The map policy has other properties that are not displayed in the user interface. For a complete list of properties, see map.

- **The Map policy structure**
  The Map policy uses a structure within its OpenAPI definition to specify the behavior of the policy.

Related tasks

- Creating a new REST OpenAPI definition

The Map policy structure

The Map policy uses a structure within its OpenAPI definition to specify the behavior of the policy.

This topic contains the following sections:

- Structure
- Input and output definitions
- Actions
- Script
- Fields
- References to inputs and outputs
- Accessing other contexts

For map policy examples, see Map policy examples.

Note: If you deploy your API to the DataPower® Gateway (v5 compatible) then, with the exception of client ID and client secret, the passing of form input as a parameter into an API is not supported. This restriction does not apply if you deploy your API to the DataPower API Gateway.

Structure

In addition to its title and description, a Map policy has the following four main sections:

`inputs`
: A list of variables that form the input of the Map policy. Each input has a context variable in which the input variable is found, the variable's name within the Map policy, the content type of the variable, and the definition of the variable or a schema defining its structure.

`outputs`
: A list of variables that form the output of the Map policy. These include a context variable where the output variable is found or should be created, the variable's name at output, and the definition of the variable or a schema defining its structure.

`action`
: An array containing details of the actions to be performed in order. Each entry includes either a **`set`** or **`create`** field, which specifies the output variable or variables that are part of the action. An action can also contain a **`from`** field, which specifies the input variable or variables that are part of the action.

  Each action also contains either a **`value`** field, when the output is set or created, or a **`foreach`** field and a new **`actions`** section, when further actions are nested within the first to set or create elements in a nested array.

`options`
: The following property options are available for you to select:

- Include empty. If the check box is selected (the default option), empty XML elements are included in the output of the map policy. Clear the check box if you do not want empty XML elements to be included in the output of the map policy.
- Namespace inheritance. If the check box is selected (the default option), XML namespaces are inherited from the parent element. Clear the check box if you want the map policy to use explicit namespaces.
- Namespace inlining. If the check box is selected (the default option), XML namespaces will be inserted into the document where they are first used. Clear the check box if you want namespaces to all be defined on the root element.
- API Gateway only Resolve XML input data type. If the check box is selected, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Clear the check box (the default option) if you want all XML element values to be returned as a string.
- API Gateway only Parse XML output: If the check box is selected, the map policy will write XML output to `message.body` as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string.
- API Gateway only Empty XML element handling. This property controls how the map policy handles the output of an empty XML element. The following choices are available:
  - String (the default option): An empty XML element is handled as an empty string.
  - Null: An empty XML element is handled as a null value.
  - None: The data is ignored.
  - API Gateway only String Badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property.
  - API Gateway only Null Badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the Allow null value option is selected.
- API Gateway only Use only first array element. If the check box is selected, if an array is encountered in the traversal of the input, only the first element is used. Clear the check box (the default option) if you want the map policy to use all array elements.
- API Gateway only Resolve API Connect variable references. If the check box is cleared (the default option), the map policy ignores API Connect variable references in the map properties. Select the check box if you want API Connect variable references found in the map properties to be resolved.
- API Gateway only Allow null value. If the check box is selected, an input property value with a null value is mapped to the output document. Clear this check box (the default option) if you want the map policy to ignore null input values.
- API Gateway only Optimize schema definition. If the check box is selected, complex schema types evaluation handles circular type references in an optimized manner. Clear this check box (the default option) to evaluate these schema types in a standard manner.
- API Gateway only Create required child properties for array objects and mapped optional objects. If the check box is selected, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
  - An array consists of objects that contain one or more required properties.
  - An object which is optional has one or more child properties that are required.

  By default, these required properties are not present in the output. If you select this option, these required properties will be present in the output. If the output schema defines a `default` property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:
  - String: empty string ("")
  - Number: 0
  - Boolean: false
  - Object: empty object
  - Array: empty array

  Example 1

  The input data has the following array of objects:

  ```
  [{"a": "value1"}, {"a": "value2", "b": "value3"}]
  ```

  The output schema defines the output object as having two properties, `a` and `b`, of which `b` is required. The map policy defines the following mappings:

  - `input.array.a` to `output.array.a`
  - `input.array.b` to `output.array.b`

  If the check box is selected, and `b` is either not mapped or has no input data present, then `b` is assigned a default value of an empty string, and the output is as follows:

  ```
  [{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]
  ```

  Example 2

  The output schema defines the following structure:

  ```
  {"a" : {"b" : {"c" : "value1", "d" : "value2"} } }
  ```

  Property `b` is optional but property `d` within `b` is required.

  The map policy defines a mapping to `output.a.b.c`.

  If the check box is selected, and `d` is not mapped, then `d` is assigned a default value of an empty string, and the output is as follows:

  ```
  {"a" : {"b" : {"c" : "value1", "d" : ""} } }
  ```

  If the check box is not selected, these required properties are **not** created in the output with their default values.

- API Gateway only Empty JSON array handling. This property controls how the map policy handles the output of an empty array. The following choices are available:
  - All (The default value): Output all empty arrays, including empty children arrays.
  - Parent: Output only the current property's empty array value. Children map actions of this property are not attempted.
  - None: Prevent any empty output array values from being produced.
- API Gateway only Enable JSON post processing. Select this check box to enable post processing of mapped JSON output. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output

property values that have a Badgerfish JSON syntax due to object mapping of an XML input. The check box is cleared by default, meaning that there is no post processing of mapped JSON output.

- API Gateway only Schema definition circular reference limit. Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition.
  The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5.
- Severity level for input data log messages; This property specifies the severity level for log messages that relate to input data. The following choices are available:
  - error
  - warn
  - info
- API Gateway only Create empty parent object for failed mapping. If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Select this check box to create an empty object for the parent of the target mapping, emulating the behavior of IBM® API Management Version 4.0.

  Example

  The map policy defines a mapping to `output.a.b.c`.
  If input data is present, the output is as follows:

  ```
  {
    "a": {
      "b": {
        "c": "inputvalue"
      }
    }
  }
  ```

  If there is no input data, and the Create empty parent object for failed mapping option is selected, the output is as follows:

  ```
  {
    "a": {
      "b": {
      }
    }
  }
  ```

  Properties `a` and `b` are created but the value of `b` is an empty object.
  The check box is cleared by default.

Input and output definitions

You define the inputs and outputs of your Map policy in their own sections. Each input or output is an element in the array inputs or outputs and is defined by a name, a schema definition or reference, and a variable within the context from which it should be read or to which it should be written. After they have been defined, inputs and outputs are referenced by the name provided in the definition, not by the name of the variable.

The following example shows the inputs and outputs sections of a Map policy.

```
inputs:
  input_string:
    schema:
      type: string
    variable: request.parameters.name_in
  input_integer:
    schema:
      type: integer
    variable: request.parameters.age_in
outputs:
  output:
    schema:
      $ref: '#/definitions/output'
    variable: message.body
```

The schema field specifies the schema that describes the variable and can be a simple type, a reference to a definition, or an inline schema definition.

The variable field describes the variable and the context that should be assigned to the input or output variable during the execution of the map policy.

Actions

The fields included in the `actions` section are used in the following ways:

`set`
: Use the `set` field when you want to assign the result of the `value` field to the output variable specified in the `set` field, replacing the existing value of the output variable. You can specify only one output variable, although this variable can be an array or object.

`create`
: Use the `create` field when you want to use the result of the `value` field to create a new entry for the output array specified in the `create` field, appending it to the array. You can specify only one output variable, although this variable can be an array or object.

`from`
: Specify which variables are used in the action as either a single variable or an array of variables, where a variable can be an array or an object. The `from` field is not included if no inputs are used.

`value`
: Use GatewayScript to provide a script that produces output variables. When a single input is mapped to a single output, the `value` field can be omitted and the variable in `from` is set or created as the variable in `set` or `create` respectively.

`default`
: Provide a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see Inline references.

foreach
Specify a variable if you want to execute the associated **actions** field for each entry of the array. The variable can be from the input or output of the Map policy.

actions
Use the **actions** field to nest actions within an action. Because another action could achieve the same result if applied only once, it is primarily for use with the **foreach** field.

Script

In a **value** or **default** field, use GatewayScript to write the behavior of the action to which the **value** field belongs.

Include the script in single quotation marks. For example: **'4 + 5'** or ***'variable_1*.toUpperCase()'**.

For information about GatewayScript, see Gateway programming model and GatewayScript

Fields

from, **set**, and **create**
Each action must have a single **set** or **create** field that specifies the output variable to which the action is applied. Each action can also have a **from** field containing one or more entries that are used to specify the input variable or variables that are used in the action.

The **set** and **create** fields are both used to assign values to the output variable.

- **set** replaces the current value of the output variable or creates the variable if it does not already exist.
- **create** appends a new array entry to the output variable.

For **set** and **create**, use ***output_variable_name*.*variable_name*** to specify which of your defined output variables to use, where *output_variable_name* is as defined in the outputs section of the Map policy and *variable_name* refers to an optional field that belongs to the output variable.

For **from**, use ***input_variable_name*.*variable_name*** to specify which of your defined output variables to use, where *input_variable_name* is as defined in the outputs section of the Map policy and *variable_name* refers to an optional field that belongs to the output variable.

foreach
Use the **foreach** field to specify an input array for which the following **actions** or **value** field will be executed for each entry of the array.

For example:

```
foreach: input.in
actions:
   actions
```

where *input.in* is an input variable that is an array and *actions* is one or more actions in the same format as the parent section. In this example the instructions specified in *actions* are executed once for each array entry of *input.in*.
Referencing the input variable specified in the **foreach** field references the array entry that the current iteration corresponds to.

If a single variable is used in the **foreach** field instead of an array, the following **actions** or **value** field will be applied to or based upon the single variable once and then the loop will terminate.

References to inputs and outputs

Reference variables from the **from** field either by name or by using a number preceded by a '$' and enclosed in parentheses. The variables are numbered from 1, where 1 is the first variable in the array, or the only variable when the **from** field lists only a single variable. For example:

```
value: '$(1) + $(2)'
```

or

```
value: '$(variable_1) + $(variable_2)'
```

where each *variable* is a variable that is included in the **from** field.
During a **foreach** loop, you can reference **$(0)**. The **$(0)** variable begins a **foreach** loop empty but, after an iteration, becomes equivalent to the output of the iteration and can then be referenced again. In this manner, you can apply an array to a single value. For example:

```
- set: out.total
from: in.input
foreach: in.input
value: '$(0) + $(in.input)'
```

where *out.total* is referenced by **$(0)**. In each iteration, the current value of *out.total* and the current array entry of *in.input* are summed, and the value of *out.total* is set as this summation.
When using a foreach to operate on an array, if the elements of the array do not have named fields, you can use **$(this)** to reference the current level of nesting.

Accessing other contexts

At any point within your Map policy's **value** or **default** fields, you can access the context of the API call using the syntax **$(*context*.*variable*)**.

Alternatively, you can include the variables from other contexts when you define an input to your map policy and then reference it as you would any other input variable.

For a list of available context variables, see API Connect context variables.

Configuring the Map policy in the user interface

The assemble view in API Designer provides a visual representation of the relations between the inputs and outputs of your Map policy.

Procedure

To configure your Map policy, complete the following steps:

1. Click the Map policy in the canvas of the Assemble view.
   The property sheet opens.
2. Click the Edit inputs icon in the Input column.
3. Add an input variable.
   a. Click + input.
   b. In the Context variable field for an input, provide the location of your input variable in the context of the assembly. For a list of context variables, see API Connect context variables.
   c. In the Name field for an input, provide a name for your input for use within only the Map policy.
      Note:
      You must ensure that the name that you provide does not exactly match the value of the Context variable field, or the result might be unpredictable.
   d. Optional: In the Content type field, specify the type of your input. If None is selected, the content type is treated as JSON.
   e. In the Definition field for an input, provide the type of the variable.
      The type can be one from a standard set of types, a definition that you have created for your API, or you can select Inline schema to provide a schema as one of the following options:
      - YAML
      - JSON
      - Generate from sample JSON
      - Generate from sample XML

      .
      If you select Object or Array, you can create a schema through the user interface after you have clicked Done and returned to the main view of the property sheet.
4. Optional: To remove a variable, click the corresponding Remove input icon .
5. After you have added all of your input variables, click Done.
6. Click the Edit outputs icon in the Output column.
7. Add an output variable.
   a. Click + output.
   b. In the Context variable field for an output, provide the location of your output. This location can be a new context or one already established during the assembly. For a list of context variables, see API Connect context variables.
   c. In the Name field for an output, provide a name for your variable to use within the Map policy and when it is included in its context at output.
      Note:
      You must ensure that the name that you provide does not exactly match the value of the Context variable field, or the result might be unpredictable.
   d. Optional: In the Content type field, specify the type of your input. If None is selected, the content type is treated as JSON.
   e. In the Definition field for an output, provide the type of the variable.
      The type can be one from a standard set of types, a definition that you have created for your API, or you can select Inline schema to provide a schema as one of the following options:
      - YAML
      - JSON
      - Generate from sample JSON
      - Generate from sample XML

      If you select Object or Array, you can create a schema through the user interface after you have clicked Done and returned to the main view of the property sheet.
8. Optional: To remove a variable, click the corresponding Remove output icon .
9. After you have added all of your output variables, click Done.
10. Optional: If you selected Object or Array for the type of an input or output, create an inline schema definition through the user interface by completing the following steps:
    a. For an Array, click add item. Provide a type for the item and then click the Add icon .
    b. For an Object, click add property. Provide a name and type for the property and then click the Add icon .

    For objects and arrays created in this manner, you can continue to add items and properties, which can themselves be objects and arrays.
11. To connect an input variable to an output variable, click the circle that is directly before the input variable and then click the circle that is directly before the output variable.
    A green line is drawn, linking the two variables together. You can connect multiple inputs to a single output, and a single input can be connected to multiple outputs.
12. To configure an output, whether it has inputs connected to it or not, click the circle directly before the output variable without first clicking on a circle for an input variable.
    The Configure mapping window opens.
13. Optional: In the Mapped from section of the window, you can view which inputs are mapped to the output you are editing. To remove an input, click the Remove input icon alongside the input.
    If the output is part of an array, further configuration options are available. The array, or levels of array in the case of a multidimensional array, can be created by iterating arrays on the input side of the mapping. For each level of your array, select which array on the input side is to be iterated. In the Value field, you can use `$(this)` to reference elements of an array that are not named within the array.
14. Optional: In the Value field, use GatewayScript to configure how any inputs are transformed to produce the output.
    For more information about valid code, see the Script section of the The Map policy structure topic.
15. Optional: In the Default field, provide a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see Inline references.
16. Optional: To delete all mappings to the output, click Delete.
17. When you have configured your outputs, click OK.
18. Optional: Click the Settings icon in the Map column.

a. Optional: Provide a Title and Description for your Map policy.
b. To control the XML output of the map policy, select the following options as required:

Include empty
: If the check box is selected (the default option), empty XML elements are included in the output of the map policy. Clear the check box if you do not want empty XML elements to be included in the output of the map policy.

Namespace inheritance
: If the check box is selected (the default option), XML namespaces are inherited from the parent element. Clear the check box if you want the map policy to use explicit namespaces.

Namespace inlining
: If the check box is selected (the default option), XML namespaces will be inserted into the document where they are first used. Clear the check box if you want namespaces to all be defined on the root element.

Resolve XML input data type
: If the check box is selected, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Clear the check box (the default option) if you want all XML element values to be returned as a string.

Parse XML output
: If the check box is selected, the map policy will write XML output to **`message.body`** as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string.

Note: These options effect the XML output only and have no effect on the JSON data.

c.

From the Empty XML element handling list, select one of the following options to control how the map policy handles the output of an empty XML element:

- String (the default option): An empty XML element is handled as an empty string.
- Null: An empty XML element is handled as a null value.
- None: The data is ignored.
-

String Badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property.
-

Null Badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the Allow null value option is selected.

d.

Select the following general configuration options as required:

Use only first array element
: If the check box is selected, then if an array is encountered in the traversal of the input, only the first element is used. Clear the check box (the default option) if you want the map policy to use all array elements.

Resolve API Connect variable references
: If the check box is cleared (the default option), the map policy ignores API Connect variable references in the map policies. Select the check box if you want API Connect variable references found in the map properties to be resolved.

Allow null value
: If the check box is selected (the default option), an input property value with a null value is mapped to the output document. Clear this check box (the default option) if you want the map policy to ignore null input values.

Optimize schema definition
: If the check box is selected, complex schema types evaluation handles circular type references in an optimized manner. Clear this check box (the default option) to evaluate these schema types in a standard manner.

Enable JSON post processing
: If the check box is selected, post processing of mapped JSON output is enabled. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. The check box is cleared by default, meaning that there is no post processing of mapped JSON output.

Create empty parent object for failed mapping
:

Use this setting to control the behavior if a mapping fails because its input is not present and there is no default mapping configured.
The default behavior is to make no change to the output, but if you select this check box an empty object is created for the parent of the target mapping, emulating the behavior of IBM API Management Version 4.0.

Example
: The map policy defines a mapping to **`output.a.b.c`**.
If input data is present, the output is as follows:

```
{
  "a": {
    "b": {
      "c": "inputvalue"
    }
  }
}
```

If there is no input data, and the Create empty parent object for failed mapping option is selected, the output is as follows:

```
{
  "a": {
    "b": {
    }
  }
}
```

Properties **`a`** and **`b`** are created but the value of **`b`** is an empty object.
The check box is cleared by default.

Create required child properties for array objects and mapped optional objects

If the check box is selected, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:

- An array consists of objects that contain one or more required properties.
- An object which is optional has one or more child properties that are required.

By default, these required properties are not present in the output. If you select this option, these required properties will be present in the output. If the output schema defines a `default` property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:

- String: empty string ("")
- Number: 0
- Boolean: false
- Object: empty object
- Array: empty array

Example 1

The input data has the following array of objects:

```
[{"a": "value1"}, {"a": "value2", "b": "value3"}]
```

The output schema defines the output object as having two properties, **a** and **b**, of which **b** is required. The map policy defines the following mappings:

- `input.array.a` to `output.array.a`
- `input.array.b` to `output.array.b`

If the check box is selected, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:

```
[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]
```

Example 2

The output schema defines the following structure:

```
{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }
```

Property **b** is optional but property **d** within **b** is required.

The map policy defines a mapping to `output.a.b.c`.

If the check box is selected, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:

```
{"a" : {"b" : {"c" : "value1", "d" : ""} } }
```

If the check box is not selected, these required properties are **not** created in the output with their default values.

e. API Gateway only From the Empty JSON array handling list, select one of the following options to control how the map policy handles the output of an empty array:
   - All (the default option): Output all empty arrays, including empty children arrays.
   - Parent: Output only the current property's empty array value. Children map actions of this property are not attempted.
   - None: Prevent any empty output array values from being produced.

f. From the Severity level for input data log messages list, select one of the following options to specify the severity level for log messages that relate to input data:
   - error
   - warn
   - info

g. API Gateway only Set the Schema definition circular reference limit field to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5.

h. Click Save when done.

Results

You have configured a Map policy to transform and map variables in your assembly flow.

Map policy examples

Examples of the OpenAPI definitions of Map policies.

- One to one mapping
- Many to one mapping
- A simple transformation using the value field
- Mapping from multiple contexts into a new context
- Mapping to an inline schema definition
- Mapping with a default value
- Mapping an array into a single value
- Mapping array elements to an array
- Using the advanced XML options
- Increasing parse settings of the Map policy

One to one mapping

The following example:

- maps parameters from the request's query to an object in the message body.
- maps one strings directly to a single string.
- maps one integer directly to a single integer.

The referenced definition, **output**, defines an object containing a string, name, and an integer, age.

```
      - map:
          title: 1-1 map
          inputs:
            input_string:
              schema:
                type: string
              variable: request.parameters.name_in     # the location of the variable, named "name_in" and found in the query
parameters of the request
            input_integer:
              schema:
                type: integer
              variable: request.parameters.age_in    # another variable in the query parameters of the request
          outputs:
            output:
              schema:
                $ref: '#/definitions/output'    # a schema definition reference to use for the output. The schema is for the
whole of the message body.
              variable: message.body
          actions:
            - set: output.name_out    # in the actions section, variables are referenced by their name within the map policy
              from: input_string      # if a value field is not used, the mapping is direct with the input value used for the
output variable
            - set: output.age_out     # because the 'output' variable is itself an object, further references are made to
variables that it contains
              from: input_integer
```

Many to one mapping

The following example:

- maps parameters from the request's query to an object in the message body.
- maps two strings to a single string by concatenating them.
- maps two integers to a single integer by summing them.

The referenced definition, **output**, defines an object containing a string and an integer.

```
      - map:
          title: many-1 map
          inputs:
            input_string_1:
              schema:
                type: string
              variable: request.parameters.first_name
            input_string_2:
              schema:
                type: string
              variable: request.parameters.last_name
            input_integer_1:
              schema:
                type: integer
              variable: request.parameters.balance_1
            input_integer_2:
              schema:
                type: integer
              variable: request.parameters.balance_2
          outputs:
            output:
              schema:
                $ref: '#/definitions/output'
              variable: message.body
          actions:
            - set: output.full_name
              from:
                - input_string_1
                - input_string_2
               value: |
                 var retValue = undefined;
                 if ($(input_string_1) !== undefined && $(input_string_2) !== undefined) {
                   retValue = $(input_string_1).toUpperCase() + ' ' + $(input_string_2).toUpperCase()"
                 }
                 retValue;
            - set: output.total_balance
              from:
                - input_integer_1
                - input_integer_2
              value:  |
                var i1 = 0;
                var i2 = 0;
                if ($(input_integer_1) !== undefined) i1 = $(input_integer_1);
                if ($(input_integer_2) !== undefined) i2 = $(input_integer_2);
                i1 + i2;
```

A simple transformation using the value field

The following example:

- maps a parameter from the request's query to an object in the message body.
- maps one string featuring lowercase characters to a single string containing only uppercase characters.

The referenced definition, `output`, defines an object containing a single string.

```
      - map:
          title: Uppercase map
          inputs:
            input_lowercase:
              schema:
                type: string
              variable: request.parameters.name_in
          outputs:
            output_uppercase:
              schema:
                $ref: '#/definitions/output'
              variable: message.body
          actions:
            - set: output_uppercase.name_out
              from: input_lowercase
              value: $(input_lowercase).toUpperCase()    # the input variable is referenced and calls the toUpperCase method to
produce a value for the output variable
```

Mapping from multiple contexts into a new context

The following example:

- maps an integer from the request's header to an integer in a new message body.
- maps a string from the message's body to the body of a new custom context, named *new_context*.

```
      - map:
          title: Context map
          inputs:
            input_integer:
              schema:
                type: integer
              variable: request.headers.age_in      # the 'age_in' header of the request is used as an input
            input_string:
              schema:
                type: string
              variable: message.body.name_in      # as is the 'name_in' field of the request body
          outputs:
            output_integer:
              schema:
                type: integer
              variable: message.body.age_out
            output_string:
              schema:
                type: string
              variable: new_context.body.name_internal    # the context named 'new_context' is created by the map policy and
exists only while the assembly is processed
          actions:
            - set: output_string
              from: input_string
            - set: output_integer
              from: input_integer
```

Mapping to an inline schema definition

The following example:

- maps parameters from the request's headers to an object in the message body, which is defined within the map policy.
- maps one string directly to a single string.
- maps one integer directly to a single integer.

```
      - map:
          title: Inline schema map
          inputs:
            input_integer:
              schema:
                type: integer
              variable: request.headers.age_in
            input_string:
              schema:
                type: string
              variable: request.headers.name_in
          outputs:
            output:
              schema:                    # instead of a simple type or a reference to a definition, an inline YAML definition
is used
                type: object
                properties:
                  name_out:
                    type: string
                    name: name_out
                  age_out:
                    type: integer
                    format: int32
                    name: age_out
                title: output
              variable: message.body
          actions:
```

```
            - set: output.age_out
              from: input_integer
            - set: output.name_out
              from: input_string
```

Mapping with a default value

The following example:

- maps one string directly to a single string.
- provides a default value for the output string if a valid input string is not provided.

```
      - map:
          title: Default Map
          inputs:
            input_string:
              schema:
                type: string
              variable: request.headers.name_in
          outputs:
            output_string:
              schema:
                type: string
              variable: message.body.name_out
          actions:
            - set: output_string
              from: input_string
              default: John Smith            # the default field is specified in the same way as a value, in this case
providing a fixed value
```

Mapping an array into a single value

The following map policy:

- maps a single array of integers into a single integer.
- sums the integers in the array.
- `$(0)` represents the accumulated output because map evaluates all array element values.

```
      - map:
          title: Summation map
          inputs:
            input:
              schema:
                $ref: '#/definitions/balance_array_in'
              variable: request.body
          outputs:
            output:
              schema:
                type: integer
              variable: message.body.total_balance_out    # instead of using a full schema definition of the message body, a
single variable in the message body is specified
          actions:
            - set: output
              from: input
              foreach: input      # the foreach field specifies that each value of the array 'input' is to be iterated over
              value: $(0)+$(input) # the $(0) reference is the accumulated value of the 'output' variable
```

Mapping array elements to an array

The following map policy:

- maps an array, whose elements are objects containing two integers, to an array, whose entries contain a single integer field.
- maps an array to an array of the same length.
- takes the difference of the values of the integers in each array element to create a single integer in each array element.

```
      - map:
          title: Array summation
          inputs:
            input:
              schema:
                $ref: '#/definitions/balance_and_credit_array'
              variable: request.body
          outputs:
            output_array:
              schema:
                type: array
              variable: message.body
          actions:
            - create: output_array
              from: input
              foreach: input
              actions:
                - set: total_balance_out
                  from:                          # inside the actions section, variables inside the array elements being
iterated over are used
                    - integer_in_1
                    - integer_in_2
                  value: $(integer_in_1)-$(integer_in_2)      # the difference of the variables is taken for each array entry
of 'input'
```

Using the advanced XML options

The following example:

- does not include empty elements in the output of the map policy.
- uses explicit name spaces rather than inheriting name spaces from the parent element
- indicates that all namespace declarations will be placed on the root XML element.
- uses all array elements rather than only the first
- ignores API Connect variable references
- maps input property values with a null value to the output document
- handles circular type references in an optimized manne

```
        actions:
            - set: output, two
              from: input, one
        options:
            includeEmptyXMLElements: false
            namespaceInheritance: false
            inlineNamespaces: false
            mapArrayFirstElementValue: false
            mapResolveApicVariables: false
            mapNullValue: true
            mapOptimizeSchemaDefinition: true
            mapCreateEmptyArray: parent
```

Increasing parse settings of the Map policy

To increase the parse-settings-reference, you can update the YAML source with the desired parse settings. Using the following example, you can update the YAML source with the necessary parse settings.

```
        - map:
          version: 2.1.0
          title: map
          inputs: {}
          outputs: {}
          actions: []
          parse-settings-reference:
            parse-settings:
              document_type: detect
              max_doc_size: 8388608
              max_nesting_depth: 512
              max_width: 8192
              max_name_length: 256
              max_value_length: 8192
              max_unique_names: 1024
              max_unique_prefixes: 1024
              max_unique_namespaces: 1024
              max_number_length: 128
          options:
            mapEmulateV4EmptyJSONObject: false
            mapEmulateV4DefaultRequiredProps: true
            mapEnablePostProcessingJSON: false
            mapReferenceLimit: 1
```

For more information, see Creating parse settings.

OAuth

An OAuth policy performs the requested OAuth processing based on the defined OAuth provider settings.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see oauth.

About

By adding an assembly OAuth policy, you specify the OAuth provider settings to use to perform the requested OAuth processing and the supported OAuth processing components.

Note: You add an OAuth policy to the assembly in a native OAuth provider. For more information, see the following topics:

- Editing the native OAuth provider configuration using the API Editor (Cloud Manager UI)
- Editing the native OAuth provider configuration using the API Editor (API Manager UI)

You can specify the settings through one or more of the following methods.

- URL reference
- Literal configuration
- Object reference

When you use more than one method to specify the same aspect of the OAuth provider settings, the following precedence rules apply to enforce the settings dynamically for the incoming transactions.

- URL reference takes precedence over any existing literal configuration or object reference.
- Literal configuration takes precedence over any existing object reference.

You can configure the policy to support one or more of the following processing components:

Validate request
: Validates the authorization request from the client.

Generate authorization code
: Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource.

Verify authorization code
: Verifies the authorization code from the client.

Verify refresh token
: Verifies the refresh token that is presented by the client.

Generate access token
: Generates the access token to the client when the authorization code or refresh token is verified.

Introspect token
: Introspects the token to determine its state and, when active, its metadata.

When the policy does not support a processing component but that processing is requested, the unsupported component is not run.

You can include multiple OAuth policies in your OAuth provider assembly. For example, your assembly might include the following flow:

1. OAuth policy that validates the request.
2. GatewayScript policy.
3. OAuth policy that generates authorization code.

For more information, see Example - using multiple OAuth policies in an OAuth provider assembly and OAuth context variables.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OAuth policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **oauth**.	string
Description	No	A description of the policy	string
Default OAuth Provider Settings Object	Yes	The name of an existing OAuth provider that defines the required settings.	string
Dynamic OAuth configuration from a URL	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings.	string
Dynamic OAuth configuration from a literal string	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings.	string
Supported OAuth components	No	Select the OAuth components that are supported by this policy.	string

Overriding the default OAuth provider settings

You can use either the Dynamic OAuth configuration from a literal string property or the Dynamic OAuth configuration from a URL property to dynamically override any OAuth provider configuration settings defined by the Default OAuth Provider Settings Object property.

For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the **OAuthProviderSettings** management schema, defined in the xml-mgmt.xsd file located in the store: directory on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

- **Example - using multiple OAuth policies in an OAuth provider assembly**
  This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

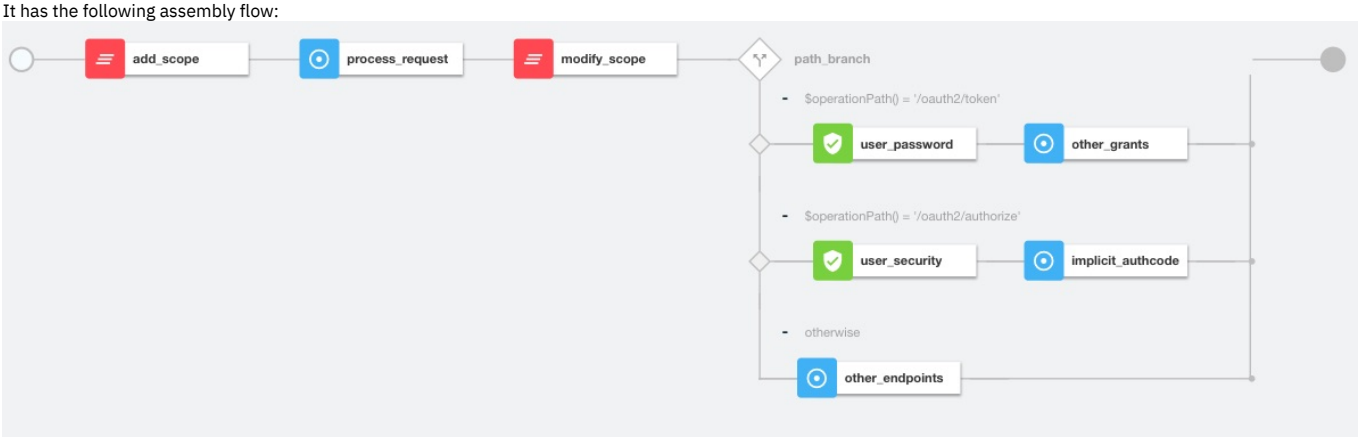
Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of **gatewayscript** policies that use OAuth context variables to manipulate the OAuth flow. For details on creating a native OAuth provider, see Configuring a native OAuth provider.

It has the following assembly flow:



The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download multiple_oauth_policies.txt.

Sample policy to add a custom scope

The **add_scope** policy is a **gatewayscript** policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: add_scope
    source: |-
      // Add another custom scope to the request
      let scope = context.get("request.parameters.scope.values[0]");
      if (scope)
        context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first **process_request** policy is an **oauth** policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the oauth.processing context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: process_request
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect protocol steps
      that are needed for OAuth Validation by default. The inputs and
      outputs of each of the steps are driven by documented context
      variables. Add or remove the Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthValidateRequest
```

Sample policy to modify the scope

The **modify_scope** policy is a **gatewayscript** policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: modify_scope
    source: |-
      let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

      // Check application and modify the scope
      let app = context.get("oauth.processing.client_id");
      let scope = context.get("oauth.processing.scope");
      if (app === admin_id) {
```

```
        context.set("oauth.processing.scope", scope + " admin");
      } else {
        context.set("oauth.processing.scope", scope + " customer");
      }
```

Branch conditionally according to the OAuth path

The **path_branch** policy is a **switch** policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
    version: 2.0.0
    title: path_branch
    case:
      - condition: ($operationPath() = '/oauth2/token')
        execute:
            .
            .
            .
          definition of the user_security and other_grants policies
            .
            .
            .
      - condition: ($operationPath() = '/oauth2/authorize')
        execute:
            .
            .
            .
          definition of the user_password and implicit_authcode policies
            .
            .
            .
      - otherwise:
            .
            .
            .
          definition of the other_endpoints policy
            .
            .
            .
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The **user_password** policy for password grant type processes the user name and password from the **x-www-form-urlencoded** body. The authentication method is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **other_grants** policy is an **oauth** policy that enables the **OAuthGenerateAccessToken**, **OAuthVerifyAZCode**, **OAuthVerifyRefreshToken**, and **OAuthCollectMetadata** components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_password
    version: 2.0.0
    description: ''
    factor-id: default
    extract-identity-method: context-var
    user-context-var: request.parameters.username.values
    pass-context-var: request.parameters.password.values
    ei-stop-on-error: false
    user-auth-method: auth-url
    au-stop-on-error: false
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
- oauth:
    title: other_grants
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for token path by default.
      The inputs and outputs of each of the steps are driven by
      documented context variables. Add or remove the Supported
      OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAccessToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
      - OAuthCollectMetadata
```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The **user_security** policy configuration is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **implicit_authcode** policy is an **oauth** policy that enables the **OAuthGenerateAZCode**, **OAuthGenerateAccessToken**, and **OAuthCollectMetadata** components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_security
    version: 2.0.0
    description: >-
      This user security policy performs EI(basic) and AU(auth
      url) check for oauth assembly. Change the security check
      method as required
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: auth-url
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
- oauth:
    title: implicit_authcode
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for az code path by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthCollectMetadata
```

Process all other endpoints

The **otherwise** condition catches all other endpoints such as the introspect and revoke endpoints. The **other_endpoints** policy in the **otherwise** condition is an **oauth** policy that enables the **OAuthIntrospectToken**, and **OAuthRevokeTokencomponents** components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: other_endpoints
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for all other paths by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthIntrospectToken
      - OAuthRevokeToken
```

Azure openai invoke

Use the Azure OpenAI invoke policy to invoke Azure OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see Azure openai-invoke.

About

The Azure OpenAI invoke policy provides access to four Azure OpenAI operations:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

The Azure OpenAI invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Azure OpenAI invoke policy properties

Property label	Required	Description	Data type
Title	No	Azure OpenAI invoke chat completions	string
Description	No	A description of the policy.	string
Azure OpenAI Operation	Yes	The Azure OpenAI operation to invoke; must be one of the following operations: • **`POST /chat/completions`** An HTTP POST operation for **`/chat/completions`**. See Create chat completion in the Azure OpenAI documentation for sample request and response examples. • **`POST embeddings`** An HTTP POST operation for **`/embeddings`**. See Create embeddings in the Azure OpenAI documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the Azure OpenAI documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the Azure OpenAI documentation for sample response examples.	string
Azure OpenAI API Key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Azure OpenAI requests.	string
Azure OpenAI Resource Id	Yes	Serves as part of endpoint of URL that points to your provisioned resources.	string
Azure OpenAI Deployment ID	Yes	Path parameter - the name of project/deployment in Azure where model is deployed.	string
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the Azure OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
Operation Version	No	The operation version specifies the version of the OpenAI operation (such as completions, chat/completions, embeddings) that the policy applies to. It is defined using YYYY-MM-DD format.	
Azure OpenAI Operation Path Parameters	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string

Property label	Required	Description	Data type
Azure OpenAI Operation Query Parameters	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the Azure OpenAI response. By default, this property uses message as the value, which enables the response to be accessible by subsequent API policies in `message.body` and `message.headers`.	string

API Gateway only

openai invoke

Use the OpenAI invoke policy to invoke OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see openai-invoke.

About

The OpenAI invoke policy provides access to four OpenAI operations:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

The OpenAI invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OpenAI invoke policy properties

Property label	Required	Description	Data type
Title	No	`OpenAI` invoke chat completions	string
Description	No	A description of the policy.	string
OpenAI Operation	Yes	The OpenAI operation to invoke; must be one of the following operations: • `POST /chat/completions` An HTTP POST operation for `/chat/completions`. See Create chat completion in the OpenAI documentation for sample request and response examples. • `POST embeddings` An HTTP POST operation for `/embeddings`. See Create embeddings in the OpenAI documentation for sample request and response examples. • `GET models` An HTTP GET operation for `/models`. See List Models in the OpenAI documentation for sample response examples. • `GET models/[model]` An HTTP GET operation for `/models/[model]`. See Retrieve model in the OpenAI documentation for sample response examples.	string
OpenAI API Key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate OpenAI requests.	string
OpenAI Organization Id	No	An optional property where you can specify the organization identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy requests specifying this property will count as usage by the organization specified.	string
OpenAI Project Id	No	An optional property where you can specify the project identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy request specifying this property will count as usage by the project specified.	string

Property label	Required	Description	Data type
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
OpenAI Operation Path Parameters	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation `GET models/[model]`, the path parameter property would be specified as `model:somename`. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
OpenAI Operation Query Parameters	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the OpenAI response. By default, this property uses message as the value, which enables the response to be accessible by subsequent API policies in `message.body` and `message.headers`.	string

Parse

Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later) 2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see parse.

About Parse

With the parse policy, you can retrieve parse settings by using the following methods in increasing order of precedence.

1. Specify a valid parse settings configuration from which to retrieve its properties as the default parse settings.
   Note: If you change the default name, you must separately configure a corresponding ParseSettings object on the DataPower API Gateway.
2. Specify a literal string as serialized XML or JSON properties as parse settings. These properties take precedence over any existing default properties. The literal string must be XML or JSON formatted.
   - The XML format is `"<ParseSettings><propertyName>propertyValue</propertyName></ParseSettings>"`.
   - The JSON format is `"{ \"ParseSettings\" : { \"propertyName\" : propertyValue } }"`.
3. A URL that represents a named context from which to retrieve the serialized XML or JSON properties as parse settings. These properties take precedence over any existing literal or default properties.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Parse policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is `parse`.	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
Use Content Type	No	If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the **`Content-Type`** specified in the request headers. If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the **`Content-Type`** specified in the request headers and fails if the **`Content-Type`** in the request headers does not match the parse setting. Enabling this setting is applicable only when the expected **`Content-Type`** is either JSON or XML. If this setting is not enabled, the parse operation uses either the document type that is specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type. The check box is cleared by default.	boolean
Parse settings object reference	No	An existing valid object from which to retrieve default property values for the dynamic object.	string

Document type	No	The type of document to parse. Select one of the following options:
		
		• Detect: the document type is detected and the payload is parsed accordingly. This type is the default option.
		• JSON: the payload is parsed as JSON.
		• XML: the payload is parsed as XML.
		• Graphql: parsing is performed in one of the following ways:
		  ◦ As GraphQL in the body of a POST request. The GraphQL is in the following format:
		
		`{ me { name } }`
		
		  ◦ As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format:
		
		`{ "query": "query MyData ($idVar: Int!) { user (id: $idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} }`
		
		  ◦ Through the URL query of a GET request. The URL is in the following format:
		
		`https://myapi/graphql?query={me{name}}`
		
		The following example includes the **`variables`** and **`operationName`** properties, with URL encoding (line-breaks are for table formatting only, your value will not include line-breaks):
		
		`https://hostname/basepath/graphql?query=query%20fetchAccounts %20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}} &variables={"limit":100}&operationName=fetchAccounts`
		
		Query variables in a GET request can be sent as a JSON string in a query parameter called **`variables`**. If the query contains several named operations, an **`operationName`** query parameter is required to determine which operation is to be executed.
		
		Note: If the Buffering is selected in Invoke policy, the document type is detected, and the payload is parsed accordingly. For more information, see Configuring the Invoke policy for DataPower API Gateway and Configuring the Invoke policy for DataPower Gateway (v5 compatible).
			string

Maximum document size	No	Optionally, the maximum document size in bytes of a JSON, XML, or GraphQL input document that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. The default value is 4194304.	integer
Maximum nesting depth	No	Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message. • When XML, it is the maximum level of element depth. • When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. • When GraphQL, it is the maximum level of nested selection sets. Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth. The default value is 512.	integer

Property label	Required	Description	Data type
Maximum width	No	Optionally, the maximum width of the payload that the parse operation accepts. • When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. • When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. • When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document. The default value is 4096.	integer
Maximum name length	No	Optionally, the maximum name length in bytes in a document that the parse operation accepts. • For XML, it is the length of the name portion of a tag. • For JSON, it is the length of the label portion of the JSON label-value pair. • For GraphQL, it is the maximum length of the identifiers, including field names and directive names. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document. The default value is 256.	integer
Maximum value length	No	Optionally, the maximum value length in bytes in a document that the parse operation accepts. • For XML, it is the length of an attribute or the length of a text value. • For JSON and GraphQL, it is the length of a string value. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document. The default value is 8192.	integer
Maximum number of unique names	No	Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts. • For XML, it is the number of unique XML local names. • For JSON, it is the number of unique JSON labels. Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document. The default value is 1024.	integer
Maximum number of unique prefixes	No	Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document. The default value is 1024.	integer
Maximum number of unique namespaces	No	Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document. The default value is 1024.	integer
Maximum number length	No	Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document. The default value is 128.	integer
Parse settings literal configuration	No	A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.	string
Parse settings URL reference	No	A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.	string
Message for parsing	No	The name of a variable in the API context. The content of the **body** field of the variable is the input to the policy. The default variable name is **message**.	string
Message for resulting parsed data	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

Use the YAML source to set the following option.

Property	Required	Description	Data type

Property	Required	Description	Data type
strict-utf8-encoding	No	For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document. • When **on**, the entire document is checked for valid UTF-8 encoding. • When **off**, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. The default value is **off**.	boolean

For examples, see parse.

Proxy

Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the **message.body** and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see proxy.

About

Only one Proxy policy is permitted to be run per unique flow of your assembly. More than one Proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.

You can use the Proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, Proxy must be the last policy in the assembly, otherwise the response that is received can be manipulated during subsequent steps, thereby causing the multipart form data to be lost.

The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the invoke policy rather than the proxy policy.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Proxy policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **proxy**.	string
Description	No	A description of the policy.	string
Invoke URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Proxy URL value is pre-supplied from information that is defined in the imported WSDL.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the proxy. Valid values are: • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **Keep**. By using **Keep**, or removing the property from the source, the HTTP method from the incoming request is used.	string
Compression	No	Select this check box to enable Content-Encoding compression on upload. The check box is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are: Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL. Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option. No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings. Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached. The default value is Protocol.	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to **`Time to Live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a **`catch`** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. This variable can then be referenced in other actions, such as 'Map'.	string
X-Forwarded header	No	This header can be provided by 1. If **`X-Forwarded-Host`** exists, processing continues. If it does not exist prior to calling the proxy policy, it is set with the value of the **`Host`** header. 2. The **`X-Forwarded-For`** header is always set, in all cases. This header maintains breadcrumbs, showing a comma-separated list of IPs, from the client through any preceding proxy. 3. If all three of **`X-Forwarded-Host`**, **`X-Forwarded-Port`**, and **`X-Forwarded-Proto`** headers are missing at the time of calling the proxy policy, they are set automatically. To prevent this, set **`X-Forwarded-Host`** header to some value before calling the proxy policy.	string

API Gateway only

Rate Limit

Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.5.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ratelimit.

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a Rate Limit policy is placed before an Invoke policy, and the call made by the Invoke policy exceeds the limits defined by the Rate Limit policy, the API call itself fails.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`ratelimit`**.	string
Description	No	A description of the policy.	string
Source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Select one of the following options: • Catalog by Name: the limits to be applied are defined in the appropriate **`api-collection`** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the **`api-collection`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan by Name: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a Plan by Name rate limit policy: ◦ Every Plan that contains the API that is being limited must have the named rate limit applied. ◦ A Plan by Name rate limit policy cannot be used with automatically generated Products. • Gateway by Name: the limits to be applied are defined in the **`apigw`** object, named **`apiconnect`**, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the **`apigw`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan Default: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies.	string
Rate Limit Name	Yes[1]	If Source property is set to Catalog by Name, the name of a rate limit as defined in the DataPower API Gateway configuration, To display the Rate Limit Name field, click Add Rate Limit; you can add as many rate limits as you want. [1]You must provide at least one rate, burst, or count limit.	string

Property label	Required	Description	Data type
Burst Limit Name	Yes[2]	If Source property is set to Catalog by Name, the name of a burst limit as defined in the DataPower API Gateway configuration. If Source is set to Plan by Name, the name of an assembly burst limit in a Plan. To display the Burst Limit Name field, click Add Burst Limit; you can add as many burst limits as you want. [2]You must provide at least one rate, burst, or count limit.	string
Count Limit Name	Yes[3]	If Source property is set to Catalog by Name, the name of a count limit as defined in the DataPower API Gateway configuration. If Source is set to Plan by Name, the name of an assembly count limit in a Plan. To display the Count Limit Name field, click Add Count Limit; you can add as many count limits as you want. [3]You must provide at least one rate, burst, or count limit.	string
Operation	No	For a rate limit, select one of the following options: • Consume: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. • Replenish: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55. Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1. The default value is Consume. For a count limit, select one of the following options: • Increment: the current count is incremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. • Decrement: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway. The default value is Increment. For a burst limit, the only option is Consume, meaning that the limit applied is that defined in the burst limit specified in the Burst Limit Name field.	string

- **Configuring a rate, burst, or count limit on the DataPower API Gateway**
  If you want to include a rate limiting policy in your API assembly flow, you must first configure the required rate, burst, and count limits on the Gateway. Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

Configuring a rate, burst, or count limit on the DataPower API Gateway

If you want to include a rate limiting policy in your API assembly flow, you must first configure the required rate, burst, and count limits on the Gateway. Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

About this task

You configure rate, burst, and count limits on the DataPower® API Gateway by defining them in one or more configuration files that you package and then add to the Gateway as a Gateway extension.

You define *Catalog scoped* rate, burst, and count limits in the appropriate **api-collection** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. The defined rate, burst, and count limits will be available to be included in Rate Limit policies in the assembly flows of all the APIs that are published to that Catalog.

You define *Gateway scoped* rate, burst, and count limits in the appropriate **apigw** object on the DataPower API Gateway. The defined rate, burst, and count limits will be available to be included in Rate Limit policies in the assembly flows of all the APIs that are published to that Gateway.

The system clock determines the start time for rate, burst, and count limits. The intervals are configured as follows:

- 1 second interval starts at each new second.
- 1 minute interval starts at the beginning of each minute.
- 1 hour interval starts at the beginning of each hour.
- 1 day interval starts at midnight UTC.
- 1 week interval starts on Thursday at 00:00:00 UTC.

Note:

- Only one Gateway extension can be in use at any one time, so you should package all required rate, burst, and count limits in a single Gateway extension.
- To apply a Catalog scoped or Gateway scoped rate, burst, or count limit, it must be referenced in a Rate Limit policy in an API assembly.
- You should ensure that all rate, burst, and count limit names are unique across all your Plans and Catalogs. When an API is called, information about any rate, burst, or count limits (such as name, limiting criteria, and remaining number of calls) is returned in the HTTP headers of the response. If two or more limit definitions with exactly the same name are applied during the invocation of an API, information about only **one** of them is returned. However, **all** limiting criteria are applied.

Procedure

1. Create a .cfg file that includes the DataPower API Gateway CLI commands that define the rate, burst, or count limit.
   To define a rate limit, use the **assembly-rate-limit** command. To define a burst limit, use the **assembly-burst-limit** command. To define a count limit, use the **assembly-count-limit** command. For details of the command parameters, see assembly-rate-limit, assembly-burst-limit, and assembly-count-limit in the DataPower product documentation.

   Example 1: Configuring a Catalog scoped rate limit

   ```
   top; config;
   switch apiconnect;

   api-collection myorg_mycatalog_collection
     assembly-rate-limit  30per1min 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-
   amount"
   exit
   ```

   In this example, the **assembly-rate-limit** command specifies a rate limit name, and the API call limits that you want to impose, 30 calls per minute in this case. The final, optional argument, **"my.vars.expected-amount - my.vars.actual-amount"**, is a weight expression. You use weight expressions in cases where you want to restore an appropriate amount of remaining rate limit balance when an earlier usage calculation in your assembly flow turns out to be too high. You define two rate limiting policies in your assembly flow, one with a **consume** operation, and a subsequent one with a **replenish** operation that restores some of the remaining rate limit balance if appropriate. The weight expression calculates the amounts to be consumed or replenished; for more information, see Rate Limit.

   The **api-collection** command specifies the **api-collection** object in which you want to configure the rate, burst, or count limits. The name of the **api-collection** object has the following format:

   ***org_catalog*_collection**

   where:
   - *org* is the name of the provider organization that contains your Catalog.
   - *catalog* is the name of the Catalog.

   This **api-collection** object name is assigned automatically by the Gateway the first time that a Product is published to the Catalog.

   Example 2: Configuring a Catalog scoped count limit

   ```
   top; config;
   switch apiconnect;

   api-collection myorg_mycatalog_collection
     assembly-count-limit  maxsixty 60 1 on on off off off off "" "1" off
   exit
   ```

   The final argument is the **autodecrement** property that controls whether the count limit is automatically decremented at the end of an API assembly. The default value is **on**, meaning that at the end of the assembly the count limit is automatically decremented by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly.

   Example 3: Configuring a Gateway scoped rate limit

   ```
   top; config;
   switch apiconnect;

   apigw apigw_object_name
     assembly-rate-limit  30per1min 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-
   amount"
   exit
   ```

   The **apigw** command specifies the name of the **apigw** object in which you want to configure the rate, burst, or count limits; the **apigw** object name is the same as the name of the API Connect domain in your DataPower API Gateway configuration.

2. Package the .cfg file in a **.zip** file.
   You can package multiple .cfg files in a single **.zip** file if you want; the .cfg files must all be at the root of the **.zip** file.
3. Add the **.zip** file to the DataPower API Gateway as a Gateway extension. For details, see Configuring your Gateway server extensions.

What to do next

Apply the rate, burst, or count limits to an API by adding a Rate Limit policy to the API assembly flow.

Related information

- Gateway extension guidelines - DataPower API Gateway.

API Gateway only

Rate Limit Info

Use the Rate Limit Info policy to return information about rate limits, burst limits, and count limits. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ratelimitinfo.

About

The Rate Limit Info policy returns information about the rate limits, burst limits, and count limits that are applied to the API.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit Info policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`ratelimitinfo`**.	string
Description	No	A description of the policy.	string
Input	No	The input context that specifies what rate limit information is requested.	string
Output	No	The destination of rate limit information.	string

API Gateway

Redaction - DataPower API Gateway

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the Redaction policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Redaction - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see redact - DataPower API Gateway.

Note: With the DataPower API Gateway, the input to the Redaction policy must be parsed data. One way to produce parsed data is to use a Parse policy before a Redaction policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`redact`**.	string
Description	No	A description of the policy.	string
Root	No	Specifies the data source that contains the content to redact or remove. If no value is entered in the Root field, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of `message.body`. The actual content to which the action is applied then depends on the positioning of the Redaction policy in the overall assembly flow; for example: • If positioned at the beginning, the action is applied to the client request. • If positioned after an Invoke policy, the action is applied to the response from the back end. • If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the Redaction policy is used after a Log policy that specifies Gather-only mode, specify a Root value of `log.request_body` for the logged request payload, or `log.response_body` for the logged response payload.	string
Path	Yes	Specifies a JSONata path expression that identifies the content to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
Action	No	Specifies whether you want to remove or redact the content. Choose one of the following options: • Remove: Completely removes the specified fields. • Redact: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is Redact. Note: If a numerical value is being redacted, the redacted value is depicted as **`******`** and the type is changed to **`string`**.	string

Tip: You can optionally click Add action to specify JSONata expressions for additional fields that you want to remove or redact from the specified content source.

- **Constructing JSONata expressions to redact fields**
  To define a field for redaction or removal when using the Redaction policy with the DataPower API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

Constructing JSONata expressions to redact fields

To define a field for redaction or removal when using the Redaction policy with the DataPower® API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - **`$eval()`**
  - **`$sift()`**
  - **`$each()`**
  - **`$error()`**
  - **`$assert()`**
  - **`$fromMillis()`** is supported with the following restrictions:
    - The **`$fromMillis()`** parameter supports numbers in the range -5364662400000 - 2903299199000.
      - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
      - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- **`$now()`** is supported with the following restrictions:
  - The following component specifiers are not supported:
    - **`W`** = Week in year
    - **`w`** = Week in month
    - **`X`** = ISO week-numbering year
    - **`x`** = ISO week-numbering month
  - Representing numbers as words are not supported, so the following presentation modifiers are not supported:
    - **`W`** = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
    - **`w`** = Lowercase word (for example: [Yw] => two thousand and twenty-four)
    - **`Ww`** = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
  - Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description

`$apiCtx()`	Generic access to an API context	The `$apiCtx()` extension gives generic access to an API context.
		• Sample transform field in an extract action:
		`"$apiCtx().request.uri"`
		• Sample condition of a case in a switch action:
		`"$apiCtx().request.path = '/simple/apictx-function'"`

`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation
`$queryParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keyword is `query`. • `request.parameters.`*`name`*`.values`	Searches for the index of `query` in `request.parameters.`*`name`*`.locations` and returns `request.parameters.`*`name`*`.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*`variable`*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

`$urlParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keywords are `path` and `query`
	• `request.parameters.`*`name`*`.values`
		Searches for the index of `path` and `query` in `request.parameters.`*`name`*`.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.`*`name`*`.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values.
		`http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese`
		The `$urlParameter('breed')` URL returns the following array of values.
		`[cats, adopt, Sphynx, Siamese]`
		In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.

`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- **`query`**
  The entire GraphQL query including operations and fragments.

- ***`operationName`***
  For an anonymous operation, ***`operationName`*** can be empty.

- ***`~fragmentSpreadName`***
- ***`on~typeCondition`***
- ***`~~fragmentDefinitionName`***

You can define the path using either of the following options:

- Use a JSONata expression
- Use the **`$xpath()`** JSONata extension

Using a JSONata expression

The path specified by the JSONata expression is relative to any value specified for the **`root`** property of the Redaction policy. If the **`root`** property has no value or is absent, begin the expression with the absolute content path. If the **`root`** property has a value then you can either begin the expression with **`$`** to use the **`root`** path directly, or you can provide a sub-path relative to the **`root`** path.

Note: If you use a JSONata expression to redact fields and soft linked copies of a field exist in different locations, the Redaction policy can cause content from all of the linked fields to be redacted.
JSONata expressions can be used with content that is in either JSON or XML format.

Example 1
: If the **`root`** property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the **`price`** field in the request and response data:

```
message.body.**.price
```

Example 2
: If the **`root`** property of the Redaction policy has the value **`log.request_body`**, use the following expression to redact or remove all occurrences of the **`price`** field, specifically within an **`item`** element, in the logged request payload:

```
$.item.price
```

Example 3
: If the **`root`** property of the Redaction policy has the value **`log`**, use the following expression to redact or remove all occurrences of the **`price`** field in the logged response payload:

```
response_body.**.price
```

The **`**`** descendant wildcard traverses all descendants at all hierarchical levels.

Using the `$xpath()` JSONata extension

The **`$xpath()`** function has the following format:

```
$xpath(content_path, xpath_expression)
```

where:

- *content_path* is the path to the content that contains the field that you want to redact or remove.
- *xpath_expression* is the XPath expression that defines the field that you want to redact or remove.

The *content_path* is relative to any value specified for the **`root`** property of the Redaction policy. If the **`root`** property has no value or is absent, provide the absolute content path. If the **`root`** property has a value then you can either provide the value **`$`** for the *content_path* parameter to use the **`root`** path directly, or you can provide a sub-path relative to the **`root`** path.

The **`$xpath()`** function can be used only with content that is in XML format.

Example 1
: If the **`root`** property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the **`price`** field in the request and response data:

```
$xpath(message.body, '//price')
```

Example 2

If the **root** property of the Redaction policy has the value **log.request_body**, use the following expression to redact or remove all occurrences of the **price** field, specifically within an **item** element, in the logged request payload:

```
$xpath($, 'item/price')
```

Example 3

If the **root** property of the Redaction policy has the value **log**, use the following expression to redact or remove all occurrences of the **price** field in the logged response payload:

```
$xpath(response_body, '//price')
```

The **//** expression in the second parameter selects all occurrences anywhere in the content.

DataPower Gateway (v5 compatible)

Redaction - DataPower Gateway (v5 compatible)

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This topic describes the Redaction policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Redaction - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see redact - DataPower Gateway (v5 compatible).

About

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **redact**.	string
Description	No	A description of the policy.	string
Path	Yes	Specifies an XPath expression that defines the field to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields.	string
Action	Yes	Specifies whether you want to remove or redact the field. Valid values: • **remove**: Completely removes the specified field. • **redact**: Redacts (obfuscates with "*"s) the field to block out the data. The default value is **redact**. Note: If a numerical value is being redacted, the redacted value is depicted as ****** and the type is changed to **string**.	string

Property label	Required	Description	Data type
From	Yes	Specifies where to remove or redact the specified field from. Valid values: • **all**: Removes or redacts the specified field from the Request body, the Response body, and the activity logs. • **request**: Removes or redacts the specified field from the Request body. • **response**: Removes or redacts the specified field from the Response body. • **logs**: Removes or redacts the specified field from the activity logs. The default value is **all**. Optionally click Add item to specify additional values.	string

Tip: You can optionally click Add item to specify XPath expressions for additional fields that you want to remove or redact from the Request body, Response body, and logs.

- **Constructing XPath expressions to redact fields**
  To define a field for redaction when using the DataPower Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

DataPower Gateway (v5 compatible) only

Constructing XPath expressions to redact fields

To define a field for redaction when using the DataPower® Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

About this task

The following sections provide examples for constructing XPath expressions to redact a field; examples are provided for API responses in both XML and JSON format:

XPaths for XML

Consider the following example of an XML response:

```
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>412 Brooklyn Avenue</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

To redact "streetAddress" in the preceding example the XPath expression would be: `//streetAddress`
where the components of the expression have the following meaning:

Expression	Meaning
`//`	search anywhere in the XML structure
`//streetAddress`	search anywhere in the XML structure for an element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New Jersey</city>
```

```
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Both incidences of "streetAddress" have been redacted.
To redact one specific incidence of "streetAddress" in the initial example, the XPath expression would be: `//secondaryAddress/streetAddress`
where the components of the expression have the following meaning:

Expression	Meaning
`//secondaryAddress`	search anywhere in the XML structure for an element of type "secondaryAddress"
`//secondaryAddress/streetAddress`	search under the preceding element for a child element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Only the secondary address has been redacted.
XPaths for JSON
Consider the following example of a JSON response:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "412 Brooklyn Avenue",
    "city": "New Jersey",
    "state": "NJ",
    "postalCode": 12302
  }
}
```

Unlike the preceding XML example, to construct an XPath for this example you must use the corresponding DataPower XML representation, JSONx. The JSONx equivalent of this JSON response is as follows:

```
<json:object xsi:schemaLocation="http://www.datapower.com/schemas/json jsonx.xsd"
xmlns:json="http://www.ibm.com/xmlns/prod/2009/jsonx" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <json:object name="primaryAddress">
    <json:string name="streetAddress">21 2nd Street</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
  <json:object name="secondaryAddress">
    <json:string name="streetAddress">412 Brooklyn Avenue</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
</json:object>]
```

To redact the element "streetAddress" from the preceding JSONx structure, the XPath expression would be: `//*[@name='streetAddress']`
where the components of the expression have the following meaning:

Expression	Meaning
`//*`	find any element anywhere in the structure
`[@name='streetAddress']`	this element has a 'name' property with value "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: All incidences of "streetAddress" have been redacted in the preceding JSON structure.
To redact a specific occurrence of the "streetAddress" element, the XPath expression would be: `//*[@name='secondaryAddress']/*[@name='streetAddress']`

where the components of the expression have the following meaning:

Expression	Meaning
`//*`	find any element anywhere in the structure
`//*[@name='secondaryAddress']`	find an element anywhere in the structure that is named "secondaryAddress"
`//*[@name='secondaryAddress']/*[@name='streetAddress']`	find a child element of any type (`/*`) where the child element has a name of "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: Only the street address for the secondary address has been redacted.

What to do next

See Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly to learn how to apply a redact policy using XPath.

Set Variable

Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see set-variable.

- **Configuring the Set Variable policy for DataPower API Gateway**
  Follow these steps to configure the Set Variable policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Set Variable policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the Set Variable policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the Set Variable policy for DataPower API Gateway

Follow these steps to configure the Set Variable policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Set Variable policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. For information about how to configure the policy in your OpenAPI source, see set-variable.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.

3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`set-variable`**.	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set , add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: • any • string • number • boolean For all values other than any, the value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when **`Set`** or **`Add`** is specified as the action. For example, to *set* a named variable of **`billing-hostname`** to a literal value, you can specify the Value as **`acme.com`**. As another example, to *set* a named variable to the value of the Content-Type header in a request, you can specify the Value entry as **`$(request.headers.content-type)`**. If the selected value of the Type field is boolean, select the Value check box to indicated a value of **`true`**. Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - set-variable:
      version: 2.0.0
      title: set-variable
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For examples, see set-variable.

DataPower Gateway (v5 compatible) only

Configuring the Set Variable policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Set Variable policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Set Variable policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see set-variable.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.

5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`set-variable`**.	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set , add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: • string • number • boolean The value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when **`Set`** or **`Add`** is specified as the action. For example, to *set* a named variable of **`billing-hostname`** to a literal value, you can specify the Value as **`acme.com`**. As another example, to *set* a named variable to the value of the Content-Type header in a request, you can specify the Value entry as **`$(request.headers.content-type)`**. If the selected value of the Type field is boolean, select the Value check box to indicated a value of **`true`**. Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - set-variable:
      version: 1.0.0
      title: set-variable
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For examples, see set-variable.

API Gateway only

Token Mediation

The Token Mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.

Table 1. Gateway support

Gateway	Policy version
DataPower® API Gateway	2.0.0

Note: The Token Mediation policy will only work for the DataPower API Gateway. The DataPower firmware version that the API Gateway is running on must be **LTS 10.6.0.0 (or later) or CD firmware release 10.6.3 (or later).**
This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see token-mediation.

Prerequisites

Before using the Token Mediation policy, ensure that distributed variable settings are enabled. Distributed variables allow you to read from or write to DataPower® facilities across transactions or domains. They serve as an alternative to system variables and must be enabled for the registration process to function end-to-end (E2E). For more details, see Configuring settings to manage distributed variables.

About

The Token Mediation policy (token-mediation_2.0.0) serves as a mediator for OAuth tokens by caching the token received from an OAuth Token Endpoint and exchanging it for a session cookie, which is sent to the Client Application via a **`Set-Cookie`** header. Depending on the policy configuration, this session token can be used to (A)

retrieve the original token from the cache or (B) instruct the policy to set the HTTP Authorization header for seamless access to resources on the Resource Server.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Token Mediation policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy.	string
Description	No	A description of the policy.	string
Cookie Name	Yes	The name of session cookie returned to the client application.	string
Token Endpoint URL	Yes	The URL of the OAuth provider's Token Endpoint.	string
Token Endpoint TLS Profile	No	The TLS profile used for connecting to the Token Endpoint URL. Note: The Token Endpoint TLS Profile property is optional for this policy but may be required by the Token Endpoint, and it is the responsibility of the policy user to determine its necessity. The policy must match the exact DataPower object name. For TLS profiles created by API Connect, the DataPower object follows this naming convention: `<provider-org>_<catalog>_<tls-profile-name>V<tls-profile-version>`. **Example:** `myorg_mycatalog_my-tls-profile1.0.0`.	string
Authorization Endpoint URL	Yes	The URL of the OAuth provider's Authorization Endpoint.	string
Output	No	The output context that receives the Authorization header. Note: The **`output`** parameter plays a key role in policy behavior. When specified, the policy retrieves the Access Token Response from the cache, extracts the access token (if available), and sets the Authorization header in the designated output message context. If the **`output`** parameter is not specified, the policy writes the Access Token Response to the **`message`** context and sets the **`Content-Type`** header to **`application/json`**.	string

User Security

Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see user-security.

About

When you define an assembly user security action, you can define the processing for identity-extraction, authentication, and authorization or you can selectively disable any of these this aspects of processing. When disabled, this processing aspect is skipped.

When identity-extraction is enabled, the following methods are supported.

- Use basic authentication, which requires no additional configuration.
- Use context variables. For this method, specify which variable contains the user name and password.
- Use a redirect. For this method, specify the URL fragment to redirect to, and the time allowed to process.
- Use an HTML login form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

When authentication is enabled, the following methods are supported.

- Contact an LDAP server. For this method, specify which server to contact.
- Send a request to an authentication endpoint. For this method, specify the URL of the endpoint, the TLS client profile to secure the connection, the pattern to select which response header to add, and the response header that contains the authenticated credentials.

When authorization is enabled, the following methods are supported.

- Implicitly accept any previously authenticated users, which requires no additional configuration.
- Use an HTML authorization form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

You can attach this policy to the REST API flow.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. User Security policy properties

Property label	Required	Description	Data type

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`user-security`**.	string
Description	No	A description of the policy.	string
Factor ID	No	The identity that identifies the results of factor-authentication in the API context.	string
Extract Identity Settings	Yes	Select the method that is used to extract the user credentials. The following options are available: Basic Use basic authentication; no additional configuration is required. Context Variable The credentials are provided by API Connect context variables; specify the following properties: • Username content variable: the context variable that is used to obtain the user name. • password context variable: the context variable that is used to obtain the password. HTML Form Use forms based identity-extraction. Select whether to use the default form or a custom form. For a custom form, specify the following properties: • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. In the HTML form time limit field, specify the time allowed to submit the form. Redirect Use a redirect for identity-extraction; specify the following properties: • Redirect URL: the URL fragment to which to redirect the request to obtain user credentials. • Redirect time limit: the time allowed for the transaction to complete. Disabled Identity-extraction is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of identity-extraction failure.	string
Authenticate User Settings	Yes	Select the authentication method. The following options are available: Authentication URL The credentials are authenticated by an external endpoint; specify the following properties: • Authentication URL: the URL of the authentication endpoint. • Authentication TLS profile: the TLS client profile that is used to secure the connection to the authentication endpoint. • Authentication response header pattern: the pattern that is used to select which response headers to add to the API context. • Authentication response header credential: the response header that contains the authenticated user credentials. LDAP The credentials are authenticated by an LDAP user registry; from the LDAP registry list, select the required registry. Disabled Authentication is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of authentication failure.	string
Authorize User Settings	Yes	Select the authorization method. The following options are available: authenticated Implicitly accept any previously authenticated users; no additional configuration is required. HTML Form The user provides authorization through an HTML form. Select whether to use the default form or a custom form. For a custom form, specify the following properties: • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. In the Dynamic table entries field, enter the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form. In the HTML form time limit field, specify the time allowed to submit the form. Disabled Authorization is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of authorization failure.	string

API Gateway

Validate - DataPower API Gateway

Use the Validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the Validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Validate - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.4.0 (DataPower API Gateway Version 10.0.4.0 or later) 2.5.0 (DataPower API Gateway Version 10.5.0.0 or later) 2.6.0 (DataPower API Gateway Version 10.5.0.2 or later 2.7.0 (DataPower API Gateway Version 10.5.0.3 or later

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate - DataPower API Gateway.

About

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

Note: With the DataPower API Gateway, the input to the Validate policy must be parsed data. One way to produce parsed data is to use a Parse policy before a Validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **validate**.	string
Description	No	A description of the policy.	string
Input	No	Specifies the name of a variable in the API context. The content of the **body** field of the variable, which is represented by ***variable_name*.body**, is the input data to validate. By default, the variable name is **message**.	string
Output	No	Specifies the name of a variable in the API context. • If the validation passes, the body field of the output variable, which is represented by ***variable_name*.body**, stores the output of the assembly validate action. • If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. • If the validation fails, no output is stored. • If an output variable is not specified, the results of the assembly validate action are not saved.	string

Property label	Required	Description	Data type
Validate against	Yes	Specifies the schema to be used for validating the payload. Select one of the following values: • **`definition`**: Select this value if you want to use a previously defined schema to validate the payload that is returned from other invoke actions or tasks in the assembly flow. From the Definition Object list, select the required schema. For information on defining a schema for an OpenAPI 2.0 API definition, see Defining schema definitions for an API. For information on defining a schema for an OpenAPI 3.0 API definition, see Defining schema components. • **`URL`**: the schema is identified by a URL location. ◦ In the JSON Schema URL field, enter the URL of the JSON schema to be used for validating a JSON payload. ◦ From the XML Validation Mode list, select how XML validation is to be performed: ▪ **`None`**: no XML payload validation is required. ▪ **`xsd`**: an XML schema will be used to validate an XML payload. In the XML Schema URL field, enter the URL of the XML schema. ▪ **`wsdl`**: a WSDL schema will be used to validate a SOAP payload. In the WSDL URL field, enter the URL of the WSDL schema. ▪ **`soap-body`**: validate the body of a SOAP message against the XML schema only. Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported. ▪ Maximum of 6,500 lines. Each key and each item in an array count as a line. ▪ Maximum recursion depth of 250. ▪ Maximum of 3,000 items in **`enum`** lists. • **`WSDL`**: (available with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. • **`body-param`**: validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Defining parameters for an operation. • **`response-param`**: validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Defining responses for an operation. • **`GraphQL`**: (available for a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables.	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property label	Required	Description	Data type
Validate message body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow xsi:type='SOAP-ENC:Array' rule	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
Wildcards ignore xsi:type rule	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

For examples, see validate - DataPower API Gateway.

DataPower Gateway (v5 compatible)

Validate - DataPower Gateway (v5 compatible)

Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.

Gateway support

Note: This topic describes the Validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Validate - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate - DataPower Gateway (v5 compatible).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the **`message.body`** variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then **`message.body`** is not set, and validate is not able to act.
- If you use the **`multipleOf`** keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
  - The value must not be less than **`0.00000099999999999999848869`**.
  - If the value is greater than 1, the amount before the decimal point must not be greater than **`99999999999999934463`**.

About

You can attach this policy to the following API flow:

- REST

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

You can apply a different OpenAPI schema definition to each Validate policy either by choosing from the set of schema definitions that is specified at the API level, or the schema definition at the operation level.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`validate`**.	string
Description	No	A description of the policy.	string
Definition	Yes	Specifies the schema definition to be used for validating the payload. Valid values: • **`request`**: Select this value to validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. • **`response`**: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. • **`#/definitions/`*`definition_name`***: Select this value for a previously defined schema definition to be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. For information on defining a schema for an API definition, see Editing an API definition.	string

Validate JWT

Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see jwt-validate.

About

JSON Web Token (JWT) is a compact, URL-safe way of representing claims that are to be transferred between two parties. The Validate JWT policy enables you to secure access to your APIs by using JWT validation. For example, when an input request that contains a JWT in the header is received, the Validate JWT policy extracts the token, verifies, and decrypts (if appropriate) the signature, and validates the claim. If valid, the claim is put in a runtime variable (for subsequent use if required), and access is allowed to the API. If the claim is not valid, access is denied.

All claims that are specified in the Validate JWT policy are validated, but this is not necessarily all the claims that are contained in the JWT. Not all claims that are in the JWT must be validated, but if any one of the claims that are specified in the Validate JWT policy fail, the whole validation fails. If the validation succeeds, the full set of claims that are contained in the JWT are written to the runtime variable specified in the Output Claims property. Thereby allowing any subsequent action to use this runtime variable to further validate the full set of claims that were in the JWT, as necessary.

Note:

- If the original message was signed with a Shared Secret Key, the cryptographic object that is specified must also be a Shared Secret Key.
- If the original message was signed with a Private Key, the cryptographic object that is specified must be a Crypto Certificate (public certificate).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If a JWK header parameter is included in the header of the JWT, the parameter must match the JWK or cryptographic object that is specified in the policy, or the JWT validation will fail.
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to decrypt or verify the JWT.
- The JWT validate action on the DataPower API Gateway can verify a JWT by using either a single JWK, or a JWK set.

Prerequisites

The following prerequisites apply:

- IBM® DataPower V7.5 with the Application Optimization (AO) option.
- If you are using one or more cryptographic objects (crypto objects), they must be located in the IBM API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or public certificate that is needed to decrypt the JWT contents or verify the signature.
- If a JSON Web Key (JWK), or JWK set, is being used, it must be referenced by a runtime variable.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate JWT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`jwt-validate`**.	string
Description	No	A description of the policy.	string
JSON Web Token (JWT)	Yes	Context or runtime variable that contains the JWT to be validated. The default value is: **`request.headers.authorization`**. However, if this property is not set, the policy looks for the JWT in the **`request.headers.authorization`** location by default. Note: The format of the authorization header must be: **`"Authorization: Bearer jwt-token"`** where *jwt-token* is the encoded JWT.	string
Output Claims	Yes	Runtime variable to which the full set of claims that are contained in the JWT is assigned. The default value is: **`decoded.claims`**.	string
Issuer Claim	No	The Perl Compatible Regular Expressions (PCRE) to use to validate the Issuer (iss) claim.	string
Audience Claim	No	The PCRE to use to validate the Audience (aud) claim.	string
Decrypt Crypto Object	No	The cryptographic object (a shared key or certificate) to use to decode the claim.[1]	string
Decrypt Crypto JWK variable name	No	Runtime variable that contains the JWK to use to decrypt the JWT.[1]	string

Property label	Required	Description	Data type
Verify Crypto Object	No	The cryptographic object (a shared key or certificate) to use to verify the signature.[2]	string
Verify Crypto JWK variable name	No	Runtime variable that contains the JWK, or JWK set, to use to verify the signature.[2]	string

Example

```
- jwt-validate:
    version: 1.0.0
    title: jwt-validate
    jwt: request.headers.authorization
    output-claims: decoded.claims
    iss-claim: "'^data.*'"
    aud-claim: "'^id.*'"
    jwe-crypto: jweCryptoObjectName
    jwe-jwk: jwe.jwk
    jws-crypto: jwsCryptoObjectName
    jws-jwk: jws.jwk
```

Errors

The following error can be thrown while the policy is being executed:

- **`RuntimeError`** - a generic error that captures all errors that occur during the execution of the policy. Upon a validation failure, the detailed error message that is received from the underlying JOSE module is written to the default system log as an error message. This detailed error message is also assigned to the runtime variable jwt-validate.error-message, so it can be retrieved via catch.

If a catch is not configured, in the case of a validation failure the Validate JWT policy returns an HTTP code 500 **`Invalid-JWT-Validate`** failure. The detailed error message from the underlying JOSE module can be found in the system log.
Attention: If you are an API developer who is troubleshooting a failure that one of your customers had with your API, consider the security risks before sending a customer the exact content of the log message. You can avoid the possibility of someone launching an attack based on the information that they receive from the log message by sending the customer only general information about the message.
For examples, see jwt-validate.

Related information

- Introduction to JSON Web Tokens

[1] A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used. If you are using one or more cryptographic objects (crypto objects), they must be located in the IBM API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or public certificate that is needed to decrypt the JWT contents or verify the signature.
[2] A JWK, or JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.

Validate Username Token

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate-usernametoken.

About

A WS-Security UsernameToken enables a user identity to be passed securely over a multi-point message path. The Validate Username Token policy extracts the UsernameToken element from the request payload, authenticates the extracted username and password, and provides access to the protected resource based on the authentication result. The policy has two authentication methods: Lightweight Directory Access Protocol (LDAP) user registry, or Authentication URL.

The Validate Username Token policy supports both passwordText and passwordDigest types of password. When the authentication method is Authentication URL with a passwordDigest, a basic authentication header that contains a Base64 encoded username and passwordDigest is sent to the URL. In addition, a custom header named X-IBM-PasswordType is set with a value of digest. The following table shows the authentication process based on password type:

Table 2. Authentication URL process by password type

passwordText	passwordDigest
Authentication: Basic base64(username:password)	Authentication: Basic base64(username:passwordDigest) X-IBM-PasswordType: 'digest'

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate Username Token policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate Username Token policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate Username Token policy after the task that collates the response.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 3. Validate Username Token policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **validate-usernametoken**.	string
Description	No	A description of the policy.	string
Authentication type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: • **Authentication URL**: Select this value to validate the user credentials against an authentication URL. • **LDAP registry**: Select this value to validate the user credentials against an LDAP user registry. The default value is: **Authentication URL**.	string
Authentication URL (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to **Authentication URL**.	string
TLS profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to **Authentication URL**.	string
LDAP registry name (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. You can select a name from the drop-down list, or type a name manually. Note: This property is required only if Authentication type is set to **LDAP registry**.	string
User Registry Name (policy version 1.1.0 and later)	Yes	Select the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
LDAP search attribute[1]	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "LDAP Registry"
    ldap-registry: "wstest"
    ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "Authentication URL"
    auth-url: "https://www.google.com"
    tls-profile: "default-ssl-profile"
```

Errors

The policy returns an HTTP `200` status code when successful, and the input payload is copied to the output flow. For all failure types the policy returns an HTTP `500` status code, and the output contains the SOAP fault.

Tip: If there are authentication failures, try verifying the LDAP user registry configuration as follows:

- Ensure Search (DN) is set as the communication method.
- Ensure Authenticated Bind is set so that specific permissions are required to search the registry.
- Ensure the Admin DN and Password fields are correctly completed for the Distinguished Name (DN) of a user authorized to carry out searches in the LDAP directory.
- Ensure that a combination of Base DN, Prefix, and Suffix are set, such that they fully describe the user DN. For example:
  - For a user named: **cn=alice**, **dc=ibm**, **dc=com**

    ```
    BaseDN: dc=ibm
    Prefix: cn=alice
    Suffix: dc=com
    ```

    where the user DN is calculated as: Prefix + BaseDN + Suffix.

Related information

- Creating an LDAP registry
- Authenticating by using your enterprise user registry

[1] When authenticating with LDAP and passwordText, the policy uses the username and password as LDAP bind credentials. However, when authenticating with LDAP and passwordDigest, the digest itself cannot be used for authentication. Instead, an LDAP search for the username is performed by using the administrator's distinguished name (DN) and password, and an attribute corresponding to the contents of the ldap-search-attribute is retrieved. A hash of the contents of this attribute (along with the Nonce and Created attributes, as in the WS-Security UsernameToken profile specification) is then compared to the passwordDigest.

API Gateway only

watsonx.ai invoke

Use the watsonx.ai invoke policy to invoke watsonx.ai operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see watsonx-ai-invoke.

About

The watsonx.ai invoke policy provides access to three watsonx.ai operations:

- **`POST /text-generate`**
- **`POST /tokenize`**
- **`GET /deployment-models`**

The watsonx.ai invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. watsonx.ai invoke policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy; the default value is **`watsonx-ai-invoke text generation`**.	string
Description	No	A description of the policy.	string
watsonx.ai Operation	Yes	The watsonx.ai operation to invoke; must be one of the following operations: • **`POST text-generate`** An HTTP POST operation for **`/text-generate`**. See Infer text in the watsonx.ai documentation for sample request and response examples. • **`POST tokenize`** An HTTP POST operation for **`/tokenize`**. See Text tokenization in the watsonx.ai documentation for sample request and response examples. • **`GET deployment-models`** An HTTP GET operation for **`/deployment-models`**. See List the available foundation models in the watsonx.ai documentation for sample response examples. If the request payload contains a **`project_id`** property, it is ignored and the policy's own **`project_id`** property is used.	string
watsonx.ai Operation Version	Yes	The watsonx.ai API operation version, using the format **`yyyy-mm-dd`**. To see the available version dates, refer to Active Version Dates in the watsonx.ai API documentation. For information on API versioning in watsonx.ai, see Versioning in the same documentation.	string
watsonx.ai Project Id	Yes	The ID of the watsonx.ai project used for resolving API requests.	string
watsonx.ai Region	Yes	The IBM Cloud region where watsonx.ai requests are sent.	string

Property label	Required	Description	Data type
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the watsonx.ai service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the watsonx.ai service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the watsonx.ai response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Websocket Upgrade

Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

- **Configuring the Websocket Upgrade policy for DataPower API Gateway**
  Follow these steps to configure the Websocket Upgrade policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the Websocket Upgrade policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the Websocket Upgrade policy for DataPower API Gateway

Follow these steps to configure the Websocket Upgrade policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types.
For information about how to configure the policy in your OpenAPI source, see websocket-upgrade.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`websocket-upgrade`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **`60`**.	integer

Property label	Required	Description	Data type
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this check box, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this check box, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the **`invoke`** policy injects the **`X-Forwarded-For`**, **`X-Forwarded-To`**, **`X-Forwarded-Host`**, and **`X-Forwarded-Proto`** headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
Queryparam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean
Header control	No	Specifies the headers in **`message.headers`** that you want to copy to the target URL. To prevent headers from being copied, complete the following steps: a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. To specify headers that you want to be copied, complete the following steps: a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. The values that you specify are in regular expression format. For example, to specify the Content-Type header, enter **`^Content-Type$`** By default, Blocklist is selected, with no blocklist entries, meaning that **all** headers are copied.	string
Parameter control	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. To prevent parameters from being copied, complete the following steps: a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. To specify parameters that you want to be copied, complete the following steps: a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. The values that you specify are in regular expression format. For example, if the incoming request is **`http://apigw/org/sandbox/petstore/base?petid=100&display=detailed`** and you specify a white list entry of **`^petid$`**, the target URL at run time will be **`http://myhost/mypath?storeid=3&petid=100`** By default, Allowlist is selected, with no allowlist entries, meaning that **no** parameters are copied.	string
Request assembly	No	The request processing assembly. For details on configuring an assembly in the **`execute`** section, see execute. For example: **`request-assembly:`** **`  execute`** `.` `.` `.` ***`  policy assembly`*** `.` `.` `.`	object
Response assembly	No	The response processing assembly. For details on configuring an assembly in the **`execute`** section, see execute. For example: **`response-assembly:`** **`  execute`** `.` `.` `.` ***`  policy assembly`*** `.` `.` `.`	object

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - websocket-upgrade:
      version: 2.0.0
      title: websocket-upgrade
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Websocket Upgrade policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Websocket Upgrade policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types. For details on how to configure the policy in your OpenAPI source, see websocket-upgrade.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`websocket-upgrade`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **`60`**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this check box, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this check box, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the **`invoke`** policy injects the **`X-Forwarded-For`**, **`X-Forwarded-To`**, **`X-Forwarded-Host`**, and **`X-Forwarded-Proto`** headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
Queryparam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean

Request assembly	No	The request processing assembly. For details on configuring an assembly in the **`execute`** section, see execute. For example:
		`request-assembly:`
		`  execute`
		`  .`
		`  .`
		`  .`
		`  policy assembly`
		`  .`
		`  .`
		`  .`
			object

Property label	Required	Description	Data type

Response assembly	No	The response processing assembly. For details on configuring an assembly in the **execute** section, see execute. For example:
		`response-assembly:`
		`  execute`
		`  .`
		`  .`
		`  .`
		`  policy assembly`
		`  .`
		`  .`
		`  .`
			object

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - websocket-upgrade:
      version: 1.0.0
      title: websocket-upgrade
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

XML to JSON

Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

The XML to JSON policy uses a simple convention, based on BadgerFish, to convert your API context payload from XML to JSON. The XML content is preserved, including the attributes and namespaces. No additional configuration is required. For more information about the BadgerFish convention, including some examples, see BadgerFish.

Use the API Designer assembly view when you are creating your API definition to add a built-in policy to the flow.

The policy must be attached to the flow at the point at which you require the conversion to be performed. For example, if you need to convert an XML-formatted request into a JSON-formatted request, the policy must be attached to the request flow.

The policy reads input from the **message.body**, if that context exists, otherwise from the **request.body**, and then writes the output to the **message.body**.

Note: If you are using the DataPower API Gateway, the input to the XML to JSON policy must be parsed data. One way to produce parsed data is to use a Parse policy before an XML to JSON policy in your assembly flow, which provides explicit control of the parse action.

Examples

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For examples, see xml-to-json.

- **Configuring the XML to JSON policy for DataPower API Gateway**
  Follow these steps to configure the XML to JSON policy for DataPower API Gateway in the assembly user interface.
- **Configuring the XML to JSON policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the XML to JSON policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the XML to JSON policy for DataPower API Gateway

Follow these steps to configure the XML to JSON policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Set Variable policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xml-to-json.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`xml-to-json`**.	string
Description	No	A description of the policy.	string
Input	No	The input message to convert. Specify the name of a variable in the API context. ***`variableName`*`.body`**, the message payload, represents the XML input to convert. The default value of the variable is **`message`** and **`message.body`** is the default input.	string
Output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***`variableName`*`.body`** represents the result of conversion from XML format to JSON format. When the specified input message is the default message, the default output is **`message.body`**. Otherwise, when the input message is the variable **`my-message-variable`**, for example, the default output is **`my-message-variable.body`**. The variable cannot be any read-only in the API context.	string
Conversion type	No	The conversion type that determines the target format of the output. The following options are available: • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. • apicv5: apicv5 convention is used to determine the target conversion format of the output.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - xml-to-json:
      version: 2.0.0
      title: xml-to-json
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For more examples, see xml-to-json.

DataPower Gateway (v5 compatible) only

Configuring the XML to JSON policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XML to JSON policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the XML to JSON policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xml-to-json.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

   Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`xml-to-json`**.	string
Description	No	A description of the policy.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - xml-to-json:
      version: 1.0.0
      title: xml-to-json
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

For examples, see xml-to-json.

XSLT

Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xslt.

Note: If you are using the DataPower API Gateway, the input to the XSLT policy must be parsed data. One way to produce parsed data is to use a Parse policy before an XSLT policy in your assembly flow, which provides explicit control of the parse action.
For examples of the OpenAPI definitions of XSLT policies, see XSLT policy examples.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Errors

The following error can be thrown while the policy is being executed:

- **`TransformError`** - a generic error that captures all errors that occur during the execution of the policy.

- **Configuring the XSLT policy for DataPower API Gateway**
  Follow these steps to configure the XSLT policy for DataPower API Gateway in the assembly user interface.
- **Configuring the XSLT policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the XSLT policy for DataPower Gateway (v5 compatible) in the assembly user interface.
- **XSLT policy examples**
  Examples of the OpenAPI definitions of XSLT policies.
- **Implementation code examples**
  Example XSLT and GatewayScript code snippets.

API Gateway only

Configuring the XSLT policy for DataPower API Gateway

Follow these steps to configure the XSLT policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the XSLT policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types.
For information about how to configure the policy in your OpenAPI source, see xslt.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XSLT policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`xslt`**.	string
Description	No	A description of the policy.	string
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Serialize output	No	If you select this option, the output tree that is generated by the XSLT policy is serialized. The content of **`message.body`** is updated with the serialized binary data rather than the XML tree. The check box is cleared by default, which indicates that the output tree is not serialized.	boolean
Source	Yes	The XSLT transform source to execute.	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property label	Required	Description	Data type
Validate message body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow xsi:type='SOAP-ENC:Array' rule	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
Wildcards ignore xsi:type rule	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - xslt:
      version: 2.1.0
```

```
      title: xslt
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

DataPower Gateway (v5 compatible) only

Configuring the XSLT policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XSLT policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the XSLT policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see xslt.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XSLT policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **xslt**.	string
Description	No	A description of the policy.	string
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Source	Yes	The XSLT transform source to execute.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - xslt:
      version: 1.0.0
      title: xslt
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

XSLT policy examples

Examples of the OpenAPI definitions of XSLT policies.

- Simple example with no context current payload
- Concatenation and transformation
- Obtain query parameter values and refer to context variables
- Return DataPower object name associated with a client TLS profile

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing an XSLT policy or user-defined policy for a new API Gateway API, use the mechanisms described in Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The XML specification https://www.w3.org/TR/xml/ does not specify a preferred order for XML namespace (XMLNS) attributes. Best practice is to not rely upon the sequence of XMLNS attributes if you write custom parsing code.

Simple example with no context current payload

The following is an example of where the XSLT input document does not use the context current payload (there is no input):

```
- xslt:
  title: example xslt
  source: |
    <xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
```

```
    <xsl:template match="/">
      <Hello>World!</Hello>
    </xsl:template>
  </xsl:stylesheet>
```

Concatenation and transformation

The following example shows a more complex XSLT transform source, where the stylesheet concatenates two input strings and transforms the third input string to the IP address of the client:

```
- xslt:
  title: xslt
  input: true
  source: |
    <?xml version="1.0" encoding="UTF-8"?>
    <xsl:stylesheet
        xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
        xmlns:xalan="http://xml.apache.org/xslt"
        xmlns:fn="http://www.w3.org/2005/xpath-functions"
        xmlns:dp="http://www.datapower.com/extensions"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xmlns:xs4xs="http://www.w3.org/2001/XMLSchema"
        xmlns:io="http://xformMessage"
        xmlns:map="http://xformMessage/xform"
        xmlns:msl="http://www.ibm.com/xmlmap"
        exclude-result-prefixes="fn dp dp map xalan msl"
        version="1.0">
      <xsl:output method="xml" encoding="UTF-8" indent="no"/>

      <!-- root wrapper template  -->
      <xsl:template match="/">
        <msl:datamap>
          <xsl:choose>
            <xsl:when test="not(msl:datamap/dataObject[1]/@xsi:nil)">
              <xsl:element name="dataObject">
                <xsl:attribute name="xsi:type">
                  <xsl:value-of select="'io:data'"/>
                </xsl:attribute>
                <xsl:call-template name="map:xform">
                  <xsl:with-param name="data" select="msl:datamap/dataObject[1]"/>
                </xsl:call-template>
              </xsl:element>
            </xsl:when>
            <xsl:otherwise>
              <xsl:element name="dataObject">
                <xsl:attribute name="xsi:type">
                  <xsl:value-of select="'io:data'"/>
                </xsl:attribute>
                <xsl:attribute name="xsi:nil">
                  <xsl:text>true</xsl:text>
                </xsl:attribute>
              </xsl:element>
            </xsl:otherwise>
          </xsl:choose>
        </msl:datamap>
      </xsl:template>

      <!-- This rule represents a type mapping: "data" to "io:data".  -->
      <xsl:template name="map:xform">
        <xsl:param name="data"/>
        <!-- a simple data mapping: "$data/StringOne"(string) to "StringOne"(string) -->
        <xsl:if test="$data/StringOne">
          <StringOne>
            <xsl:value-of select="concat($data/StringOne, $data/StringTwo)"/>
          </StringOne>
        </xsl:if>
        <!-- a simple mapping with no associated source:  to "StringTwo"(string) -->
        <StringTwo>
          <xsl:value-of select="dp:client-ip-addr()"/>
        </StringTwo>
        <!-- a simple data mapping: "$data/NumberOne"(int) to "NumberOne"(int) -->
        <xsl:if test="$data/NumberOne">
          <NumberOne>
            <xsl:value-of select="$data/NumberOne"/>
          </NumberOne>
        </xsl:if>
        <!-- a simple data mapping: "$data/NumberTwo"(int) to "NumberTwo"(int) -->
        <xsl:if test="$data/NumberTwo">
          <NumberTwo>
            <xsl:value-of select="$data/NumberTwo"/>
          </NumberTwo>
        </xsl:if>
        <!-- a simple data mapping: "$data/NumberThree"(int) to "NumberThree"(int) -->
        <xsl:if test="$data/NumberThree">
          <NumberThree>
            <xsl:value-of select="$data/NumberThree"/>
          </NumberThree>
        </xsl:if>
      </xsl:template>

      <!-- *****************    Utility Templates    *****************  -->
      <!-- copy the namespace declarations from the source to the target -->
      <xsl:template name="copyNamespaceDeclarations">
        <xsl:param name="root"/>
```

```
      <xsl:for-each select="$root/namespace::*[not(name() = '')]">
        <xsl:copy/>
      </xsl:for-each>
    </xsl:template>
  </xsl:stylesheet>
```

Obtain query parameter values and refer to context variables

The following example shows a complete OpenAPI source file. The API includes an XSLT policy that obtains a query parameter value in XSLT, and also uses the **getvariable** method to retrieve the value of the context variable **request.headers.user-agent**.

```

Return DataPower object name associated with a client TLS profile

The following example uses the `apim:getTLSProfileObjName` function to return the DataPower object name associated with a specified client TLS profile.

```
- xslt:
  title: xslt
  input: false
  version: 2.0.0
  source: >-
    <?xml version="1.0" encoding="UTF-8"?>
    <xsl:stylesheet
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
      xmlns:dp="http://www.datapower.com/extensions"
      xmlns:apim="http://www.ibm.com/apimanagement"
      exclude-result-prefixes="dp apim"
      extension-element-prefixes="dp"
      version="1.0">

      <!-- For apigw ... store:///dp/apim.custom.xsl -->
      <!-- For v5/v5c ... local:///isp/policy/apim.custom.xsl -->
      <!-- <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"/
> -->
      <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl"/>

      <xsl:template match="/">
        <xsl:variable name="httpHeaders">
          <header name="Accept">application/xml</header>
        </xsl:variable>
        <!--
          For v5, the name returned is client:<orgname>-my-test
          For v5c, the name returned is client:<orgname>-my-testV1.0.0
          For API Gateway, the name returned is client:<orgname>_<catalogname>_tlsp-my-testV1.0.0
        -->
        <xsl:variable name="tlsClientProfile" select="apim:getTLSProfileObjName('my-test')" />
        <xsl:variable name="targetUrl" select="'https://127.0.0.1:6201/PingRequest'"/>
        <dp:url-open target="{$targetUrl}" response="responsecode" timeout="20" http-headers="$httpHeaders" ssl-proxy="
{$tlsClientProfile}"/>
      </xsl:template>

    </xsl:stylesheet>
```

Note that references to the "v5c" (v5-compatible) gateway do not apply to API Connect Enterprise as a Service.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower® API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Implementation code examples

Example XSLT and GatewayScript code snippets.

Note: If you are using GatewayScript, you must include one or other of the following commands depending on your gateway type:

DataPower Gateway (v5 compatible) `var apic = require(./apim.custom.js);`

API Gateway `var apic = require('apim');`

where *apic* is the common name used for the GatewayScript examples in this topic. However, *apic* could be any given name of your choice, for example you could use:

```
var apim = require(./apim.custom.js);
```

and then you would start your calls with `apim`.

- Access to input properties code snippet

- Access to runtime context code snippet
- Access to input payload code snippet
- Access to HTTP headers code snippet
- Modify the payload code snippet
- Configure error information code snippet
- Accessing the caught exception in a catch block
- Set variables code snippet

Access to input properties code snippet

The following code block shows an example of how to access the input properties by using the XSLT **policyProperties()** function. The example defines a property that is named **a_property**, which is declared as an integer value, but is retrieved in XSLT as text.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:apigw="http://www.ibm.com/xmlns/datapower/2017/11/apigateway"
  exclude-result-prefixes="dp func apim apigw"
  extension-element-prefixes="dp func apim apigw">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="p" select="apim:policyProperties()" />
    <xsl:message>
      The value of my input property is
      <xsl:value-of select="$p/a_property" />
      <apigw:set-variable name="'propfound'" value="'true'"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getPolicyProperty(propertyName)
```

where ***propertyName*** is the name of the input property that you want to access. If the input property name is blank, the action will return all input properties.

Access to runtime context code snippet

The following code block shows an example of how to access the runtime context by using the XSLT **getContext()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="client-id" select="apim:getContext('client.app.id')" />
    <xsl:message>
      The calling application is
      <xsl:value-of select="$client-id" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getContext(varName)
```

where ***varName*** is the name of the context variable that you want to access.
For a complete list of context variables, see API Gateway context variables. If you are using the DataPower® API Gateway, see also Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Access to input payload code snippet

The following code block shows an example of how to access the input payload by using the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="input" select="apim:payloadRead()" />
    <xsl:message>
      The input payload is
      <xsl:copy-of select="$input" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.readInput(callback)
```

A callback is required because the actual payload read is asynchronous. The callback method is called when the payload is ready.
This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.
The following example shows how to use the **payloadType()** function to determine what type of payload (XML or JSONx) will be returned by the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="payloadType" select="apim:payloadType()" />
    <xsl:message>
      <xsl:text>Payload type is [</xsl:text>
      <xsl:value-of select="$payloadType" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

Access to HTTP headers code snippet

The following code block shows an example of how to access the HTTP headers in XSLT by using the **getContext()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
```

```
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="content-type" select="apim:getContext('request.headers.content-type')" />
    <xsl:message>
      The request content type is
      <xsl:value-of select="$content-type" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getContext(request.headers.headerName)
```

where ***headerName*** maps to the name of the header you want to access.
Note: Access or modification of HTTP headers by using DataPower extensions, such as `dp:set-request-header`, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.

Modify the payload code snippet

The output from a user-defined policy must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. The following code block shows an example of how to modify the payload in XSLT. To assist the API Gateway policy framework to accept the new or transformed message, call the `apim-output` template, as shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:jsonx="http://www.ibm.com/xmlns/prod/2009/jsonx"
  exclude-result-prefixes="apim"
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
```

DataPower Gateway (v5 compatible)

```
<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
```

API Gateway

```
<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <!-- Creates a JSON document (empty object is for simplicity) -->
    <jsonx:object>
    </jsonx:object>

    <!-- Indicates the media type of the output being produced -->

    <xsl:call-template name="apim:output">
      <xsl:with-param name="mediaType" select="'application/json'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where `mediaType`:

- `'application/json'` is when the output is written in JSONx format.
- `'application/xml'` is when the output is written in XML format.

If you are using GatewayScript, call the following function:

```
apic.output(mediaType)
```

where ***mediaType*** is:

- `application/json` is when the output is written in JSONx format.
- `application/xml` is when the output is written in XML format.

Specifying the media type allows the next steps in the assembly flow to understand how to process the new payload.

Tip: The output from a user-defined policy must be XML or JSONx. JSONx is an IBM standard format to represent JSON as XML. One way to convert output GatewayScript JSON data into JSONx, is to add a `Convert Query Params to XML` action to follow the GatewayScript action within the same policy rule. The `Convert Query Params to XML` action must have an `Input Conversion` with the `Default Encoding` set to `JSON`. The output from the GatewayScript action must be the input for the `Convert Query Params to XML` action for JSONx to be produced.

Configure error information code snippet

The following XSLT code block shows an example of how to configure the policy implementation to produce error information by calling the `apim-error` template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="apim"
```

```
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
    <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
    <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <!-- Indicates this policy has a failure and provides
       additional information for the client application -->
  <xsl:template match="/">
    <xsl:call-template name="apim:error">
      <xsl:with-param name="httpCode" select="'401'" />
      <xsl:with-param name="httpReasonPhrase" select="'Unauthorized'" />
      <xsl:with-param name="errorMessage" select="'Please select a Plan'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

DataPower Gateway (v5 compatible)

API Gateway

where:

- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **errorMessage** is the suggested action for the user.

If you are using GatewayScript, call the following function:

```
apic.error(name, httpCode, httpReasonPhrase, message)
```

where:

- **name** is the name of the error.
- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **message** is the suggested action for the user.

Accessing the caught exception in a catch block

The following XSLT code block shows an example of how, in the **catch** block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

For DataPower Gateway (v5 compatible):

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  extension-element-prefixes="dp"
  exclude-result-prefixes="dp apim">

  <xsl:output method="xml" />

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">

    <xsl:variable name="exception" select="apim:getError()"/>
    <!-- output desired error message based on the exception -->
    <myError>
       <errorReason><xsl:value-of select="$exception/error/message"/></errorReason>
    </myError>

    <!-- Propagate the HTTP status code and reason phrase from the exception -->
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.code'"/>
      <xsl:with-param name="value" select="$exception/error/status/code"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.reason'"/>
      <xsl:with-param name="value" select="$exception/error/status/reason"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    </xsl:template>

</xsl:stylesheet>
```

For API Gateway:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
```

```
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:apigw="http://www.ibm.com/xmlns/datapower/2017/11/apigateway"
  extension-element-prefixes="dp apim apigw"
  exclude-result-prefixes="dp apim apigw">

  <xsl:output method="xml" />

  <!-- Contains the APIM functions -->
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">

    <xsl:variable name="exception" select="apigw:get-error()"/>
    <!-- output desired error message based on the exception -->
    <myError>
       <errorReason><xsl:value-of select="$exception/error/message"/></errorReason>
    </myError>

    <!-- Propagate the HTTP status code and reason phrase from the exception -->
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.code'"/>
      <xsl:with-param name="value" select="$exception/error/status/code"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.reason'"/>
      <xsl:with-param name="value" select="$exception/error/status/reason"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    </xsl:template>

</xsl:stylesheet>
```

The `apim:getError()` and `apigw:get-error()` functions return an XML node set; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<error>
    <name>RuntimeError</name>
    <message>This is a thrown Runtime Error</message>
    <policyTitle>Throw Runtime Error</policyTitle>
    <status>
        <code>500</code>
        <reason>Internal Server Error</reason>
    </status>
</error>
```

If you are using GatewayScript, call the following function:

```
apim.getError()
```

which returns a JSON object; for example:

```
{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}
```

Set variables code snippet

The following XSLT code block shows an example of how to set a runtime variable to a specified string value by calling the `setVariable` template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
    DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
    API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="" select="'https://endpoint.host.com/data'" />
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'serviceEndpoint'" />
```

```
      <xsl:with-param name="value" select="$targetUrl" />
      <xsl:with-param name="action" select="'set'" />
    </xsl:call-template>
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$targetUrl" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$targetUrl}" response="xml" http-method="get"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **varName** is the name of the runtime variable that you want to set a value to.
- **value** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **value** as **$(request.headers.content-type)**.

If you are using GatewayScript, call the following function:

```
apic.setvariable(varName, varValue, action)
```

where:

- **varName** is the name of the runtime variable that you want to set a value to, or that you want to add or clear.
- **varValue** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **varValue** as **request.headers.content-type**. This property is only required when **set** or **add** is specified as the action.
- **action** is the action that you want to apply to the variable. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

The following XSLT example shows how to retrieve the value of a runtime variable by using the **getVariable()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" /> <!--
Use this include for XSLT 2.0.0 only (API Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="varValue" select="apim:getVariable('serviceEndpoint')" />
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$varValue" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$varValue}" response="xml" http-method="get"/>
  </xsl:template>

</xsl:stylesheet>
```

where

- **varValue** is the name of the runtime variable that you want to retrieve a value for.

If you are using GatewayScript, call the following function:

```
apic.getvariable(varName)
```

where ***varName*** is the name of the runtime variable that you want to retrieve a value for.

Logic Constructs

IBM® API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.

Logic constructs are configured in the context of an API. You can use the API Designer assembly editor to add a logic construct to an API and to configure the properties for that construct.

The logic constructs are described in the following subtopics:

- **if**
  Use the if construct to apply a section of the assembly when a condition is fulfilled.
- **operation-switch**
  Use the operation-switch component to apply a section of the assembly to a specific operation.
- **switch**
  Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.
- **throw**
  Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Related concepts

- The assembly editor

if

Use the if construct to apply a section of the assembly when a condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see if.

An if construct provides a way to branch an API's assembly when a specified condition is fulfilled. Each if construct contains a section of the assembly that is only executed when the script within the construct returns a **`true`** value.

When using the assemble view's property sheet, use the Condition field to write your condition that returns **`true`** or **`false`**.

If you want one or more policies or constructs to be executed when the condition of the if construct is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the if construct. Constructs and policies included in the if construct are part of the case that is executed when the condition of the if construct is returned as true.

For information about the OpenAPI implementation of an if construct, see if.

In the Condition field, use the form **`apim.getvariable('`*`context.location.variable`*`')`** to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of an if construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, **`if`** is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
Condition	Yes	Use GatewayScript to provide conditions. A list of context variables that you can use to generate conditions can be found in API Connect context variables.

operation-switch

Use the operation-switch component to apply a section of the assembly to a specific operation.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see operation-switch.

An operation-switch component provides a way to branch an API's assembly depending on the operation that is called. For each case, a separate piece of the assembly is applied to the operations that belong to the case.

When using the assemble view's property sheet, click the Case field to view suggested operations. Type in the Case field to refine the list of suggested operations.

Each case behaves as an assembly. To add components to a case, drag the component from the palette to the area included in the operation-switch component. Dashed boxes are displayed where the component can be included in the case.

For information about the OpenAPI implementation of an operation-switch component, see operation-switch.

Restriction: Nesting an operation-switch component inside an if or switch construct, or another operation-switch component, is **not** supported.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of an operation-switch component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, `operation-switch` is used by default.
Description	No	A description of your component, it is not displayed on the canvas.
Case	Yes	Each case includes one or more operations to which the branch provided by the operation switch applies.

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see switch.

A switch construct provides a way to branch an assembly based on multiple conditions. Each switch component contains multiple cases, each corresponding to a section of the assembly that is only executed when the condition or operation specified by the case is met or used. Additionally, an otherwise case executes when no other case is fulfilled.

Add new cases by clicking + Case and add an "otherwise" case by clicking + Otherwise.

If multiple cases are fulfilled, the highest priority case will be executed. Change the priority of cases by clicking the Move up ↑and Move down ↓ icons.

To configure a case to be executed if a specific operation is called, use the search operations field and select your operation from the list. You can refine the results of the search by typing in the search operations field.

To configure a case to be executed based on a GatewayScript condition, click edit condition and enter your script in the "Condition editor" window. When you have supplied a script, you can edit your script either in the Condition field or by clicking edit condition.

If you are using the DataPower Gateway (v5 compatible), you enter your condition as GatewayScript directly in a code area in the Condition editor. If you are using DataPower API Gateway, the Condition editor provides a script builder to help you construct your condition script; for more information, see Using the switch policy condition editor.

To delete a case, click the Remove case icon 🗑.

If you want one or more policies or constructs to be executed when the condition of a case is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the case's section of the switch construct.

Note: A switch case **must** contain at least one policy, otherwise the Gateway server returns an error.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of a switch construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, `switch` is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
case	Yes (one or more)	Specify one or more operations or write a script for a condition. API Gateway Use the Condition editor to construct your condition script. See Using the switch policy condition editor. DataPower Gateway (v5 compatible) Use GatewayScript to provide conditions. You can reference variables by using the form `apim.getvariable('context.location.variable')`, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable. A list of context variables that you can use to generate conditions can be found in API Connect context variables.

Property	Required	Description
otherwise	No	Add an otherwise case if you want to execute a section of the assembly when no other cases are fulfilled.

- **Using the switch policy condition editor**
  The switch policy condition editor provides a user interface to help you build the conditions for the `case` clauses in a switch policy.

API Gateway only

Using the switch policy condition editor

The switch policy condition editor provides a user interface to help you build the conditions for the `case` clauses in a switch policy.

You build a condition script by using the Add Group and Add Condition options, together with operator selections, and pre-supplied function selections. The Output field shows the resultant condition script, and updates dynamically as you build your condition.

Adding conditions

When you open the policy condition editor, an initial condition is pre-supplied ready for you to configure.

Use the drop-down list to select the function that you want to begin your condition.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - `$eval()`
  - `$sift()`
  - `$each()`
  - `$error()`
  - `$assert()`
  - `$fromMillis()` is supported with the following restrictions:
    - The `$fromMillis()` parameter supports numbers in the range -5364662400000 - 2903299199000.
      - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
      - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- `$now()` is supported with the following restrictions:
  - The following component specifiers are not supported:
    - `W` = Week in year
    - `w` = Week in month
    - `X` = ISO week-numbering year
    - `x` = ISO week-numbering month
  - Representing numbers as words are not supported, so the following presentation modifiers are not supported:
    - `W` = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
    - `w` = Lowercase word (for example: [Yw] => two thousand and twenty-four)
    - `Ww` = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
  - Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description

`$apiCtx()`	Generic access to an API context	The `$apiCtx()` extension gives generic access to an API context.
		• Sample transform field in an extract action:
		`"$apiCtx().request.uri"`
		• Sample condition of a case in a switch action:
		`"$apiCtx().request.path = '/simple/apictx-function'"`

`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation

Extension	Variable	Description
`$queryParameter('name')`	• `request.parameters.name.locations` The supported keyword is `query`. • `request.parameters.name.values`	Searches for the index of `query` in `request.parameters.name.locations` and returns `request.parameters.name.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*variable*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

`$urlParameter('name')`	• `request.parameters.name.locations` The supported keywords are `path` and `query`
	• `request.parameters.name.values`
		Searches for the index of `path` and `query` in `request.parameters.name.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.name.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values.
		`http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese`
		The `$urlParameter('breed')` URL returns the following array of values.
		`[cats, adopt, Sphynx, Siamese]`
		In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.

`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- ***operationName***
  For an anonymous operation, ***operationName*** can be empty.

- ***~fragmentSpreadName***
- **on~*typeCondition***
- ***~~fragmentDefinitionName***

After you select the function, additional fields are displayed, depending on the selected function, so that you can complete the condition. For example, if you select the function **$httpVerb()**, a comparison operator selection list is displayed (**=** or **!=**), together with a list of HTTP verbs to select on the right hand side of the expression (**GET**, **PUT**, **POST**, **DELETE**, **HEAD**, **OPTIONS**, or **PATCH**).

If you select NOT, your condition is negated with a **$not** function.

To add further conditions, click Add Condition; you then select whether to insert an **and** or an **or** operator between this condition and the preceding one.

To group two or more conditions inside parentheses, click Add Group, then add your conditions to the group; you then select whether to insert an **and** or an **or** operator between this group and the preceding condition or group.

To write your own condition from scratch, select Custom, then enter your script in the field provided.

Example

To build the following condition:

```
($statusCode() != 200 and ($httpVerb() = 'GET' or $httpVerb() = 'PUT'))
```

complete these steps in the condition editor:

1. Select **$statusCode()**, select **!=** for the comparison operator, and enter **200** in the field on the right hand side of the condition.
2. Click Add Group.
3. In the new group sub pane that is displayed, click Add Condition.
4. Select **httpVerb()**, leave the comparison operator as **=**, and select **GET** on the right hand side of the condition.
5. Click Add Condition in the group sub pane again.
6. Select **httpVerb()**, leave the comparison operator as **=**, and select **PUT** on the right hand side of the condition.
7. For the comparison operator between the two conditions, select **or**.

Simple condition statements

The following examples show conditions that use a single function.

This example uses the **$httpVerb()** extension to specify the HTTP method of the request.

```
$httpVerb()="GET"
```

This example uses the **$operationPath()** extension to specify the path of the operation.

```
$operationPath()="/base/path-2"
```

This example uses the **$operationID()** extension to specify the operation ID.

```
$operationID()="test-gatewayscript-GET"
```

This example uses the **$statusCode()** extension to specify the message status code.

```
$statusCode()=200
```

This example uses the **$header(name)** extension to specify the content type of the message header.

```
$header("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use **and** and **or** operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to **test-gatewayscript-GET**.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a **POST** or **PUT** request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to **test-gatewayscript_POST** and a message status code equal to **200**, or an API operation ID equal to **test-gatewayscript-GET** and a message status code equal to **500**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and
$statusCode()=500)
```

This example specifies an API operation ID equal to **test-gatewayscript-POST** and a message status code equal to **200** with an API operation path equal to **/base/path-2**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to **text/plain** and a message header length equal to **300**, or a message status code equal to **200**.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

Note: When users sign in by using the Toolkit login path (a URL that includes `?from=TOOLKIT`), the generated API key has a fixed time-to-live (TTL) of 5 minutes.

throw

Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see throw.

When the throw policy is encountered, the specified error and error message is produced.

If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

If no catch is triggered by the thrown error, then a `500 Internal Server Error` is returned to the API caller.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of a throw component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, `throw` is used by default.
Error name	Yes	The error name that is thrown by the policy.
API Gateway only Error status code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the `$(variable)` format to reference the `error.status.code` API context variable.
API Gateway only Error status reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the `$(variable)` format to reference the `error.status.reason` API context variable.
Error message	No	The error message that is returned with the error name.

API Gateway only

Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway

In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.

All API context variables are stored in a JSON-like tree; each context variable is a node in this tree. A non-leaf node can be either an object or an array, while a leaf node can be a number, string, boolean, or document; a document can contain an XML document, BLOB, Stream, or another JSON document.

Each context variable has a name and a value. You can access a context variable by name when using the GatewayScript and XSLT APIs. Dot notation is used to access a context variable, reflecting the position of the corresponding node in the JSON-like tree; for example, `request.headers.Host`. Where a node name contains special characters, bracket notation is supported; for example, `request.headers['Content-Type']`.

For the GatewayScript policy, all the APIs for the DataPower® API Gateway are in the `context` module, which is a global module. You can therefore access the `context` module directly, you do not need to use the `require()` function first.

For the XSLT policy, the APIs are in the `http://www.ibm.com/xmlns/datapower/2017/11/apigateway` namespace; to use these APIs you must declare this namespace.

Note: If you are using apigw extension elements, you must specify the "apigw" namespace prefix in the "extension-element-prefixes" attribute of the xsl:stylesheet. This prefix must also be added to the "exclude-result-prefixes" attribute to make sure that this namespace is not added to any XML output that is the result of this stylesheet. Attention: The mechanisms described here for interacting with the API Connect context are preferred and provide the best performance if you are writing new GatewayScript or XSLT policies, or if you are authoring user-defined policies. However, for v5-compatible gateways and v5 compatibility for APIs created for the API Gateway, the preferred mechanisms are as described in GatewayScript code examples and XSLT policy examples.

- Accessing context variables
- About payloads
- Manipulating the message headers
- Manipulating the message status - examples
- Accessing the message body
- Rejecting the session

Accessing context variables

GatewayScript examples

To read the `client.app.id` context variable:

```
var clientID = context.get('client.app.id');
```

To set the value of a context variable:

```
context.set('my.vars.amount', 100);
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
context.clear('my.vars');
```

The resulting tree has the following structure:

```
{ "my": { } }
```

XSLT examples

To read the `client.app.id` context variable:

```
<xsl:variable name="clientID" select="apigw:get-variable('client.app.id')"/>
```

To set the value of a context variable:

```
<apigw:set-variable name="'my.vars.amount'" value="100"/>
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
<apigw:clear-variable name="'my.vars'"/>
```

The resulting tree has the following structure:

```
{ "my": { } }
```

About payloads

When the assembly flow for an API call begins, the following two message objects are predefined in the API context tree:

- `request`: holds the information for the original payload; the `request` message is a read-only object.
- `message`: holds the information for the current payload.

Typically, a message object has `headers` and `body` properties. For the current payload, the `message` message object might have `variables` and `status` properties, and other properties created during the execution of the assembly.
The following example shows the general structure of a typical message:

```
{
  "headers": {
    "Content-Type": "application/xml",
    "X-Client-ID": "1234567890"
  },
  "variables": {
    "amount": 123,
    "name": "xyz"
  },
  "status": {
    "code": 200,
    "reason": "OK"
  },
  "body": <XML/Blob/Stream/JSON Document>
}
```

Manipulating the message headers

GatewayScript examples

To delete a header:

```
context.message.header.remove('X-My-Header');
```

To read a header:

```
var reqType = context.request.header.get('Content-Type');
var currType = context.message.header.get('Content-Type');
```

To set a header:

```
context.message.header.set('Content-Type', 'application/json');
```

To iterate through the headers:

```
var reqHdrs = context.request.headers;
for (var h in reqHdrs) {
   console.log('>>> Reading the request header: ', h, '=', reqHdrs[h]);
}

var currHdrs = context.message.headers;
for (var h in currHdrs) {
   console.log('>>> Reading the current header: ', h, '=', currHdrs[h]);
}
```

To create a message context called **headersContext**, if one doesn't already exist, and add to it a boolean context variable called **HelloWorld**, with the value **true**:

```
var ctx = context.getMessage("headersContext") || context.createMessage("headersContext");
ctx.setVariable('HelloWorld', true);
```

The **setVariable** call writes the variable into **headersContext.variables.HelloWorld**; therefore a condition statement in any subsequent **switch** policy should check for **headersContext.variables.HelloWorld** rather than **headersContext.HelloWorld**.
To read the context variable in any subsequent **gatewayscript** policy, use the following call:

```
ctx.getVariable("HelloWorld")
```

Note: If you are either migrating an API from IBM® API Connect Version 5.0, or from the DataPower Gateway (v5 compatible), to the DataPower API Gateway, or you are configuring a new API for the DataPower API Gateway, creating a message context, rather than using the context variable mechanism described in Accessing context variables, is the preferred option. In the case of migration, it most closely matches the behavior of IBM API Connect Version 5.0, and **setVariable** and **getVariable** calls will continue to work without modification.
Creating a message context is also the preferred option if you are creating a new API for the DataPower API Gateway because it most closely aligns the API context with the way that various native DataPower API Gateway policies process it.

XSLT examples

To delete a header:

```
<apigw:clear-header message="'message'" name="'X-My-Header'"/>
```

To read a header:

```
<xsl:variable name="reqType" select="apigw:get-header('request', 'Content-Type')"/>
<xsl:variable name="currType" select="apigw:get-header('message', 'Content-Type')"/>
```

To set a header:

```
<apigw:set-header name="'Content-Type'" value="'text/xml'"/>
```

To get all headers:

```
<xsl:variable name="allReqHdrs" select="apigw:all-headers('request')"/>
<xsl:variable name="allCurrHdrs" select="apigw:all-headers('message')"/>
```

Manipulating the message status - examples

Note: Only the **message** object has the status property, not the **request** object.

GatewayScript examples

To read the status code and reason phrase:

```
var code = context.message.statusCode;
var reason = context.message.reasonPhrase;
```

To update the status code:

```
context.message.statusCode = 400; //integer, update the code, with default reason
```

To update the status code and reason phrase in a single operation:

```
context.message.statusCode = '200 Wonderful'; //string, update code along with customized reason
```

Note: The **context.message.reasonPhrase** context variable is read-only.

XSLT examples

To read the status code and reason phrase:

```
<xsl:variable name="code" select="apigw:get-variable('message.status.code')"/>
<xsl:variable name="reason" select="apigw:get-variable('message.status.reason')"/>
```

```
<apigw:set-variable name="'message.status.code'" value="200"/>
<apigw:set-variable name="'message.status.reason'" value="'OK'"/>
```

Accessing the message body

Note: The request body is read-only.

GatewayScript examples

To read the request body:

```
context.request.body.readAsJSON(function(error, json) {});
context.request.body.readAsXML(function(error, xml) {});
context.request.body.readAsBuffer(function(error, buffer) {});
```

To read the message body:

```
context.message.body.readAsJSON(function(error, json) {});
context.message.body.readAsXML(function(error, xml) {});
context.message.body.readAsBuffer(function(error, buffer) {});
```

To write the message body and update the content type accordingly:

```
// text response
context.message.body.write("Hello world.");
context.message.header.set('Content-Type', "text/plain");

// JSON response
var pet = { "kind": "dog", "age": 3, "color": "black" };
context.message.body.write(pet);
context.message.header.set('Content-Type', "application/json");

// XML response
var resp = "<order><id>100</id><timestamp>20181231</timestamp><status>fulfilled</status></order>";
context.message.body.write(resp);
context.message.header.set('Content-Type', "text/xml");
```

XSLT examples

Note:

- There is no XSLT API to write the message body; the output of the stylesheet transformation is used to update **message.body**.
- To read the request body or the message body, you must parse **message.body** with a Parse policy before the XSLT policy is executed. At the beginning of the assembly flow, **message.body** contains **request.body** so, after parsing **message.body**, you can then read the request from **message.body**.
- If the XSLT input document uses the context current payload, **message.body** is used for the input document **'/'** that can be accessed from the XSLT policy if **message.body** has been parsed as XML in advance; this is determined by the **input** property of the XSLT policy, see xslt.

Read the message body:

```
<xsl:variable name="currentPayload" select="apigw:read-payload('message')" />
```

Read the message body when the **input** property of the XSLT policy is set to **true**:

```
<xsl:variable name="currentPayload" select="/" />
```

Rejecting the session

Note: After the session is rejected, the API assembly flow is stopped and a fault response is returned, unless a catch handler is defined.

GatewayScript example

To reject the session with an error name and message, and update the status reason and code:

```
context.reject('CustomError', 'You are not authorized to make this API call');
context.message.statusCode = '401 Unauthorized';
```

XSLT example

To reject the session with an error name and message, and update the status reason and code:

```
<apigw:reject identifier="'CustomError'" status-code="401" reason="'Unauthorized'">You are not authorized to make this API call</apigw:reject>
```

- **Manipulating attachments in a message object**
  The message object provides APIs and properties to manipulate message attachments.

API Gateway only

Manipulating attachments in a message object

The message object provides APIs and properties to manipulate message attachments.

If the assembly includes a parse policy, attachments in the request or response of a multipart message can be manipulated and sent back to the client. By default, the response is sent to the client in multipart format.
Restriction: You cannot add an attachment to a request or response which does not contain existing attachments.
Alternatively, you can clear **context.message.attachments** to discard the attachments and send only **message.body** to the client.
Note: If the assembly does not include a parse policy, the following processing rules apply.

- For a multipart request where the **message.body** variable is not changed, the invoke policy keeps and passes the attachments to the server.
- For a multipart request or response where the **message.body** variable is not changed, the result API action passes the attachments as the final response.
- If the **message.body** variable is changed, attachments are discarded.

- Retrieving an attachment
- Appending an attachment to the message
- Retrieving the number of attachments in an array
- Removing an attachment from the message
- Reading, accessing, and manipulating the body of an attachment
- Manipulating the headers of an attachment

Retrieving an attachment

GatewayScript examples

Retrieve the attachment by index location.

```
context.message.attachments[1]
```

Retrieve the attachment by looking up the value of `pic1` in the `Content-Id` header.

```
context.message.attachments['cid:pic1']
```

Retrieve the attachment by looking up the value of `uri1` in the `Content-Location` header.

```
context.message.attachments['uri1']
```

Appending an attachment to the message

GatewayScript example

```
var headers = JSON.parse ( '{ "Content-Type": "text/xml; charset=utf-8", "Content-Id": "<data>" }' );
context.message.attachments.append(headers, 'Hello world.');
```

Retrieving the number of attachments in an array

Example

```
for (var i = 0; i < context.message.attachments.count; i++) {
  context.message.attachments[i].header.set('X-Foo', 'bar');
}
```

Removing an attachment from the message

GatewayScript examples

Remove the attachment by index location.

```
context.message.attachments.remove(1)
```

Remove the attachment by looking up the value of `pic1` in the `Content-Id` header.

```
context.message.attachments.remove('cid:pic1')
```

Remove the attachment by looking up the value of `uri1` in the `Content-Location` header.

```
context.message.attachments.remove('uri1')
```

Reading, accessing, and manipulating the body of an attachment

GatewayScript examples

To read the payload of an attachment in binary and return the contents as either a `Buffer`, `Buffers`, `JSON`, or `XML NodeList` object:

```
context.message.attachments[0].body.readAsBuffer(function(errorObject,bufferObject){})
context.message.attachments[0].body.readAsBuffers(function(errorObject,buffersObject){})
context.message.attachments[0].body.readAsJSON(function(errorObject,jsonObject){})
context.message.attachments[0].body.readAsXML(function(errorObject,nodeList){})
```

To write content `Hello world` to the current payload of the attachment:

```
message.attachments[0].body.write("Hello world")
```

Manipulating the headers of an attachment

GatewayScript examples

To retrieve the values of the whole attachment headers:

```
context.message.attachments[0].headers
```

To retrieve the value of the named header of the attachment:

```
context.message.attachments[0].header.get();
```

To delete the current `Content-Type` header of the attachment.

```
context.message.attachments[0].header.remove('Content-Type');
```

You can set the value of the named header of an attachment. The header can be coalesced and noncoalesced. Take the following code as an example.

```
context.message.attachments[0].header.set('MyCookie', ['cookie1', 'cookie2']);
```

If the value type is array, the `MyCookie` header is noncoalesced and it is present with different entries in HTTP header.

```
MyCookie: cookie1
MyCookie: cookie2
```

User-defined policies

Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

A policy is a piece of configuration that controls a specific aspect of processing in the Gateway server during the handling of an API invocation at run time. IBM® API Connect provides built-in policies for many capabilities, including logging, redaction, proxy, and transformations, but you can also create user-defined policies to provide more processing control.

The following information outlines how to create and manage user-defined policies:

Creating a user-defined policy
: A user-defined policy is created outside of API Connect by using a standard development tool, but the policy must conform to a particular schema. For information about how to create a policy, see Authoring policies.
Note: If you are running your policies on a DataPower® Gateway, you must ensure that the DataPower processing to be controlled by the user-defined policy, is supported by the level of IBM DataPower Gateway that the policy will be run on. When using the GatewayScript actions, the minimum DataPower firmware that should be used is version 7.2.0.

Importing a user-defined policy into API Connect
: To make a user-defined policy available to an API, the policy must be imported into one or more Catalogs in the API Manager. If you also want to be able to apply the policy to your policy assembly in API Designer, you will have to import that policy into the developer toolkit environment.
Make your policy accessible to API Designer by using the developer toolkit. For detailed instructions, see Packaging and importing your policies into IBM API Connect.

  Make your policy available by using the API Manager UI. For detailed instructions, see:

  - Importing a user-defined policy into a Catalog. If you want to create a new Catalog and import a user-defined policy as part of the configuration, follow the instructions in Creating and configuring Catalogs.
  - Packaging and importing your policies into IBM API Connect.

  Note: You must import a user-defined policy into every Catalog in API Manager that you require the policy to run in.

Applying a user-defined policy to an API
: Apply a user-defined policy to an API definition by using the assemble view in API Designer or API Manager, to add the component to your assembly and configure its properties. For detailed instructions, see Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly.

Deleting a user-defined policy
: Delete a user-defined policy from a Catalog, by clicking the Delete icon next to the policy in the associated Catalog in API Manager.

Tags in API Connect

There are a number of forms of tagging in IBM® API Connect.

- You can create tags in an API that are visible in its OpenAPI definition and can be used to filter operations in the Developer Portal.
- You can tag items in the Developer Portal so that they can be searched for.

Tags within an API

The OpenAPI specification allows the inclusion of tags in an API definition, and you can create these tags through the API Manager user interface. You can assign tags to an operation within an API.

Tags that are assigned to an operation can be used to group the operations of an API in the Developer Portal, by using the filter options for the API. These tags are visible to anyone who can view any of the Products to which the API belongs.

For more information, see Editing an OpenAPI 2.0 API definition and Configuring an operation.

Note: Though you can tag the API itself in the API Setup section, by using this method the tag is not visible in the Developer Portal.

Tags in the Developer Portal

An administrator can assign tags to items in the Developer Portal, which are then available through the API Products search function in the Developer Portal.

For more information, see Editing tags for a specific item and Managing tags in the Developer Portal.

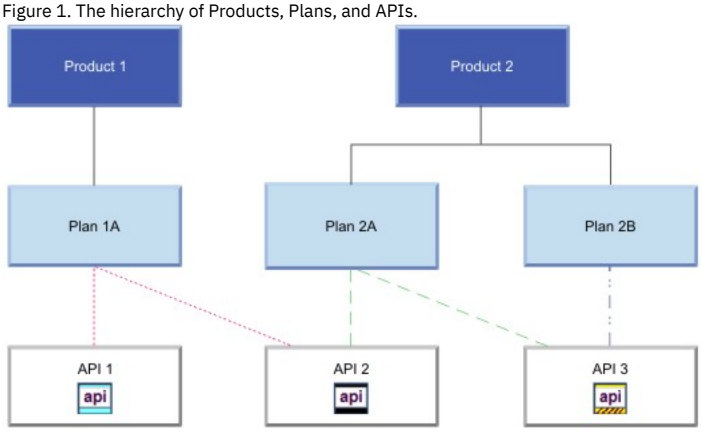
Working with Products

In IBM® API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The following diagram demonstrates how Products, Plans, and APIs relate to one another.
Note: Plans belong to only one Product, but they can possess different APIs to other Plans within the same Product, and they can share APIs with Plans from any Product.

Figure 1. The hierarchy of Products, Plans, and APIs.



Products provide a method by which you can group APIs into a package that is intended for a particular use. Additionally, they contain Plans, which can be used to differentiate between different offerings. Plans can share APIs, but whether subscription approval is required depends upon the Plan itself. Additionally, you can enforce rate limits through these Plans, or through operations within the APIs of a Plan that override the rate limit of the Plan. You can also assign different subscription costs to your Plans to differentiate the rates of API calls. For more information, see Monetizing your Products.

To make an API available to an application developer, it must be included in a Plan. You can create Plans only within Products, and these Products are then published in a Catalog. A lifecycle manager can then control the availability and visibility of APIs and Plans through the API Manager. By using the API Manager, you can specify the Plans that an application developer is able to subscribe to through the Developer Portal. The application developer can only subscribe to one Plan from a specific Product. Multiple Plans within a single Product are useful in that they can fulfill similar purposes but with differing levels of performance and cost. For example, you can have a "Demo Plan", which makes a single API available free of charge, and a "Full Plan" which makes several APIs available with a monthly subscription cost.

As well as controlling which APIs an application developer can use, different Plans can be used to implement different rate limits. A rate limit can be implemented as a default rate that is shared across an entire Plan, or can be set for specific operations of an API within that Plan, exempting them from the shared Plan rate limit. Different Plans can have differing rate limits, both between operations and for the overall limit. This is useful for providing differing levels of service to customers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note:

- Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
- The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see Working with Catalogs

API Connect also supports the implementation of multiple versions of Products. You can choose version numbers and use them to aid the development of your Products and Plans.
Note: The version for a Product is distinct from the version of any APIs that are contained in the associated Plans. Plans cannot themselves have their own version, they use the version of their parent Product.

- **Creating a draft Product**
  Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.
- **Downloading a draft Product**
  You can download the details of your draft Product so that you can store them for later recovery.
- **Importing a draft Product**
  You can create a Product by importing a Product definition in a .yaml file.
- **Searching for a draft Product**
  Quickly locate a draft API or Product by searching on the title and version.
- **Editing a draft Product**
  After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.
- **Staging a draft Product**
  Stage a draft Product to a Catalog to create a specific version of that Product, before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- **Publishing a draft Product**
  Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- **Creating a new version of your Product**
  You can have multiple versions of a Product in IBM API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.
- **Specifying the gateway type for a Product**
  You can edit the Product configuration to specify a gateway type.
- **Deleting a draft Product**
  You can delete draft Products that are no longer required.
- **Organizing your Products into categories**
  You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal, in their defined categories.

- Working with Products in the API Manager

Creating a draft Product

Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.

Before you begin

Define your APIs. For more information, see Creating an API definition.
Tip: As well as using the method described in this task, you can also create a Product when you create an API. If you create an API by using the developer toolkit command line editor, a Product is automatically created for you. You can then change any of the Product settings by opening your new Product in the Products page of the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you first create your Product, it has *draft* status. When you have finished configuring your draft Product, you stage it to a Catalog so that the APIs in the Product can be made available to your application developers.

Procedure

To create a Product, complete the following steps:

1. In the navigation pane, click Develop, select the Products tab, then click Add > Product.
   The Add Product page opens.
2. Select New Product, then click Next.
3. On the Info page, complete the following steps:
   a. Enter the Title and Version of the Product and, optionally, a description. A Name is entered automatically.
      Note: The value in the Name field is a single string that is used to identify the Product in developer toolkit CLI commands. The Title is used for display.
      To view the CLI commands to manage draft Products, see the toolkit CLI reference documentation.

   b. Click Next.
4. On the APIs page, select the APIs that you want to include in the Product. For staging or publishing, you can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled. The API for which the Enforced option is disabled is not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see API Connect gateway types, Specifying the gateway type for a Product, and Specifying the gateway type for an API definition.
5. Click Next.
6. On the Plans page, complete the following steps:
   a. Optional: Change the Title, Description, or Rate limit settings for the default Plan.
   b. Optional: To add further Plans, click Add, then scroll down and modify the Plan settings as required.
   c. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
   Note: The publish option is not available in the API Designer UI.
8. If Publish product is selected, you can select which gateway service the Product is published to. By default, the Product is published to all relevant gateway services.
9. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

   Visibility can also be set at the Catalog or Space level. For more information, see Configuring Product visibility in a Catalog.

10. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
    If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
    Note: If you select custom visibility or subscribability, the consumer organizations and consumer organization groups that you can choose from are those in the Sandbox Catalog for the management server and provider organization that you are connected to. If you want to specify consumer organizations or groups that are in another Catalog, or in a Space, publish the Product to that Catalog or Space, then configure the visibility or subscribability there; for details, see Changing the availability of a Product.
    If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

    If you are working offline in API Designer, you must type in the exact name of the organization or group.

    For more information about consumer organizations in a Catalog, see Administering Consumer organizations.

11. Click Next to create your Product.
    a. To further configure your Product, click Edit Product.

For details, see Editing a draft Product

b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task.
For details on how to configure your Product later, see Editing a draft Product.

Results

You have created a draft Product, and specified a set of APIs and Plans into one offering that you can now make available to your developers.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

Downloading a draft Product

You can download the details of your draft Product so that you can store them for later recovery.

Before you begin

To complete this task, you must have created a draft Product. For more information, see Creating a draft Product.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Product-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

You can download the details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to export an entire implementation. For information about creating a Product from a .yaml file, see Importing a draft Product.

Procedure

To download a .yaml file containing details of your Product, complete the following instructions:

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon ⋮ and then click Download.
4. Save the file to the required location.

Results

You have downloaded a .yaml representation of your Product.

Related tasks

- Importing a draft Product

Related information

- Creating a Product

Importing a draft Product

You can create a Product by importing a Product definition in a .yaml file.

Before you begin

To complete this task, you must have a .yaml representation of a Product. This can be created as described in the Downloading a draft Product task.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can import details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to import an entire implementation.

You can import the file from your local file system.

Procedure

To create a Product from a .yaml file, complete the following instructions:

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Click Add > Product.
4. Select Existing Product, then click Next.
5. To import a file from your local file system, you can either drag and drop your files, or click Browse and select the file that you want to use.
   The wizard checks the validity of the YAML, and displays a message indicating successful validation.
6. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
8. Click Next to create your Product.
   a. To further configure your Product, click Edit Product.
      For details, see Editing a draft Product
   b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task.
      For details on how to configure your Product later, see Editing a draft Product.

Results

You have imported a Product from a .yaml file. If the same APIs and versions of APIs as referenced in the file are present, then they will be included in the Product.

Importing a Product in this way does not include the API definitions, only references to them.

Related tasks

- Downloading a draft Product

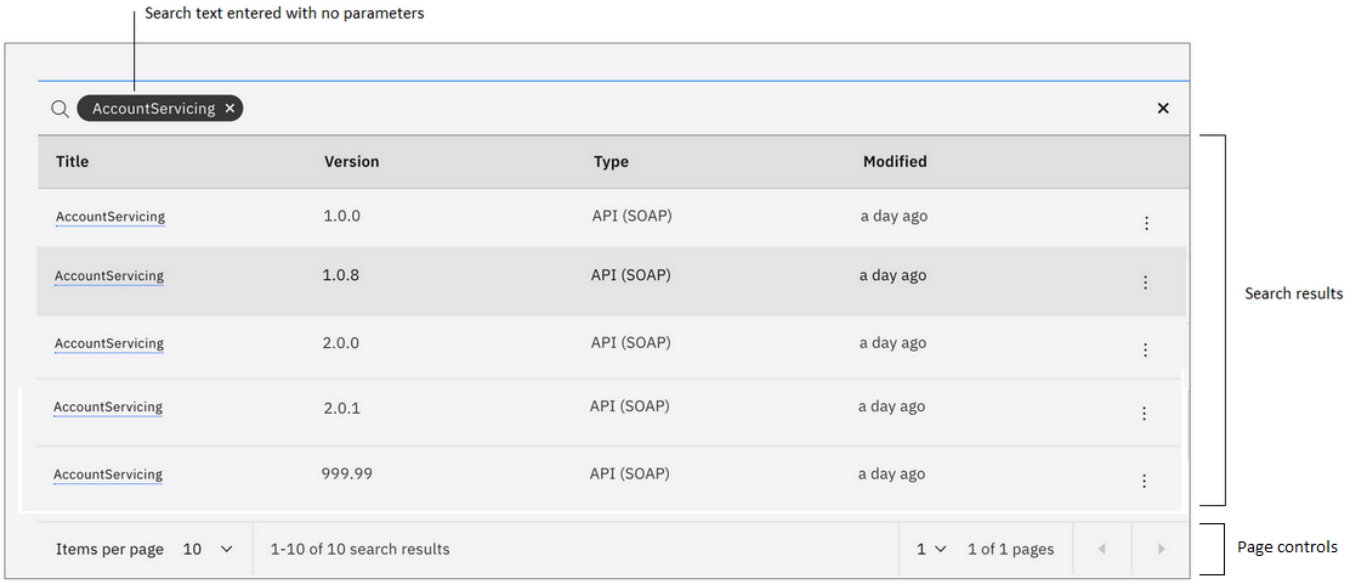
Searching for a draft Product

Quickly locate a draft API or Product by searching on the title and version.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

On the Develop page, type your search string into the search field and click (or press Enter) to run the search.

The search returns a list of APIs (or Products) that most closely resemble your keywords, rather than limiting the results to identical matches. The following image shows a search string that includes "AccountServicing". The results include all draft APIs and Products with a title that is similar to the search text, with duplicates sorted by creation date.



Resources with a name, title, or version that are not similar to the search text are not included in the results. If you select a resource type to search for but do not specify any keywords, the results are sorted by title and then by creation date. For example, if you search for Products but do not include any keywords, then all Products appear in the results table.

Search text
: The search is case insensitive. Trailing spaces and accents (for example: é, è, â) are ignored. For best results, provide as much of the title and version as possible in your search text. Detailed search strings return more accurate results. Results include all titles that are similar to your search string, and not just identical matches.

What's included in the search?
: The scope of the search includes the API or Product Title, Name and Version fields. The search applies only to the current provider organization (displayed in the product banner's Organization field).
You can optionally restrict your search to Products only, or to a specific type of API. Click in the search field and then in the "Types" list that displays, select Product or an API type (REST or SOAP).

How are results displayed?
: Search results display as a table, sorted by API or Product title and version. If the results overflow onto additional pages, navigate between pages using the standard page controls that follow the table. When you clear the search, APIs and Products are listed alphabetically by title and, within each title, by newest version first.

Editing a draft Product

After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

Procedure

To edit a draft Product, complete the following steps:

1. Access the Product Setup page in one of the following ways:
   - After completing the initial creation of the Product, click Edit Product.
   - In the navigation pane, click Develop, then select the Products tab.
   - Click the title of the Product that you want to edit.
2. On the Product Setup page, you can make the following configuration changes:
   a. In the Info section, change the Title, Version, or Summary.
   b. Use the Contact, Terms of Service, and License sections to enter the corresponding details as required.
   c. Change the gateway type. For more information, see API Connect gateway types and Specifying the gateway type for a Product.
   d. Click Save to save your changes.
3. Optional: Specify Product metadata to be displayed with the Product in the Developer Portal:
   a. Click the Source tab to see the OpenAPI source for the Product.
   b. Add the custom attribute `x-name: value` into the `info` section. For example:

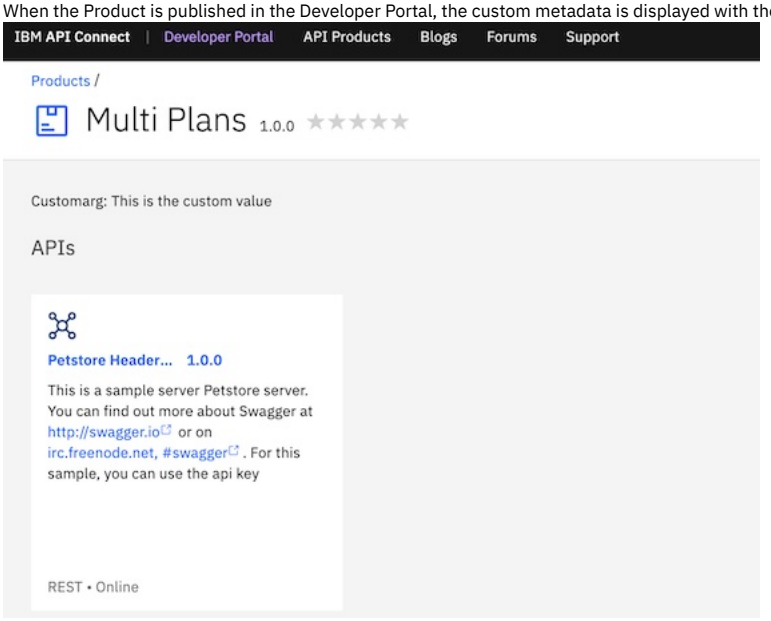
```
info:
  version: 1.0.0
  title: Multi Plans
  name: multi-plans
```

```
  x-customarg: This is the custom value
...
```

Where `customarg` is the name of the custom metadata, and `This is the custom value` is the information content.

c. Click Save.

When the Product is published in the Developer Portal, the custom metadata is displayed with the Product. For example:



4. Click Visibility, then make the following changes as required:
   a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, complete the following steps:
      - Select the Catalog for which you want to control visibility.
      - Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. If needed, you can enter the name of a consumer organization or organization group that doesn't currently exist but will be added in the future. Later, create it using the same name. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

   b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
   If you select Custom, complete the following steps:
      - Select the Catalog for which you want to control subscribability.
      - Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If needed, you can enter the name of a consumer organization or organization group that doesn't currently exist but will be added in the future. Later, create it using the same name. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

   Note:
      - If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
      - Although the title of each organization or group is displayed, followed by the name in parentheses, in the table of selected organizations and groups only the name is displayed

   a. Click Save to save your changes.

   Note: You can change the visibility and subscribability settings when you publish the Product; see Publishing a draft Product. You can also change the settings in the Catalog to which the Product is published; see Changing the availability of a Product.
5. To specify the APIs that you want to include in the Product, click APIs, then complete the following steps:.
   a. Click Edit.
   All draft APIs are listed.
   b. Select the APIs that you want to include. For staging or publishing, you can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled. The API for which the Enforced option is disabled is not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see API Connect gateway types, Specifying the gateway type for a Product, and Specifying the gateway type for an API definition.
   c. Click Save when done.
   The selected APIs are listed.

   Note: To make an API available to application developers, you must include it in a Plan.
6. Optional: Add billing integration to the Product. Click Plans, and in the Billing integration section, select the billing integration resource that you want to apply to the Product.
   In the Plans section, you can then either edit the Default Plan to add pricing information, or create a new Plan with pricing information. For more information about billing integration, see Monetizing your Products.
7. Optional: Add one or more Plans to the Product, or modify an existing Plan. Note that a default plan is automatically created for you, with a rate limit of 100 API calls per hour.
   a. Click Plans.
   b. To add a new Plan, click Add. To modify an existing Plan, click the options icon ⋮ alongside the required Plan, then click Edit.
   c. Specify the Title of the Plan and, optionally, a description. A Name is entered automatically.
   Note: The value in the Name field is a single string that is used to identify the Plan in developer toolkit CLI commands. The Title is used for display.

d. Specify whether your Plan requires subscription approval. If you want subscriptions by developers to require approval, select the Approval check box; otherwise, ensure the check box is cleared.
Note:
To view the subscription tasks history, complete the following steps:
- In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
- Click Tasks tab.
- Click Approvals history from the navigation pane.

e. In the Plan pricing section, you can add pricing information by completing the following steps:
i. Change the toggle to On for Plan pricing. The Plan pricing definition section is displayed.
ii. If you want to include any free trial days in your Plan, select Include free trial days, and then enter the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.
iii. Select the Currency for the billing process use.
iv. Enter the Price per month to bill the subscriber for. If the selected currency supports fractional units, enter the price including any fractional units, such as cents.
For more information about Product billing integration, see Defining a Product with billing integration.

f. In the Plan Rate Limits section, you can modify a rate limit, and click Add to add further rate limits. You can set multiple rate limits, at second, minute, hour, day, and week time intervals. To remove a rate limit, click the corresponding delete icon .
Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

g. In the Plan Burst Limits section, you can modify a burst limit, and click Add to add further burst limits. You use burst limits to prevent usage spikes that might damage infrastructure. You can set multiple burst limits, at second and minute intervals. To remove a burst limit, click the corresponding delete icon .
Rate and burst limits work together to manage network traffic for the APIs covered under a Plan. A Plan can have multiple rate and burst limits, but it is recommended that each time interval be assigned only one set of limits. Adjust the rate and burst limits to allow for maximum traffic without overloading your network. The **rate limit** sets the maximum amount of sustainable, ongoing traffic for accessing the APIs on your network within a time interval (for example, one day). The **burst limit** sets the maximum short-term traffic volume for your network within a time interval (per second or minute).

The **burst limit** allows for short bursts of increased traffic. When the **burst limit** is exceeded, all subsequent API calls are rejected until the start of the next **burst limit interval**. The **burst limit counter** is reset to zero at the start of the next interval, which allows API calls to be accepted again. These API calls count toward the **rate limit counter**, but the resetting of the **burst limit counter** does not affect the **rate limit counter**.

The **rate limit** is the number of API calls allowed in a time interval, for example, 1000 calls per day. When the **rate limit** is exceeded, and Hard limit is enabled, all subsequent API calls will be rejected. The **rate limit counter** is reset to zero at the start of the next **rate limit interval**, which allows API calls to be accepted again. If Hard limit is disabled, all subsequent API calls are still accepted, and a message is logged stating that the **rate limit** has been exceeded. This is referred to as a "soft limit."

Hard limit affects only the **rate limit**, as illustrated by the following scenarios:

Scenario A

Table 1. Hard limit enabled

Hard limit	Burst limit	Rate limit
ON	100 calls/minute	1000 calls/day

- If a user calls an API 100 times in one minute, the **burst limit** is reached. The 101st call (and any subsequent calls) within the same minute will be rejected. Once the minute is up, the **burst limit counter** is reset. All API calls are tallied toward the **rate limit** of 1000 calls per day. The resetting of the **burst limit counter** does not affect the **rate limit counter**.
- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day rate limit, and the 1001st call will be rejected until the end of the same one day **rate limit interval**. During the period of time when API calls are rejected due to the daily **rate limit** being exceeded, the **burst limit** will not be activated since the calls are already rejected.
- Both **burst limits** and **rate limits** are applied per consumer.

Scenario B

Table 2. Hard limit disabled

Hard limit	Burst limit	Rate limit
OFF	100 calls/minute	1000 calls/day

- As in Scenario A, if a user calls the API 100 times in one minute, the 101st call within the same minute will be rejected, until that minute is up and the counter resets. These calls count toward the 1000 calls per day **rate limit** as well.
- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day **rate limit**, and the 1001st call will be accepted (since there is no hard limit). A message will be logged for each subsequent call until the time interval (one day) is up and the counter resets. During the remainder of the day, the **burst limit** will still be enforced, and calls will be rejected once the number of calls exceeds the 100 calls per minute within any given minute.
- Both burst limits and rate limits are applied per consumer.
Note: When Hard limit is unchecked, the **rate limit** is considered a "soft limit." With a soft limit, calls are not rejected after the **rate limit** is reached. Instead, a message is recorded in the log file. With a soft limit, the **burst limit** still rejects API calls after it is exceeded.

h. To include in the Plan all the APIs that were included in the Product in step 5, select Same as product in the Plan APIs section.
i. In the GraphQL Rate Limits section you can configure rate limits that will be applied to any GraphQL proxy APIs that are added to the Product.
The following rate limits are available:

graphql-field-cost
: Applies a limit to the total calculated field cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-design-request
: Applies a limit to the total number of calls of any of the following types made to the GraphQL proxy APIs in this Plan:
- Requests sent to the `graphql/cost` endpoint for retrieving the cost of a GraphQL query. For more information, see Enabling the cost endpoint for a GraphQL API.
- Standard introspection requests sent to the `/graphql` endpoint. For more information, see Supporting introspection for a GraphQL API.
- HTML web browser requests for a GraphiQL editor sent to the `/graphql` endpoint. For more information, see Enabling the GraphiQL editor for a GraphQL API.

graphql-input-type-cost
: Applies a limit to the total calculated input type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-type-cost
: Applies a limit to the total calculated type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

The calculated costs depend on weighting factors applied to the types and fields in the GraphQL schema. For details on the GraphQL proxy API, and configuring type and field weights, see Creating a GraphQL proxy API and Using the GraphQL schema editor.

j. To define one or more assembly burst limits or assembly count limits, click Add in the Assembly Burst Limits or Assembly Count Limits section as appropriate. For a burst limit you specify the maximum number of calls allowed in a specified time period, for a count limit you specify a maximum call limit. The name that you supply is for use in a Rate Limit policy in an API assembly, enabling the policy to define the burst or count limit that is to be applied; for more information, see Rate Limit.

k. To select the APIs that you want to include in the Plan, select Customize the plan API list in the Plan APIs section, then click Edit. The Edit plan APIs window opens. The APIs that are available for selection are those that were included in the Product in step 5. Use the check boxes to specify the required APIs, then click Save when done.

l. To select specific API operations to include in the Plan, click the options icon ⋮ alongside the required API , then click Edit operation list. The Select operations you want to include window opens. Use the check boxes to specify the required operations, then click Save when done.

m. To remove an API from the Plan, click the options icon ⋮ alongside the required API in the Plan APIs section, then click Remove.

n. For any GraphQL APIs in the Plan, if you want to prevent subscribers to this Plan from using certain types or fields, complete the following steps:

   i. Click the options icon ⋮ alongside the required GraphQL API in the Plan APIs section, then click Edit show/hide settings.
   ii. To prevent use of a GraphQL type, clear the check box selection alongside that type.
   iii. To prevent use a of a field in a type, expand the type then clear the check box selection alongside that field.
   iv. When done, click Next. A summary window opens. If the operation is permitted, any related elements that will also be hidden are listed; for example, if you hide a type, and that type is referenced as the data type of a field on another type, that field is also hidden. If the operation is not permitted, an explanation is displayed.
   v. If the operation is permitted, click Done to apply your changes. If the operation is not permitted, either click Cancel to close the window or click Back and amend your settings.

   You can use the Edit show/hide settings option to change existing settings; you can hide additional types or fields, and you can show types or fields that were previously hidden.

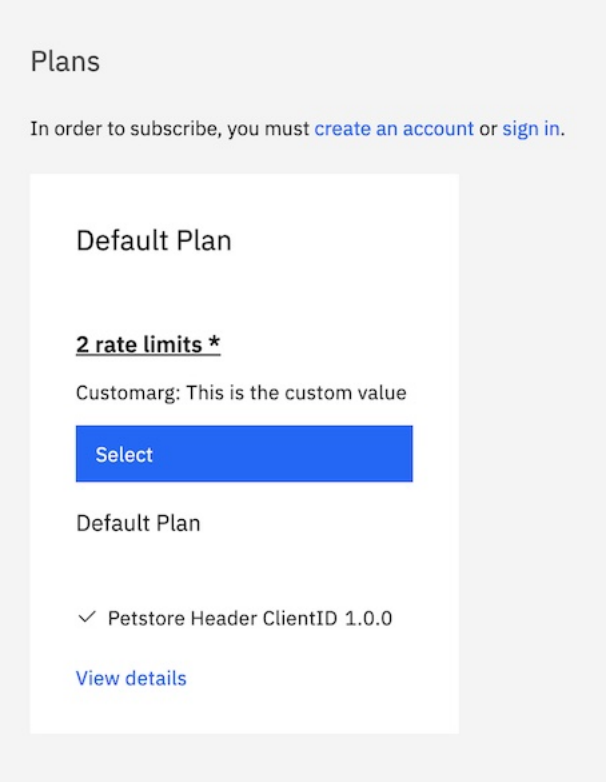
o. To define rate limits for specific API operations, select Override plan rate limits for individual operation in the Plan APIs section; for further details, see Defining rate limits for an API operation

p. Click Save to save your changes.

8. Optional: Specify Plan metadata to be displayed with the Plan in the Developer Portal:
   a. Click the Source tab to see the OpenAPI source for the Plan.
   b. Add the custom attribute **`x-name: value`** into the appropriate **`plan`** section. For example:

```
...
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    x-customarg: This is the custom value
    rate-limits:
      default:
        value: 100/1hour
        hard-limit: false
      minute:
        value: 20/1minute
        hard-limit: false
    apis:
      petstore-header-clientid1.0.0: {}
...
```

   Where ***`customarg`*** is the name of the custom metadata, and ***`This is the custom value`*** is the information content.
   c. Click Save.
   When the Plan is published in the Developer Portal, the custom metadata is displayed with the Plan. For example:



9. Optional: Click Categories, then define any categories that you want to organize your Product into. Click Save to save any updates.
   By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal. For more information, see Organizing your Products into categories.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

- **Defining rate limits for an API operation**
  For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

Defining rate limits for an API operation

For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Procedure

1. Access the Product Setup page in one of the following ways:

- After completing the initial creation of the Product, click Edit Product.
- In the navigation pane, click Develop, then select the Products tab.
- Click the title of the Product that you want to edit.

2. Click Plans.
3. Click the options icon ⋮ alongside the required Plan, then click Edit.
4. Scroll down to the Plan APIs section, then select Override plan rate limits for individual operation.
   The Override Rate Limits section is displayed.
5. Click Add. The Override plan rate limits window opens.
6. Select the API, and the specific operation in that API, to which you want to apply rate limits.
   By default, calls to the operation are unlimited.
7. To apply one or more rate limits to the operation, select Rate Limits.
8. To define a rate limit, click Add.
9. Supply a name for the rate limit, and define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute. If you select HARD LIMIT and the limit is exceeded, subsequent calls are rejected, otherwise calls are still accepted and a message is logged.
10. Click Save when done.
    An entry for the operation is listed in the Override Rate Limits section.
11. To modify the rate limiting definition for an operation, click the options icon ⋮ alongside the required operation, then click Edit Operation; to delete it, click Remove.
12. Click Save to save your changes.

Staging a draft Product

Stage a draft Product to a Catalog to create a specific version of that Product, before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.
Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.
Note: Staging is not available when working offline in API Designer.
A Catalog is a staging target, and behaves as a logical partition between the DataPower® Gateway and Developer Portal.

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests. For information on publishing a Product, see Publishing a Product.

You cannot re-stage an existing Product version to a production Catalog. If you update an API, you must create a new version of that API. Then, create a new version of the Product so that it includes the newer version of the API. For more information on creating new versions of APIs and Products, see Creating a new version of an API definition and Creating a new version of your Product. If Spaces are enabled in a production Catalog, you cannot re-stage the same API or Product version to any Space in the Catalog.

You can, however, re-stage a Product version to the Sandbox Catalog, or other non-production Catalog, for ease of iterative testing. Note that when you re-stage a Product version to a non-production Catalog, any application subscriptions are deleted; this is done to facilitate scripted deployment in a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts. If Spaces are enabled in a non-production Catalog and you re-stage a Product version to a different Space to the one in which it was previously staged, it is removed from the previous Space and staged to the newly specified Space. If billing integration is enabled in a Product, you cannot re-stage the same Product version into a non-production, or production, Catalog. For more information about billing integration, see Monetizing your Products.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **`X-IBM-Client-Id`** or **`X-IBM-Client-Secret`**.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of **`$ref`** properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **`$ref`** field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

To stage a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
2. In the navigation pane, click Develop.
3. Select the Products tab.
4. You can stage a Product either from the Develop listing page, or from within the Product itself.
    a. To stage a Product from the Develop listing page, click the options menu icon alongside the required Product version, and then select Stage.
    b. To stage a Product from within the Product itself, complete the following steps:
        i. Click the Product version that you want to work with.
        ii. Click the options menu icon:
        
        iii. Select Stage.
5. Select the Catalog to which you want to stage the Product.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.
7. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. Click Next.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

What to do next

- Publish your Product for application developers to access it in the Developer Portal. For more information, see Publishing a Product.

Related information

- Managing your Products
- Removing a Product from a Catalog
- Working with Products in the API Manager

Publishing a draft Product

Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.
Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Manage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

You cannot re-publish a Product version to a production Catalog, you must create a new version of the Product for publication; see Creating a new version of your Product. If Spaces are enabled in a production Catalog, you cannot re-publish the same Product version to any Space in the Catalog, neither the same Space nor a different Space.

You can, however, re-publish a Product version to the Sandbox Catalog, or other non-production Catalog, for ease of iterative testing. When you re-publish a Product version to a non-production Catalog, you can choose whether or not to preserve any application subscriptions; deleting subscriptions can facilitate scripted deployment in a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts.

If Spaces are enabled in a non-production Catalog and you re-publish a Product version to a different Space to the one in which it was previously published, it is removed from the previous Space and published to the newly specified Space.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **`X-IBM-Client-Id`** or **`X-IBM-Client-Secret`**.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of **`$ref`** properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **`$ref`** field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

To publish a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
2. In the navigation pane, click Develop.
3. Select the Products tab.
4. You can publish a Product either from the Develop listing page, or from within the Product itself.
   a. To publish a Product from the Develop listing page, click the options menu icon alongside the required Product version, and then select Publish.
   If you are re-publishing a Product to non-production Catalog, and the Product has application subscriptions, the Publish option deletes them. To preserve application subscriptions, click Publish (Preserve Subscriptions) instead.
   Note: If there are any existing subscriptions to the Product, the Publish (Preserve Subscriptions) operation will fail if you remove any consumer organizations or consumer organization groups from the Product visibility or subscribability settings; you can, however, add further organizations or groups.
   For information on managing visibility and subscribability settings, see Editing a draft Product.

   For information on consumer organization groups, see Working with consumer organization groups.

   b. To publish a Product from within the Product itself, complete the following steps:
      i. Click the Product version that you want to work with.
      ii. Click the options menu icon:

      iii. Select Publish.
5. Select the Catalog to which you want to publish the Product. You must have a compatible gateway type associated with the catalog to proceed, as described in Creating and configuring Catalogs.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.

7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. The Visibility and Subscribability sections display the visibility and subscribability settings that have been configured for the draft Product, but you can modify these before publishing if required; proceed as follows:
   a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
   b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
   If you select Custom, use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
   Note:
   - If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
   - If custom visibility or subscribability has already been configured in the draft Product, the titles that are displayed in the table of selected organizations and groups are derived by taking the names that are defined in the draft Product and finding the corresponding titles in the Catalog that has been selected as the publish target.
9. Click Publish.

Results

Your Product is published to a Catalog. The state of the Product is shown as Published in the header of the Product itself, and you can click Published to see which Catalogs or Spaces the Product is published to.

You can also view the state of the product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

If your Product is DataPower® API Gateway compatible, the following states are available:

Staged - Success
: The product is successfully staged and ready for publishing. This phase prepares the product for availability in the Catalog.

Published-in-progress
: The product is published to the Catalog. Publishing to the Gateway(s) is in progress.

Published-success
: The product is successfully published to the Catalog and the Gateway(s).

Published-failed
: The product is published to the Catalog, but publishing to the Gateway(s) failed.
Note:
If the product is published to multiple Gateways, the operation might succeed on some and fail on others.

You can view the status for each Gateway by expanding the panel. APIs in this state cannot be invoked. Although subscriptions can still be created, they will not function as expected.

Deprecated - In Progress
: The product is being deprecated in the Catalog, and deprecation is in progress on the Gateway(s). During this phase, new subscriptions are restricted, and the product is prepared for retirement.

Deprecated-success
: The product is deprecated. Existing subscriptions remain active, but new subscriptions are blocked.

Deprecated - Failed
: The product is deprecated in the Catalog, but deprecation failed on Gateway(s). Because the Catalog status is Deprecated, new subscriptions are blocked. Existing subscriptions remain active.

Retired-in-progress
: The product is being retired from the Catalog, and retirement is in progress on the Gateway(s).

Retired - Success
: The product is retired. It is no longer available, and all subscriptions are terminated.

Retired - Failed
: The product is retired in the Catalog, but retirement failed on Gateway(s).
Note:
If the product is retired to multiple Gateways, the operation might succeed on some and fail on others.

You can view the status for each Gateway by expanding the panel. On Gateways where retirement fails, the product remains in the Published state, and all subscriptions continue to be active.

To know more about the status of a product, click the information icon next to the product. A window with the product's state details opens. It shows the plan, subscription, and product status.
Note: The DataPower Gateway (v5 compatible) products do not have this feature.
If required, you can hide the product status feedback on the products page, see Disabling the status feedback on products page.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the publishing state. The Product is published to the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see Publishing a Product.
For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Creating a new version of your Product

You can have multiple versions of a Product in IBM® API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.

Before you begin

Create your Product and assign it a version. For more information, see Creating a draft Product.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create multiple versions of a Product, and these versions can be named according to your own preferences, and function as distinct Products when staged.

Procedure

To create a new version of a Product, complete the following steps:

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon, then click Save as a new version.
   The Save Product as a new version window opens.
4. Enter your new version number, then click Save.

Results

Your Product is saved as a new version.

Related information

- Managing your Products
- Working with Products in the API Manager

Specifying the gateway type for a Product

You can edit the Product configuration to specify a gateway type.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See Specifying the gateway type for an API definition.

When you create a new Product, or import a Product definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new Product

Gateway Service enablement in Sandbox Catalog	Default gateway type for new Product
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import a Product definition that already has a gateway type configured, that gateway type is retained.
For details of how to enable gateway services in a Catalog, see Creating and configuring Catalogs.

Procedure

To specify the gateway type for a Product, complete the following steps:

1. Ensure that you know the type of gateway that your APIs are configured to use.
2. In the navigation pane, click Develop, then select the Products tab.
3. Click the title of the Product you want to update.
4. On the Product Setup page, go to the Gateway Type section. Select the gateway type for your Product:
   - DataPower Gateway (v5 compatible)
   - DataPower API Gateway

   Note:
   You can only select the gateway type that satisfies the selected enforced APIs in your Product. To change the APIs included in your product, see Editing a draft Product.
5. Click Save to retain your changes.

Deleting a draft Product

You can delete draft Products that are no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Product-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Note:

- Deleting a draft Product does not remove it from any Catalogs to which it has been published. For details on how to remove a Product from a Catalog, see Removing a Product from a Catalog.
- You cannot directly delete a Product that was generated automatically from an API with the Activate API option; these Products have the title *api_title* auto product. To delete such Products, delete the API from which it was generated; the Product is deleted together with the API. For more information, see Deleting an API definition.

Procedure

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to delete, click the options icon ⋮ and then click Delete.

Organizing your Products into categories

You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal, in their defined categories.

Before you begin

Your role must have the necessary permissions to stage and publish Products.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal.
Note: Organizing Products into a hierarchical view in the API Designer or API Manager UI is different to tagging in the Developer Portal.

Procedure

1. In the navigation pane, click Develop, then select the Products tab..
2. Click the title of the Product that you want to work with.
3. Click Categories.
4. In the Categories text box, enter the hierarchical taxonomy path that you want your Product to follow, in the following format:

   ```
   top_level_element / next_level_element / x_level_element
   ```

   For example:

   ```
   Animals / Fluffy / Cat
   ```

5. After you have completed entering the category specifications for the Product, click Save.

What to do next

- Publish the Product; see Publishing a draft Product.
- After publishing the Product, you can, in the Developer Portal, display Products in the categories that you have defined. For more information, see Displaying APIs and Products in categories.

Creating and validating API and Product definitions by using the CLI

The developer toolkit of IBM® API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.

The following topics explain how to use the command line interface to create an OpenAPI definition file, create a Product definition file, and validate a YAML or JSON definition.

- **Creating an OpenAPI definition file**
  APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the **create** command and then modify it by using an editor of your choice.
- **Specifying a gateway type for an API definition**
  An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify which type of gateway the API uses.
- **Referring to an extension in an API definition**
  To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an `extensions` key under `x-ibm-configuration`.
- **Using $ref to reuse code fragments in your OpenAPI files**
  If you deploy an API to an IBM API Connect Management server by using the developer toolkit command line, you can use the `$ref` field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the `$ref` field is replaced with the contents of the target file.
- **Creating a Product definition file**
  You define a Product by creating a Product definition file.
- **Using x-ibm-languages to create multilingual API and Product documentation**
  Create multilingual API and Product documentation by using the `x-ibm-languages` extension in your API and Product OpenAPI definitions.
- **Using x-example to control the examples displayed in the Developer Portal**
  OpenAPI does not support the use of `example` attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use `x-example` in OpenAPI parameters.
- **Using x-embedded-doc to add additional documentation to products and APIs**
  You can use `x-embedded-doc` to add additional documentation to a product or an API as part of their definition.
- **Using x-pathalias to give consistent URLs for products and APIs**
  You can use `x-pathalias` to assign a URL to a product or an API.
- **Validating the YAML or JSON definition of an API or Product**
  You can validate a YAML or JSON definition by using the IBM API Connect developer toolkit.
- **Creating and using API and Product definitions templates**
  You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Creating an OpenAPI definition file

APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the **create** command and then modify it by using an editor of your choice.

You can stage or publish the API directly to a Catalog in API Manager by referencing the API in a Product definition file, and then using the `apic products:publish` command to publish the Product. You can also create a draft API in API Manager by using the **apic draft-apis:create** command.

You can create an API in the CLI by running `apic create:api`, and supplying additional arguments on the command line.

Another option is to create an API interactively in the command line by running `apic create:api` and following the prompts.

You can see further details and available options for the `apic create:api` command by running:

```
apic create:api --help
```

IBM provides an extension to the OpenAPI specification; this extension is described in IBM extensions to the OpenAPI specification.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

Creating an API definition from a template

You can use a custom Handlebars template to create an API by using the following command:

```
apic create:api --template template_filename --title api_title
```

where *template_filename* is the name of the Handlebars template to use, and *api_title* is the title of your API.
An API template file must have a .hbs file name extension. You can create a template from scratch, or start with the example (default) API template provided in API and Product definition template examples.

You can create multilingual API and Product documentation by using an `x-ibm-languages` extension directly in the OpenAPI definition. For more information, see Using x-ibm-languages to create multilingual API and Product documentation.

- **IBM extensions to the OpenAPI specification**
  You use the `x-ibm-configuration` object in your OpenAPI definition file to add extensions that are specific to IBM API Connect.

Related reference

- API development and management commands

IBM extensions to the OpenAPI specification

You use the **x-ibm-configuration** object in your OpenAPI definition file to add extensions that are specific to IBM® API Connect.

The x-ibm-configuration extension has the following structure:

```
x-ibm-configuration:
  enforced: enforced_boolean
  forceHttp500ForSoap11: forceHttp500ForSoap11_boolean
  compile-json-schemas: compile_json_schemas_boolean
  phase: Phase
  testable: test_boolean
  cors:
    enabled: cors_boolean
  buffering: buffering_boolean
  activity-log:
      activity_logging_extension
  assembly:
    execute:
      - assembly_component
  gateway: gateway_type
  type: api_type
  properties:
      properties_extension
  catalogs:
      catalogs_extension
```

The following table lists the various extensions used by API Connect, whether they are required, a description of their use and behavior, and their type.

Table 1. IBM extensions

Extension	Required	Description	Type
phase	No	Use the phase extension to describe the maturity of the API. It can take the following values: • **identified**: the API is in the early conceptual phase and is neither fully designed nor implemented. • **specified**: the API has been fully designed and passed an internal milestone but has not yet been implemented. • **realized**: the API is in the implementation phase.	String
testable	No	Use the **testable** extension to specify whether the API can be tested using the test tool in the Developer Portal.	Boolean
enforced	No	Use the **enforced** extension to specify if the API Connect gateway is used to enforce the API. • **true** indicates that the API Connect gateway is used to enforce the API. • **false** indicates that the API Connect gateway is not used to enforce the API.	Boolean
cors	No	Use the **cors** extension to specify whether CORS access control is used for the API. The extension has an **enabled** field which is a Boolean.	Object (with a single Boolean field)
API Gateway only activity-log	No	Use the **activity-log** extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.	Object
assembly	No	Use the **assembly** extension to describe the application of policies and logic to an API. It contains an **execute** field that contains an array of policies that are applied in order. It can contain a **catch** field that contains an array of error cases to be caught. For information about use of the **execute** field, see execute. For information about use of the **catch** field, see catch.	Object
gateway	No	Use the **gateway** extension to specify which type of gateway you want to use. If you are using the DataPower® Gateway (v5 compatible) or DataPower API Gateway, it must be included and take one of the following values: • `datapower-gateway` (DataPower Gateway (v5 compatible)) • `datapower-api-gateway` (DataPower API Gateway) For information about types of gateways, see API Connect gateway types.	String
type	No	The **type** extension takes one of the following values: • **rest** • **wsdl**	
properties	No	Use the **properties** extension to define properties for use in an API.	Object (properties)
catalogs	No	Use the **catalogs** extension to define Catalog-specific values for properties defined in the **properties** extension.	Object (catalogs)
API Gateway only forceHttp500ForSoap11	No	Use the **forceHttp500ForSoap11** extension to force a 500 response code when an error occurs on a SOAP 1.1 API. This property works only with DataPower fix packs containing APAR IT46043.	Boolean
compile-json-schemas	No	Use this extension to enable precompilation of JSON schemas during configuration deployment. When set to true, JSON schemas are compiled and cached as the new configuration is applied, ensuring the compilation is ready and available when the first message is processed.	Boolean

Extension	Required	Description	Type
buffering	No	Use this extension to control whether to buffer API requests and responses before processing. It enables the DataPower **message-buffering** command • **true**: buffer API requests and responses before processing. API requests and responses are read as a binary large object (BLOB). • **false**: do not buffer API requests and responses before processing. API requests and responses are streamed. Only an asynchronous API call can read the streamed data. If the message processing requires parsing data at the payload level, then buffering is performed to capture the data. This setting is the default value.	Boolean

The following example shows the **x-ibm-extension** section of an API that is enforced by API Connect, is in the realized state, is testable through the test tool in the Developer Portal, has CORS access control enabled, and has a simple assembly that invokes a URL and then redacts a field from the request or response.

```
x-ibm-configuration:
  enforced: true
  phase: realized
  testable: true
  cors:
    enabled: true
  assembly:
    execute:
      - invoke:
          title: Example Invoke
          target-url: 'https://example.com/api'
          description: Example description
      - redact:
          actions:
            - action: redact
              from:
                - request
                - response
              path: //*[@name='secondaryAddress']/*[@name='streetAddress']
  properties:
    ID:
      value: 1234
      description: An ID to be used for validating.
      encoded: false
  catalogs:
    Sandbox:
      properties:
        ID: 5678
```

- **catch**
  Use the catch extension to catch errors that occur during an API call.
- **properties**
  Use the **properties** extension to define properties for referencing in an API.
- **catalogs**
  Use the **catalogs** extension to assign catalog-specific values to properties defined in the **properties** section.
- **activity-log**
  If you're using the DataPower API Gateway, you can use the **activity-log** extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.
- **finally**
  The finally extension specifies the final API rule to apply to the API call. This executes policies after the main assembly execution, catch extension, or both have been processed. It ensures that specific actions are performed before the API response is returned.

execute

The execute field of an assembly has the following structure:

```
execute:
 - Policy_1
 - Policy_2
```

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

- 
Indicates that the policy can be run on the DataPower Gateway (v5 compatible).
-

Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see API Connect gateway types.

The following table describes the possible policies and logic constructs that can be included in an execute field.

Table 1. execute properties

Property	Required	Description	Data Type	DataPower Gateway	API Gateway
activity-log	No	Use the activity-log policy to log information that relates to the calling of API operations.	object (activity-log)	✓	✓ Functionality provided by the activity-log extension

Property	Required	Description	Data Type	DataPower Gateway	API Gateway
client-security	No	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	object (client-security)	✗	✓
gatewayscript	No	Include a GatewayScript program.	object (gatewayscript)	✓	✓
graphql-cost-analysis	No	Use the graphql-cost-analysis policy to return a cost analysis of a target query.	object (graphql-cost-analysis)	✗	✓
graphql-execute	No	Use the graphql-execute policy to execute a GraphQL query by using sub-queries.	object (graphql-execute)	✗	✓
graphql-introspect	No	Use the graphql-introspect policy to introspect a GraphQL schema.	object (graphql-introspect)	✗	✓
if	No	Use the if policy to execute a section of the assembly only when a condition is fulfilled.	object (if)	✓	✓ Functionality provided by switch
invoke	No	Use the invoke policy to call an API. The last invoke in your policy might be replaced by a proxy automatically to improve performance. To disable this, see: API properties.	object (invoke)	✓	✓
json-to-xml	No	Convert payload from JSON to XML.	object (json-to-xml)	✓	✓
jwt-generate	No	Generate a JSON Web Token (JWT).	object (jwt-generate)	✓	✓
jwt-validate	No	Validate a JSON Web Token (JWT).	object (jwt-validate)	✓	✓
log	No	Use the log policy to customize or override the default activity logging configuration for an API.	object (log)	✗	✓
map	No	Use the map policy to transform variables.	object (map)	✓	✓
operation-switch	No	Use the operation-switch policy when you want to execute alternative policy assemblies, conditional on the operation that is being called.	object (operation-switch)	✓	✓
oauth	No	Use the oauth policy to policy to perform OAuth processing based on defined OAuth provider settings.	object (oauth)	✗	✓
parse	No	Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	object (parse)	✗	✓
proxy	No	Proxy a service.	object (proxy)	✓	✓ Functionality provided by invoke
ratelimit	No	Use the ratelimit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	object (ratelimit)	✗	✓
redact	No	Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	object (redact - DataPower API Gatewayredact - DataPower Gateway (v5 compatible))	✓	✓
set-variable	No	Use the set-variable policy to set a runtime variable to a string value, or to add or clear a runtime variable.	object (set-variable)	✓	✓
switch	No	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	object (switch)	✓	✓
throw	No	Use the throw policy to specify points at which an error should be thrown.	object (throw)	✓	✓
user-defined-policy	No	You can apply your own user-defined policies to your APIs.	object (User-defined policies)	✓	✓
user-security	No	Extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	object (user-security)	✗	✓
validate	No	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	object (validate - DataPower API Gateway, validate - DataPower Gateway (v5 compatible))	✓	✓
validate-usernametoken	No	Validate a WS-Security UsernameToken.	object (validate-usernametoken)	✓	✗
xml-to-json	No	Convert payload from XML to JSON.	object (xml-to-json)	✓	✓
xslt	No	Apply an XSLT transform to the payload.	object (xslt)	✓	✓

The following example shows an execute field for an assembly that invokes a URL and then redacts a field from the request or response.

```
execute:
 - invoke:
  title: Example Invoke
  target-url: 'https://example.com/api'
  description: Example description
 - redact:
  actions:
   - action: redact
     from:
      - request
      - response
    path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

activity-log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Activity Log.

Note: If you are using the DataPower API Gateway, you configure your logging preferences by using the activity-log extension.

About

The activity-log policy has the following format:

```
- activity-log:
  version: version
  title: title
  description: description
  content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

You can also apply an activity-log policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Activity Log in the built-in policies section.

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
buffering: true
```

Properties

The following table describes the policy properties:

Table 2. Activity Log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	A title for the policy.	string
description	No	A description of the policy.	string
content	Yes	Defines the type of content to be logged when the operation is successful. Valid values: • `none`: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • `activity`: Logs invocation only (only the resource URI is recorded). • `header`: Logs activity and header. • `payload`: Logs activity, header, and payload (the original request, if any, and the final response). The default value is `activity`.	string
error-content	No	Indicates what content to log if an error occurs. Valid values: • `none`: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • `activity`: Logs invocation only (only the resource URI is recorded). • `header`: Logs activity and header. • `payload`: Logs activity, header, and payload (the original request, if any, and the final response). The default value is `payload`.	string

Example 1

```
# use defaults

- activity-log:
  version: 1.0.0
  title: default activity logging
```

Example 2

```
- activity-log:
  version: 1.0.0
  title: no logging for successful calls
  content: none
  error-content: activity
```

client-security

The client-security policy can be used to extend client authentication access for your APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Client Security.

About

You use the client-security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
  - For all methods except `http`, use the id-name and the secret-name properties to specify the location that contains the ID and the location that contains the secret.
    - When `cookie`, specify which cookie.
    - When `context-var`, specify which runtime context variable.
    - When `form`, specify the form data.
    - When `header`, specify which header.
    - When `query`, specify which query parameter.
  - For the `http` method, use the http-type property to specify the format of the authorization header, which expects the `basic` form in the `basic base64_id:secret` format.
- Define the method to authenticate the extracted client credentials. The supported methods are `native` (this means by using IBM® API Connect), or by using a specified `third-party` user registry.
  - If `third-party`, use the user-registry property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The client-security policy has the following format:

```
- client-security:
    version: version
    title: title
    description: description
    stop-on-error: is_processing_stopped_on_client_security_failure
    secret-required: is_client_secret_required_in_request
    extract-credential-method: method_for_supplying_credentials
    id-name: parameter_that_specifies_client_id
    secret-name: parameter_that_specifies_client_secret
    http-type: authentication_type
    client-auth-method: method_for_client_authentication
    user-registry: user_registry_for_client_authentication
```

Table 2. client-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
stop-on-error	Yes	If set to `true`, assembly processing stops if client security fails, and an error is returned.	boolean
secret-required	Yes	If set to `true`, the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID.	boolean

Property	Required	Description	Data type
extract-credential-method	Yes	Specify one of the following values to define how the calling application authenticates: • **header**: client ID and client secret credentials must be supplied in the request header. • **query**: client ID and client secret credentials must be supplied as query parameters in the request URL. • **form**: client ID and client secret credentials must be supplied as form data sent in a POST request. • **cookie**: client ID and client secret credentials must be supplied in a header called **Cookie**. • **http**: the calling application must authenticate by using basic authentication. • **context-var**: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a gatewayscript policy for example. The names of these context variables are determined by the values that you supply in the id-name and secret-name properties of the client-security policy.	string
id-name	Yes, unless extract-credential-method is set to **http**	The name of the parameter whose value specifies the client ID. For all values of extract-credential-method other than **context-var** and **http**, the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For **context-var**, this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to **http**.	string
secret-name	Yes, if secret-required is set to **true** and extract-credential-method is other than **http**	The name of the parameter whose value specifies the client secret. For all values of extract-credential-method other than **context-var** and **http**, the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For **context-var**, this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to **http**.	string
http-type	Yes, if extract-credential-method is set to **http**	The authentication type. Currently, this must be set to **basic**.	string
client-auth-method	Yes	Specify one of the following values: • **native**: only client ID and client secret are used to authenticate the request. If extract-credential-method is set to **http** then the calling application must supply the client ID for the user name, and the client secret for the password. • **third-party**: a user registry is used to authenticate the client. If extract-credential-method is set to a value other than **http** then the calling application must supply the user name for the client ID, and the password for the client secret.	string
user-registry	Yes, if the client-auth-method is set to **third-party**	Specify the value of the **name** property of the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

client-security policy example

```
- client-security:
    version: 2.0.0
    title: client-security
    stop-on-error: true
    secret-required: true
    extract-credential-method: cookie
    id-name: my-client-id
    secret-name: my-client-secret
    client-auth-method: third-party
    user-registry: myauthurl
```

API Gateway only

extract

Use the extract policy to extract and transform data from fields in the API context.

Gateway support

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Extract.

About

The extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see Constructing JSONata expressions to extract and transform data.

The input to the extract policy must be parsed data. One way to produce parsed data is to add a parse policy before the extract policy in your assembly.

The extract policy has the following format:

```
- extract:
    version: 2.0.0
    title: title
    root: data source
    extracts:
      - capture: path expression that identifies the field
        transform: expression that defines how to transform the content
                   .
                   .
                   .
    description: description
```

Apply this policy by adding an **assembly** extension with an **execute** field to your OpenAPI definition file.

Properties

Table 2. extract policy properties

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	Yes	The title of the policy. The default value is **extract**.	string
description	No	A description of the policy.	string
root	Yes	The data source that contains the content to transform. The default value is **message.body**.	string
capture	Yes	The path expression that identifies the field. The default setting is **$**, which indicates the entire input.	string
transform	Yes	The expression that defines how to transform the content.	string

Example

Transform the contents of the **account** field to include only the last 4 characters.

```
- extract:
    version: 2.0.0
    title: extract
    root: message.body
    extracts:
      - capture: $.members.policy.**.account
        transform: $substring($,-4)
    description: Include only the last 4 characters of the account field.
```

gatewayscript

Use the gatewayscript policy to execute a specified DataPower GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GatewayScript.

About

The gatewayscript policy has the following structure:

```
- gatewayscript:
    version: version
    title: Title
    desription: Description
    source: Script
```

Properties

The following table describes the policy properties:

Table 2. gatewayscript policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string

Property	Required	Description	Data type
title	No	The title of the policy.	string
description	No	A description of the policy.	string
source	Yes	The GatewayScript source code to execute.	string

Example

The following is an example of a simple gatewayscript policy:

```
- gatewayscript:
    version: 1.0.0
    title: Example_GatewayScript
    source: console.debug('Hello World!');
    description: A simple GatewayScript policy.
```

For more information about how to use a gatewayscript policy, see GatewayScript in the built-in policies section.

For more code examples, see GatewayScript code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- GatewayScript APIs for API management
- Accessing and manipulating a variable in the API context
- OAuth context variables

API Gateway only

gemini-invoke

Use the Gemini invoke policy to invoke Gemini operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Gemini invoke.

About

The Gemini invoke policy provides access to six Gemini operations:

- `POST models/[model]:generateContent`
- `POST models/[model]:countTokens`
- `POST models/[model]:embedContent`
- `POST models/[model]:batchEmbedContents`
- `GET models/[model]`
- `GET models`

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Gemini invoke policy properties

Property name	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is Gemini invoke count tokens.	string
description	No	A description of the policy.	string

Property name	Required	Description	Data type
operation	Yes	The Gemini operation to invoke; must be one of the following operations: • **`POST models/[model]:generateContent`** An HTTP POST operation for **`generateContent`**. See Generating Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:countTokens`** An HTTP POST operation for **`/countTokens`**. See Counting tokens in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:embedContent`** An HTTP POST operation for **`embedContent`**. See Embed Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:batchEmbedContents`** An HTTP POST operation for **`batchEmbedContents`**. See Batch Embed Content in the Gemini API documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the Gemini API documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the Gemini API documentation for sample response examples.	string
api_key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Gemini requests.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the Gemini service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into theDataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the Gemini service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
path_params	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
query_params	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
output	No	The name of the DataPower API Gateway context message that receives the Gemini response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Example

```
gemini-invoke:
                    title: Gemini invoke count tokens
                    enable_cache: true
                    version: 2.0.0
                    api_key: $(gemini-apikey)
                    cache_ttl: 60
                    operation: POST models/[model]:countTokens
                    output: message
                    description: description goes here
                    cache_scope: cachescopevalue
```

graphql-cost-analysis

Use the graphql-cost-analysis policy to return a cost analysis of a target query.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GraphQL Cost Analysis.

Properties

Table 2. graphql-cost-analysis policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
input	No	A variable in the API context that contains the input to the GraphQL cost analysis. The content of the body field of the variable is the GraphQL cost query. By default, the variable name is **message**. The query should be in the format as specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.	string
output	No	A variable in the API context where the results of the GraphQL cost analysis are stored. The content of the body field of the variable is the result of GraphQL cost analysis. The default variable name is the same as that of the variable specified for the input field. Therefore, by default, the input of the GraphQL cost analysis is overwritten by the output.	string
target	No	A variable in the API context that contains the target for the GraphQL cost analysis. The content of the body field of the variable is the GraphQL context. By default, the variable name is **graphql_execute_args**. The target context specifies the query to analyze and, optionally, the result of the query execution.	string

graphql-execute

Use the graphql-execute policy to execute a GraphQL query by using sub-queries.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 (DataPower API Gateway Version 10.0.4.0 and later) 2.1.0 (DataPower API Gateway Version 10.5.2.0 and later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GraphQL Execute.

About

The graphql-execute policy executes a GraphQL query by using sub-queries. The policy splits up the original GraphQL query into different sub-queries that can then be processed in different ways. The graphql-execute policy supports the following four different sub-queries as targets:

1. **root**; contains the core GraphQL query that you want to invoke on the backend.
2. **__introspection**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend.
3. **__rateLimit**; contains the **__rateLimit** query that specifies the different rate limit data that you want to receive.
4. **__cost**; contains the **__cost** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **__cost**.

The **root**, **__rateLimit**, and **__introspection** targets can be executed in any order, or at the same time. The **__cost** target can be executed at any time if no response data is expected. If response data is expected, then the **__cost** target is executed after the **root** target in order to accurately return correct response cost data. After all the targets are executed, the graphql-execute policy combines all of the responses together. To enable the responses of the individual targets to be correctly merged with each other into a final, single response, the graphql-execute policy must include all of the introspection types that are associated with each level of the response data.
The graphql-execute policy has the following format:

```
- graphql-execute:
    version: version
    title: title
    description: description
    targets:
      - execute: []
        catch:
        - execute: []
          otherwise: []
```

Properties

Table 2. graphql-execute policy properties

Property	Required	Description	Data type

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
targets	No	The targets for the sub-queries. Valid values are: • `root`; contains the core GraphQL query that you want to invoke on the backend. • `__introspection`; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend. • `__rateLimit`; contains the `__rateLimit` query that specifies the different rate limit data that you want to receive. • `__cost`; contains the `__cost` query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: `__cost`.	string

Example

The following example shows a graphql-execute policy that includes all of the available targets.

```
- graphql-execute:
    title: GraphQL execute
    version: 2.1.0
    allowCostIntrospection: false
    targets:
      - target: root
        execute:
          - validate:
              input: message
              version: 2.7.0
              validate-against: graphql
              description: >-
                Validate the GraphQL query and analyze
                the expected cost
              title: validate & analyze
          - ratelimit:
              version: 2.4.0
              title: ratelimit expected
              description: >-
                Consume expected cost of query from rate
                limits
              rate-limit:
                - name: graphql-type-cost
                  operation: consume
                - name: graphql-field-cost
                  operation: consume
              burst-limit: []
              source: plan-named
          - invoke:
              cache-ttl: 900

                target: graphql_execute_args
```

graphql-introspect

Use the graphql-introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GraphQL Introspect.

Properties

Table 2. graphql-introspect policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
input	No	A variable in the API context that contains the input to introspect. The content of the `body` field of the variable is the input to introspect. By default, the variable name is `message`.	string
output	No	A variable in the API context where the results of the introspection are stored. The content of the `body` field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified for the `input` field. Therefore, by default, the input of the introspection is overwritten by the output.	string

Example

```
- graphql-introspect:
    version: 2.0.0
    title: introspect the accounts graphql schema
    input: message
```

API Gateway only

ibm-cloud-authentication

Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see IBM Cloud Authentication.

About

The ibm-cloud-authentication policy provides an API key to the IBM Access Manager and, if successfully authenticated, returns a Bearer token to be used by all subsequent watsonx.ai operation requests. The Bearer token is cached and will be valid for approximately 60 minutes. A new token is retrieved when a response for the API key was not cached. or expired.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. ibm-cloud-authentication policy properties

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is `ibm-cloud-authentication`. The title displays in the API assembly editor in the UI.	string

Property label	Required	Description	Data type
description	No	A description of the policy.	string
apikey	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate subsequent watsonx.ai requests.	string

Example

```
- ibm-cloud-authentication:
    version: 2.0.0
    title: ibm-cloud-authentication
    apikey: $(watsonx-ai-apikey)
```

if

Use the if construct when you want to execute a portion of your assembly only when a specific condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see if.

About

The if policy has the following format:

```
- if:
  version: version
  title: title
  description: description
  condition: 'condition_1
      execute:
        policy_assembly_1 ...
```

In the condition field, use the form `apim.getvariable('context.location.variable')` to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

The `execute:` section can define any policy assembly, including further if policies. For more information, see execute.

Properties

Table 2. if policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
condition	Yes	A script that returns `true` or `false`. Use GatewayScript for a DataPower Gateway implementation. For information about the context variables you can use and how to reference them in your script, see API Connect context variables.	string
execute	Yes	The policy assembly that you want to execute if the condition returns `true`. For more information, see execute.	string

Example

```
# carry out different redaction actions depending on the operation

- if:
  version: 1.0.0
  title: clear_region_and_set_body
  condition: 'apim.getvariable('request.body.secret') == true'
    execute:
      - redact:
          title: remove secret field
          actions:
            - action: remove
              from: all
              path: /document/user/secret
```

invoke

Use the invoke policy to call an API.

Gateway support

Restriction: It is not possible to cache a request that includes the Authorization request header.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.1 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Invoke.

About

The invoke policy has the following format:

```
- invoke:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  backend-type: how_payload_is_sent_to_backend
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
  password: password_if_authentication_required
  output: location_of_the_invoke_result
  cache-key: unique_identifier_of_the_document_cache_entry
  cache-response: cache_behavior
  cache-putpost-response: response_caching_behavior
  cache-ttl: cache_time_to_live
  inject-proxy-headers: are_proxy_headers_sent_to_target_url
  decode-request-params: are_request_parameters_decoded
  encode-plus-char: are_plus_characters_encoded
  keep-payload: is_payload_sent_on_delete
  use-http-10: are_transactions_restricted_to_http_1.0
  chunked-uploads: are_chunked_encoded_documents_sent_to_the_server
  persistent-connection: are_persistent_connections_enabled
  header-control:
        .
        .
        .
    headers_to_copy_to_target_url
        .
        .
        .
  parameter-control:
        .
        .
        .
    parameters_to_copy_to_target_url
        .
        .
        .
  follow-redirects: url_redirection_behavior
  stop-on-error: errors_that_stop_the_flow
```

Properties

The following table describes the properties of the invoke policy.

Table 2. Invoke policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
target-url	Yes	The URL of the target API. Note: Do not manually append path or query parameters to the target-url field in the invoke policy. If these parameters are defined in the API operation, API Connect injects them into the target URL at run time. Avoid manually adding values such as **$(request.search)** or path segments, as doing so might result in duplication or malformed URLs. Use the **parameter-control** policy to manage query parameter inclusion.	string

Property	Required	Description	Data type
API Gateway only backend-type	No	Specify one of the following values to determine how the payload is sent to the backend: • **detect**: detect the message type and send the payload to the backend accordingly. • **xml**: package the payload as XML and send. If the message type is not XML, the operation fails. • **json**: package the payload as JSON and send. If the message type is not JSON, the operation fails. • **binary**: package the payload as binary and send, regardless of the message type. • **graphql**: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. The default value is **detect**.	string
API Gateway only graphql-send-type(policy version 2.2.0 and later)	Yes, if backend-type is set to **graphql** or **detect**, and verb is set to **POST** or **keep**.	Specify one of the following values to determine how the GraphQL payload is sent to the back end: • **detect**: detect the message type and send the payload to the back end accordingly. • **graphql**: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. • **json**: package the payload as JSON and send. If the message type is not GraphQL, the operation fails. Note: graphql-send-type is supported only if backend-type is set to **graphql** or **detect**, and verb is set to **POST** or **keep**.	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data. Note: If you want to edit the API in the source view, make sure that the tls-profile value follows this format: name:version. For instance, it should look like nameofmytlsclientprofile:1.0.0.	string
verb	No	The operation method type. Valid values: • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **GET**. However, if the property is omitted from the source, the HTTP method from the incoming request is used.	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
API Gateway only http-version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Valid values: • **HTTP/1.0** • **HTTP/1.1** • **HTTP/2**	string
API Gateway only http2-required (policy version 2.1.0 and later)	No	Set this property to **true** to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if http-version is set to **HTTP/2**.	boolean
compression	No	Specifies whether data is to be compressed by using compress before it is uploaded. The default value is **false**.	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
output	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable *message*. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as map. Note: If you want the response to be saved in *message*, leave the output property blank, do **not** supply the value `message`.	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
API Gateway only websocket-upgrade (policy version 2.1.0 and later)	No	Set this property to **true** to allow an HTTP or HTTPS connection to be upgraded to the WebSocket protocol if the request received by the corresponding HTTP or HTTPS handler on the DataPower API Gateway uses WebSocket (ws) or WebSocket Secure (wss). Note: • This property is available only for GraphQL APIs. • The **websocket-upgrade** property is deprecated. To allow WebSocket upgrade requests that can manage API processing data, define an assembly WebSocket upgrade policy. For more information, see websocket-upgrade.	boolean

Property	Required	Description	Data type
cache-response	No	The cache response type. Valid values: • **protocol**: The cache behavior is defined by the Cache-Control headers on the request and response. • **no-cache**: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. • **time-to-live**: Specifies that the response stays in the cache for the specified time. The default value is **protocol**.	string
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is **false**.	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to **time-to-live**. Enter a value in the range 5 - 31708800. The default value is **900**. Note: When users sign in by using the Toolkit login path (a URL that includes **?from=TOOLKIT**), the generated API key has a fixed time-to-live (TTL) of 5 minutes.	integer
API Gateway only inject-proxy-headers	No	When set to true, the **invoke** policy injects the **X-Forwarded-For**, **X-Forwarded-To**, **X-Forwarded-Host**, and **X-Forwarded-Proto** headers to the request that is sent to the t**target-url**. The default value is **false**.	boolean
API Gateway only decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the **target-url** of the invoke policy are URL-decoded. The default value is **false**.	boolean
API Gateway only encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the **target-url** are encoded to %2F. The default value is **false**.	boolean
API Gateway only keep-payload	No	When set to true, the invoke policy sends a payload on an **HTTP DELETE** method. The default value is **false**.	boolean
API Gateway only use-http-10 (policy version 2.0.0 only)	No	When set to true, HTTP transactions are restricted to version 1.0. The default value is **false**.	boolean
API Gateway only chunked-uploads	No	If you set this property to **true**, chunked-encoded documents are sent to the server. When the HTTP 1.1 protocol is used, the body of the document can be delimited by either **Content-Length** or chunked encoding. While all servers can interpret **Content-Length**, many applications fail to understand chunked-encoded documents. For this reason, **Content-Length** is the standard method. The use of **Content-Length** interferes with the ability of the DataPower Gateway to fully stream. If you must stream full documents to the target server, enable this property. When enabled, the server must be RFC 2616 compatible. Unlike all other HTTP 1.1 features that can be negotiated down at run time, you must know beforehand that the target server is RFC 2616 compatible. The default value is **true**. Note: Chunked encoding is not supported by the HTTP 1.0 protocol.	boolean
API Gateway only persistent-connection (policy version 2.3.0 and later)	No	Set this property to **true** to enable HTTP persistent connections, allowing connection re-use. The default value is **true**.	boolean
API Gateway only **header-control:** **type** **values**	No	Specifies the headers in **message.headers** that you want to copy to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the headers that you don't want to be copied. If the **values** property is empty then all headers are copied. If the **type** property is set to **allowlist**, the **values** property lists the headers that you want to be copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **header-control** property is **header-control:** **type: blocklist** **values: []** See header-control examples	object

Property	Required	Description	Data type

API Gateway only
`parameter-control:`
`type`
`values`
	No	Specifies the parameters in the incoming request that you want to be copied to the target URL.
		If the `type` property is set to `blocklist`, the `values` property lists the parameters that you don't want to be copied.
		
		If the `type` property is set to `allowlist`, the `values` property lists the parameters that you want to be copied. If the `values` property is empty then no parameters are copied.
		
		The items that are listed in the `values` property are in regular expression format. The values are not case-sensitive. The default value of the `parameter-control` property is
		
		`parameter-control:`
		`type: allowlist`
		`values: []`
		
		See parameter-control examples
			object

API Gateway only follow-redirect	No	Specifies the behavior if the back-end server returns the HTTP status code `301 Moved Permanently`. If this property is set to `true`, the `invoke` policy follows the URL redirection by making a further call to the URL specified in the `Location` header in the response. If this property is set to `false`, the `invoke` saves the `301` status code and the API call is considered to be complete. Note: The `follow-redirect` property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the `invoke` always follows the URL redirection; the `proxy` policy (not supported by the DataPower API Gateway) saves the `301` status code and completes the API call without following the URL redirection.	boolean
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a `catch` flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

Example

```
- invoke:
    version: 2.0.0
    title: get the account status
    target-url: https://example.com/accounts/{id}?status={status}
    cache-response: time-to-live
    cache-putpost-response: true
    tls-profile: MyTLSProfile:1.0.0
    verb: POST
    timeout: 60
    compression: false
    username: MyUser
    password: MyPassword
    stop-on-error:
      - ConnectionError
      - OperationError
```

API Gateway only `header-control` examples

```
# copy all headers to the target URL

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values:
        - ^X-Client-ID$
        - ^Content-Type$

# copy no headers

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values: []

# copy only the Content-Type header

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^Content-Type$
```

API Gateway only `parameter-control` examples

```
# copy no request parameters to the target URL

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values: []

# append the petid parameter to the target URL
# if the incoming request is http://apigw/org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values:
        - ^petid$

# The API definition includes a query parameter petid.
# Incoming request: https://apigw/org/sandbox/pets?petid=123
# API Connect will automatically forward petid to the target URL at runtime.

- invoke:
    target-url: https://myhost/pets
    parameter-control:
      type: allowlist
      values:
        - ^petid$
```

json-to-xml

Use the json-to-xml policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see JSON to XML.

About

The json-to-xml policy has the following structure:

```
- json-to-xml:
   version: version
   title: Title
   description: Description
```

Note: If you are using the DataPower API Gateway, the input to the json-to-xml policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a json-to-xml policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
API Gateway only input	No	The input message to convert. Specify the name of a variable in the API context. ***variableName*.body**, the message payload, represents the JSON input to convert. The default value of the variable is **message** and **message.body** is the default input.	string
API Gateway only output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***variableName*.body** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **message.body**. Otherwise, when the input message is the variable **my-message-variable**, for example, the default output is **my-message-variable.body**. The variable cannot be any read-only in the API context.	string
API Gateway only conversionType	No	The conversion type that determines the target format of the output. The following options are available: • None: No conversion of the output takes place. • badgerFish: BadgerFish convention is used to determine the target conversion format of the output.	string
root-element-name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the always-output-root-element property is set to **true**.	

Property	Required	Description	Data type
always-output-root-element	Yes	Select this property to **true** you always want the policy to output the root element, even if it is not required to make the XML document well formed.	boolean
unnamed-element-name	No	The XML element name to be used for JSON array elements.	string

Example

The following is an example of a json-to-xml policy:

```
- json-to-xml:
    version: 1.0.0
    title: JSON to XML transform
    description: Transforms JSON message body to XML format
```

jwt-generate

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.1.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Generate JWT.

Note:

- For algorithm types HS256, HS384, and HS512 the cryptographic objects referenced must be a Shared Secret Key.
- For algorithm types RS256, RS384, RS512, ES256, ES384, ES512, PS256, PS384, PS512 the cryptographic objects referenced must be a Crypto Key (private key).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to sign the JWT.

About

The jwt-generate policy has the following structure:

```
- jwt-generate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  jti-claim: jwt_id_claim
  iss-claim: issuer_claim
  exp-claim: validity_period
  sub-claim: subject_claim
  aud-claim: audience_claim
  jws-jwk: sign_jwk_variable_name
  jws-alg: cryptographic_algorithm
  jws-crypto: sign_crypto_object
  custom-kid-value-jws: jws.kid
  jwe-enc: encryption_algorithm
  jwe-jwk: encrypt_jwk_variable_name
  jwe-alg: key_encryption_algorithm
  jwe-crypto: encrypt_crypto_object
  custom-kid-value-jwe: jwe.kid
```

Properties

The following table describes the policy properties:

Table 2. Generate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
jwt	No	Runtime variable in which to place the JWT that is generated. The default value is: **generated.jwt**. However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
jti-claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to **true**, and a UUID is generated and set as the JTI claim value.	boolean
iss-claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: **iss.claim**	string
sub-claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string

Property	Required	Description	Data type
aud-claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
exp-claim	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is **3600**.	integer
private-claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
jws-jwk	No	Runtime variable that contains the JWK that is used to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-alg	No	The cryptographic algorithm to use. Valid values are: • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512	string
jws-crypto	No	The cryptographic object to use to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string
custom-kid-value-jws	No	The customized **kid** value for JWT signing.	string
jwe-enc	No	The encryption algorithm to use. Valid values are: • A128CBC-HS256 • A192CBC-HS384 • A256CBC-HS512	string
jwe-jwk	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string
jwe-alg	No	The key encryption algorithm to use. Valid values are: • RSA1_5 • RSA-OAEP • RSA-OAEP-256 • dir • A128KW • A192KW • A256KW	string
jwe-crypto	No	The cryptographic object to use to encrypt the claim.	string
custom-kid-value-jwe	No	The customized **kid** value for JWT encryption.	string

Example

The following is an example of a jwt-generate policy:

```
    - jwt-generate:
        version: 2.1.0
        title: jwt-generate
        description: New jwt-generate v2.1.0 policy.
        jwt: generated.jwt
        jti-claim: true
        iss-claim: iss.claim
        sub-claim: sub.claim
        aud-claim: aud.claim
        exp-claim: 3600
        private-claims: private.claims
        jws-jwk: jws.jwk
        jws-alg: HS256
        jws-crypto: jwsCryptoObjectName
        custom-kid-value-jws: jws.kid
        jwe-enc: A128CBC-HS256
        jwe-jwk: jwe.jwk
        jwe-alg: RSA1_5
        jwe-crypto: jweCryptoObjectName
        custom-kid-value-jwe: jwe.kid
```

For more information about how to use a jwt-generate security policy, see Generate JWT in the built-in policies section.

jwt-validate

Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate JWT.

Note:

- If the original message was signed with a Shared Secret Key, the cryptographic object that is specified must also be a Shared Secret Key.
- If the original message was signed with a Private Key, the cryptographic object that is specified must be a Crypto Certificate (public certificate).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If a JWK header parameter is included in the header of the JWT, the parameter must match the JWK or cryptographic object that is specified in the policy, or the JWT validation will fail.
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to decrypt or verify the JWT.
- The JWT validate action on the DataPower API Gateway can verify a JWT by using either a single JWK, or a JWK set.

About

The jwt-validate policy has the following structure:

```
- jwt-validate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  output-claims: output_full_set_of_jwt_claims
  iss-claim: issuer_claim
  aud-claim: audience_claim
  jwe-crypto: decrypt_crypto_object
  jwe-jwk: decrypt_crypto_jwk_variable_name
  jws-crypto: verify_crypto_object
  jws-jwk: verify_crypto_jwk_variable_name
```

Properties

The following table describes the policy properties:

Table 2. Validate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
jwt	Yes	Context or runtime variable that contains the JWT to be validated. The default value is: **`request.headers.authorization`**. However, if this property is not set, the policy looks for the JWT in the **`request.headers.authorization`** location by default. Note: The format of the authorization header must be: **`"Authorization: Bearer jwt-token"`** where *jwt-token* is the encoded JWT.	string
output-claims	Yes	Runtime variable to which the full set of claims that are contained in the JWT is assigned. The default value is: **`decoded.claims`**.	string
iss-claim	No	The Perl Compatible Regular Expressions (PCRE) to use to validate the Issuer (iss) claim.	string
aud-claim	No	The PCRE to use to validate the Audience (aud) claim.	string
jwe-crypto	No	The cryptographic object (a shared key or certificate) to use to decode the claim. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jwe-jwk	No	Runtime variable that contains the JWK to use to decrypt the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-crypto	No	The cryptographic object (a shared key or certificate) to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-jwk	No	Runtime variable that contains the JWK, or a JWK set, to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string

Example

The following is an example of a jwt-validate policy:

```
- jwt-validate:
    version: 1.0.0
```

```
    title: jwt-validate
    jwt: request.headers.authorization
    output-claims: decoded.claims
    iss-claim: "'^data.*'"
    aud-claim: "'^id.*'"
    jwe-crypto: jweCryptoObjectName
    jwe-jwk: jwe.jwk
    jws-crypto: jwsCryptoObjectName
    jws-jwk: jws.jwk
```

For more information about how to use a jwt-validate security policy, see Validate JWT in the built-in policies section.

log

Use the log policy to customize or override the default activity logging configuration for an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Log.

About

The log policy has the following format:

```
- log:
  version: version
  title: title
  description: description
  mode: activity_logging_actions
  log-level: type_of_content_to_log
```

Properties

The following table describes the properties of the log policy.

Table 2. log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

mode	Yes	Specify one of the following values:
		• **`gather-only`**: gather all analytics data and write it to the **`log`** context variable, which populates the API event record on completion of the API execution. For more information on the fields in the **`log`** context variable, and the consequent API event record, see API event record field reference.
		• **`send-only`**: perform the following actions:
		  ◦ Read the data from the **`log`** context variable.
		  ◦ Truncate all message payloads and convert to a textual representation.
		  ◦ Send the data to the analytics server.
		• **`gather-and-send`**; perform a **`gather-only`** operation, immediately followed by a **`send-only`** operation.
		
		If you use the Send-only or Gather-and-send option, data is buffered and sent to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information, see Configuring an analytics endpoint in the DataPower knowledge center.
		
		Note: If you are offloading to a third party analytics server, you can redact any aspect of the event data. If you are using API Connect analytics, you can redact only request and response payloads.
			string

log-level	No	The type of content to log. Specify one of the following values: • **`none`**: Indicates no logging. • **`activity`**; Logs the invocation only, which is only the resource URI. • **`header`**: Logs activity and header. • **`payload`**:Logs activity, header, and payload. • **`default`**; Use the log level setting defined in the API definition; for more information, see activity-log. This is the default value. • **`$(value)`**: An inline parameter in the format **`$(value)`** to retrieve a value from the API context.	string

Example

```
- log:
  version: 2.0.0
  title: Gather activity log data for processing
  mode: gather-only
```

map

Use the map policy to transform your assembly flow and specify relationships between variables.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.5.0.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Map.

About

For information about the use and structure of the map policy, see The Map policy structure. For more information about API properties that affect the map policy, see API properties.

The map policy has the following format:

```
- map
   version: version
   title: title
   description: description

   inputs:
      - input_1:
         variable: context_1
         $ref: '#/definitions/definition_1'
      - input_2
         variable: context_2
         type: type_2
         content: content_type

   outputs:
      - output_3
         variable: context_3
         type: type_3

   actions:
      - set: output_3.output_property_3
        from: input_1.input_property_1

      - set: output3.output_property_3
        from:
         - input1.input_property_1
         - input2.input_property_2
        value: 'script_A'
        default: 'default_A'

      - create: output3.output_property_3
        from: input1.input_property_1
        foreach: input1.input_property_1
        actions:
          - further_actions
   options:
         .
         .
         .
    advanced_XML_and_general_configuration_options
         .
         .
         .
```

Properties

Table 2.

Property	Required	Description	Data type	Belongs to
version	Yes	The policy version number	string	N/A
title	No	A title for the policy.	String	N/A
description	No	A policy description.	String	N/A
inputs	No	An array listing the inputs of the map policy.	Object	N/A
outputs	Yes	An array listing the outputs of the map policy.	Object	N/A
variable	Yes	A reference to the context variable that is the location of the input or output variable..	String	inputs or outputs

Property	Required	Description	Data type	Belongs to
$ref	Yes[1]	A reference to the definition of the type of the variable.	String	inputs or outputs
type	Yes[1]	The type of the variable.	String	inputs or outputs
content	No	The content type of the variable: `application/xml` or `application/json`. If None is selected, or the field is not included, then the type is treated as JSON.	String	inputs or outputs
actions	Yes	Lists actions to be performed by the map policy.	Object	N/A
set	Yes[2]	Specifies by name the output variable that is to be set to a value by the action.	String	actions
create	Yes[2]	Specifies by name the output variable that is to have a value appended to it by the action.	String	actions
from	No	Specifies by name any input variables used by the action.	String	actions
value	No	Contains a script that maps and transforms input variables into output variables.	String	actions
default	No	Contains a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see Inline references.	String	actions
foreach	No	Specifies by name an array for which further actions should be performed for each element.	String	actions
includeEmptyXMLElements	No	If set to **`true`**, empty XML elements are included in the output of the map policy. Set to **`false`** if you do not want empty XML elements to be included in the output of the map policy. The default value is **`true`**.	Boolean	options
namespaceInheritance	No	If set to **`true`**, XML namespaces are inherited from the parent element. Set to **`false`** if you want the map policy to use explicit namespaces. The default value is **`true`**.	Boolean	options
inlineNamespaces	No	If set to **`true`**, XML namespaces will be inserted into the document where they are first used. Set to **`false`** if you want namespaces to all be defined on the root element. The default value is **`true`**.	Boolean	options
API Gateway only mapResolveXMLInputDataType	No	If set to **`true`**, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Set to **`false`** if you want all XML element values to be returned as a string.	Boolean	options
API Gateway only mapParseXMLOutput	No	If set to **`true`**, the map policy will write XML output to **`message.body`** as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string. The default value is **`false`**.	Boolean	options
API Gateway only mapXMLEmptyElement	No	This property controls how the map policy handles the output of an empty XML element. Specify one of the following values: • **`string`** (the default option): An empty XML element is handled as an empty string. • **`null`**: An empty XML element is handled as a null value. • **`none`**: The data is ignored. • API Gateway only **`string-badgerfish`**: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. • API Gateway only **`null-badgerfish`**: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the **`mapNullValue`** property is set to **`true`**.	String	options
API Gateway only mapArrayFirstElementValue	No	If set to **`true`**, then if an array is encountered in the traversal of the input, only the first element is used. Set to **`false`** if you want the map policy to use all array elements. The default value is **`false`**.	Boolean	options
API Gateway only mapResolveApicVariables	No	If set to **`true`**, API Connect variable references found in the map properties are resolved. Set to **`false`** if you want the map policy to ignore API Connect variable references in the map policies. The default value is **`false`**.	Boolean	options
API Gateway only mapNullValue	No	If set to **`true`**, an input property value with a null value is mapped to the output document. Set to **`false`** if you want the map policy to ignore null input values. The default value is **`false`**.	Boolean	options
API Gateway only mapOptimizeSchemaDefinition	No	If set to **`true`**, complex schema types evaluation handles circular type references in an optimized manner. Set to **`false`** to evaluate these schema types in a standard manner. The default value is **`false`**.	Boolean	options

Property	Required	Description	Data type	Belongs to

API Gateway only
mapEmulateV4DefaultRequiredProps
	No	If set to **true**, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
		• An array consists of objects that contain one or more required properties.
		• An object which is optional has one or more child properties that are required.
		By default, these required properties are not present in the output. If you set this property to **true**, these required properties will be present in the output. If the output schema defines a **default** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:
		• String: empty string ("")
		• Number: 0
		• Boolean: false
		• Object: empty object
		• Array: empty array
		Example 1
		The input data has the following array of objects:
		`[{"a": "value1"}, {"a": "value2", "b": "value3"}]`
		The output schema defines the output object as having two properties, **a** and **b**, of which **b** is required. The map policy defines the following mappings:
		• **input.array.a** to **output.array.a**
		• **input.array.b** to **output.array.b**
		If this property is set to **true**, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:
		`[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]`
		Example 2
		The output schema defines the following structure:
		`{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }`
		Property **b** is optional but property **d** within **b** is required.
		The map policy defines a mapping to **output.a.b.c**.
		If this property is set to **true**, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:
		`{"a" : {"b" : {"c" : "value1", "d" : ""} } }`
		If this property is set to **false**, these required properties are **not** created in the output with their default values.
		The default value is **false**.
			Boolean	options

API Gateway only mapEnablePostProcessingJSON	No	If set to **true**, mapped JSON output is post processed. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set to **false** if you want no post processing of mapped JSON output. The default value is **false**.	Boolean	options
API Gateway only mapCreateEmptyArray	No	This property controls how the map policy handles the output of an empty array. Specify one of the following values: • **all**: Output all empty arrays, including empty children arrays. • **parent**: Output only the current property's empty array value. Children map actions of this property are not attempted. • **none**: Prevent any empty output array values from being produced. The default value is **all**.	String	options
API Gateway only mapReferenceLimit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String	options
messagesInputData	No	This property defines the severity level for log messages that relate to input data. Specify one of the following values: • **error** • **warn** • **info**	String	options

Property	Required	Description	Data type	Belongs to

API Gateway only
mapEmulateV4EmptyJSONObject
	No	If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set this property to **true** to create an empty object for the parent of the target mapping, emulating the behavior of IBM® API Management Version 4.0.
		
		Example
		The map policy defines a mapping to **output.a.b.c**.
		If input data is present, the output is as follows:
		`{ "a": { "b": { "c": "inputvalue" } } }`
		If there is no input data, and the mapEmulateV4EmptyJSONObject option is set to **true**, the output is as follows:
		`{ "a": { "b": { } } }`
		Properties **a** and **b** are created but the value of **b** is an empty object.
		The default value is **false**.
			Boolean	options

[1] There must be one of $ref or type in the description of a variable.

[2] There must be one of set or create in an actions field.

Example

```
    - map:
        version: 1.0.0
        title: Output mapping
        inputs:
          Monthly_cost:
            schema:
              type: double
            variable: loan_invoke.body.monthly_payment
            content: application/json
          Duration:
            schema:
              type: integer
            variable: request.parameters.duration
        outputs:
          Quote_Output:
            schema:
              $ref: '#/definitions/Quote_Output'
            variable: message.body
            content: application/json
        actions:
          - set: Quote_Output.monthly_repayment
            from: Monthly_cost
            value: ''
          - set: Quote_Output.total_cost
            from:
              - Duration
              - Monthly_cost
            value: '$(Duration)*$(Monthly_cost)'
        description: Maps and transforms contexts to the operation output.
        options:
          includeEmptyXMLElements: false
          namespaceInheritance: false
          inlineNamespaces: false
          API Gateway only mapResolveXMLInputDataType: true
          API Gateway only mapXMLEmptyElement: null
          API Gateway only mapArrayFirstElementValue: false
          API Gateway only mapResolveApicVariables: false
          API Gateway only mapNullValue: true
          API Gateway only mapOptimizeSchemaDefinition: true
          API Gateway only mapCreateEmptyArray: parent
          API Gateway only mapReferenceLimit: 5
          messagesInputData: warn
          mapEmulateV4EmptyJSONObject: true
```

operation-switch

Use the operation-switch construct when you want to execute alternative policy assemblies, conditional on the operation that is being called.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see operation-switch.

About

An operation can be described with a **verb**/**path** pair, or with an **operationId**. The **operationIds** are strings, or names, that are defined in the OpenAPI document.

The operation-switch policy has the following format:

```
- operation-switch:
  version: version
  title: title
  description: description
  case:
    - operations:
      - verb: operation_verb_1_1
        path: operation_path_1_1
      - verb: operation_verb_1_2
        path: operation_path_1_2
                      .
                      .
                      .
          further verb/path combinations
                      .
                      .
                      .
      execute:
        policy_assembly_1 ...
    - operations:
      - verb: operation_verb_2_1
        path: operation_path_2_1
      - verb: operation_verb_2_2
        path: operation_path_2_2
                      .
                      .
                      .
          further verb/path combinations
                      .
                      .
                      .
      execute:
        policy_assembly_2 ...
                    .
                    .
                    .
    - operations:
      - operationID_3_1
      - operationID_3_2
      - operationID_3_3

                      .
                      .
                      .
          further operationIDs
                      .
                      .
                      .
      execute:
        policy_assembly_3 ...
                    .
                    .
                    .
        further operations sections
                    .
                    .
                    .
```

For each **operations:** section, if the operation that is being called matches any of the **verb**/**path** combinations or **operationId** strings listed in that **operations:** section, then the policy assembly that is defined in the **execute:** section is executed. Therefore, each **operations:** section defines execution of a policy assembly conditional on the operation that is being called.

You can have as many **operations:** sections as you want, and each **operations:** section can have one or more **verb**/**path** combinations or **operationId** strings.

The **execute:** section can define any policy assembly, including further operation-switch policies.

Properties

Table 2. operation-switch policy properties

Property	Required	Description	Data type	Contained in
version	Yes	The policy version number	string	N/A
title	No	A title for the policy.	string	N/A
description	No	A policy description.	string	N/A
case	Yes	An array containing different cases, each entry contains an operations and execute field.	array (object)	N/A
operations	Yes	The operations to which a case applies.	object	case
verb	No	An operation verb. Valid values: • `GET` • `POST` • `PUT` • `DELETE` • `HEAD` • `PATCH` • `OPTIONS`	string	operations
path	No	A relative path to an individual endpoint. For example, `/account_status`.	string	operations
operationID	No	The operation is defined in OpenAPI. The policy operation refers to the OpenAPI operation.	string	operations
execute	Yes	The policy assembly that you want to execute if the operation that is being called matches any one of the verb/path combinations. For more information, see execute.	string	case

Example

Example that defines match operations with `verb/path` combinations:

```
# carry out different redaction actions depending on the operation

- operation-switch:
  version: 1.0.0
  title: clear_region_and_set_body
  case:
    - operations:
      - verb: GET
        path: /account_details
      execute:
        - redact:
            title: remove secret field
            actions:
              - action: remove
                from: all
                path: /document/user/secret
    - operations:
      - verb: GET
        path: /account_status
      execute:
        - redact:
            title: redact address
            actions:
              - action: redact
                from: response
                path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

Example that defines match operation with `operationIDs`:

```
# match on operationIDs

- operation-switch:
  title: customer_actions
  case:
    - operations:
      - getCustomerByName
      - deleteCustomer
      - addACustomer
      execute:
           .
           .
           .
```

oauth

Use the oauth policy to policy to perform OAuth processing based on defined OAuth provider settings.

Gateway support

Table 1. Table showing which gateways support this policy, and the

corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see OAuth.

About

The oauth policy has the following format:

```
- oauth:
  version: version
  title: title
  description: description
  oauth-provider-settings-ref:
            .
            .
            .
    references_to_oauth_settings
            .
            .
            .
  supported-oauth-components:
    - oauth_component_1
    - oauth_component_2
            .
            .
            .
```

Note: You add an oauth policy to the OpenAPI source in a native OAuth provider. For more information, see the following topics:

- Editing the native OAuth provider configuration using the API Editor (Cloud Manager UI)
- Editing the native OAuth provider configuration using the API Editor (API Manager UI)

Properties

Table 2. oauth policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A description of the policy.	string
`oauth-provider-settings-ref: default`	Yes	The name of an existing OAuth provider that defines the required settings.	string
`oauth-provider-settings-ref: url`	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings. URL reference takes precedence over any existing literal configuration or object reference.	string
`oauth-provider-settings-ref: literal`	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings. Literal configuration takes precedence over any existing object reference.	string
`supported-oauth-components: - oauth_component_1 - oauth_component_2 . . .`	Yes	Specify the OAuth components that are supported by this policy, as follows: - OAuthValidateRequest Validates the authorization request from the client. - OAuthGenerateAZCode Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource. - OAuthVerifyAZCode Verifies the authorization code from the client. - OAuthVerifyRefreshToken Verifies the refresh token that is presented by the client. - OAuthCollectMetadata Collects metadata about a client for later user interaction - OAuthGenerateAccessToken Generates the access token to the client when the authorization code or refresh token is verified. - OAuthIntrospectToken Introspects the token to determine its state and, when active, its metadata.	string

Overriding default OAuth provider settings

You can use either the **`literal`** property or the **`url`** property to dynamically override any OAuth provider configuration settings to dynamically override any OAuth provider configuration settings defined by the **`default`** property.

For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the **`OAuthProviderSettings`** management schema, defined in the xml-mgmt.xsd file located in the store: directory on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

oauth policy example

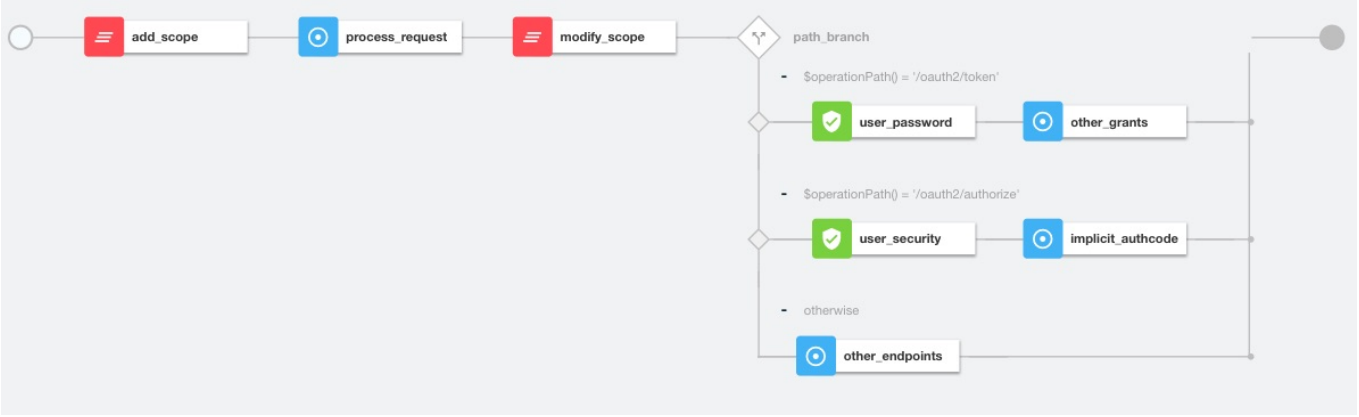
```
- oauth:
    version: 2.0.0
    title: my-oauth-policy
    oauth-provider-settings-ref:
      default: my-oauth
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthIntrospectToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
```

Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of **gatewayscript** policies that use OAuth context variables to manipulate the OAuth flow. For details on creating a native OAuth provider, see Configuring a native OAuth provider.

It has the following assembly flow:



The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download multiple_oauth_policies.txt.

Sample policy to add a custom scope

The **add_scope** policy is a **gatewayscript** policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: add_scope
    source: |-
      // Add another custom scope to the request
      let scope = context.get("request.parameters.scope.values[0]");
      if (scope)
        context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first **process_request** policy is an **oauth** policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the oauth.processing context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: process_request
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect protocol steps
      that are needed for OAuth Validation by default. The inputs and
      outputs of each of the steps are driven by documented context
      variables. Add or remove the Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthValidateRequest
```

Sample policy to modify the scope

The **modify_scope** policy is a **gatewayscript** policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: modify_scope
    source: |-
      let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

      // Check application and modify the scope
      let app = context.get("oauth.processing.client_id");
      let scope = context.get("oauth.processing.scope");
      if (app === admin_id) {
        context.set("oauth.processing.scope", scope + " admin");
      } else {
        context.set("oauth.processing.scope", scope + " customer");
      }
```

Branch conditionally according to the OAuth path

The **path_branch** policy is a **switch** policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
    version: 2.0.0
    title: path_branch
    case:
      - condition: ($operationPath() = '/oauth2/token')
        execute:
            .
            .
            .
          definition of the user_security and other_grants policies
            .
            .
            .
      - condition: ($operationPath() = '/oauth2/authorize')
        execute:
            .
            .
            .
          definition of the user_password and implicit_authcode policies
            .
            .
            .
      - otherwise:
            .
            .
            .
          definition of the other_endpoints policy
            .
            .
            .
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The **user_password** policy for password grant type processes the user name and password from the **x-www-form-urlencoded** body. The authentication method is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **other_grants** policy is an **oauth** policy that enables the **OAuthGenerateAccessToken**, **OAuthVerifyAZCode**, **OAuthVerifyRefreshToken**, and **OAuthCollectMetadata** components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_password
    version: 2.0.0
    description: ''
    factor-id: default
    extract-identity-method: context-var
    user-context-var: request.parameters.username.values
    pass-context-var: request.parameters.password.values
    ei-stop-on-error: false
    user-auth-method: auth-url
    au-stop-on-error: false
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
- oauth:
    title: other_grants
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for token path by default.
```

```
      The inputs and outputs of each of the steps are driven by
      documented context variables. Add or remove the Supported
      OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAccessToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
      - OAuthCollectMetadata
```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The **user_security** policy configuration is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **implicit_authcode** policy is an **oauth** policy that enables the **OAuthGenerateAZCode**, **OAuthGenerateAccessToken**, and **OAuthCollectMetadata** components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_security
    version: 2.0.0
    description: >-
      This user security policy performs EI(basic) and AU(auth
      url) check for oauth assembly. Change the security check
      method as required
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: auth-url
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
- oauth:
    title: implicit_authcode
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for az code path by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthCollectMetadata
```

Process all other endpoints

The **otherwise** condition catches all other endpoints such as the introspect and revoke endpoints. The **other_endpoints** policy in the **otherwise** condition is an **oauth** policy that enables the **OAuthIntrospectToken**, and **OAuthRevokeTokencomponents** components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: other_endpoints
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for all other paths by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthIntrospectToken
      - OAuthRevokeToken
```

Azure openai-invoke

Use the Azure OpenAI invoke policy to invoke Azure OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Azure openai invoke.

About

The Azure OpenAI invoke policy provides access to four Azure OpenAI operations:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Azure OpenAI invoke policy properties

Property name	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is Azure OpenAI invoke chat completions.	string
description	No	A description of the policy.	string
operation	Yes	The Azure OpenAI operation to invoke; must be one of the following operations: • `POST /chat/completions` An HTTP POST operation for `/chat/completions`. See Create chat completion in the Azure OpenAI documentation for sample request and response examples. • `POST embeddings` An HTTP POST operation for `/embeddings`. See Create embeddings in the Azure OpenAI documentation for sample request and response examples. • `GET models` An HTTP GET operation for `/models`. See List Models in the OpenAI documentation for sample response examples. • `GET models/[model]` An HTTP GET operation for `/models/[model]`. See Retrieve model in the Azure OpenAI documentation for sample response examples.	string
api_key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Azure OpenAI requests.	string
deployment_id	Yes	Name of project/deployment in Azure where model is deployed.	string
resource_id	Yes	Serves as part of endpoint of URL that points to your provisioned resources.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into theDataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string

Property name	Required	Description	Data type
op-version	No	The operation version specifies the version of the OpenAI operation (such as completions, chat/completions, embeddings) that the policy applies to. It is defined using YYYY-MM-DD format.	
path_params	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
query_params	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
output	No	The name of the DataPower API Gateway context message that receives the OpenAI response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Example

```
azure-openai-invoke:
          title: Azure-OpenAI invoke policy
          description: Azure-OpenAI invoke policy desc
          api_key: keyvalue
          deployment_id: $(dep-id)
          resource_id: $(res-id)
          operation: POST chat/completions
          op-version: $(azure-op-version)
          path_params:
          enable_cache: true
          cache_ttl: 60
          cache_scope: azureScope
          output: request
          version: 2.0.0
```

API Gateway only

openai-invoke

Use the OpenAI invoke policy to invoke OpenAI operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see openai invoke.

About

The OpenAI invoke policy provides access to four OpenAI operations:

- **`POST /chat/completions`**
- **`POST /embeddings`**
- **`GET /models`**
- **`GET /models/[model-id]`**

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OpenAI invoke policy properties

Property name	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is **`OpenAI`** invoke chat completions.	string
description	No	A description of the policy.	string

Property name	Required	Description	Data type
operation	Yes	The OpenAI operation to invoke; must be one of the following operations: • **`POST /chat/completions`** An HTTP POST operation for **`/chat/completions`**. See Create chat completion in the OpenAI documentation for sample request and response examples. • **`POST embeddings`** An HTTP POST operation for **`/embeddings`**. See Create embeddings in the OpenAI documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the OpenAI documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the OpenAI documentation for sample response examples.	string
api_key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate OpenAI requests.	string
organization_id	No	An optional property where you can specify the organization identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy request specifying this property will count as usage by the organization specified.	string
project_id	No	An optional property where you can specify the project identifier associated with your OpenAI account that will be associated with the requests sent by this policy. Policy request specifying this property will count as usage by the project specified.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into theDataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
path_params	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
query_params	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
output	No	The name of the DataPower API Gateway context message that receives the OpenAI response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Example

```
openai-invoke:
                    title: OpenAI invoke chat completions
                    enable_cache: true
                    version: 2.0.0
                    api_key: $(openai-apikey)
                    cache_ttl: 60
                    operation: POST chat/completions
                    output: message
                    description: description goes here
                    project_id: openai project id
                    cache_scope: cachescopevalue
                    organization_id: openai organization id
```

parse

Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the

corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later) 2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Parse.

About parse

The parse policy has the following format:

```
- parse:
  version: version
  title: title
  description: description
  use-content-type: request_header_usage_setting
  parse-settings-reference:
            .
            .
            .
    references_to_parse_settings
            .
            .
            .
  input: input_message
  output: output_message
```

Properties

Table 2. parse policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
use-content-type	No	If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the **Content-Type** specified in the request headers. If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the **Content-Type** specified in the request headers and fails if the **Content-Type** in the request headers does not match the parse setting. Enabling this setting is applicable only when the expected **Content-Type** is either JSON or XML. If this setting is not enabled, the parse operation uses either the document type specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type. The default value is **false**.	boolean
parse-settings-reference: default	No	An existing valid object from which to retrieve default property values for the dynamic object.	string

Property	Required	Description	Data type

document_type	No	The type of document to parse. Specify one of the following values:
		• **detect**: the document type is detected and the payload is parsed accordingly. This type is the default option.
		• **JSON**: the payload is parsed as JSON.
		• **XML**: the payload is parsed as XML.
		• **graphql**: parsing is performed in one of the following ways:
		◦ As GraphQL in the body of a POST request. The GraphQL is in the following format:
		`{ me { name } }`
		◦ As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format:
		`{ "query": "query MyData ($idVar: Int!) { user (id: $idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} }`
		◦ Through the URL query of a GET request. The URL is in the following format:
		`https://myapi/graphql?query={me{name}}`
		The following example includes the **variables** and **operationName** properties, with URL encoding:
		`https://hostname/basepath/graphql?query=query%20fetchAccounts%20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}}&variables={"limit":100}&operationName=fetchAccounts`
		Query variables in a GET request can be sent as a JSON string in a query parameter called **variables**. If the query contains several named operations, an **operationName** query parameter is required to determine which operation is to be executed.
			string

max_doc_size	No	Optionally, the maximum document size in bytes that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. This setting is applicable to JSON, XML, or GraphQL input documents. The default value is 4194304.	integer
max_nesting_depth	No	Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message. • When XML, it is the maximum level of element depth. • When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. • When GraphQL, it is the maximum level of nested selection sets. Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth. The default value is 512.	integer
max_width	No	Optionally, the maximum width of the payload that the parse operation accepts. • When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. • When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. • When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document. The default value is 4096.	integer
max_name_length	No	Optionally, the maximum name length in bytes in a document that the parse operation accepts. • For XML, it is the length of the name portion of a tag. • For JSON, it is the length of the label portion of the JSON label-value pair. • For GraphQL, it is the maximum length of the identifiers, including field names and directive names. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document. The default value is 256.	integer

Property	Required	Description	Data type
max_value_length	No	Optionally, the maximum value length in bytes in a document that the parse operation accepts. • For XML, it is the length of an attribute or the length of a text value. • For JSON and GraphQL, it is the length of a string value. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document. The default value is 8192.	integer
max_unique_names	No	Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts. • For XML, it is the number of unique XML local names. • For JSON, it is the number of unique JSON labels. Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document. The default value is 1024.	integer
max_unique_prefixes	No	Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document. The default value is 1024.	integer
max_unique_namespaces	No	Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document. The default value is 1024.	integer
max_number_length	No	Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document. The default value is 128.	integer
strict-utf8-encoding	No	For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document. • When **`on`**, the entire document is checked for valid UTF-8 encoding. • When **`off`**, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. The default value is **`off`**.	boolean
`parse-settings-reference: literal`	No	A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.	string
`parse-settings-reference: url`	No	A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.	string
input	No	The name of a variable in the API context. The content of the **`body`** field of the variable is the input to the policy. The default variable name is **`message`**.	string
output	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

parse policy example

```
- parse:
    version: 2.0.0
    title: my-parse-policy
    use-content-type: true
    parse-settings-reference:
      default: my-parse
    input: input-message
    output: output-message
```

parse-settings-reference: literal example

In XML:

```
- parse:
    version: 2.0.0
```

```
    title: parse
    parse-settings-reference:
    default: apic-default-parsesettings
    literal: <ParseSettings><DocumentType>xml</DocumentType></ParseSettings>
```

In JSON:

```
- parse:
    version: 2.0.0
    title: parse
    parse-settings-reference:
    default: apic-default-parsesettings
    literal: { \"ParseSettings\" : { \"propertyName\" : propertyValue } }
```

proxy

Apply the proxy policy to proxy another API within your operation, particularly if you need to call a large payload.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Proxy.

About

Keep the following considerations in mind regarding the proxy policy.

- Only one proxy policy is permitted to be called per assembly.
- More than one proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.
- You can use the proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, proxy must be the final policy in the assembly, otherwise the response that is received is manipulated causing the multipart form data to be lost.
- The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the invoke policy rather than the proxy policy.
- The Proxy policy does not currently attempt to rewrite a Location header that is returned from the back end.

The proxy policy has the following structure:

```
- proxy:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  http-version: HTTP_version
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
  password: password_if_authentication_required
  output: location_of_the_proxy_result
  cache-key: unique_identifier_of_the_document_cache_entry
  cache-response: cache_behavior
  cache-putpost-response: response_caching_behavior
  cache-ttl: cache_time_to_live
  stop-on-error: errors_that_stop_the_flow
```

Properties

The table describes the properties of the proxy policy.

Table 2. Proxy policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
target-url	Yes	The URL of the target API.	string
tls-profile	No	The TLS profile to be used.	string

Property	Required	Description	Data type
verb	No	The operation method type. Valid values: • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **Keep**.	string
http-version	No	The HTTP version. The default value is **1.1**.	string
timeout	No	The timeout value in seconds. The default value is **60**.	integer
compression	No	Specifies whether data is to be compressed by using gzip before it is uploaded. The default value is **false**.	boolean
username	No	The user name, if authentication is required.	string
password	No	The password, if authentication is required.	string
output	No	Specifies the location of the proxy result. By default, the proxy result, that is the body, headers, statusCode and statusMessage, is saved in the variable **context.message**. The assembly developers can specify an additional location to store the proxy result with the output property.	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
cache-response	No	The cache response type. Valid values: • protocol: The cache behavior is defined by the Cache-Control headers on the request and response. • no-cache: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. • time-to-live: Specifies that the response stays in the cache for the specified time. The default value is **protocol**.	string
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is **false**.	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to **time-to-live**. Enter a value in the range 5 - 31708800. The default value is **900**. Note: When users sign in by using the Toolkit login path (a URL that includes **?from=TOOLKIT**), the generated API key has a fixed time-to-live (TTL) of 5 minutes.	integer
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a **catch** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

API Gateway only

ratelimit

Use the ratelimit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.5.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Rate Limit.

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a ratelimit policy is placed before an invoke policy, and the call made by the invoke policy exceeds the limits defined by the ratelimit policy, the API call itself fails.

The ratelimit policy has the following format:

```
- ratelimit:
    version: version
```

```
    title: title
    description: description
    source: rate_and_burst_limit_location
    rate-limit: rate_limits_to_apply
    burst-limit: burst_limits_to_apply
```

Properties

The following table describes the properties of the ratelimit policy.

Table 2. ratelimit policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Specify one of the following values: • **`catalog-named`**: the rate or burst limits to be applied are defined in the appropriate **`api-collection`** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the **`api-collection`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • **`plan-named`**: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a **`plan-named`** rate limit policy: ◦ Every Plan that contains the API that is being limited must have the named rate limit applied. ◦ A **`plan-named`** rate limit policy cannot be used with automatically generated Products. • **`gateway-named`**: the limits to be applied are defined in the **`apigw`** object, named **`apiconnect`**, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the **`apigw`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • **`plan-default`**: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies.	string
rate-limit	Yes[1]	If the **`source`** property is set to **`catalog-named`**, a list of rate limit names as defined in the DataPower API Gateway configuration, [1]You must provide at least one rate, burst, or count limit.	string
burst-limit	Yes[2]	If the **`source`** property is set to **`catalog-named`**, a list of a burst limit names as defined in the DataPower API Gateway configuration. If **`source`** is set to **`plan-named`**, a list of names of assembly burst limits defined in a Plan. [2]You must provide at least one rate, burst, or count limit.	string
count-limit	Yes[3]	If **`source`** property is set to **`catalog-named`**, a list of count limit names as defined in the DataPower API Gateway configuration. If **`source`** is set to **`plan-named`**, a list of names of assembly count limits defined in a Plan. [3]You must provide at least one rate, burst, or count limit..	string

Property	Required	Description	Data type
operation	No	For a rate limit, specify one of the following values: • **consume**: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified by the **rate-limit** property. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. • **replenish**: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified by the **rate-limit** property. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55. Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1. The default value is **consume**. For a count limit, specify one of the following values: • **inc**: the current count is incremented by the value that results from the weight expression defined in the count limit specified by the **count-limit** property. • **dec**: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the **count-limit** field. By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway. The default value is **inc**. For a burst limit, the only possible value is **consume**, meaning that the limit applied is that defined in the burst limit specified by the **burst-limit** field.	string

Example

```
- ratelimit:
    version: 2.0.0
    title: Apply rate and burst limits
    source: catalog-named
    rate-limit:
      - 30perMinute
      - 2000per3Hours
    burst-limit:
      - 5per10Seconds
```

API Gateway only

ratelimitinfo

Use the ratelimitinfo policy to return information about rate limits, burst limits, and count limits. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Rate Limit Info.

About

The Rate Limit Info policy returns information about the rate limits, burst limits, and count limits that are applied to the API.

The ratelimitinfo policy has the following format:

```
- ratelimitinfo:
    version: version
    title: title
    description: description
    input: input_context
    output: output_location
```

Properties

The following table describes the properties of the ratelimitinfo policy.

Table 2. ratelimitinfo policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
input	No	The input context that specifies what rate limit information is requested.	string
output	No	The destination of rate limit information.	string

API Gateway

redact - DataPower API Gateway

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see redact - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Redaction - DataPower API Gateway.

About

The redact policy has the following format:

```
- redact:
    version: version
    title: title
    description: description
    redactions:
      - action: remove_or_redact
        path: JSONata_expression_for_field_to_remove_or_redact
                .
                .
                .
    root: content_source
```

Note: With the DataPower API Gateway, the input to the redact policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a redact policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the properties of the redact policy.

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

Property	Required	Description	Data type
root	No	Specifies the data source that contains the content to which the redact or remove action applies. If the root property is omitted, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of `message.body`. The actual content to which the action is applied then depends on the positioning of the redact policy in the overall assembly flow; for example: • If positioned at the beginning, the action is applied to the client request. • If positioned after an invoke policy, the action is applied to the response from the back end. • If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the redact policy is used after a log policy that specifies **`gather-only`** for the mode property, specify a root value of **`log.request_body`** for the logged request payload, or **`log.response_body`** for the logged response payload.	string
path	Yes	Specifies a JSONata path expression that identifies the fields to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
action	Yes	Specifies whether you want to remove or redact the content. Supply one of the following values: • **`remove`**: Completely removes the specified fields. • **`redact`**: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is **`redact`**. Note: If a numerical value is being redacted, the redacted value is depicted as **`******`** and the type is changed to **`string`**.	string

Example

```
# Specify separate remove and redact actions

- redact:
    version: 2.0.0
    title: remove price, redact author
    redactions:
      - action: remove
        path: xpath($, ''//price'')"
      - action: redact
        path: $.**.author"
    root: message.body
```

DataPower Gateway (v5 compatible)

redact - DataPower Gateway (v5 compatible)

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see redact - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Redaction - DataPower Gateway (v5 compatible).

About

The redaction policy has the following format:

```
- redact:
  version: version
  title: title
  description: description
  actions:
    - action: remove_or_redact
      from:
        - where_the_redaction_is_to_be_applied
      path: XPath_expression_for_field_to_remove_or_redact
```

```
                    .
                    .
                    .
          further action/from/path combinations
                    .
                    .
                    .
```

You can specify as many **action**/**from**/**path** combinations as you want.

Properties

The following table describes the policy properties:

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
action	No	Specifies whether you want to remove or redact the fields. Valid values: • **remove**: Completely removes the specified fields. • **redact**: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is **redact**. Note: If a numerical value is being redacted, the redacted value is depicted as ****** and the type is changed to **string**.	string
from	No	Determines where the redaction is to be applied. Valid values: • **all**: Apply the redaction to the request body, the response body, and the activity logs. • **request**: Apply the redaction to the request body only. • **response**: Apply the redaction to the response body only. • **logs**: Apply the redaction to the activity logs only. You can supply one or more values. The default value is **all**.	string
path	Yes	Specifies an XPath expression that defines the fields to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields.	string

Example

```
# Specify separate remove and redact actions

- redact:
  version: 1.0.0
  title: remove secret field, redact address
  actions:
    - action: remove
      from:
        - all
      path: /document/user/secret
    - action: redact
      from:
        - request
        - response
      path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

set-variable

Use the set-variable policy to set the value of a runtime variable, or to add or clear a runtime variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Set Variable.

About

The set-variable policy has the following format:

```
- set-variable:
  version: version
  title: title
  description: description
  actions:
    - action_type: variable_name
      value: value
      type: data_type
```

Properties

Table 2. set-variable policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
actions	Yes	Lists the actions to be performed by the set-variable policy.	array
set	Yes[1]	For setting a variable. specifies the name of the variable that you want to set. [1]One of the properties set, add, or clear is required.	string
add	Yes[2]	For adding a variable. specifies the name of the variable that you want to add. [2]One of the properties set, add, or clear is required.	string
clear	Yes[3]	For clearing a variable. specifies the name of the variable that you want to clear. [3]One of the properties set, add, or clear is required.	string
value	Yes[4]	Allocates this value to the specified variable. Can be a literal value, or another variable. [4]value is required only when **`set`** or **`add`** is specified as the action.	string
type	Yes	Specifies the data type of the variable. Valid values: • **`any`** • **`string`** • **`number`** • **`boolean`** For all values other than **`any`**, the value is validated against the specified data type. If the data type is specified as **`boolean`**, the value property must be set to **`true`** or **`false`**.	string

Example 1

```
# clear a variable

set-variable:
  version: 1.0.0
  title: clear_region
  actions:
    - clear: message.headers.region
```

Example 2

```
# set a variable to the value of an API Gateway context variable

set-variable:
  version: 2.0.0
  title: set content type
  actions:
    - set: message.headers.contenttype
      value: $(message.headers.content-type)
      type: string
```

Example 3

```
# add a variable

assembly:
    execute:
      - set-variable:
          version: 2.0.0
          title: set-variable
          actions:
            - value: testing add
              add: message.headers.jja
              type: string
```

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see switch.

About

The switch policy has the following format:

```
- switch:
  version: version
  title: switch
  description: 'Description'
  case:
    - condition: Script_1
      execute:
      Assembly_Section_1
    - condition: Script_2
      execute:
      Assembly_Section_2
    - otherwise:
      Assembly_Section_3
```

The **execute:** section can define any policy assembly, including further switch policies. For more information, see execute.

Properties

Table 2. switch policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
case	Yes	Contains the condition and execute pairs of the switch policy.	string
condition	Yes (one or more)	A script that returns **true** or **false**. API Gateway Use the JSONata expression language to define your condition. See Writing switch condition scripts - DataPower API Gateway DataPower Gateway (v5 compatible) Use GatewayScript to define your condition. See Writing switch condition scripts - DataPower Gateway (v5 compatible).	string
execute	Yes (one per condition)	The policy assembly that you want to execute if the condition returns **true**. For more information, see execute.	string
otherwise	No	The case you want to execute if no other cases are fulfilled. It functions in the same manner as an execute property. For more information, see execute.	string

For examples, see one or other of the following topics, depending on which gateway type you are using:

- Writing switch condition scripts - DataPower API Gateway
- Writing switch condition scripts - DataPower Gateway (v5 compatible)

API Gateway only

Writing switch condition scripts - DataPower API Gateway

You write condition scripts for the switch policy in the DataPower® API Gateway by using the JSONata expression language.

The payload of the message must be parsed before you can use JSONata in a switch policy condition. Therefore, a parse policy must precede the switch policy. You can then use a JSONata condition on the parsed content that is stored in the **body** field of the output variable. The default variable is **message**. For example, if the output variable is **message**, you can use the JSONata condition **$exists(message.body.username)** on the parsed content.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.
- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - **$eval()**

    - `$sift()`
    - `$each()`
    - `$error()`
    - `$assert()`
    - `$fromMillis()` is supported with the following restrictions:
        - The `$fromMillis()` parameter supports numbers in the range -5364662400000 - 2903299199000.
            - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
            - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- `$now()` is supported with the following restrictions:
    - The following component specifiers are not supported:
        - `W` = Week in year
        - `w` = Week in month
        - `X` = ISO week-numbering year
        - `x` = ISO week-numbering month
    - Representing numbers as words are not supported, so the following presentation modifiers are not supported:
        - `W` = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
        - `w` = Lowercase word (for example: [Yw] => two thousand and twenty-four)
        - `Ww` = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
    - Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description

`$apiCtx()`	Generic access to an API context	The `$apiCtx()` extension gives generic access to an API context.
		• Sample transform field in an extract action:
		`"$apiCtx().request.uri"`
		• Sample condition of a case in a switch action:
		`"$apiCtx().request.path = '/simple/apictx-function'"`

`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation
`$queryParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keyword is `query`. • `request.parameters.`*`name`*`.values`	Searches for the index of `query` in `request.parameters.`*`name`*`.locations` and returns `request.parameters.`*`name`*`.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*`variable`*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

`$urlParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keywords are `path` and `query`
	• `request.parameters.`*`name`*`.values`
		Searches for the index of `path` and `query` in `request.parameters.`*`name`*`.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.`*`name`*`.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values.
		`http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese`
		The `$urlParameter('breed')` URL returns the following array of values.
		`[cats, adopt, Sphynx, Siamese]`
		In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.

`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.

Extension	Variable	Description
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- *`operationName`*
  For an anonymous operation, *`operationName`* can be empty.

- *`~fragmentSpreadName`*
- *`on~typeCondition`*
- *`~~fragmentDefinitionName`*

Simple condition statements

The following examples show conditions that use a single function.

This example uses the `$httpVerb()` extension to specify the HTTP method of the request.

```
$httpVerb()="GET"
```

This example uses the `$operationPath()` extension to specify the path of the operation.

```
$operationPath()="/base/path-2"
```

This example uses the `$operationID()` extension to specify the operation ID.

```
$operationID()="test-gatewayscript-GET"
```

This example uses the `$statusCode()` extension to specify the message status code.

```
$statusCode()=200
```

This example uses the `$header(name)` extension to specify the content type of the message header.

```
$header("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use `and` and `or` operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to `test-gatewayscript-GET`.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a `POST` or `PUT` request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to `test-gatewayscript_POST` and a message status code equal to `200`, or an API operation ID equal to `test-gatewayscript-GET` and a message status code equal to `500`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and $statusCode()=500)
```

This example specifies an API operation ID equal to `test-gatewayscript-POST` and a message status code equal to `200` with an API operation path equal to `/base/path-2`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to `text/plain` and a message header length equal to `300`, or a message status code equal to `200`.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

Note: When users sign in by using the Toolkit login path (a URL that includes `?from=TOOLKIT`), the generated API key has a fixed time-to-live (TTL) of 5 minutes.

Example switch policy

```
- switch:
  version: 2.0.0
  title: switch
  case:
    - condition: ($statusCode() = 200)
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/1'
    - condition: ($statusCode() != 200 and ($httpVerb() = 'GET' or $httpVerb() = 'PUT'))
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/2'
    - otherwise:
      - set-variable:
        title: set-variable
        actions:
          - set: message.body
            value: Default result
            description: 'Set the default result for the otherwise case'
```

DataPower Gateway (v5 compatible) only

Writing switch condition scripts - DataPower Gateway (v5 compatible)

You write condition scripts for the `switch` policy in the DataPower® Gateway (v5 compatible) by using GatewayScript.

To reference variables in your `switch` conditions, use the form `apim.getvariable('context.location.variable')`, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

to define a `switch` condition based on the operation called, use one of the following forms:

```
- condition: "((request.verb==='GET')&&(api.operation.path==='/path-1'))"
```

```
- condition: "((api.operation.id=='Operation_ID'))"
```

where the context variables `request.verb` and `api.operation.path` retrieve the HTTP verb and the path segment of the API and operation that you want your case to apply to, while `api.operation.id` retrieves the operation ID of your operation, if one has been specified.
For information about the context variables you can use and how to reference them in your script, see API Connect context variables.

Example switch policy

```
- switch:
  version: 1.0.0
  title: switch
  case:
    - condition: message.status.code===200
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/1'
    - condition: ((request.verb==='GET')&&(api.operation.path==='/path-2'))||((request.verb==='GET')&&
(api.operation.path==='/path-1'))
      execute:
        - invoke:
```

```
        title: invoke
        timeout: 60
        verb: GET
        cache-response: protocol
        cache-ttl: 900
        target-url: 'https://example.com/2'
  - otherwise:
    - set-variable:
      title: set-variable
      actions:
        - set: message.body
          value: Default result
          description: Set the default result for the otherwise case
```

throw

Use the throw construct to throw an error when it is reached during an assembly flow, usually as a result of a condition being reached.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see throw.

About

The throw policy has the following format:

```
- throw:
   title: title
   name: 'error_name'
   error-status-code: http_status_code_for_error
   error-status-reason: http_reason_phrase_for_error
   message: error_message
```

When the throw policy is encountered, the specified error and error message is returned. If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

Properties

Table 2. throw policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
name	Yes	The name of the error to be thrown.	string
API Gateway only error-status-code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the `$(variable)` format to reference the `message.status.code` API context variable.	integer
API Gateway only error-status-reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the `$(variable)` format to reference the `message.status.reason` API context variable.	string
message	No	The message to accompany the error.	string

Example

```
    - throw:
        version: 1.0.0
        title: throw
        name: '404'
        message: Not found
```

API Gateway only

token-mediation

The token-mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.

Table 1. Gateway support

Gateway	Policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

Note: The token-mediation policy will only work for the DataPower API Gateway. The DataPower firmware version that the API Gateway is running on must be **LTS 10.6.0.0 (or later) or CD firmware release 10.6.3 (or later).**
This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see Token Mediation.

Prerequisites

Before using the token-mediation policy, ensure that distributed variable settings are enabled. Distributed variables allow you to read from or write to DataPower® facilities across transactions or domains. They serve as an alternative to system variables and must be enabled for the registration process to function end-to-end (E2E). For more details, see Configuring settings to manage distributed variables.

About

The token-mediation policy (token-mediation_2.0.0) serves as a mediator for OAuth tokens by caching the token received from an OAuth Token Endpoint and exchanging it for a session cookie, which is sent to the Client Application via a `Set-Cookie` header. Depending on the policy configuration, this session token can be used to (A) retrieve the original token from the cache or (B) instruct the policy to set the HTTP Authorization header for seamless access to resources on the Resource Server.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. token-mediation policy properties

Property label	Required	Description	Data type
`title`	No	The title of the policy.	string
`description`	No	A description of the policy.	string
`cookie- name`	Yes	The name of session cookie returned to the client application.	string
`token-url`	Yes	The URL of the OAuth provider's Token Endpoint.	string
`token-url-tls`	No	The TLS profile used for connecting to the `token-url`. Note: The `token-url-tls` property is optional for this policy but may be required by the Token Endpoint, and it is the responsibility of the policy user to determine its necessity. The policy must match the exact DataPower object name. For TLS profiles created by API Connect, the DataPower object follows this naming convention: `<provider-org>_<catalog>_<tls-profile-name>V<tls-profile-version>`. **Example:** `myorg_mycatalog_my-tls-profile1.0.0`.	string
`auth-url`	Yes	The URL of the OAuth provider's Authorization Endpoint.	string
`output`	No	The output context that receives the Authorization header. Note: The `output` parameter plays a key role in policy behavior. When specified, the policy retrieves the Access Token Response from the cache, extracts the access token (if available), and sets the Authorization header in the designated output message context. If the `output` parameter is not specified, the policy writes the Access Token Response to the `message` context and sets the `Content-Type` header to `application/json`.	string

User-defined policies

You can apply your own user-defined policies to your APIs.

The policy configuration that you add to the OpenAPI definition file must conform to the schema that you defined in the YAML file that describes the policy, and will have the following general format:

```
policy_name:
  property1: value1
  property2: value2
      .
      .
      .
```

For details on user-defined policies, and how to describe and implement them, see Authoring policies.

user-security

Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.1.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see User Security.

About

The user-security policy has the following format:

```
- user-security:
  version: version
  title: title
  description: description
  factor-id: factor ID
  extract-identity-method: method_used_to_extract_credentials
        .
        .
        .
     properties_specific_to_the specified_identity_extraction_method
        .
        .
        .
  user-auth-method: authentication_method
        .
        .
        .
     properties_specific_to_the specified_authentication_method
        .
        .
        .
  user-az-method: authorization_method
        .
        .
        .
     properties_specific_to_the specified_authorization_method
        .
        .
        .
```

Properties

Table 2. user-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
factor-id	No	The identity that identifies the results of factor-authentication in the API context.	string
extract-identity-method	Yes	Select the method that is used to extract the user credentials. The following options are available: basic Use basic authentication; no additional configuration is required. context-var The credentials are provided by API Connect context variables; specify the following properties: • user-context-var: the context variable that is used to obtain the user name. • pass-context-var: the context variable that is used to obtain the password. html-form Use forms based identity-extraction. You can use the default form or a custom form. To use the default form, specify `ei-default-form: true`. To use a custom form, specify `ei-default-form: false` and supply the following properties: • ei-custom-form: the location of the form. • ei-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. Use the ei-form-time-limit property to specify the time allowed to submit the form. redirect Use a redirect for identity-extraction; specify the following properties: • redirect-url: the URL fragment to which to redirect the request to obtain user credentials. • redirect-time-limit: the time allowed for the transaction to complete. disabled Identity-extraction is disabled; this aspect of processing is skipped. Specify `ei-stop-on-error: true` to halt assembly processing in the event of identity-extraction failure. This field is required if identity extraction is not disabled.	string

Property	Required	Description	Data type
user-auth-method	Yes	Select the authentication method. The following options are available: auth-url The credentials are authenticated by an external endpoint; specify the following properties: • auth-url: the URL of the authentication endpoint. • auth-tls-client-profile: the TLS client profile that is used to secure the connection to the authentication endpoint. ldap The credentials are authenticated by an LDAP user registry; use the ldap-registry property to specify the required registry. disabled Authentication is disabled; this aspect of processing is skipped. Specify **`au-stop-on-error: true`** to halt assembly processing in the event of user authentication failure. This field is required if authentication is not disabled.	string
user-az-method	Yes	Select the authorization method. The following options are available: authenticated Implicitly accept any previously authenticated users; no additional configuration is required. html-form The user provides authorization through an HTML form. You can use the default form or a custom form. To use the default form, specify **`az-default-form: true`**. To use a custom form, specify **`az-default-form: false`**. Supply the following properties: • az-table-dynamic-entries: the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form. • az-form-time-limit: the time allowed to submit the form. For a custom form, supply the following properties: • az-custom-form: the location of the form. • az-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. disabled Authorization is disabled; this aspect of processing is skipped. Specify **`az-stop-on-error: true`** to halt assembly processing in the event of user authorization failure. This field is required if authorization is not disabled.	string

Example

```
# basic authentication with LDAP registry

- user-security:
    version: 2.0.0
    title: user-security
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: ldap
    ldap-registry: corporate-ldap
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
```

validate - DataPower API Gateway

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see validate - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version

Gateway	Policy version
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.4.0 (DataPower API Gateway Version 10.0.4.0 or later) 2.5.0 (DataPower API Gateway Version 10.5.0.0 or later) 2.6.0 (DataPower API Gateway Version 10.5.0.2 or later 2.7.0 (DataPower API Gateway Version 10.5.0.3 or later

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate - DataPower API Gateway.

About

The validate policy has the following format:

```
- validate:
    version: version
    title: title
    description: description
    validate-against: validation_mechanism
          .
          .
          .
       properties_specific_to_the specified_validation_mechanism
          .
          .
          .
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Note: With the DataPower API Gateway, the input to the validate policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
input	No	Identifies a variable in the API context. The content of the **body** field of the variable, which is represented by ***variable_name*.body**, is the input data to validate. By default, the variable name is **message**.	string
output	No	Specifies the name of a variable in the API context. • If the validation passes, the body field of the output variable, which is represented by ***variable_name*.body**, stores the output of the assembly validate action. • If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. • If the validation fails, no output is stored. • If an output variable is not specified, the results of the assembly validate action are not saved.	string

Property	Required	Description	Data type
validate-against	Yes	Specifies the schema to be used for validating the payload. Valid values: • **`definition`**: A previously defined schema will be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. In addition, supply a **`definition`** property to specify the required schema. • **`url`**: the schema is identified by a URL location. In addition, supply the following properties: ◦ **`json-schema`** field: the URL of the JSON schema to be used for validating a JSON payload. ◦ **`xml-validation-mode`**, specify one of the following values to define how an XML payload is validated: ▪ **`xsd`**: use an XML schema; in addition, supply an **`xml-schema`** property that specifies the URL of the XML schema. ▪ **`wsdl`**: use a WSDL schema; in addition, supply an **`xml-schema`** property that specifies the URL of the WSDL schema to be used for validating a SOAP payload.. ▪ **`soap-body`**: validate the body of a SOAP message against the XML schema only. Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported. ▪ Maximum of 6,500 lines. Each key and each item in an array count as a line. ▪ Maximum recursion depth of 250. ▪ Maximum of 3,000 items in **`enum`** lists. • **`wsdl`**: (use with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. • **`body-param`**: validate the request input against the schema definition that is specified in the **`schema`** property for the request parameter for this operation. • **`response-param`**: validate the response to be returned to the client application, against the schema definition that is specified in the **`schema`** property for the response parameter for this operation. • **`graphql`**: (use with a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables. .	string
xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
wsi-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property	Required	Description	Data type
wsdl-validate-body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
wildcards-ignore-xsi-type	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
allow-xop-include	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

You can also apply a validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Validate - DataPower API Gateway in the built-in policies section.

Example 1

```
- validate:
    version: 2.0.0
    title: 'validate, response parameter schema'
    validate-against: response-param
```

Example 2

```
- validate:
    version: 2.0.0
    title: 'validate, predefined schema'
    validate-against: definition
    definition: '#/definitions/RouteOutput'
```

Example 3

```
- validate:
    version: 2.0.0
    title: 'validate, JSON and XML schema URLs'
    validate-against: url
    json-schema: 'https://my.json.schema'
    xml-validation-mode: xsd
    xml-schema: 'https://my.xml.schema'
```

DataPower Gateway (v5 compatible)

validate - DataPower Gateway (v5 compatible)

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see validate - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate - DataPower Gateway (v5 compatible).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the `message.body` variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then `message.body` is not set, and validate is not able to act.
- If you use the `multipleOf` keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
  - The value must not be less than `0.00000099999999999999848869`.
  - If the value is greater than 1, the amount before the decimal point must not be greater than `99999999999999934463`.

About

The validate policy has the following format:

```
- validate:
  version: version
  title: title
  description: description
  definition: swagger_schema_definition_to_be_used
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

Property	Required	Description	Data type
definition	Yes	The schema to be used to validate the payload. Valid values: • **`request`**: Select this value to validate the request input against the schema definition that is specified in the Type field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. • **`response`**: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the Schema field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. • The name of a schema definition, in the following format: **`#/definitions/`*`schema_name`*** The schema must be defined in the **`definitions:`** section of your OpenAPI file.	string

You can also apply an validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Validate - DataPower Gateway (v5 compatible) in the built-in policies section.

Example 1

```
validate:
  version: 1.0.0
  title: validate the response
  definition: #/definitions/RouteOutput
```

validate-usernametoken

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate Username Token.

About

The validate-usernametoken policy has the following format:

```
- validate-usernametoken:
    version: version
    title: title
    description: description
    auth-type: Authentication URL_or_LDAP Registry (policy version 1.0.0 only)
    auth-url: authentication_url_to_use (policy version 1.0.0 only)
    tls-profile: tls_profile_to_use (policy version 1.0.0 only)
    ldap-registry: name_of_the_ldap_user_registry (policy version 1.0.0 only)
    registry: name_of_the_ldap_or_authurl_user_registry (policy version 1.1.0 and later)
    ldap-search-attribute: name_of_the_ldap_user_password_attribute
```

Properties

The following table describes the policy properties:

Table 2. Validate Username Token policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
auth-type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: • **`Authentication URL`**: Specify this value to validate the user credentials against an authentication URL. • **`LDAP registry`**: Specify this value to validate the user credentials against an LDAP user registry. The default value is: **`Authentication URL`**.	string

Property	Required	Description	Data type
auth-url (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to `Authentication URL`.	string
tls-profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to `Authentication URL`.	string
ldap-registry (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to `LDAP registry`.	string
registry (policy version 1.1.0 and later)	Yes	The name of the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
ldap-search-attribute	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "LDAP Registry"
    ldap-registry: "wstest"
    ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "Authentication URL"
    auth-url: "https://www.google.com"
    tls-profile: "default-ssl-profile"
```

For more information about how to use a validate-usernametoken security policy, see Validate Username Token in the built-in policies section.

API Gateway only

watsonx-ai-invoke

Use the watsonx.ai invoke policy to invoke watsonx.ai operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see watsonx.ai invoke.

About

The watsonx.ai invoke policy provides access to three watsonx.ai operations:

- `POST /text-generate`
- `POST /tokenize`
- `GET /deployment-models`

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. watsonx.ai invoke policy properties

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	No	The title of the policy; the default value is `watsonx-ai-invoke text generation`.	string
description	No	A description of the policy.	string

Property label	Required	Description	Data type
operation	Yes	The watsonx.ai operation to invoke; must be one of the following operations: • **`POST text-generate`** An HTTP POST operation for **`/text-generate`**. See Infer text in the watsonx.ai documentation for sample request and response examples. • **`POST tokenize`** An HTTP POST operation for **`/tokenize`**. See Text tokenization in the watsonx.ai documentation for sample request and response examples. • **`GET deployment-models`** An HTTP GET operation for **`/deployment-models`**. See List the available foundation models in the watsonx.ai documentation for sample response examples. If the request payload contains a **`project_id`** property, it is ignored and the policy's own **`project_id`** property is used.	string
op-version	Yes	The watsonx.ai API operation version, using the format **`yyyy-mm-dd`**. To see the available version dates, refer to Active Version Dates in the watsonx.ai API documentation. For information on API versioning in watsonx.ai, see Versioning in the same documentation.	string
project_id	Yes	The ID of the watsonx.ai project used for resolving API requests.	string
region	Yes	The IBM Cloud region where watsonx.ai requests are sent.	string
enable_cache	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the watsonx.ai service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the output property. If there is no cached response, the request is passed to the watsonx.ai service, and the response is cached for subsequent operations using the time-to-live specified in the cache_ttl property.	boolean
cache_ttl	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
cache_scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
output	No	The name of the DataPower API Gateway context message that receives the watsonx.ai response. By default, this property uses **`message`** as the value, which enables the response to be accessible by subsequent API policies in **`message.body`**.	string

Example

```
- watsonx-ai-invoke:
    version: 2.0.0
    title: watsonx-ai-invoke text generation
    description: get an AI response to the provided prompt
    region: us-south
    operation: POST text-generate
    op-version: '2024-03-14'
    enable_cache: true
    cache_ttl: 60
    project_id: $(watsonx-ai-projectid)
    output: watsonxaiResponse
    cache_scope: somesaltkey
```

websocket-upgrade

Use the websocket-upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Websocket Upgrade.

The websocket-upgrade policy has the following format:

```
- websocket-upgrade:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
```

```
timeout: timeout_value_in_seconds
follow-redirects: redirect_behavior_on_301_error
username: username_if_authentication_required
password: password_if_authentication_required
inject-proxy-headers: are_proxy_headers_sent_to_target_url
decode-request-params: are_request_parameters_decoded
encode-plus-char: are_plus_characters_encoded
header-control:
      .
      .
      .
  headers_to_copy_to_target_url
      .
      .
      .
parameter-control:
      .
      .
      .
  parameters_to_copy_to_target_url
      .
      .
      .
```

Properties

Table 2. websocket-upgrade policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
target-url	Yes	Specify the URL to be invoked.	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
follow-redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **301 Moved Permanently**. If this property is set to **true**, the **invoke** policy follows the URL redirection by making a further call to the URL specified in the **Location** header in the response. If this property is set to **false**, the **invoke** saves the **301** status code and the API call is considered to be complete. Note: The **follow-redirect** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **invoke** always follows the URL redirection; the **proxy** policy (not supported by the DataPower API Gateway) saves the **301** status code and completes the API call without following the URL redirection.	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
inject-proxy-headers	No	When set to true, the **invoke** policy injects the **X-Forwarded-For**, **X-Forwarded-To**, **X-Forwarded-Host**, and **X-Forwarded-Proto** headers to the request that is sent to the t**target-url**. The default value is **false**.	boolean
decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the **target-url** of the invoke policy are URL-decoded. The default value is **false**.	boolean
encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the **target-url** are encoded to %2F. The default value is **false**.	boolean
header-control: **type** **values**	No	Specifies the headers in **message.headers** that you want to copy to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the headers that you don't want to be copied. If the **values** property is empty then all headers are copied. If the **type** property is set to **allowlist**, the **values** property lists the headers that you want to be copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **header-control** property is **header-control:** **type: blocklist** **values: []** See header-control examples	object
parameter-control: **type** **values**	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the parameters that you don't want to be copied. If the **type** property is set to **allowlist**, the **values** property lists the parameters that you want to be copied. If the **values** property is empty then no parameters are copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **parameter-control** property is **parameter-control:** **type: allowlist** **values: []** See parameter-control examples	object

Property	Required	Description	Data type

`request-assembly:`
`  execute`
`  .`
`  .`
`  .`
`  policy assembly`
`  .`
`  .`
`  .`
	No	The request processing assembly. For details on configuring an assembly in the **execute** section, see execute.	object

`response-assembly:`
`  execute`
`  .`
`  .`
`  .`
`  policy assembly`
`  .`
`  .`
`  .`
	No	The response processing assembly. For details on configuring an assembly in the **execute** section, see execute.	object

Example

```
- websocket-upgrade:
  version: 2.0.0
  title: websocket-upgrade
  timeout: 60
  target-url: 'https://my.websocket.upgrade.com'
  secure-gateway: false
  follow-redirects: true
  inject-proxy-headers: true
  decode-request-params: false
  encode-plus-char: true
  response-assembly:
    execute:
      - parse:
          version: 2.0.0
          title: parse
          parse-settings-reference:
            default: apic-default-parsesettings
          description: Parse the response from the backend server
```

`header-control` examples

```
# copy all headers to the target URL

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^X-Client-ID$
        - ^Content-Type$

# copy no headers

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values: []

# copy only the Content-Type header

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^Content-Type$
```

`parameter-control` examples

```
# copy no request parameters to the target URL

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values: []
```

```
# append the petid parameter to the target URL
# if the incoming request is http://apigw/org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values:
        - ^petid$
```

xml-to-json

Use the xml-to-json policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see XML to JSON.

About

The xml-to-json policy has the following structure:

```
- xml-to-json:
   version: version
   title: Title
   description: Description
```

Note: If you are using the DataPower API Gateway, the input to the xml-to-json policy must be parsed data. One way to produce parsed data is to use a **parse** policy before an xml-to-json policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
API Gateway only input	No	The input message to convert. Specify the name of a variable in the API context. ***variableName*.body**, the message payload, represents the JSON input to convert. The default value of the variable is **message** and **message.body** is the default input.	string
API Gateway only output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***variableName*.body** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **message.body**. Otherwise, when the input message is the variable **my-message-variable**, for example, the default output is **my-message-variable.body**. The variable cannot be any read-only in the API context.	string
API Gateway only conversionType	No	The conversion type that determines the target format of the output. The following options are available: • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. • apicv5: apicv5 convention is used to determine the target conversion format of the output.	string

Example

The following is an example of a xml-to-json policy:

```
- xml-to-json:
   version: 1.0.0
   title: XML to JSON transform
   description: Transforms XML message body to JSON format
```

xslt

Use the xslt policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see XSLT.

About

The xslt policy has the following structure:

```
- xslt:
    version: version
    title: Title
    description: Description
    input: Input_True_False
    source: Transform
```

Note: If you are using the DataPower API Gateway, the input to the xslt policy must be parsed data. One way to produce parsed data is to use a **parse** policy before an xslt policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. xslt policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The default value is **false**.	boolean
API Gateway only serialize-output	No	If set to **true**, the output tree that is generated by the XSLT policy is serialized. The content of **message.body** is updated with the serialized binary data rather than the XML tree. The default value is **false**.	boolean
source	Yes	The XSLT transform source to execute.	string
API Gateway only xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
API Gateway only strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
API Gateway only profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
API Gateway only debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
API Gateway only stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
API Gateway only try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
API Gateway only minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
API Gateway only stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
API Gateway only wsi-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property	Required	Description	Data type
API Gateway only wsdl-validate-body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-validate-headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
API Gateway only allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
API Gateway only validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
API Gateway only wildcards-ignore-xsi-type	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
API Gateway only wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
API Gateway only xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
API Gateway only allow-xop-include	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

You can also apply an xslt policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see XSLT in the built-in policies section.

For examples of the OpenAPI definitions of xslt policies, see XSLT policy examples in the built-in policies section.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

catch

Use the catch extension to catch errors that occur during an API call.

The catch extension takes the following form:

```
catch:
   - errors:
      - Error_1
      - Error_2
   - execute:
      assembly_1
   - errors:
      - Error_3
   - execute:
      assembly_2
   - default:
      assembly_3
```

The following table shows the properties of the **catch** extension:

Table 1. The properties of the catch extension

Property	Required	Description	Type
errors	Yes	The errors for which the catch will activate. For a list of errors, see Error cases supported by assembly catches.	Array (String)
execute	Yes	The section of the assembly that will execute when the catch is activated.	Array (Object)
default	No	The section of the assembly that will execute when an error does not trigger other catches. It behaves in the same manner and has the same structure as **execute**	Array (Object)

The following is an example of a **catch** extension:

```
    catch:
      - errors:
          - ConnectionError
          - JavaScriptError
        execute:
          - activity-log:
              title: activity-log
              content: activity
              error-content: payload
      - default:
          - activity-log:
              title: activity-log
              content: activity
              error-content: payload
```

properties

Use the **properties** extension to define properties for referencing in an API.

The **properties** extension has the following structure:

```
properties:
   property_1:
      value: default_value_1
      description: description_1
      encoded: encoded_boolean_1
   property_2
      value: default_value_2
      description: description_2
      encoded: encoded_boolean_2
```

The following table lists the fields found in the **properties** extension:

Table 1. The properties extension

Property	Required	Description	Data type
property	Yes	The name of the property. It is used when referencing the property. Note that this is the field name, not the contents of the field.	Object
value	No	The default value that the property takes. It can be empty.	String
description	No	The description of the property. It can be empty.	String

Property	Required	Description	Data type
`encoded`	No	Specifies whether to encode the value of this property.	Boolean

The following example shows a sample `properties` field:

```
properties:
  ID:
    value: 1234
    description: An ID to be used for validating.
    encoded: false
```

catalogs

Use the `catalogs` extension to assign catalog-specific values to properties defined in the `properties` section.

The `catalogs` section has the following structure:

```
catalogs:
   catalog_name_1:
      properties:
         property_name_1: value_1
         property_name_2: value_2
   catalog_name_2:
      properties:
         property_name_1: value_3
```

The following table lists the fields found in the `catalogs` extension:

Table 1. Catalogs properties

Property	Required	Description	Data type
`catalog_name`	Yes	The name of the catalog. It must match a catalog in API Manager. Note that this is the field name, not the contents of the field.	Object
`properties`	Yes	This field contains any properties that are to be set.	Object
`property_name`	Yes	The field name is the property to be set and must match a property defined in the `properties` extension. It contains the value of the property for the catalog to which the field belongs. If, in the `properties` extension, it has been specified as encoded, this will be encoded when saved or staged by IBM® API Connect.	String

The following is an example of a `catalogs` extension:

```
catalogs:
  Sandbox:
    properties:
      ID: 5678
```

activity-log

If you're using the DataPower® API Gateway, you can use the `activity-log` extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is `activity` for when API execution completes successfully, and `payload` for when API execution completes with an error code. When you compose your API definition, you can change the type of content to log in these API event records. For more information about API event records, see API event record field reference.

Note that if you're using the DataPower Gateway (v5 compatible), you can configure your logging preferences by using an `activity-log` policy in your API assembly. For more information, see activity-log.

The `activity-log` extension takes the following form:

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
```

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
buffering: true
```

The following table shows the properties of the `activity-log` extension:

Table 1. The properties of the activity-log extension

Property	Required	Description	Type

Property	Required	Description	Type
`success-content`	No	Defines the type of content to be logged when the operation is successful. Valid values: • **`none`**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **`activity`**: Logs invocation only (only the resource URI is recorded). • **`header`**: Logs activity and header. • **`payload`**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **`activity`**.	String
`error-content`	No	Indicates what content to log when an error occurs. Valid values: • **`none`**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **`activity`**: Logs invocation only (only the resource URI is recorded). • **`header`**: Logs activity and header. • **`payload`**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **`payload`**.	String
`enabled`	No	Indicates whether activity logging is enabled or disabled.	Boolean

Example 1

Override the default activity logging settings:

```
activity-log:
    success-content: none
    error-content: header
    enabled: true
```

Example 2

Turn off activity logging:

```
activity-log:
    enabled: false
```

finally

The finally extension specifies the final API rule to apply to the API call. This executes policies after the main assembly execution, catch extension, or both have been processed. It ensures that specific actions are performed before the API response is returned.

The finally extension takes the following form:

```
finally:
   - Policy_1
   - Policy_2
```

The following is an example of a **`finally`** extension:

```
assembly:
    execute:
      - set-variable:
          version: ...
    catch:
      - errors:
          - ConnectionError
        execute:
          - set-variable:
              version: ...
      - default:
          - set-variable:
              version: ...
    finally:
      - Policy_1
      - Policy_2
```

Specifying a gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify which type of gateway the API uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see execute.

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see invoke.

Procedure

1. Edit the API definition YAML file and add the gateway type. For example:
   - DataPower Gateway (v5 compatible):

     ```
     gateway: datapower-gateway
     ```

   - DataPower API Gateway

     ```
     gateway: datapower-api-gateway
     ```

   Note: If your API YAML file includes the `gateway:` property, the `enforced:` property must be set to `true`
2. Ensure that the policies, including policy versions, in your APIs are supported by the gateway type. Review the list of policies on the execute page. If necessary, review the individual policy pages to determine the supported version number.
3. Ensure that any Product that uses this API is configured to use the same gateway type. See Specifying a gateway type for your Product.

Referring to an extension in an API definition

To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an `extensions` key under `x-ibm-configuration`.

Before you begin

Add the OpenAPI extension to any Catalogs that the API is to be published to, by importing its definition file; for details, see Working with OpenAPI extensions. If the target Catalog does not contain the OpenAPI extension then attempts to publish the API to it will fail.

About this task

The following example shows an extension definition file that defines a bank branch, in YAML format:

```
extension: '1.0.0'

info:
   title: Banking services
   name: banking
   version: 1.0.0
   description: Banking extensions
   contact:
     name: IBM API Connect
     url: https://apiconnect.ibm.com/
     email: myname@ibm.com

portal-visible: true

properties:
  title: "Branch"
  type: "object"
  properties:
    Branch type:
      type: "string"
      enum:
        - "ATM"
        - "Walk in"
    location:
      type: "object"
      title: "Location"
      properties:
        city:
          type: "string"
```

```
        default: "San Francisco"
      state:
        type: "string"
        default: "CA"
      citystate:
        type: "string"
        description: "This is generated automatically from the previous two fields"
        template: "{{city}}, {{state}}"
        watch:
          city: "location.city"
          state: "location.state"
required:
  - Branch type
```

The following table provides more information on the available fields when creating an API extension.

Table 1. Description of the fields

Field	Description	Required	Default value	Example
`version`	Version number of the extension Note: The `version` field must follow the `version.release.modification` version numbering scheme.	Yes		`1.0.0`
`title`	Title of the extension Note: The `title` and `name` fields must be kept short so that they can be displayed in the API Manager user interface.	Yes		Banking service
`name`	Short name for the extension Note: The `name` field must be a single word and contain only alphanumeric characters, dash, and underscore characters.	Yes		banking
`description`	Short description of the extension	No		Banking extensions
`termsofservice`	Terms of service for the extension	No		Terms_of_Service
`license.name`	Name of the license	No		IBM API Connect
`license.URL`	URL to the license	No		https://apiconnect.ibm.com/
`contact.name`	Name of the contact	No		myname@ibm.com
`contact.URL`	URL for contacting the organization	No		https://www.example.com/support
`contact.email`	Email for contacting the organization	No		support@example.com
`portal`	Whether the extension is visible in the developer portal	No	`true`	`true` or `false`
`gateways`	List of gateways the extension can be used with Note: The `gateways` field is optional, but if included, it must list the types of gateways the extension can be used with.	No		• `datapower-api-gateway` • `datapower-gateway`

`properties`	The custom properties to be included in the OpenAPI extension.	No		The `properties` field can be customized to include any valid OpenAPI properties.
				`properties:`
				`  title: "Branch"`
				`  type: "object"`
				`  properties:`
				`  Branch type:`
				`  type: "string"`
				`  enum:`
				`  - "ATM"`
				`  - "Walk in"`

Procedure

To enable the use of custom extensions in an API definition, complete the following steps:

1. Edit the API definition YAML file and add the reference. For example:

```
x-ibm-configuration:
      .
      .
      .
  extensions:
    banking: 1.0.0
```

2. In your API definition file, add a property whose name must begin with `x-` and references the name of the extension you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file.
   The following example uses the banking extension:

```
      .
      .
      .
x-banking:
  Branch type: ATM
  location:
    city: San Francisco
    state: CA
    citystate: 'San Francisco, CA'
```

Using $ref to reuse code fragments in your OpenAPI files

If you deploy an API to an IBM® API Connect Management server by using the developer toolkit command line, you can use the **$ref** field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the **$ref** field is replaced with the contents of the target file.

Use the following syntax in your source YAML file:

```
$ref: path_to_file_containing_code_fragment
```

Use the following syntax in your source JSON file:

```
{
$ref: path_to_file_containing_code_fragment
}
```

For example:

```
$ref: code_fragments/my_fragment.yaml
```

```
{
  "$ref": "code_fragments/my_fragment.json"
}
```

The replacement of the **$ref** field with the target code fragment occurs when you perform any of the following actions on the API defined by the source API definition file:

- Stage or publish an API to an API Connect Management server by using the **apic publish** command. For more information, see Publishing APIs and applications.
- Validate the API definition YAML file by using the **apic validate** command. For more information, see Validating the YAML or JSON definition of an API or Product.

Important: You cannot insert a $ref field at the root level of your OpenAPI file.

Example 1

A source YAML file contains the following OpenAPI code:

```
swagger: '2.0'
info:
  version: 1.0.0
  title: Branches
  x-ibm-name: Branches
  description: Provides operations relating to BankA branch information.
basePath: /branches
paths:
  /details:
    get:
      responses:
        - $ref: code_fragments/paths.yaml#/details/get/responses
        .
        .
        .
```

The file paths.yaml contains the following OpenAPI code fragment:

```
details:
  get:
    responses:
      '200':
        description: 200 OK defined in $ref file
        schema:
          $ref: '#/definitions/branch'
    summary: Branch details
    description: Retrieve details of the current branches of BankA.
```

When API Connect processes the source YAML file, the **$ref** field is replaced with the target code fragment, yielding the following OpenAPI code:

```
swagger: '2.0'
info:
  version: 1.0.0
  title: Branches
  x-ibm-name: Branches
  description: Provides operations relating to BankA branch information.
basePath: /branches
paths:
  /details:
    get:
      responses:
        '200':
          description: 200 OK
          schema:
            $ref: '#/definitions/branch'
      summary: Branch details
      description: Retrieve details of the current branches of BankA.
        .
        .
        .
```

Example 2

Example of a reference to an external file that contains just the parameter details:

```
openapi: 3.0.0

info:
  version: 3.0.1
  title: BeamUp API
  x-ibm-name: BeamUpAPI
servers:
  - url: /
paths:
  /customers:
    get:
      parameters:
        - $ref: tests/fixtures/api/referenceFile.yaml
      responses:
        200:
          description: An array of customers
          content:
            application/json:
              schema:
                type: object
                properties:
                  customerID:
                    type: string
                  customerName:
                    type: string
.
.
.
```

The file referenceFile.yaml contains the following OpenAPI code fragment:

```
name: page
in: query
description: page of results to return
required: true
schema:
  type: integer
```

Example of a reference to an external file that contains the parameters inside a path code fragment:

```
openapi: 3.0.0

info:
  version: 3.0.1
  title: BeamUp API
  x-ibm-name: BeamUpAPI
servers:
  - url: /
paths:
  /customers:
    get:
      parameters:
        - $ref: tests/fixtures/api/referenceFileWithPath.yaml#/customers/get/parameters
      responses:
        200:
          description: An array of customers
          content:
            application/json:
              schema:
                type: object
                properties:
                  customerID:
                    type: string
                  customerName:
                    type: string
```

The file referenceFileWithPath.yaml contains the following OpenAPI code fragment:

```
customers:
  get:
    parameters:
      name: page
      in: query
      description: page of results to return
      required: true
      schema:
        type: integer
```

Creating a Product definition file

You define a Product by creating a Product definition file.

About this task

You can create a Product definition file in either of the following ways:

- Create the file in an editor of your choice.
- Create a Product definition file by using the `apic create:product` command and then modify it. You can base your Product definition file on the default Product template or on your own custom template.

This topic describes the syntax that is needed for both options and also the structure needed when the file is created in the editor. For details on what you can include in the product definition file, see Product definition schema.
You can create a Product in the CLI by running **apic create:product** and supplying additional arguments on the command line. For example, you can enter the following text in a single command:

```
apic create:product --name product_name --title product_title --filename product_file_name.yaml
--apis "filename_of_api1.yaml filename_of_api2.yaml"
```

where:

- *product_name* is the name for your new Product.
- *product_title* is the title of your new Product.
- *product_file_name.yaml* is the name of the yaml file that is created for your new Product.
- *filename_of_api1.yaml* is the file name of one of the APIs that is used within the new Product.
- *filename_of_api2.yaml* is the file name of one of the APIs that is used within the new Product.

Another option is to create a Product interactively in the command line by running **apic create:product** and following the prompts.
You can see further details and available options for the **apic create:product** command by entering the command:

```
apic create:product --help
```

You can also create a Product from a custom Handlebars template by using the following command:

```
apic create:product --template template_filename --title product_title
```

where *template_filename* is the name of the Handlebars template to use, and *product_title* is the title of your Product. A Product template file must have a .hbs file name extension. You can create a template from scratch, or start with the example (default) Product template provided in API and Product definition template examples.
A Product definition file contains the following sections:

- The specification version
- An information section
- A visibility section
- An APIs section
- A Plans section

In this topic, YAML is used, but the instructions can be adapted to use JSON. Both .yaml and .yml file extensions are supported, but the use of the .yaml file extension is recommended by yaml.org.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Procedure

Structure your Product definition file by completing the following steps:

1. Set the specification version by adding the following line to the beginning of the file: `product: 1.0.0`.
   This line specifies the template version, and is always **product: 1.0.0**.
   Note: The specification version is distinct from your Product version. The specification version refers to this YAML file, while the Product version is by your discretion.
2. Include an information section with details about the Product, as described in Completing the information section of your Product description.
3. Include a visibility section that specifies who can view and subscribe to the Product, as described in Specifying the visibility of your Product.
4. Include an APIs section that references the APIs to be included in the Product, as described in Referencing the APIs for your Product.
5. Include a Plans section that described the Plans you want include in your Product, as described in Describing Plans in your Product.

Results

You have completed a YAML representation of your Product. A complete example with full indentation can be found in An example YAML representation of a Product.

You can create multilingual API and Product documentation by using an **x-ibm-languages** extension directly in the OpenAPI definition. For more information, see Using x-ibm-languages to create multilingual API and Product documentation.

- **Product definition schema**
  The product definition schema defines the properties (and their data types) that you can include in a product definition file.
- **Converting a Product YAML file to use DataPower API Gateway**
  IBM API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

Related information

- Changing the availability of a Product

Product definition schema

The product definition schema defines the properties (and their data types) that you can include in a product definition file.

              "month"
            ]
          },
          "trial-period": {
            "type": "integer"
          },
          "trial-period-unit": {
            "type": "string",
            "enum": [
              "day"
            ]
          }
        }
      }
    }
}
```

Completing the information section of your Product description

Provide users with information about your Product.

About this task

The information section of a YAML representation of a Product contains the Product's name and version. It can also include contact and license details.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
An example information section for a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To complete the information section of your Product description, complete the following steps.

1. Begin the section and provide a name, title, description, and version number; use the following syntax:

   ```
   info:
     version: Product_Version
     title: Product_Title
     name: Short_Name
     summary: Product_Description
   ```

   where:
   - *version* is the version number of the policy.
     Tip: The `version.release.modification` version numbering scheme is recommended, for example `1.0.0`.
   - *Product_Title* is the title of the Product. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - *Short_Name* is the short name for the policy. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface of IBM API Connect.
   - *Product_Description* is a short description of the policy. Any string can be used.
2. Optional: Under info, supply contact information; use the following syntax:

```
  contact:
    name: Contact_Name
    url: 'Contact_URL'
    email: Contact_email
```

where:

- *Contact_Name* is the name of the contact for this Product.
- *Contact_URL* is the URL for contact your organization.
- *Contact_email* is an email for contacting your organization.

3. Optional: Under info, add license information for your Product; use the following syntax:

```
  license:
    name: License_Name
    url: 'License_URL'
```

where:

- *License_Name* is the name of the license that applied to your Product.
- *License_URL* is the URL at which information about the license can be accessed.

4. Optional: Under info, add your terms of service; use the following syntax:

```
 termsOfService: Terms
```

where *Terms* is a string that details the terms of service for using your Product.

Results

You have completed the information section of your Product's YAML representation. It should have the following form:

```
info:
  version: Product_Version
  title: Product_Title
  name: Short_Name
  description: Product_Description
  contact:
    name: Contact_Name
    url: 'Contact_URL'
    email: Contact_email
  license:
    name: License_Name
    url: 'License_URL'
  termsOfService: Service_Terms
```

where all variables are as described in previously in this topic. The indentation must be as in the example.

Specifying a gateway type for your Product

Product definitions must specify which type of gateway the Product uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See Specifying a gateway type for an API definition.

Procedure

1. Determine the gateway type that is configured for the APIs in your Product. The Product gateway type must match the APIs gateway type.
   To review the APIs for your Product, see Referencing the APIs for your Product.

2. Edit the Product definition file (YAML source) to add the gateway type you want to use:
   - DataPower Gateway (v5 compatible):

     ```
     gateways:
                 datapower-gateway
     ```

   - DataPower API Gateway

     ```
     gateways:
                 datapower-api-gateway
     ```

3. Ensure that the policies, including policy versions, in the APIs in your Product are supported by the gateway type. Review the list of policies on the execute page. If necessary, review the individual policy pages to determine the supported version number.

Related information

- DataPower API Gateway porting notes

Converting a Product YAML file to use DataPower API Gateway

IBM® API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

Before you begin

IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

Product definitions can specify only one type of gateway. The type of gateway must match the gateway type that is used by the APIs that are included in the product. If you want to take advantage of the capabilities of DataPower API Gateway, you can easily modify your existing Product definitions to specify it as the gateway type.

Procedure

1. Verify that the APIs in the product specify DataPower API Gateway as the gateway type, and that the APIs have been converted for use with the DataPower API Gateway.
2. Open the Product YAML file for editing.
   For example:

```
product: '1.0.0'          .

info:
  name: testprod
  title: testprod
  version: 1.0.0
           .
           .
           .
```

3. Add a **gateways:** setting, and specify **datapower-api-gateway**.
   For example:

```
product: '1.0.0'          .

info:
  name: testprod
  title: testprod
  version: 1.0.0
gateways:
  - datapower-api-gateway
              .
              .
              .
```

4. Save the modified YAML file.

Specifying the visibility of your Product

How to set the availability of your Product by specifying its visibility and subscribability levels.

About this task

The visibility section of your Product's YAML representation determines who can view and subscribe to your Product in IBM® API Connect.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
An example visibility section of a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To complete the visibility section of your Product description, complete the following steps:

1. Title the section by adding **visibility:**
2. Under **visibility:**, specify who can **view** the Product; use the following syntax:

```
   view:
      enabled: View_Toggle
      type: View_Audience
      tags: View_Tag
      orgs: View_Organizations
```

where

- *View_Toggle* determines whether the Product is visible to anybody or not. It must be **true** or **false**. If **false**, the Product will not be visible in the Developer Portal.
- *View_Audience* must be **public**, in which case the Product is visible to anybody who uses the Developer Portal, **authenticated**, in which case the Product is visible to anybody registered through the Developer Portal, or **custom**, in which case the Product is visible to a specified group of users. You can specify these custom users as one or more consumer organizations in the **orgs:** section, and as one or more consumer organization groups in the **tags:** section.
- The *View_Tag* specifies the consumer organization groups that can view the Product if *View_Audience* is set to **custom**. If *View_Audience* is not set to **custom**, do not include **tags:**. If *View_Audience* is **custom**, you can specify groups in the following manner:

  ```
      tags:
         - Organization group 1
         - Organization group 2
  ```

  where the *Organization group* variables are the names of the groups that are to be allowed to view the Product. Note that when a Product is published, the **tags:** property name becomes **group_urls:**, and the content is changed to URL strings.
- *View_Organizations* specifies the consumer organizations that can view the Product if *View_Audience* is set to **custom**. If *View_Audience* is not set to **custom**, do not include **orgs:**. If *View_Audience* is **custom**, you can specify organizations in the following manner:

  ```
      orgs:
         - Organization 1
         - Organization 2
  ```

  where the *Organization* variables are the names of the organizations that are to be allowed to view the Product. Note that when a Product is published, the **orgs:** property name becomes **org_urls:**, and the content is changed to URL strings.

3. Under **visibility:**, specify who can **subscribe** to your Product's Plans; use the following syntax:

```
   subscribe:
      enabled: Subscribe_Toggle
      type: Subscribe_Audience
      tags: Subscribe_Tag
      orgs: Subscribe_Organizations
```

where:

- *Subscribe_Toggle* must be **true** or **false**. If **false**, no developers will be able to subscribe to the Product.
- *Subscribe_Audience* must be **authenticated**, in which case the Product's Plans can be subscribed to by anybody who is registered through the Developer Portal, or **custom**, in which case the Product's Plans can be subscribed to by a specified group of users.
- The *Subscribe_Tag* specifies the consumer organization groups that can subscribe to the Product's Plans if *Subscribe_Audience* is set to **custom**. If *Subscribe_Audience* is not set to **custom**, omit it or set as **[]**. If *Subscribe_Audience* is **custom**, you can specify groups in the following manner:

  ```
      tags:
         - Organization group 1
         - Organization group 2
  ```

  where the *Organization group* variables are the names of the groups that are to be allowed to subscribe to the Product. Note that when a Product is published, the **tags:** property name becomes **group_urls:**, and the content is changed to URL strings.
- *Subscribe_Organizations* specifies the organizations that can subscribe to the Product's Plans if *Subscribe_Audience* is set to **custom**. If *Subscribe_Audience* is not set to **custom**, omit it or set as **[]**. If *Subscribe_Audience* is **custom**, you can specify organizations in the following manner:

  ```
      orgs:
         - Organization 1
         - Organization 2
  ```

  where the *Organization* variables are the names of the organizations that are to be allowed to subscribe to the Product. Note that when a Product is published, the **orgs:** property name becomes **org_urls:**, and the content is changed to URL strings.
  Note: If a Product is to be available for subscription, it must already be visible. As a result, for the subscription audience to be **authenticated**, the view audience cannot be **custom**.

Results

You have completed the visibility section of your Product's YAML representation. It should have the following form:

```
visibility:
   view:
      enabled: View_Toggle
      type: View_Audience
      tags:
         - View_Tag_1
         - View_Tag_2
      orgs:
         - Organization_1
         - Organization_2

   subscribe:
      enabled: Subscribe_Toggle
      type: Subscribe_Audience
      tags:
         - Subscribe_Tag_1
         - Subscribe_Tag_2
      orgs:
         - Organization_1
         - Organization_2
```

where all variables are as described previously in this topic. The indentation must be as in the example.

What to do next

You can also define Product visibility at a Catalog or Space level. For more information, see Configuring Product visibility at a Catalog or Space level.

Related information

- Configuring Product visibility at a Catalog or Space level

Referencing the APIs for your Product

Detail the file paths for the APIs you want to include in your Product in IBM® API Connect.

About this task

Before an API can be included in a Plan, it must first be referenced in the APIs section of your Product description.

Procedure

Begin the APIs section and reference the APIs you want to include in your Product. The syntax that you use depends on which user interface you are using, as follows:

- API Designer:

```
apis:
  API_1_NameAPI_1_Version
    $ref: API_1_File_Path
  API_2_NameAPI_2_Version
    $ref: API_2_File_Path
```

- API Manager:

```
apis:
  API_1_NameAPI_1_Version
    name: 'API_1_Name:API_1_Version'
  API_2_NameAPI_2_Version
    name: 'API_2_Name:API_2_Version'
```

  where
  - the *API_n_Name* variables are the case-sensitive names of your APIs.
  - the *API_n_Version* variables are the versions of your APIs.
  - the *API_n_File_Path* variables are the file paths for the YAML files containing OpenAPI representations of your APIs.

The following example shows a complete sample APIs section:

```
apis:
  api11.0.0:
    name: 'api1:1.0.0'
  api21.0.0:
    name: 'api2:1.0.0'
  api31.0.0:
    name: 'api3:1.0.0'
```

For more information about creating OpenAPI definitions, see Creating an OpenAPI definition file.

The indentation must be as in the examples and the APIs must have been created before they can be referenced.

Results

You have referenced the APIs that are to be included in your Product. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Describing Plans in your Product

Describe the Plans that you want to include in your IBM® API Connect Product and which APIs they will contain, as well as any rate limits that apply.

About this task

A Plan contains APIs and their operations. It can be used to implement rate limits and tailor visibility.

Note: If you are using more than one DataPower® server in a Gateway service, then to properly calculate API calls for rate limits the servers must be able to communicate with each other by using SLM peer groups, using either SLM unicast peering or SLM multicast peering depending on your network configuration. For more information, see SLM peering.
In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
Two example Plan descriptions from a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To describe your Plans, include APIs in them, and set rate limits for Plans or specific operations, complete the following instructions:

1. Begin the Plans section with `plans:`
2. Under Plans, begin the description of your first Plan by providing a name, description, and specifying whether approval is required for subscription requests; use the following syntax:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
```

   where:
   - *Plan_Name* is the name of the Plan. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface.
   - *Plan_Title* is the title of the Plan.Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - *Plan_Description* is a description of your Plan.
   - *Approval_Toggle* must be either `true`, in which case approval is needed for subscription requests, or `false`, in which case subscriptions are automatically approved.
3. Optional: Under your Plan, add multiple burst and rate limits that will be shared across all the operations in the Plan; use the following syntax:
   Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

```
    rate-limits:
      Name:
        value: Rate_Limit
        hard-limit: Limit_Toggle
      Name:
        value: Rate_Limit
        hard-limit: Limit_Toggle
    burst-limits:
      Name:
        value: Burst_Limit
```

   where:
   - *Name* is the name of the limit.
   - *Rate_Limit* is your rate limit. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: **`1/2minute`**. If the time unit is singular, then it is not necessary to precede it with a number, for example, **`1/minute`**. If you do not want to apply a rate limit, set *Rate_Limit* as `unlimited`.
   - *Limit_Toggle* must be `true` or `false`. If *true*, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Rate_Limit* to `unlimited`.
   - *Burst_Limit* is your burst limit. It can be for multiples of seconds or minutes, written as `second` or `minute`; do not use the plural forms of the words.

   Note:
   - Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
   - The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see Working with Catalogs
4. Under your Plan, specify which APIs are to be included.
   Reference APIs by name and version, as follows:

```
    apis:
      API_1_nameAPI_1_version: {}
      API_2_nameAPI_2_version: {}
```

   where
   - the *API_n_name* variables are the case-sensitive names of your APIs.
   - the *API_n_version* variables are the versions of your APIs.
5. Optional: If you want to include only a subset of an API's operations, list the operations that are to be included; use the following syntax:

```
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_1_Verb
            path: Operation_1_Path
          - operation: Operation_2_Verb
            path: Operation_2_Path
```

   where
   - the *Operation_n_Path* variables are the paths of operations that is to be included. The dash is required for each new operation.
   - the *Operation_n_Verb* variables are the appropriate REST verbs for the operations.
6. Optional: If you want to specify multiple rate limits for a single operation; use the following syntax:

```
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_Verb
            path: Operation_Path
            rate-limits:
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
              Name:
```

```
              value: Operation_Limit
              hard-limit: Operation_Limit_Toggle
```

where:

- *Operation_Limit* is the rate limit that you want to apply to your operation. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: **`1/2minute`**. If the time unit is singular, then it is not necessary to precede it with a number, for example, **`1/minute`**. If you do not want to apply a rate limit, set *Operation_Limit* as `unlimited`.
- *Operation_Limit_Toggle* must be `true` or `false`. If *true*, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Operation_Limit* to `unlimited`.

Results

You have described the Plans that are to be included in your Product. Your Plans section should be similar to the following scenarios.

If you have enforced a rate limit for your Plan and not specified individual operations, your Plans section should have the following form:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
    rate-limits:
      Name:
        value: Limit
        hard-limit: Limit_Toggle
    apis:
      API_1_nameAPI_1_version: {}
      API_2_nameAPI_2_version: {}
```

If you have enforced rate limits at the Plan level and want to include two operations, with a separate rate limit one for one of the operations, your Plans section should have the following form:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
    rate-limits:
      Name:
        value: API_Limit
        hard-limit: API_Limit_Toggle
    burst-limits:
      Name:
        value: Burst_limit
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_1_Verb
            path: Operation_1_Path
            rate-limits:
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
          - operation: Operation_2_Verb
            path: Operation_2_Path
```

In both examples, variables are as in the previous steps and the indentation must be as presented.

The following example shows a complete sample Plans section:

```
plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  my-plan:
    title: my_plan
    rate-limits:
      Default rate-limit:
        value: 50/1hour
        hard-limit: false
    burst-limits:
      Default burst-limit:
        value: 10/1second
    apis:
      api21.0.0:
        operations:
          - operation: get
            path: /path2
      api31.0.0:
        operations:
          - operation: get
            path: /path3
            rate-limits:
              limit3:
                value: 10/1second
                hard-limit: true
              limit4:
                value: 100/1hour
```

```
                hard-limit: true
    api11.0.0: {}
```

An example YAML representation of a Product

Products in IBM® API Connect can be represented by using a YAML file in a similar fashion to how APIs can be represented by using OpenAPI.

The following code describes a complete Product, with sample values.

```
info:
  version: 1.0.0
  title: SampleProduct
  name: SampleProduct
  summary: This is a sample product
gateways:
  - datapower-gateway
product: 1.0.0
visibility:
  view:
    enabled: true
    type: public
    tags: []
    orgs: []
  subscribe:
    enabled: true
    type: authenticated
    tags: []
    orgs: []
plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  newplan:
    title: NewPlan
    rate-limits:
      low:
        value: 10/1hour
        hard-limit: true
    burst-limits:
      Default burst-limit:
        value: 10/1second
apis:
  SampleAPI:
    name: 'Sampleapi:1.0.0'
```

Using `x-ibm-languages` to create multilingual API and Product documentation

Create multilingual API and Product documentation by using the **`x-ibm-languages`** extension in your API and Product OpenAPI definitions.

You can scale your API initiatives to a global user base, while still maintaining a single API definition. Translations are custom configured and controlled, so that they can be tailored to both your API documentation and the API consumer. The extensions that are used in API Connect are added directly to the YAML file as **`x-ibm-languages`**. These extensions are then used in the Developer Portal, so that whatever language the Developer Portal is set to reflects the translations that are contained in the API and Product definitions.

Add the following syntax into your API or Product YAML file at every point that you require some translated text:

```
x-ibm-languages:
  item_name:
    language_code: translated_text
```

Where:

- ***`item_name`*** is the name of the item that you want to translate, for example **`summary`**.
- ***`language_code`*** is the ISO code for the translation language. Supported languages with their ISO codes are listed in the following table.

Table 1. List of supported language codes

Language	Code
Chinese, simplified	`zh_cn`
Chinese, traditional	`zh_tw`
Dutch	`nl`
English	`en`
French	`fr`
German	`de`
Italian	`it`
Japanese	`ja`
Korean	`ko`

Language	Code
Portuguese	`pt`
Spanish	`es`
Turkish	`tr`

- *translated_text* is the translated text that you want to be displayed for the item in the Developer Portal.

Note: The Developer Portal automatically assumes that the default language in the OpenAPI definition is English. If you want to use a different default language in the definition, you must provide both the English translation and the default language text in the **`x-ibm-languages`** extension sections of your OpenAPI definition, by using the following syntax:

```
x-ibm-languages:
  item_name:
    en: English_translated_text
    default_language_code: default_language_text
```

For an example of how to write an OpenAPI YAML file with French as the default language, see the Examples section.

Examples

An example API OpenAPI YAML file that contains the **`fr`** language extension, where English is the default language:

```
swagger: '2.0'
info:
  x-ibm-name: climbing-weather-api
  title: Climbing Weather API
  version: 1.0.0
  x-ibm-languages:
    title:
      fr: Climat d'escalade
schemes:
  - https
host: $(catalog.host)
consumes:
  - application/json
produces:
  - application/json
x-ibm-configuration:
  assembly:
    execute:
      - invoke:
          target-url: 'https://1234.com'
          title: 3 day forecast invocation
          cache-response: time-to-live
          cache-key: $(request.search)
  gateway: datapower-gateway
  enforced: true
  testable: true
  phase: realized
  cors:
    enabled: true
paths:
  /weather/forecast:
    get:
      summary: Retrieve the 3 day forecast for a location
      description: Retrieve the locations weather forecast descriptions for the next 3 days and nights
      operationId: getWeather
      x-ibm-languages:
        summary:
          fr: Récupérer la prévision de 3 jours pour un emplacement
        description:
          fr: Récupérer les descriptions des prévisions météo pour les 3 prochains jours et les nuits
      tags:
        - Weather
      parameters:
        - name: zip

    100 Calls per day:
      hard-limit: true
      value: 100/1day
```

An example of how to write an OpenAPI YAML file with French as the default language:

```
info:
  name: climat-d-escalade
  title: Climat d'escalade
  version: 1.0.0
  x-ibm-languages:
    title:
      en: Climbing Weather API
      fr: Climat d'escalade
...
```

This example shows that both the default French language, and the English language translation, must be provided in the **x-ibm-languages** section.

Related information

- Expand your API Initiatives Globally with Multi-Lingual Support of API and Product Definitions

Using `x-example` to control the examples displayed in the Developer Portal

OpenAPI does not support the use of **example** attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use **x-example** in OpenAPI parameters.

In this example, you cannot use **example** as it isn't supported by the OpenAPI spec, but you can use **x-example**.

```
- name: city
  in: query
  required: false
  type: string
  maxLength: 50
```

```
   description: "Location"
   x-example: "New York"
```

An **example** attribute is honored where set and allowed by the spec. If **example** is not found, **default** is honored where set and allowed by the spec. An **x-example** attribute is honored if found, if not found, a random example to match the schema is generated.

If the spec allows you to use **example**, then you should use it in preference to **x-example**.

Using x-embedded-doc to add additional documentation to products and APIs

You can use **x-embedded-doc** to add additional documentation to a product or an API as part of their definition.

You can embed additional documentation pages within the api swagger documentation. These pages can be base64 encoded strings or markdown strings of the html content of the page. These pages show up in the navigation, on the left side, underneath the overview for that product or API, and above the paths. Any styling that is needed to theme the documentation can be included in the Developer Portal custom theme.

Embedded docs for products and APIs

You can embed documentation for individual products and APIs by specifying an additional **x-embedded-doc** object in the product or API specification.

Field name	Type	Description
name	**string**	Required, the name of the embedded document
title	**string**	Required, The display title of the embedded document
format	**string**	Optional, the format of the embedded document content value. Values are **b64html** or **md**. Default value is **md**.
content	**string**	The base64 encoded html of page, or, the markdown string.
docs	**x-embedded-doc**	Additional embedded documentation. If no content is specified for parent, then the first child is the content that is shown.

Hierarchies of documents are supported by nesting of further doc properties. Language support is available by using **x-ibm-languages**.

Examples

Documentation can be added to an api, by using the following JSON:

```
"x-embedded-doc": [
   {
     "name": "introduction",
     "title": "Introduction",
     "format": "md",
     "content": "# some markdown"
   },
   {
     "name": "concepts",
     "title": "Concepts",
     "format": "md",
     "content": "## more markdown"
   },
   {
       "name": "authentication",
       "title": "Authentication",
       "docs": [{
             "name": "auth_clientid_secret",
             "title": "Obtaining a Client ID and Secret",
             "format": "md",
             "content": "### even more markdown"
             },
             {
               "name": "auth_bearertoken",
               "title": "Getting and Using a Bearer Token",
               "format": "md",
               "content": "#### yet more markdown"
             }
             ]
   }
 ]
```

Alternatively, by using base 64 encoded HTML:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImludHJvZHVjdGlvbiIgY2xhc3M...."
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImNvbmNlcHRzIiBjbGFzcz0icGFnZSI....."
  },
  {
    "name": "authentication",
    "title": "Authentication",
    "docs": [{
           "name": "auth_clientid_secret",
           "title": "Obtaining a Client ID and Secret",
```

```
            "format": "b64html",
            "content": "PGFydGljbGUgaWQ9ImNsaWVudC1pZC1zZWNyZX....."
            },
            {
            "name": "auth_bearertoken",
            "title": "Getting and Using a Bearer Token",
            "format": "b64html",
            "content": "ICA8YXJ0aWNsZSBpZD0iYmVhcmVyLXRva2VuIiBjbGFz....."
            }
          ]
      }
]
```

Or mixed formats:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImludHJvZHVjdGlvbiIgY2xhc3M...."
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "md",
    "content": "# some markdown"
  }
]
```

An example of some `x-embedded-doc` code and how it might render:

```
x-embedded-doc:
  - name: document
    title: Interesting
    format: b64html
    content: >-
      PGFydGljbGUgaWQ9ImNsaWVudC1pZ...=
securityDefinitions:
  api_key:
    type: apiKey
    in: header
    name: api_key
```

Obtaining a Client ID and Secret

Each client app that accesses the API Connect REST API must be reg
that determine which operations the app may access.

To register a client app, use the apic registrations:create API Connec

name
short name to identify the client
title
display name of the client
client_id
a generated client ID value
client_secret
a generated client secret value
client_type
one of portal, gateway, toolkit, consumer_toolkit, ui, consumer_ui, ibm_clouc

An example of some `x-embedded-doc` code into a product and how it might render:

```
x-embedded-doc:
  - name: introduction
    title: Introduction
    format: md
    content: >-
      ## Overview

      ### Philosophy

      Markdown is intended to be as easy-to-read and easy-to-write as is
      feasible. Compellingly facilitate 2.0 intellectual capital for
      cross-platform networks.  Dynamically incubate ethical sources after
      optimal technologies. Phosfluorescently restore global users via excellent
      niche markets. Credibly impact cross-media mindshare through strategic
      best practices. Synergistically impact interdependent web services rather
      than unique interfaces.

      Continually reintermediate enabled sources rather than professional
      architectures. Appropriately embrace viral collaboration and idea-sharing
      whereas granular solutions. Energistically revolutionize competitive
      paradigms vis-a-vis highly efficient models. Objectively incentivize
      enterprise customer service through compelling e-markets. Competently grow
      multifunctional e-markets with business methods of empowerment.

      Dramatically iterate equity invested scenarios and focused data.
      Compellingly reconceptualize next-generation deliverables rather than
      out-of-the-box architectures. Competently foster cross-unit web services
      with interactive innovation. Quickly revolutionize enabled communities and
      alternative content. Globally administrate resource maximizing
      deliverables whereas corporate e-business.

      Progressively develop maintainable leadership.
  - name: concepts

- Using x-ibm-languages to create multilingual API and Product documentation

Using `x-pathalias` to give consistent URLs for products and APIs

You can use **`x-pathalias`** to assign a URL to a product or an API.

The information section of a YAML representation of a Product or API can include **`x-pathalias`**. This option can be useful as it allows the same URL to be used on different revisions of your product. It also allows the use of a vanity URL, which might better represent the branding of your site, or make the URL easier to pronounce.

In this example, you set an API called `Climbing weather API` in product `Weather watch` to have a URL of ***`portalURL`*`/product/weather/api/climbing`**.

Product information:

```
info:
  version: 1.0.0
  title: Weather watch
  name: weather-watch
  x-pathalias: weather
```

API information:

```
info:
  title: Climbing Weather API
  x-ibm-name: climbing-weather-api
  version: 1.0.0
  x-pathalias: climbing
```

Validating the YAML or JSON definition of an API or Product

You can validate a YAML or JSON definition by using the IBM® API Connect developer toolkit.

Before you begin

To complete the steps that are described in this topic, you must have installed the developer toolkit. For more information, see Installing the toolkit.

Procedure

To perform validation by using the developer toolkit, enter the following command:

```
apic validate filename
```

where *filename* is the file name of the API definition file you want to validate.

- Include `--product-only` to validate only a Product definition and not any APIs that it references.
- Include `--no-extensions` to validate only the default OpenAPI section of the API and none of its extensions.

Note:

- If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the draft API is created with the **apic drafts:validate** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "**`(?`**" cannot be validated or published. An error message is returned. For example:

  ```
  Product has not been published!
  The multipart 'openapi' field contains an OpenAPI definition with validation errors.
      definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,
  col: 0)
  400
  ```

- Creating an OpenAPI definition file

Creating and using API and Product definitions templates

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Before you begin

To complete the steps that are described in this topic, you must have installed the IBM® API Connect developer toolkit. For more information, see Installing the toolkit.

Procedure

1. Create a Product or API definition template, either from scratch, or by copying one of the examples provided in API and Product definition template examples. The template file must have `.hbs` filename extension, and may contain any of the handlebars variables described in Template variables for API and Product definitions.
2. To create a Product or API definition from a template, enter the following command:

   ```
   apic create:[api | product] --template template_file --title [api_title | product_title] options
   ```

   where *template_file* is the template `.hbs` file to use, *api_title* or *product_title* is the title of the API or Product to create, and *options* is any additional command-line options. The path to the template file can be either an absolute path or relative to the location where the command is executed.

   When the Product or API definition is created, the value of each command-line option is substituted for the corresponding handlebars template variable. For example, the value of the required `--title` option is substituted for the `info.title` field in the template file. The command creates an API or Product definition YAML file with the name specified in the `--name` option. If you don't supply the `--name` option, the command derives the name of the API or Product YAML file from the specified title by down-casing the title and replacing spaces with dashes.

Working with global policies

Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can upload global policies into each of the gateway services in your Catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.

Note: Global policies are not the same as global-scoped policies, which you define with gateway extensions as documented on Authoring policies for the DataPower® API Gateway.

Prerequisites

IBM® DataPower Gateway version that is compatible with your deployed version of API Connect.

To complete the global policy management tasks described in this topic, you must be the owner of the provider organization, or be assigned a role that has the `Settings:Manage` permission. The pre-supplied Administrator role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Overview

For each of the gateway services in a Catalog, a global policy that you want to be called before any API assembly is called is designated as a *pre-request* global policy, and a global policy that you want to be called after any API assembly is called is designated as a *post-response* global policy. A policy that you want to be called when an error is thrown is called an *error* global policy. You can upload as many global policies into a gateway service as you want, but you can designate at most one global policy to be pre-request, one to be post-response, and one to be an error, at any one time.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
Note:

- If you are using the DataPower Gateway (v5 compatible), there can be only one `proxy` policy across the combined pre-request, API, and post-response assembly flows.
- Catalog properties, as described in Creating and configuring Catalogs, and API properties, as described in Setting API properties, are not supported with global policies. Therefore, if you use such properties in a global policy, they are **not** replaced with the values specified in the API or Catalog property definitions.

A global policy is defined in a .yaml file. The global policy file specifies the policy assembly that you want to call. A global policy file has the following structure:

```
global-policy: 1.0.0

info:
    name: global_policy_name
    title: global_policy_title
    version: global_policy_version

gateways:
    - gateway_type

assembly:
    - policy_assembly_to_be_called
```

where *gateway_type* has the value **datapower-gateway** if you want to use the global policy in a DataPower Gateway (v5 compatible), and **datapower-api-gateway** if you want to use the global policy in a DataPower API Gateway. For more information on the different types of gateway, see API Connect gateway types.
Note: Error global policies are supported only by the DataPower API Gateway, not by the DataPower Gateway (v5 compatible).
The **assembly** section for a pre-request or post-response global policy can contain any valid API assembly flow. For more information, see the execute section.

The **assembly** section for an error global policy can only contain a **catch** extension in the assembly, an **execute** section is not valid. For details of the **catch** extension, see catch.

Sample global policy .yaml file for pre-request or post-reponse

```
global-policy: 1.0.0

info:
  name: sample-policy
  title: Sample Policy
  version: 2.0.0

gateways:
  - datapower-api-gateway

assembly:
  execute:
    - invoke:
        target-url: http://myhost.com/mytarget
        version: 2.0.0

  catch:
    - errors:
        - ConnectionError
      execute:
        - activity-log:
            title: activity-log
            content: activity
            error-content: payload
            version: 2.0.0
```

Sample error global policy .yaml file

Note: An error global policy .yaml file can contain only a **catch** extension in the assembly.

```
global-policy: 1.0.0

info:
  name: sample-error-policy
  title: Sample Error Policy
  version: 2.0.0

gateways:
  - datapower-api-gateway

assembly:
  catch:
    - errors:
        - ConnectionError
      execute:
        - activity-log:
            title: activity-log
            content: activity
            error-content: payload
            version: 2.0.0
    - errors:
        - SOAPError
      execute:
        - xslt:
            version: 2.0.0
            title: xslt
            input: true
            source: |-
              <!-- Placeholder -->
              <xsl:stylesheet xmlns:xsl=''/>
```

Logging in to the Management server

You work with global policies by using developer toolkit CLI commands. Before you can run the commands, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
```

```
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

Uploading a global policy to a gateway service

You upload a global policy to a gateway service by using the **apic global-policies:create** command. The command has the following format:

```
apic global-policies:create --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] filename
```

where:

- *catalog_name* is the value of the `name` property of the Catalog that contains the gateway service to which you want to upload the global policy.
- *gateway_service_name* is the value of the `name` property of the gateway service.
- *organization_name* is the value of the `name` property of the provider organization that contains the Catalog.
- *mgmt_endpoint_url* is the platform API endpoint URL.
- *scope* has one of the following values:
  - `catalog` if the Catalog does not have Spaces enabled.
  - `space` if the Catalog has Spaces enabled. If you specify `space` for the `--scope` parameter you must also supply the `--space` parameter to specify the Space that contains the gateway service.
- (optional) *space* is the name of the Space that contains the gateway service. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope space` in the command.
- *filename* is the name of the global policy .yaml file that you want to upload.

Note: If Spaces are enabled in a Catalog, a global policy that you apply to one Space is applied to **all** Spaces; you cannot apply a global policy to an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.
You can confirm the global policies that have been uploaded by using the **apic global-policies:list-all** command, which has the following format:

```
apic global-policies:list-all --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space]
```

For reference details of the `apic global-policies` commands, see the toolkit CLI reference documentation.

Designating the pre-request global policy

To designate the pre-request policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

   ```
   apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
   ```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy `.yaml` file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string `url` with `global_policy_url`. The resulting file has the following format:

   ```
   global_policy_url: >-
     https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-policies/policy_id
   ```

3. Designate the global policy to be the pre-request policy by using the following command:

   ```
   apic global-policy-prehooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
   ```

To replace the designated pre-request global policy with another policy, repeat steps 1 and 2, then use the `apic global-policy-prehooks:update` command. To remove the pre-request global policy designation, use the `apic global-policy-prehooks:delete` command.
For reference details of the `apic global-policy-prehooks` commands, see the toolkit CLI reference documentation.

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a pre-request global policy you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization. For more information, see Customizing the preflow policies.

Designating the post-response global policy

To designate the post-response policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

   ```
   apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
   ```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy `.yaml` file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string `url` with `global_policy_url`. The resulting file has the following format:

```
global_policy_url: >-
  https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
policies/policy_id
```

3. Designate the global policy to be the post-response policy by using the following command:

```
apic global-policy-posthooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated post-response global policy with another policy, repeat steps 1 and 2, then use the **apic global-policy-posthooks:update** command. To remove the post-response global policy designation, use the **apic global-policy-posthooks:delete** command.
For reference details of the **apic global-policy-posthooks** commands, see the toolkit CLI reference documentation.

Designating the error global policy

The error global policy is applied to an error caught in the API pre-request, assembly, and post-response stages unless any of those stages has its own error rule defined for the same error, in which case that error rule takes priority.

To designate the error global policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

```
apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
--server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy **.yaml** file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string **url** with **global_policy_url**. The resulting file has the following format:

```
global_policy_url: >-
  https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
policies/policy_id
```

3. Designate the global policy to be the error policy by using the following command:

```
apic global-policy-errors:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated error global policy with another policy, repeat steps 1 and 2, then use the **apic global-policy-errors:update** command. To remove the error global policy designation, use the **apic global-policy-errors:delete** command.

For reference details of the **apic global-policy-errors** commands, see the toolkit CLI reference documentation.

Customizing the preflow policies

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a global policy you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization.

Before you begin

- For details on how to configure and deploy a global policy, see Working with global policies.
- For details on how to avoid authentication errors on a WSDL action, see the IBM troubleshooting tech note, API Connect HTTP GET ?WSDL retrieval returns "401 - Unauthorized Invalid client id or secret".

Default preflow policies

The following preflow policies are invoked by default:

- **cors**: handles cross-origin resource sharing (CORS) requests for the API; invoked if CORS is enabled in the API definition settings.
- **wsdl**: handles WSDL requests.
- **html-page**: for a GraphQL API, if the GraphQL editor option is enabled, returns the GraphQL HTML page.
- **client-identification**: examines the API key credentials that are carried in the API request and matches the API Plan through which the target API is made available to the client.
- **ratelimit**: enforces the rate limit scheme that is configured for the matching API Plan. When the rate limit is reached, the request is rejected.
- **security**: performs the authentication and authorization checks that are required by the target API and operation. if the security requirement is not fulfilled, the request is rejected.

Configuring a global policy to customize the preflow policies

To customize the preflow policies, complete the following steps:

1. add the following property to the **info:** section of your global policy .yaml file:

```
mode: mode_type
```

   Where ***mode_type*** is one of the following options:
   - **after-builtin** - this means that your preflow policies are applied after the default preflow policies.
   - **before-builtin** - this means that your preflow policies are applied before the default preflow policies.

- `full-custom` - this means that you must explicitly add the preflow policies to the assembly of your global policy. You can, however, remove, reposition, or replace any of the preflow policies as required.

2. Configure the policies in your global policy assembly as required.
   An `after-builtin` global policy example:

```
global-policy: 1.0.0
info:
  name: foo-example
  title: foo-example
  version: 2.0.0
  mode: after-builtin
gateways:
  - datapower-api-gateway
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-Flexible-Preflow
            value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed after all default builtins'
            type: string
```

   A `before-builtin` global policy example:

```
global-policy: 1.0.0
info:
  name: foo-example
  title: foo-example
  version: 2.0.0
  mode: before-builtin
gateways:
  - datapower-api-gateway
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-Flexible-Preflow
            value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed before all default builtin
policies'
            type: string
```

   A `full-custom` global policy example:

```
global-policy: 1.0.0
info:
  name: preflow-4-actions
  title: preflow-4-actions
  version: 2.0.0
  mode: full-custom
gateways:
  - datapower-api-gateway
assembly:
  execute:
    - cors:
        version: 2.0.0
        title: cors-in-preflow
    - wsdl:
        title: default-wsdl
    - html-page:
        title: html-page-in-preflow
        output: message
        version: 2.0.0
    - helloworld:
        version: 1.0.0
        title: helloworld
    - client-identification:
        version: 2.0.0
        title: ci-in-preflow
    - ratelimit:
        version: 2.0.0
        title: assembly-rt-in-preflow
        source: plan-default
    - security:
        version: 2.0.0
        title: sec-in-preflow
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-Flexible-Preflow
            value: 'Hello reboot with 4 actions'
            type: string
```

3. Deploy your global policy as a pre-request global policy.

Reference

Reference information for developing your APIs in API Connect, including context variables, and template variables.

Note: For product-wide reference material, including command-line tool and REST APIs documentation, see Reference information for IBM® API Connect.

- **API Connect context variables**
  List of IBM API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext()` function when defining a policy.
- **OAuth context variables**
  You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.
- **Error cases supported by assembly catches**
  Several error cases that can be returned by the assembly are available to the catch function.
- **API and Product definition template examples**
  You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by `apic` to create Products and APIs as examples you can use to copy and customize for your own use.
- **Template variables for API and Product definitions**
  You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Related information

- IBM API Connect overview

API Connect context variables

List of IBM® API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext()` function when defining a policy.

The following tables are presented:

- General context variables.
- OAuth context variables - DataPower Gateway (v5 compatible).
- Application certificate context variables.
- API activity logging context variables.
- GraphQL context variables.

For more information about implementing an assembly component, see Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly, and for information about how to reference context variables in API Connect see Variable references in API Connect and Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For more information about creating a user-defined policy, see Authoring policies.

General context variables

Note:

- For plan variables (such as `plan.name` or `plan.version`), plan information is available only when the requested operation requires identification and the client passes the authentication check.
- If you deploy your API to the DataPower® Gateway (v5 compatible) then, with the exception of client ID and client secret, the passing of form input as a parameter into an API is not supported. This restriction does not apply if you deploy your API to the DataPower API Gateway.

Table 1. API Connect context variables

Name	Description	Permission
API Gateway only `api.catalog.id`	The ID of the Catalog in which the API is published.	Read/write
API Gateway only `api.catalog.name`	The name of the Catalog in which the API is published.	Read/write
API Gateway only `api.catalog.path`	The path segment that represents this Catalog.	Read/write
`api.endpoint.address`	The address of the API Gateway endpoint.	Read/write
`api.endpoint.hostname`	The host name of the API Gateway endpoint, as requested by the application.	Read/write
API Gateway only `api.id`	The identifier of the API.	Read/write
`api.name`	The name of the API; this corresponds to the `x-ibm-name` field in the OpenAPI definition for the API.	Read/write
`api.operation.id`	The ID of the operation.	Read/write
`api.operation.path`	The path of the operation.	Read/write
`api.org.id`	The organization ID of the API provider.	Read/write
`api.org.name`	The organization short name of the API provider.	Read/write
`api.properties.`*`propertyname`*	The name of a custom API property. Property values are Catalog specific. Note: • You have write permission to a custom property **only** from the user interface, **not** from GatewayScript.	Read/write
`api.root`	The API base path.	Read/write
`api.type`	The API type; REST or SOAP.	Read/write

Name	Description	Permission
`api.version`	The version string of the API.	Read/write
`client.app.id`	The client ID or application key that is received on the request.	Read/write
API Gateway only `client.app.'lifecycle-state'`	The lifecycle status of the calling client application. The possible values are as follows: • `DEVELOPMENT` • `PRODUCTION` (default)	Read/write

API Gateway only `client.app.metadata.key`	The string value of an application metadata key, where *key* is the name of the key.
	You can add metadata keys to an application by using either the **apic apps:create** or the **apic apps:update** command; you include the metadata keys in the configuration file parameter that is passed to the command.
	For example:
	`apic apps:create myapp.yaml --server myserver.com --org myorg --catalog mycatalog --consumer-org mycorg`
	where myapp.yaml contains the following:
	`name: myapp`
	`title: My test application`
	`metadata:`
	`  key1: value1`
	`  key2: value2`
	`  key3: value3`
	`  key4: value4`
	`  key5: value5`
	You can then retrieve the value of a metadata key in an API assembly policy by using a context variable such as the following:
	`client.app.metadata.key3`
	Note that adding application metadata might impact gateway trans performance.
		Read/write

`client.app.name`	The name of the application that is identified as having issued the request.	Read/write
`client.app.secret`	The client secret that is received in the request.	Read/write
`client.app.type`	The type of the client application that issued the request.	Read/write
`client.org.id`	The unique identification key of the organization that owns this application.	Read/write
`client.org.name`	The name of the organization that owns this application.	Read/write
API Gateway only `client.result`	The result of the client security policy, which is `SUCCESS` or `FAILURE`.	Read/write
API Gateway only `client.third_party.type`	The type of user registry used for third-party authentication of the extracted client credentials. The possible values are `LDAP` and `auth-url`.	Read/write
API Gateway only `client.third_party.headers`	The array of headers added to the request that was sent to that API authentication URL during third-party authentication.	Read/write
API Gateway only `client.third_party.response.authenticated`	The third-party authentication results. The possible values are as follows: • `true`: the authentication was successful. • `false`: the authentication failed.	Read/write
API Gateway only `client.third_party.response.user`	The user for third-party authentication.	Read/write
API Gateway only `client.title`	The title for the credentials that are received in the request.	Read/write
DataPower Gateway (v5 compatible) only `env.name`	The name of the Catalog in which the API is published.	Read/write
DataPower Gateway (v5 compatible) only `env.path`	The path segment that represents this Catalog.	Read/write
API Gateway only `error.message`	The message text for the error.	Read/write
API Gateway only `error.name`	The name of the error.	Read-only
API Gateway only `log`	The transaction data gathered in an assembly log action.	Read/write
`message.attachments`	The array of attachments in a multipart message.	Read/write
`message.attachments[].body`	The attachment payloads in a multipart message.	Read/write
`message.attachments[].headers`	The attachment headers in a multipart message.	Read/write
`message.body`	The payload of the request or response message. Note: The `message.body` context variable is not supported with `getContext()` function. Use the `getvariable()` function instead.	Read/write
`message.headers.name`	The value of the current named header of the message or of the current named header of the root part of a multipart message. The *name* segment is case-insensitive.	Read/write

Name	Description	Permission
API Gateway only **message.original.headers.*name***	The value of the original named header of the HTTP message. When the assembly contains an invoke action, the value is automatically populated by the original named header of the response message from the invoked URL. The *name* segment is case-insensitive.	Read-only
API Gateway only **message.package.headers.*name***	The value of the current named header of the multipart message. The *name* segment is case-insensitive.	Read/write
message.status.code	The HTTP status code of the response.	Read/write
message.status.reason	The HTTP reason phrase of the response.	Read/write
API Gateway only **message.variables.*name***	The value of a property in the message. For example, when **myvar** is the property in the message, you can retrieve the value of the **myvar** property by reading **message.variables.myvar**.	Read/write
plan.name	The name of the plan.	Read/write
plan.id	The unique identifier of the plan.	Read/write
plan.rate-limit	The rate limit of the plan, which is the number of API calls per time interval.	Read/write
API Gateway only **plan.rate-limit[index].hard-limit**	The hard limit setting for the rate limit scheme that is identified by **[index]**.	Read/write
API Gateway only **plan.rate-limit[index].value**	The value of the rate limit scheme that is identified by **[index]**. The syntax is **rate/interval**.	Read/write
plan.spaceId	The unique identifier of the space that the plan is contained within.	Read/write
plan.spaceName	The name of the space that the plan is contained within.	Read/write
plan.version	The version number of the plan.	Read/write
request.authorization	The parsed HTTP **authorization** header.	Read-only
request.body	The payload from the incoming request.	Read-only
request.content-type	Normalized content-type value.	Read-only
request.date	A date object that represents approximately when the request was received by the Gateway.	Read-only
request.headers.*name*	The value of the original named header of the HTTP request, or the value of the current named header of the root part of a multipart request. The *name* segment is case-insensitive. The request header can be modified only in preflow policies. For more information, see Customizing the preflow policies.	Read/write
API Gateway only **request.original.headers.*name***	The value of the original named header of the HTTP request. This variable is created only when the request header is modified. The *name* segment is case-insensitive.	Read-only
API Gateway only **request.package.headers.*name***	The value of the named header of the multipart request. The *name* segment is case-insensitive.	Read-only
API Gateway only **request.parameters**	You can obtain your incoming parameters from path and query parameters.	
API Gateway only **request.parameters.*name*.locations**	An array of strings that specify the parameter types associated with the parameter specified in name. The supported keywords for parameter types are as follows. **formData** The parameter is in the body as form data **header** The parameter is in the request header **path** The parameter is in the path **query** The parameter is in the query	Read-only
API Gateway only **request.parameters.*name*.values**	An array containing values of the parameter types associated with the parameter specified in name. For example, when the first value is **path** in **request.parameters.myparam.locations[]**, the first value in **request.parameters.myparam.values[]** is the array of path values associated with **myparam**. Request parameters can be modified only in preflow policies. For more information, see Customizing the preflow policies.	Read/write
API Gateway only **request.original.parameters.*name*.values**	An array containing the original values of the parameter types associated with the parameter specified in *name*. This variable is created only when a request parameter value is modified.	Read-only
request.path	The path section of the **request.uri** that starts with the base path of the API, including the '/' character that begins the base path.	Read-only
API Gateway only **request.protocol**	The protocol that is used to receive the request: **http** or **https**.	Read-only
request.querystring	The request query string without the leading question mark.	Read-only
request.search	The request query string with the leading question mark.	Read-only
request.uri	The full HTTP request URI from the application.	Read-only
request.verb	The HTTP verb of this request.	Read-only
API Gateway only **session.apiGateway**	The gateway that receives the request.	Read-only

Name	Description	Permission
API Gateway only `session.apiGatewayName`	The name of the API gateway as defined in the API Manager.	Read-only
API Gateway only `session.clientAddress`	The address of the client that sent the request.	Read-only
API Gateway only `session.domainName`	The name of the domain that the gateway belongs to.	Read-only
API Gateway only `session.globalTransactionID`	The global transaction ID in the logs.	Read-only
API Gateway only `session.localAddress`	The address of the gateway on the DataPower® Gateway.	Read-only
API Gateway only `session.timeStarted`	The time that the gateway started to process the request.	Read-only
API Gateway only `session.transactionID`	The transaction ID of the gateway request.	Read-only
`system.datetime`	Returns a string that represents the current date and time in the system time zone of the gateway.	Read-only
`system.time`	Returns a string that represents the current time in the system time zone of the gateway.	Read-only
`system.time.hour`	Returns a number 0 - 23 inclusive, representing the hour of the current time in the system time zone of the gateway.	Read-only
`system.time.minute`	Returns a number 0 - 59 inclusive representing the minute of the current time in the system time zone of the gateway.	Read-only
`system.time.seconds`	Returns a number 0 - 59 inclusive representing the seconds of the current time in the system time zone of the gateway.	Read-only
`system.date`	Returns a string that represents the current date in the system time zone of the gateway.	Read-only
`system.date.day-of-week`	Returns a number 1 - 7 (Monday to Sunday) inclusive representing the day of the week in the system time zone of the gateway.	Read-only
`system.date.day-of-month`	Returns a number 1 - 31 representing the day of the month in the system time zone of the gateway.	Read-only
`system.date.month`	Returns a number 1 - 12 representing the month in the system time zone of the gateway.	Read-only
`system.date.year`	Returns a four-digit number that represents the year in the system time zone of the gateway.	Read-only
`system.timezone`	Returns a system time zone ISO 8601 identifier for the gateway, which might include a sign, a two-digit hour, and minutes. For example, `-04:00`.	Read-only

OAuth context variables - DataPower Gateway (v5 compatible)

The OAuth context variables described in this section apply only to the DataPower Gateway (v5 compatible). For details of the OAuth context variables that apply to the DataPower API Gateway, see OAuth context variables.

Table 2. OAuth context variables (DataPower Gateway (v5 compatible)).
Note: Most OAuth context variables are available only when IBM API Connect is acting as the OAuth resource server. However, the `oauth.introspect` variables are also available when integrating with third party providers.

Name	Description
`oauth.access-token`	If the request is authenticated with OAuth, this variable contains the access token string.
`oauth.miscinfo`	This variable contains information explicitly included in the Authentication URL and Metadata URL headers. For more information, see Authenticate URL.
`oauth.not-after`	If the request is authenticated with OAuth, this variable contains the date when the token expires.
`oauth.not-before`	If the request is authenticated with OAuth, this variable contains the date when the token was issued.
`oauth.resource-owner`	If the request is authenticated with OAuth, this variable contains the name of the resource owner.
`oauth.scope`	If the request is authenticated with OAuth, this variable contains the scope of this access token.
`oauth.introspect.active`	Always available to introspection. Boolean value.
`oauth.introspect.response`	Always available to introspection. Shows the complete current response payload. Example payload value: `{"active":true, "client_id", "xxx-xxx", "token_type", "bearer", "scope":"neon"}`

Other variables might be available from the third party, in the form of: `oauth.introspect.<variable>`	Decoding the previous example payload, the following variables are made available for further processing.
	`oauth.introspect.client_id: xxx-xxx`
	`oauth.introspect.token_type: bearer`
	`oauth.introspect.scope: neon`

Application certificate context variables

The following table describes context variables that are available when a certificate is used to verify access to an API, although these will vary depending on the signature mechanism that is being used; for more information, see the Internet X.509 Public Key Infrastructure Certificate and CRL Profile specification.

Table 3. Application certificate context variables

Name	Description
`application.certificate.Base64`	Base64 format.
`application.certificate.fingerprint`	Fingerprint
`application.certificate.Version`	Version
`application.certificate.SerialNumber`	Serial number
`application.certificate.SignatureAlgorithm`	Signing algorithm
`application.certificate.Issuer`	The issuer of the certificate
`application.certificate.Subject`	Subject

Name	Description
`application.certificate.NotBefore`	Not valid before this date
`application.certificate.NotAfter`	Not valid after this date
`application.certificate.SubjectPublicKeyAlgorithm`	Algorithm for the subject public key
`application.certificate.SubjectPublicKeyBitLength`	Length for the subject public key
`application.certificate.KeyValue.type`	Various context variables that depend on the algorithm and key. The following are possible context variables: • `application.certificate.KeyValue.RSAKeyValue.Modulus` • `application.certificate.KeyValue.RSAKeyValue.Exponent`

API activity logging context variables

If activity logging is enabled for an API, a `log` context variable is created; the `log` context variable contains the data relating to an API execution event. On completion of API execution, the `log` context variable is written to an API event record that is stored for subsequent access by API analytics. For details of the fields contained in the `log` context variable, see API event record fields.

The way in which you enable and configure activity logging depends on the type of gateway you are using, as follows:

- If you are using the DataPower API Gateway, you configure activity logging in the API configuration settings; see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).
- If you are using the DataPower Gateway (v5 compatible), you configure activity logging by adding an Activity Log policy to the API assembly.

The activity logging configuration defines the default content of the `log` context variable, but you can modify it in an API assembly; for example:

- Add your own data values by using a Set Variable policy.
- Remove or redact data values by using a Redaction policy; see Redaction - DataPower API Gateway or Redaction - DataPower Gateway (v5 compatible).
- API Gateway only Modify or replace the `log` context variable by using a Log policy.

GraphQL context variables

The GraphQL query and response variables generated from API processing and assembly actions are stored in the API context in the `message.attributes.graphql` context variables.

Table 4. GraphQL context variables

Name	Description
`message.attributes.graphql`	The query and response attributes of the GraphQL message.
`message.attributes.graphql.query`	The attributes of a GraphQL query, including the query string, operation name, and variables.
`message.attributes.graphql.query.query`	The GraphQL query string.
`message.attributes.graphql.query.variables`	The map of GraphQL variables.
`message.attributes.graphql.query.operationName`	The name of the operation to execute.
`message.attributes.graphql.query.operationType`	The type of the operation to execute.
`message.attributes.graphql.request`	The attributes of the GraphQL request.
`message.attributes.graphql.request.fieldCost`	The weighted sum of the cost of all fields accessed in the query. The cost of each field access is configured in the schema. This count includes fields whose field costs are not set to 0.0.
`message.attributes.graphql.request.fieldCounts`	The maximum number of times that each field can be retrieved by the given query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. This count includes fields whose field costs are not set to 0.0.
`message.attributes.graphql.request.typeCost`	The weighted sum of the cost of all types retrieved in the query. The cost of each type is configured in the schema. This count includes types whose type costs are not set to 0.0.
`message.attributes.graphql.request.typeCounts`	The maximum number of times that a value of each type can be retrieved by the given query. This count includes types whose type costs are not set to 0.0.
`message.attributes.graphql.response.fieldCost`	The weighted sum of the cost of all fields in the response to the query. The cost of each field access is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the field cost is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.fieldCounts`	The number of times that each field was retrieved in the response to the query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. If this sum cannot be calculated based on the analysis configuration in the request, the field count is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.typeCost`	The weighted sum of the cost of all types in the response to the query. The cost of each type is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the type cost is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.typeCounts`	The number of times that a value of each type was contained in the response to the query. If this sum cannot be calculated based on the analysis configuration in the request, the type count is expressed as the maximum integer value that can be assigned.

Name	Description
`message.attributes.parse.GraphQLIntrospection`	The introspection type of the assembly GraphQL introspect action. When a GraphQL query is parsed, this context variable is populated with one of the following values: • `not-introspection` • `custom-introspection` • `default-introspection`

- Variable references in API Connect

OAuth context variables

You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.

Note: The OAuth context variables described here apply only to the DataPower® API Gateway. For details of the OAuth context variables that apply to the DataPower Gateway (v5 compatible), see OAuth context variables - DataPower Gateway (v5 compatible).
There are two main types of OAuth context variables:

- Information variables, outputs of an OAuth policy.
- Processing variables, processed during the execution of an OAuth policy.

Information variables

These context variables are outputs of an OAuth policy. They are not used in the processing of the OAuth action.

`oauth.result`
: The result of the latest action; returns `SUCCESS` or `FAILURE`.

`oauth.settings.variable_name`
: Basic settings from the OAuth provider. The following context variables are available:

```
oauth.settings.allowed_scopes
oauth.settings.access_token_ttl
oauth.settings.authorization_code_ttl
oauth.settings.refresh_token_ttl
oauth.settings.refresh_token_limit
oauth.settings.maximum_consent_ttl
```

`oauth.executed_components[0].variable_name`
: The components that have executed in this transaction, with their result. If a failure occurs then the error and error description will be added. The following context variables are available:

```
oauth.executed_components[0].result
oauth.executed_components[0].type
oauth.executed_components[0].error_description
oauth.executed_components[0].error
```

The possible values for the `type` variable are as follows:

```
ValidateRequestComponent
GenerateAZCodeComponent
VerifyAZCodeComponent
VerifyRefreshTokenComponent
GenerateAccessTokenComponent
IntrospectTokenComponent
RevokeTokenComponent
CollectMetaDataComponent
```

The following example shows a corresponding JSON extract from the OAuth context:

```
"executed_components": [
  {
    "type": "ValidateRequestComponent",
    "result": "SUCCESS"
  },
  {
    "type": "GenerateAccessTokenComponent",
    "result": "SUCCESS"
  }
]
```

`oauth.verified_access_token.variable_name`
: The token that was verified in the security requirement for a native OAuth provider. The following context variables are available:

```
oauth.verified_access_token.access_token

oauth.verified_access_token.client_id
oauth.verified_access_token.consented_on
oauth.verified_access_token.consented_on_text
```

`oauth.verified_access_token.grant_type`
`oauth.verified_access_token.misc_info`
`oauth.verified_access_token.not_after`
`oauth.verified_access_token.not_after_text`
`oauth.verified_access_token.not_before`
`oauth.verified_access_token.not_before_text`
`oauth.verified_access_token.one_time_use`
`oauth.verified_access_token.resource_owner`
`oauth.verified_access_token.scope`

`oauth.third_party.variable_name`
The token that was verified in the security requirement for a third party OAuth provider. Provides the following information:

- The response headers from the external, third-party OAuth provider.
- The body of response from the external, third-party OAuth provider.
- Whether the response is cached. When cached, the value is **`true`**. When not cached, the value is **`false`**.

The following context variables are available:

`oauth.third_party.headers`
`oauth.third_party.response`
`oauth.third_party.cached`

`oauth.code.variable_name`
The code that was generated during the execution of a component of type **`GenerateAZCodeComponent`**. The following context variables are available:

`oauth.code.client_id`
`oauth.code.code`
`oauth.code.redirect_uri`
`oauth.code.resource_owner`
`oauth.code.scope`

`oauth.token.variable_name`
The token that was generated during the execution of a component of type **`GenerateAccessTokenComponent`**. The following context variables are available:

`oauth.token.token_type`
`oauth.token.access_token`
`oauth.token.scope`
`oauth.token.expires_in`
`oauth.token.consented_on`
`oauth.token.redirect_uri`
`oauth.token.resource_owner`
`oauth.token.client_id`
`oauth.token.refresh_token`
`oauth.token.refresh_token_expires_in`
`oauth.token.refresh_token_count`

`oauth.introspect.variable_name`
The token that was introspected during execution of a component of type **`IntrospectTokenComponent`**. The following context variables are available:

`oauth.introspect.active`
`oauth.introspect.scope`
`oauth.introspect.client_id`
`oauth.introspect.resource_owner`
`oauth.introspect.token_type`
`oauth.introspect.grant_type`
`oauth.introspect.ttl`
`oauth.introspect.expires`
`oauth.introspect.expires_text`
`oauth.introspect.iat`
`oauth.introspect.not_before`
`oauth.introspect.not_before_text`
`oauth.introspect.consented_on`
`oauth.introspect.consented_on_text`
`oauth.introspect.one_time_use`

`oauth.external_manager.variable_name`
Token management when using an external token manager. Provides the following information:

- The response headers from the external management server.
- The response JSON body from the external management server.
- When caching is enabled, whether the response is found in the cache or set in the cache. When caching is not enabled, that the response is not set in the cache.

The following context variables are available:

`oauth.external_manager.headers`
`oauth.external_manager.response`
`oauth.external_manager.cached`

Processing variables

These context variables are processed during the execution of an OAuth policy in your API assembly. If they are set prior to any OAuth policy then the value overrides what was sent in the request. They can also be modified between OAuth policies to manipulate the next component that executes. The following context variables are available:

`oauth.processing.assertion`
`oauth.processing.client_id`
`oauth.processing.client_secret`
`oauth.processing.grant_type`
`oauth.processing.redirect_uri`
`oauth.processing.scope`
`oauth.processing.response_type`
`oauth.processing.state`

```
oauth.processing.resource_owner
oauth.processing.refresh_token
oauth.processing.code
oauth.processing.token
oauth.processing.token_type_hint
oauth.processing.nonce
oauth.processing.max_age
oauth.processing.oidc_values_requested
oauth.processing.id_token_requested
oauth.processing.oidc_signing_algorithm
oauth.processing.code_challenge
oauth.processing.code_challenge_method
oauth.processing.code_verifier

oauth.processing.metadata.access_token
oauth.processing.metadata.payload
oauth.processing.metadata.azcode_miscinfo

oauth.processing.verified_code.client_id
oauth.processing.verified_code.resource_owner
oauth.processing.verified_code.misc_info
oauth.processing.verified_code.scope
oauth.processing.verified_code.is_verified
oauth.processing.verified_code.nonce

oauth.processing.verified_refresh_token.client_id
oauth.processing.verified_refresh_token.resource_owner
oauth.processing.verified_refresh_token.misc_info
oauth.processing.verified_refresh_token.scope
oauth.processing.verified_refresh_token.refresh_token_count
oauth.processing.verified_refresh_token.is_verified
oauth.processing.verified_refresh_token.one_time_use
oauth.processing.verified_refresh_token.grant_type
```

The following example shows the OpenAPI source code for a `gateway-script` policy that executes before an OAuth policy in your API assembly and adds a custom scope to the request:

```
// Add another custom scope to the request
let scope = context.get("request.parameters.scope.values[0]");
if (scope)
  context.set("oauth.processing.scope", scope + " custom");
```

The following example shows the OpenAPI source code for a `gateway-script` policy that between OAuth policies in your assembly and modifies the scope depending on the resource owner:

```
// Check resource owner and modify the scope
let owner = context.get("oauth.processing.resource_owner");
let scope = context.get("oauth.processing.scope");

if (owner === 'admin') {
    context.set("oauth.processing.scope", scope + " admin");
} else {
    context.set("oauth.processing.scope", scope + " customer");
}
```

Advanced scope context variables

The following context variables are used in OAuth advanced scope checking. They are populated by the values entered in the Endpoint and TLS Client Profile fields for the Application scope check and Owner scope check in the native OAuth provider configuration. Do not change these values as this might result in incorrect advanced scope operation.

For information on scope configuration, see Configuring scopes for a native OAuth provider. For information on advanced scope checking, see Scope.

```
oauth.advscope.app.url
oauth.advscope.app.tls-profile
oauth.advscope.own.url
oauth.advscope.own.tls-profile
```

Custom error context variables

These context variables are used to stop OAuth processing and specify the respective error details. They can be used before OAuth processing takes place.

```
oauth.custom_error.status.code
oauth.custom_error.status.reason
oauth.custom_error.message
oauth.custom_error.description
```

Error cases supported by assembly catches

Several error cases that can be returned by the assembly are available to the catch function.

ConnectionError

An error occurred while establishing a connection to another URL.

JavaScriptError
: An error occurred while executing JavaScript or GatewayScript in a policy.

PropertyError
: An error occurred due to an incorrect property during an invoke call or during the execution of a set-variable policy when an action was not set, add, or clear.

RedactionError
: An error occurred during the redaction of a field as part of a redact policy.

TransformError
: An error occurred during a transformation policy.

RuntimeError
: An otherwise unspecified error occurred.

BadRequestError
: An error occurred while trying to access the request. This is not supported by the default catch; to catch this condition, specify it in your catch definition.

SOAPError
: A SOAP Fault response was received as the result of a web service invoke request.

OperationError
: An invoke request received a response with an unsuccessful HTTP status code.

ValidateError
: An error occurred while trying to schema validate a message payload.

API Gateway only AssemblyRateLimitError
: The request exceeds the transaction count threshold specified in the API's Plan.

UnauthorizedError
: The API cannot be invoked based on the client ID and/or client secret provided, or id/secret were specified in the wrong location. This is not supported by the default catch; to catch this condition, specify it in your catch definition.

ForbiddenError
: The application making the API request has been disabled or is not active. This is not supported by the default catch; to catch this condition, specify it in your catch definition.

API and Product definition template examples

You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form **{{variable-name}}** that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by **apic** to create Products and APIs as examples you can use to copy and customize for your own use.

Default API definition template (OpenAPI 2.0)

The following example template, which is for an OpenAPI 2.0 API definition, is the default template that developer toolkit uses when you create an API definition. Copy this example template into your own template file (which must have the **.hbs** extension), then edit it for your purposes. Template variables are enclosed by double curly braces, for example **{{name}}**. For information on template variables, see Template variables for API and Product definitions. For more information on Handlebars, see https://handlebarsjs.com/.

    produces:
      - application/json
    summary: Request Access Tokens
```

```
    description: |
      This endpoint allows requesting an access token following one of the flows below:
      - Authorization Code (exchange code for access token)
      - Client Credentials (2-legged, there isnt resource owner information)
      - Resource Owner Password Credentials (2-legged, client provides resource owner name and password)
      - Refresh Token (exchange refresh token for a new access code)

      The table below indicates the required parameters for each specific grant_type options.
      Empty cells indicate a parameter is ignored for that specific grant type.

      Client authentication:
      - Confidential clients should authenticate using HTTP Basic Authentication. Alternatively, they may post
        their client_id and client_secret information as a formData parameter.
      - Public clients should send their client_id as formData parameter.

      | grant_type           | code       | client_credentials | password    | refresh_token |
      |----------------------|------------|--------------------|-------------|---------------|
      | client_id            | required*  | required*          | required*   | required*     |
      | client_secret        | required*  | required*          | required*   | required*     |
      | code                 | required   |                    |             |               |
      | redirect_uri         | required   |                    |             |               |
      | username             |            |                    | required    |               |
      | password             |            |                    | required    |               |
      | scope                |            | optional           | optional    |               |
      | refresh_token        |            |                    |             | required      |

      The implicit grant requests, see /oauth2/authorize.

Template variables for API and Product definitions

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form **{{variable-name}}** that are substituted with values when you create the API or Product definition.

Product definition variables

The following table describes the Handlebars template variables that can be used in a product definition file. For more information on Handlebars, see https://handlebarsjs.com/. Product definition template files must have a **.hbs** filename extension.

Table 1. Product definition Handlebars template variables

Variable	Type	Description

{{apis}}	Array of string	The APIs to which the product definition refers. After substitution, the array values become the values of **apis.routes[*n*].$ref** fields, for example:
		`apis:`
		`  'routes':`
		`  $ref: apidef.yaml`
		`  ...`

{{name}}	String	Value of **info.x-ibm-name** field.
{{title}}	String	Value of **info.title** field.
{{version}}	String	Value of **info.version** field.

API definition variables

The following table describes the Handlebars template variables that can be used in an API definition file. For more information on Handlebars, see https://handlebarsjs.com/. API definition template files must have a **.hbs** filename extension.

Table 2. API definition Handlebars template variables

Variable	Type	Description
{{basepath}}	String	Base path on which the API is served, which is relative to the **host**.
{{definitions}}	OpenAPI definitions objectconverted to a YAML string ("stringified").	API contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{definitionsObj}}	OpenAPI definitions objectconverted to a YAML string ("stringified").	API contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{hostname}}	String	Value of the **host** field.
{{name}}	String	Value of **info.x-ibm-name** field.
{{paths}}	OpenAPI paths object	API contains the relative paths to the individual endpoints. The path is appended to **{{basePath}}** to construct the full URL.
{{pathsObj}}	OpenAPI paths object	API contains the relative paths to the individual endpoints. The path is appended to **{{basePath}}** to construct the full URL.
{{schemes}}	Array of string	Transfer protocol of the API. Values must be one of: **"http"**,**"https"**, **"ws"**, or **"wss"**.
{{targeturl}}	String	Value of **x-ibm-configuration.assembly.execute[invoke]**. Default is **$(runtime-url)$(request.path)**.
{{title}}	String	Value of **info.title** field.
{{version}}	String	Value of **info.version** field.

Managing your APIs

You manage your APIs by using the API Manager user interface of IBM® API Connect. You can also analyze your API usage by using the analytics that are provided and socialize your APIs in a developer portal.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Why use APIs?

Whether you are a business user, an IT user, or an application developer, APIs are increasingly important to your business. You can use an API to publicize your company. The assets, data, or services of your company can be provided to external application developers to expand your enterprise and open new markets.

The API Manager UI provides a solution for companies to manage APIs for private internal APIs, and public external APIs. This on-premises offering provides the capabilities that are required so that you can externalize and manage your services as REST or SOAP APIs.

What do you need to know?

Depending on your role, you can complete different tasks relating to managing your API Catalogs and these are outlined in the documentation. Each task is covered in the order that they are executed.

Each task introduces new features of the API Manager UI as they become relevant to the Catalog that you are building.

For security reasons, your session times out after a period of inactivity.

Before you start, check that the browser you are using is supported and meets the required minimum levels; for details, open the Detailed system requirements for a specific product page, search for the IBM API Connect product, then select the required version.

The ways in which you can manage your APIs are described in the following subtopics:

- **API management checklist**
  A summary, with links, of the key tasks for managing APIs in IBM API Connect.
- **Activating your API Manager user account**
  Before you can access the API Manager user interface of IBM API Connect, you must activate the user account that your Cloud Manager administrator invited you to join.
- **Accessing the API Manager user interface**
  The IBM API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.
- **Searching for items in API Manager**
  Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- **Using Engagement to automate notification tasks**
  The Engagement feature in the API Manager helps the user to create complex workflows that automate tasks based on the specified criteria and enhances the overall API management experience.
- **Working with Catalogs**
  Products must be staged to a Catalog and then published; application developers are able to access the APIs in a Product by being members of consumer organizations to which the Product is made available.
- **Managing the application lifecycle**
  By using the application lifecycle capability in IBM API Connect, the applications that are created in the associated Developer Portal initially has Development status, and can make API calls through the Development endpoints. When application testing is complete, the application developer can request to upgrade the application to Production status. After the request is approved, the application is upgraded can make API calls through Production endpoints.
- **Using syndication in API Connect**
  With the API Connect syndication feature, you can partition your catalogs into *Spaces*. Each space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that space, enabling each team to manage their APIs independently.
- **Working with Products**
  In IBM API Connect, Plans and APIs are grouped together in Products.
- **Working with APIs**
  For a specific Product, you can work with the APIs that are contained in the Plans in that Product.
- **Working with Plans**
  After a Product has been published to a Catalog, you can work with the Plans in that Product.
- **Working with consumer organizations**
  Manage the consumer organizations that access your APIs and Plans when their users sign up to use the IBM API Connect Developer Portal.
- **Working with developer applications**
  You can work with the applications that have been registered in the Developer Portal associated with a Catalog.
- **Working with application subscriptions**
  You can work with the subscriptions to the Plans in all the Products in a specific Catalog. Plan subscriptions are created by application developers in the Developer Portal.
- **Security and authentication**
  In API Manager, you can use TLS profiles to secure the transmission of data between the management server and other API Connect subsystems and external services, and also configure user registries to securely authenticate your catalogs and APIs.
- **API Analytics**
  You can use API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.
- **Configuring governance in the API Manager**
  How to add custom governance rulesets to your API development process, to validate and enforce organizational governance policies and best practices in your provider organization.
- **Administering user access**
  If you have permission to administer users in IBM API Connect, you can add and delete users. After users are removed from an organization through deletion, the user account remains in API Manager.
- **Changing your API Manager password**
  You can change your API Manager password in IBM API Connect.

- **Resolving login problems by increasing HTTP header size**
  You can resolve login problems for the API Manager UI by increasing the maximum HTTP client header size.
- **Reviewing processing status and downloading gateway logs**
  View and download the processing status information for the Gateway services that are enabled in your API Connect Catalogs and Spaces.
- **Reference**
  Reference information for the API Manager component in IBM API Connect.
- **API Manager tutorials**
  Tutorials for using the API Manager user interface in IBM API Connect.
- **Using Config Sync to replicate catalog data**
  Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

API management checklist

A summary, with links, of the key tasks for managing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	To connect to a Management server using the API Manager user interface, you must be an owner or a member of a provider organization.
Log in to the API Manager user interface	After you have activated your account, you can log in to your Management server from the API Manager user interface.
Configure your Catalogs	APIs are published to a Catalog to make them available to application developers. The URLs for API calls, and for the Developer Portal, are specific to a particular Catalog. By default, a *sandbox* Catalog is provided for API testing, but you can create your own Catalogs; for example, a production Catalog for hosting APIs that are ready for full use.
Manage the membership of your Catalogs	You can add users to your Catalogs, and assign roles and permissions to control their level of access.
Configure API security	You can configure user registries of various types for authenticating API access, TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Manage your Products	Move your Products through their lifecycle, from initially staging a Product to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. You can also display analytics information, and control who can see or subscribe to your Products.
Analyze your API usage	You can use IBM API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.
Manage user access to your provider organization	You can add users to your provider organization, remove users, and assign roles and permissions.
Partition your Catalogs into Spaces for syndication	With the syndication feature, you can partition your Catalogs into *Spaces*. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

Activating your API Manager user account

Before you can access the API Manager user interface of IBM® API Connect, you must activate the user account that your Cloud Manager administrator invited you to join.

Before you begin

The Cloud Manager administrator invited you to join API Connect .

Procedure

1. Complete the following steps to create your API Manager account:

   If the Identity Provider uses LDAP
   : An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If the Identity Provider uses a local registry
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:
     - Uppercase letters
     - Lowercase letters

- Numbers
- Special characters (for example: ! # $ %)

Note:

- The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
- If you previously had an account that the administrator removed, and they are inviting you again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

If the Identity Provider uses an authentication URL

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your API Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for API Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.

2. Click Sign up to complete your registration, then click Sign in to open the API Manager login page.

Results

You have created your API Connect account.

What to do next

Log in to the API Manager user interface and, depending on your role, start to work with Catalogs, consumer organizations, APIs and Products.
To access the API Manager login page in the future, use the following URL:

`https://host/manager`

where *host* is the fully qualified host name or IP address of the Management server.

Accessing the API Manager user interface

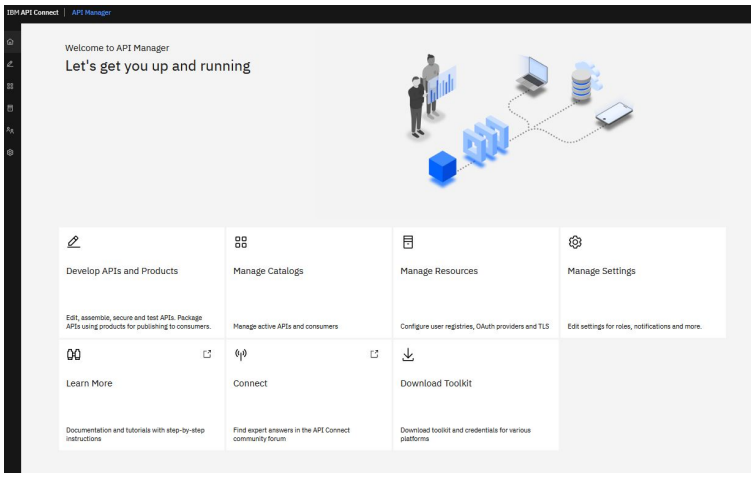
The IBM® API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.

To log in to the API Manager user interface, complete the following steps:

1. In a web browser, enter the following URL:

   `https://host/manager`

   where *host* is the fully qualified host name or IP address of the Management server.
2. If your cloud contains multiple user registries, then select the user registry that contains the login credentials for your API Manager account. You might need to ask your administrator which user registry is appropriate for your account.
   For information on configuring user registries and making them available for API Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.
3. Enter your user name and password, then click Sign in.
   The API Manager user interface opens:



Depending on your role, you can now start to work with Catalogs, consumer organizations, APIs and Products.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager. To start searching, just type a string into the Search field and press Enter. Whenever you press Enter in the Search field, the Search page displays with results and additional options. If you press Enter in an empty Search field, or click Search in the navigation list, then the Search page displays a list all items. If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose you searched for "Crafted". The results might look like the following image, with items that don't match the search string exactly, but do include the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the . . . actions menu next to the item's "Modified" date to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view additional types. If you select a type from the More menu, it replaces a type in the list.

If you want to refine the search further, click Options. On the Options panel, click Catalogs to Search and select which catalogs to search (the default is all catalogs). You can select up to 5 catalogs for a limited search.

You can also choose whether only exact matches (the complete string) are included in results, or items containing similar strings are also included.

Using Engagement to automate notification tasks

The Engagement feature in the API Manager helps the user to create complex workflows that automate tasks based on the specified criteria and enhances the overall API management experience.

Engagement allows external HTTP(S) endpoints to be triggered when specific criteria are met within the IBM® API Connect. This helps the user to create multiple complex workflows that automate tasks. The Engagement resources are provisioned within a specific provider organization or catalog, enabling targeted access and management.

To use Engagement, click on the API Manager and specify the criteria as required.

Note: You can use Engagement only if there is at least one active analytics service and storage is enabled.
You can specify the criteria as required, and a guided workflow facilitates the creation of rules. Each rule can have multiple triggers, which can be configured to run multiple actions that target specific destinations. When you configure rules and triggers, make sure to fulfill the following criteria:

- Each rule can have up to 7 filter criteria and 5 triggers
- Each trigger can have up to 3 actions

For more information on creating a notification task, see Creating a notification task.

Users can utilize Engagement on their API manager to receive notifications for various purposes. The API consumers receive notifications based on the datasource option they select while configuring rules for the notification tasks. For more information, see Engagement datasource.

- **Creating a notification task**
  The user can use Engagement on their API Manager to receive notifications based on the defined criteria.

- **Engagement datasource**
  Utilize Engagement on the API Manager to receive notifications for various purposes.

Creating a notification task

The user can use Engagement on their API Manager to receive notifications based on the defined criteria.

Before you begin

You must have at least one active Analytics service to use Engagement in the API Manager. When you create your notification task, you must fulfill the following criteria:

- Each rule can have only up to 7 filter criteria and 5 triggers.
- Each trigger can have only up to 3 actions.

About this task

The Engagement feature in the API Manager helps the user to create complex workflows that automate tasks and enhance the overall API management experience. Based on the criteria defined while creating notification tasks, each user receives notifications.

Create a notification task

To use Engagement, click on the API Manager and specify the criteria as required.

You can create a notification task by configuring a destination, rules, triggers, and actions.

1. Configure a **`destination`**, which is the definition of the HTTP(S) endpoint that will receive the notification tasks. For more information, see Create a destination.
2. Configure a **`rule`**, which is the job that runs on a defined schedule and send queries to the data source. For more information, see Create a rule.
3. Configure a **`trigger`**, which define the conditions that generate events. For more information, see Add triggers.
4. Configure an **`action`**, which defines what happens after a notification task is triggered. For more information, see Add actions.

Create a destination

1. Click the Destinations tab.
   Note: The API Manager sends emails by using the SMTP settings that you configure in the Cloud Manager. The **`Email`** destination is available out of the box, so you do not need to create a new destination. The system automatically creates an email destination for each provider organization and catalog. Each email destination has a unique ID specific to its provider organization and catalog. Ensure that you use the correct email destination ID for your configuration.
2. Click Create and provide the following details:
   a. In the **`Title`**, provide a `Title` for the destination.
   b. In the `Description` box, provide a description.
   c. In the Configuration section, select the type. The available types are Webhook, PagerDuty, and Slack. When you add types, the system displays fields that vary depending on the selected destination type.
   d. To configure Webhook, complete the following steps:
      i. Select Webhook as the **`type`**.
      ii. Select an option from the **`Method`** list to specify the HTTP method for the destination. The available options are **`POST`**, **`PUT`**, and **`PATCH`**.
      iii. In the **`Webhook URL`** field, enter the target HTTP(S) endpoint.
      iv. **Optional:** Click Add + to include extra HTTP headers.
   e. To configure PagerDuty, complete the following steps:
      i. Select PagerDuty as the type.
      ii. Enter your `pagerduty integration routing key` in **`Routing key`** field. For more information about **`pagerduty integration`**, see Services and Integrations.
      Note: When integrating with PagerDuty, select `Events API v2` as the integration type.
   f. To configure Slack, complete the following steps:
      i. Select Slack as the type.
      ii. In the **`Token`** field, enter the Slack API token.
      iii. In the **`Channel ID`** field, enter your `Channel ID`. For more information about **`Token and Channel ID`**, see How to quickly get and use a Slack API bot token.
      Note: Use the Channel ID, not the channel's name. For example: **`C1234567890`**.
   g. To configure Amazon Simple Notification Service, complete the following steps:
   Note: To enable Amazon SNS for Engagement, you must create the AWS client secret and reference the secret in the analytics custom resource YAML file. For more information, see Enable Amazon SNS for Engagement.
      i. Select Amazon SNS as the type.
      ii. In the Topic ARN field, enter the Amazon SNS topic's ARN.
      iii. In the Role ARN field, enter the Amazon SNS role's ARN.
   h. To configure Kafka HTTP Bridge, complete the following steps:
      i. Select Webhook as the **`type`**.
      ii. Select an option from the **`Method`** list to specify the HTTP method for the destination. The available options are **`POST`**, **`PUT`**, and **`PATCH`**.
      iii. In the **`Webhook URL`** field, enter the target HTTP(S) endpoint.

      `http://<route-name>.apps.<cluster-name>.<namespace>.com/topics/<topic-name>`

      For more information about **`Kafka HTTP Bridge`** configuration, see Connecting over HTTP with Kafka Bridge.
      iv. Click Add + to add an HTTP header.
      v. In the **`Name`** filed, enter `content-type`.
      vi. In the **`Value`** field, enter `application/vnd.kafka.json.v2+json`.
      vii. Define the JSON payload to be sent to the Kafka topic in the trigger action of your rule.

Note: Check your Kafka setup and adjust the payload format if needed. The following example shows a JSON message format required by some Kafka implementations:

```
{
     "records": [
        {
            "key": "my-key",
            "value": "my-value"
        }
    ]
}
```

i. To configure IBM MQ, complete the following steps:
   i. Select Webhook as the **type**.
   ii. Select an option from the **Method** list to specify the HTTP method for the destination. The available options are **POST**, **PUT**, and **PATCH**.
   iii. In the **Webhook URL** field, enter the target HTTP(S) endpoint.

   ```
   https://<host>:<port>/ibmmq/rest/v3/messaging/qmgr/<your_qm_name>/queue/<your_queue_name>/message
   ```

   For more information about **IBM MQ messaging REST API**, see IBM MQ messaging REST API.
   iv. Click Add + to add an HTTP header.
   v. In the **Name** filed, enter `content-type`.
   vi. In the **Value** field, enter the value of the content type you are using, for example: **text/plain;charset=utf-8**.
   vii. Click Add + to add a second HTTP header.
   viii. In the **Name** filed, enter `authorization`.
   ix. In the **Value** field, enter `Basic <base64encodedstring>`.
   Where:

   - **base64encodedstring** is the **username:password** base 64 encoded.

   x. Click Add + to add a third HTTP header.
   xi. In the **Name** filed, enter `ibm-mq-rest-csrf-token`.
   xii. You can leave the value field blank.
   Note: Ensure that this header is included, even if the value field is blank, as the IBM MQ Queue Manager rejects the payload without it.

j. To configure IBM Cloud Event Notification Service, complete the following steps:
Note: The destinations in IBM Cloud Event Notification Service are not linked to the destinations in API Connect. You must configure the destination in IBM Cloud Event Notification Service before configuring Engagement in API Connect.
   i. Select Webhook as the **type**.
   ii. Select **POST** from the **Method** list to specify the HTTP method for the destination.
   iii. In the **Webhook URL** field, enter the target HTTP(S) endpoint.

   ```
   {base_url}/v1/instances/{instance_id}/notifications
   ```

   Where:

   base_url
   : Enter the base URL path

   instance_id
   : Enter the identifier corresponding to the instance

   For more information about **IBM Cloud Event Notification Service**, see Event notifications API.
   iv. Click Add + to add an HTTP header.
   v. In the **Name** filed, enter `content-type`.
   vi. In the **Value** field, enter `application/json`.
   vii. Click Add + to add a second HTTP header.
   viii. In the **Name** filed, enter `Authorization`.
   ix. In the **Value** field, enter your IAM token.
   x. Define the JSON payload that you want to send to the notification service in the trigger action of your rule. For more information, see Event notifications API.

3. Click Create.

Create a rule

1. Click the Rules tab.
2. Click Create and provide the following details:
   a. In the **Title** field, provide a `Title` for the rule.
   b. In the Schedule section, specify a schedule to run this rule. You can specify a schedule either by defining a time interval or a cron string.
   c. Click Next to select data and define query.
   d. In the Select data section, select an option from the Data source list based on the data against which you want to run the rule.
   e. In the Query section, define the aggregation metric that you want to use for the query. The default is a count of matching records. You can also use mathematical aggregations for numerical fields, such as the maximum value or the average over a time period.
   f. In the Data time range for the last fields, enter the time range based on how far back in the past you want to run the search for matching data items.
   g. Click Add filter + to select up to 7 data filters to based on the data you want to include while running the query. You can use any of the analytics event record fields.
   h. Click Add group by + to select a group based on how you want to group the selected data and streamline the target criteria. For example, a rule that matches 10 API events with a status code of 500 within a 24-hour period can use **Group by** on **api_name** to call for 10 matching events for an individual API as opposed to a total across all events for all APIs.
   i. Click Next to configure triggers.

Add triggers:

   a. Click Add trigger +. You can add up to 5 triggers.
   b. In the Trigger details section, provide a `Title` for the trigger and then, select the severity level and trigger condition from the corresponding lists.

c. Define the numerical target, which allows a single rule to have multiple triggers with different severity and trigger conditions. When the specified criteria are met, each trigger can trigger up to 3 actions, which then invokes different endpoints or with different payloads.

Add actions:

a. Click Add action + to configure the action that happens when the trigger criteria are met.
b. In the Trigger action section, provide a `title` for the action, and from the Destination list, select the destination to be invoked when the criteria are met.
c. Enable throttling and define the throttling window to prevent invoking multiple triggers for the same rule in the same time period.
d. In the Payload section, provide a message subject and a payload value. You can add context variables in the Payload field based on the task payload information you want to display in the destination. For more information, see Context variables in the task payload.
Note: The message subject is not sent to the HTTP endpoint. The payload value acts as the HTTP body of the notification task that is sent to the destination endpoint

3. Click Save.
4. Click Finish.

What you did in this task

On your API Manager, you used Engagement to automate notification tasks based on the specified criteria. The Task status tab displays the latest notification tasks for each trigger.

Engagement datasource

Utilize Engagement on the API Manager to receive notifications for various purposes.

The API consumers receive notifications based on the datasource option they select while configuring rules for the notification tasks. The available datasource options are:

- **API events**
  Reference table and example use cases for API event based engagement rules.
- **Audit events**
  Reference table and example use cases for audit event based engagement rules.
- **API summary**
  Reference table and example use cases for API summary based engagement rules.
- **Config sync**
  Reference table and example use cases to monitor the use of config sync based engagement rules for artifact replication.

API events

Reference table and example use cases for API event based engagement rules.

The following are some of the example use cases for API event based engagement rules:

- An API Provider can use Engagement to get notified:
  - If there are more than 3 HTTP 500 errors on any single API in any 24 hr period.
  - When the average response time for an API goes beyond a certain threshold.
- A corporate security officer can use engagement to receive an email if someone accesses their banking APIs from an embargoed country.
- An AI API Provider can use engagement to get notified if the total of the AI Tokens used within an hour goes beyond a certain threshold.

The following table shows the list of fields available for an API event record. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. API event record fields

Field name	Type	Description
ai_cache_hit	Boolean	Indicates whether the AI response was served from cache.
ai_model	String	The name or identifier of the AI model that is used.
ai_request_tokens	Number	The number of tokens in the input prompt to the AI model.
ai_response_tokens	Number	The number of tokens that are generated in the AI response.
ai_total_tokens	Number	The total number of tokens that are used in the AI interaction that includes both request and response.
alert_action	String	The action that is taken in response to an alert.
alert_description	String	The description or message that is associated with the alert.
alert_source	String	The source system or module that generated the alert.
alert_type	String	The type or category of the alert.
api_id	String	The API identifier.
api_name	String	The name of the API.
api_resource_id	String	Field format is: **`api_name:api_version:method:path`**. Only available on API Gateway v10.5.3 or higher.
api_version	String	The version number of the API.
api_type	String	The type of API. For example, REST, GraphQL, SOAP.
app_id	String	The identifier for the registered application.
app_lifecycle_state	String	The lifecycle state of the application.

Field name	Type	Description
app_name	String	The name of the registered application. Note: The property is set to **undefined** when a client ID is not used or is invalid on the API. The gateway needs a client ID to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app was invoked, because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
app_type	String	The application type, with a value of **Production** or **Development**.
backend_method	String	The HTTP method that is used in the backend request.
backend_request_body	String	The body content of the backend request.
backend_request_headers	Object	The headers that are sent in the backend request.
backend_response_body	String	The body content of the backend response.
backend_response_headers	Object	The headers that are received in the backend response.
backend_status_code	String	The HTTP status code returned by the backend.
backend_time_to_serve_request	Number	Time in milliseconds taken by the backend to serve the request.
backend_url	String	The URL of the backend service invoked.
bytes_received	Number	The number of bytes received from the consumer in the request.
bytes_sent	Number	The number of bytes sent to the consumer in the response.
cached_response	Boolean	Indicates whether the response was served from a cache.
callback_request	Boolean	Indicates whether the request was a callback.
catalog_id	String	The Identifier of the API catalog.
catalog_name	String	The name of the API catalog.
client_geoip.area_code	Number	The public switched telephone network (PSTN) area code of the client, as identified from its IP address.
client_geoip.city_name	String	The city name of the client, as identified from its IP address.
client_geoip.continent_code	String	The two-letter continent code of the client, as identified from its IP address.
client_geoip.country_code2	String	The two-letter country code of the client, as identified from its IP address.
client_geoip.country_code3	String	The three-letter country code of the client, as identified from its IP address.
client_geoip.country_name	String	The country name of the client, as identified from its IP address.
client_geoip.dma_code	Number	The Designated Market Area (DMA) code of the client, as identified from its IP address.
client_geoip.ip	String	The IP address of the client.
client_geoip.latitude	Number	The latitude of the client location, as identified from its IP address.
client_geoip.location	String	The longitude and latitude of the client location (separated by a comma), as identified from its IP address.
client_geoip.longitude	Number	The longitude of the client location, as identified from its IP address.
client_geoip.postal_code	String	The postal code of the client, as identified from its IP address.
client_geoip.region_code	String	The region code based on client IP.
client_geoip.region_name	String	The abbreviated form of the region that corresponds to the IP address of the client.
client_geoip.timezone	String	The time zone of the client, as identified from its IP address.
client_id	String	The unique ID of the client that is attached to the API request.
client_ip	String	The IP address of the client.
consumer_organization_id	String	The Identifier of the consumers organization.
consumer_organization_name	String	The name of the consumers organization
consumer_organization_title	String	The title or display name of the consumer organization.
custom_data	Array map	Custom data can be added to this field.
datetime	Date	A timestamp that records when the API was invoked. The timestamp is always shown in Coordinated Universal Time.
developer_org_id	String	The identifier for the consumer organization that owns the application.

Field name	Type	Description
developer_org_name	String	The name of the consumer organization that owns the application.
endpoint_url	String	When the request failed, **endpoint_url** identifies the proxy or invoke target URL on which the request failed. It is not included with a successful request. On V5 compatible gateway, this field is only populated when the backend server URL that was invoked returns an HTTP 404 code.
error_description	String	A detailed description of any error encountered.
error_message	String	A brief message describing the error.
event_type	String	The type of event.
filter_name	String	The name of the filter that is applied during the request.
gateway_geoip.area_code	Number	The public switched telephone network (PSTN) area code of the gateway, as identified from its IP address.
gateway_geoip.city_name	String	The city name of the gateway, as identified from its IP address.
gateway_geoip.continent_code	String	The two-letter continent code of the gateway, as identified from its IP address.
gateway_geoip.country_code2	String	The two-letter country code of the gateway, as identified from its IP address.
gateway_geoip.country_code3	String	The three-letter country code of the gateway, as identified from its IP address.
gateway_geoip.country_name	String	The country name of the gateway, as identified from its IP address.
gateway_geoip.dma_code	Number	The Designated Market Area (DMA) code of the gateway, as identified from its IP address.
gateway_geoip.ip	String	The IP address of the gateway.
gateway_geoip.latitude	Number	The latitude of the gateway location, as identified from its IP address.
gateway_geoip.location	String	The longitude and latitude of the gateway location (separated by a comma), as identified from its IP address.
gateway_geoip.longitude	Number	The longitude of the gateway location, as identified from its IP address.
gateway_geoip.postal_code	String	The postal code of the gateway, as identified from its IP address.
gateway_geoip.region_name	String	The abbreviated form of the region that corresponds to the IP address of the gateway.
gateway_geoip.timezone	String	The time zone of the gateway, as identified from its IP address.
gateway_host_name	String	The hostname of the API gateway.
gateway_ip	String	The IP address of the gateway.
gateway_port	Number	The port number used by the API gateway.
gateway_service_name	String	The name of the DataPower API gateway service. Configured by the cloud admin user when registering the gateway service. Only available on DataPower API Gateway v10.5.3 or higher.
gateway_time_to_serve_request	Number	Time in milliseconds taken by the gateway to serve the request.
gateway_type	String	The type and version of the gateway that processed the call, in format: **type**/**version**. Set by all gateway types except for v5c, and only available on v10.0.8.0 or higher.
global_transaction_id	String	The DataPower global transaction ID. See https://www.ibm.com/docs/en/datapower-gateway/latest?topic=variables-varserviceglobal-transaction-id-servicevarsglobaltransactionid.
graphql_document_hash	String	The hash value of the GraphQL query document.
graphql_error_count	Number	The number of errors encountered in the GraphQL query execution.
graphql_operation_name	String	The name of the GraphQL operation.
graphql_operation_type	String	The type of the GraphQL operation.
graphql_request_field_cost	Number	GraphQL APIs only. The maximum cost of all fields accessed in the query. The cost of each field access is configured in the schema.
graphql_request_max_nesting	Number	GraphQL APIs only. The maximum nesting depth found in the query by the assembly validate action. The schema configuration is used to determine which types are nested, so this value might be less than the nesting depth found by the assembly parse action.
graphql_request_top_field_counts	Object	GraphQL APIs only. The maximum number of times that a query can retrieve each field. This number is equal to the number of times that the resolver is required to run. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_request_top_type_counts	Object	GraphQL APIs only. The maximum number of times that a query can retrieve an object of each type. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.

Field name	Type	Description
graphql_request_type_cost	Number	GraphQL APIs only. The maximum cost of all types retrieved in the query. The cost of each type is configured in the schema.
graphql_response_field_cost	Number	GraphQL APIs only. The cost of all fields accessed in the query. The cost of each field access is configured in the schema.
graphql_response_max_nesting	Number	GraphQL APIs only. The nesting depth found in the query by the assembly validate action. The schema configuration is used to determine which types are considered nested, so this value might be less than the nesting depth found by the assembly parse action.
graphql_response_top_field_counts	Object	GraphQL APIs only. The number of times that each field was retrieved by the query. This number is equal to the number of times that the resolver is required to run. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_response_top_type_counts	Object	GraphQL APIs only. The number of times that an object of each type was retrieved by the query. This field is stored in JSON format and is not indexed, so it is not available for visualizations. A limited number of query requests and responses are stored for each entry, based on the amount of data that each contains. The maximum amount of data that can be stored is subject to change.
graphql_response_type_cost	Number	GraphQL APIs only. The cost of all types that were retrieved in the query. The cost of each type is configured in the schema.
headers.*field_name*	String	Internal information that is related to analytics ingestion. headers.*field_name* is not related to the API call or its response, see **`request_http_headers`** for that information.
host	String	The hostname or IP address of the ingestion node that received the API event.
http_user_agent	String	The value of the User Agent header on the inbound request.
immediate_client_ip	String	The client IP address that is directly in front of the gateway. Usually **`immediate_client_ip`** is the IP of a load balancer.
latency_info.started	Number	The time delay (in milliseconds) between when the request was received and when the gateway started the corresponding task. Starting a task comprises multiple steps to prepare for executing an API; for example, completing the TCP/TLS handshake, verifying an app's client ID and secret, and matching the request URI to a catalog, API, and Plan. When the gateway receives a request, the "Start" duration is set to 0. The duration of each step within the Start task is then added up, and the total represents the duration of the Start task.
latency_info.task	String	The API transaction that was processed.
log_policy	String	The defined logging policy. Values include none, event, headers, and payload.
method	String	The HTTP method used in the request. For example, GET, POST.
monitor_attribute	String	The custom attribute that is used for API monitoring.
opentracing_info	Object	The distributed tracing data for the request.
operation_path	String	The specific operation path within the API.
org_id	String	The identifier for the provider organization that owns the API and associated Products.
org_name	String	The name of the provider organization that owns the API and associated Products.
path	String	The full path of the API request.
path_id	String	The Identifier for the API path that is accessed.
plan_id	String	The Plan identifier.
plan_name	String	The name of the Plan. Note: The property is set to **`undefined`** when a client ID is not used or is invalid on the API. The gateway needs a client id to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app was invoked because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
plan_version	String	The version number of the Plan.
product_id	String	The Identifier of the product that is associated with the API.
product_name	String	The Product name. Note: The property is set to **`undefined`** when a client ID is not used or is invalid on the API. The gateway needs a client ID to determine which app was invoking the API. From this app, the gateway can determine what plan the app is subscribed to on the product that contains the API. Without a client ID, the gateway is unable to determine what plan, product, or app wasinvoked because a single API can belong to multiple products (each of which have multiple plans and apps that are subscribed to those plans with client IDs).
product_title	String	The title of the Product.
product_version	String	The version number of the Product.
query_string	String	The URL query string value on the inbound request.
rate_limit	String	The maximum number of requests an application is allowed to make to the API during a specified time window.
rate_limit.count	Number	The number of API calls remaining in the specified rate limit time window.
rate_limit.interval	Number	The total time window during which a certain number of API calls are allowed.
rate_limit.limit	Number	The maximum number of requests an application is allowed to make to the API during a specified time window.
rate_limit.period	Number	The time window that is used to set a rate limit for API calls.
rate_limit.reject	String	An indication of whether calls that exceed the specified rate limit are rejected. If true, the API call is rejected with a 429 status code. If false, a record is created in the Activity log.
rate_limit.shared	String	An indication of whether the rate limit is shared at a Plan level by all operations, or whether a rate limit is specified on indivIDual operations.
rate_limit.unit	Number	The time unit used for calculating the rate limit. Note: Allowed values are second, minute, hour, day, and week

Field name	Type	Description
request_body	String	The body of the inbound request.
request_http_headers.*field_name*	String	A component of the HTTP header section of the inbound request; for example, the acceptable encodings, the identification string for the user agent, or the proxies through which the request was sent. Note: The following types of headers are considered sensitive and do not show in analytics data for security reasons: • Any secret key configured in the API security • Any header that contains **`secret`** • Any header that contains **`Authorization`**
request_method	String	The method of the inbound request.
request_protocol	String	The protocol of the inbound request.
resource	String	The name of the operation.
resource_id	String	The operation identifier.
resource_path	String	The operation path.
response_body	String	The body of the outbound response.
response_http_headers.*field_name*	String	A component of the HTTP header section of the outbound response; for example, the MIME type of the content or the data and time when the message was sent.
rule_name	String	The name of the rule that is applied to the request.
scope	String	Not used for DataPower® API Gateway or DataPower Gateway.
space_id	String	The Identifier of the space under which the API call was made.
space_name	String	The name of the space.
status_code	String	The status code set on the outbound response.
time_to_serve_request	Number	The time elapsed (in milliseconds) from when the gateway received the request to when it sent a response.
transaction_id	String	The identifier for the API transaction. See https://www.ibm.com/docs/en/datapower-gateway/latest?topic=variables-varservicetransaction-id-servicevarstransactionid.
uri_path	String	The URI path on the inbound request.
user_agent	Object	The parsed contents of the **`http_user_agent`** field, which contains information about the user that made the API call.
user_agent.device	String	Device name.
user_agent.major	String	User agent major version number.
user_agent.minor	String	User agent minor version number.
user_agent.name	String	User agent name.
user_agent.os_full	String	Detected operating system full name.
user_agent.os_major	String	Detected operating system major version number.
user_agent.os_minor	String	Detected operating system minor version number.
user_agent.os_name	String	Detected operating system name.
user_agent.os_patch	String	Detected operating system patch version.
user_agent.os_version	String	Detected operating system version.
user_agent.patch	String	User agent patch version.
user_agent.version	String	Detected user agent version.
websocket_message_type	String	The type of WebSocket message.
websocket_origin	String	The origin header of the WebSocket connection.

Audit events

Reference table and example use cases for audit event based engagement rules.

The following are some of the example use cases for audit event based engagement rules:

An API Provider can use Engagement to get notified:

- When catalogs are created, updated, or deleted.
- When Catalog or Cloud configuration settings are modified.
- On user login, logout, and failed login.

The following table shows the list of fields available for an audit event record. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. Audit event record fields

Field name	Type	Description
action	String	The type of action performed.
attachments.component	String	The name of the system or module where the event originated.
attachments.scope	String	The contextual boundary or scope of the event. For example, org, catalog, cloud.
attachments.method	String	The HTTP method or action method involved in the operation. For example, POST, GET
attachments.summary	String	A brief description or summary of the event or action.
attachments.operation	String	The specific operation or function executed.
attachments.resource	String	The type or name of the resource that is affected.
attachments.user.url	String	The URL involved in the action.
attachments.user.context	String	The context from which the user initiated the action.
attachments.user.idp_name	String	The name of the Identity Provider.
attachments.user.name	String	The display name of the user who initiated the action.
attachments.registration.url	String	The registration URL.
attachments.registration.type	String	The type of registration.
catalogId	String	The identifier for the catalog associated with the action.
initiator.host	String	The hostname of the initiator system.
initiator.host.address	String	The network address (for example, IP) of the initiator system.
initiator.host.agent	String	The software agent or process running on the initiator system.
initiator.id	String	The unique identifier that initiated the action.
initiator.name	String	The name of the initiator of the action.
initiator.typeURI	String	The URI indicating the type or classification of the initiator.
outcome	String	The result or outcome of the action.
reason.reasonCode	String	The code representing the reason for the action or outcome.
reason.reasonType	String	The category or type of the reason provided.
spaceId	String	The Identifier for the space where the action occurred.
target.id	String	The Identifier of the target resource affected by the action.
target.typeURI	String	The URI indicating the type of the target resource.
typeURI	String	The URI representing the type of the event .

API summary

Reference table and example use cases for API summary based engagement rules.

The following are some example use cases for API summary based engagement rules:

- An API Provider can use Engagement to get notified:
  - If the calls for a particular API decrease quarter to quarter.
  - If there is an increase in the time to serve requests for the current month when compared to the previous month.

Note: The API summary data is retained for longer periods and the rules created for API summary data can be used to perform long-term trend analysis over months or quarters.
The following table shows the list of fields available for the API summary datasource. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. API summary data

Field	Type	Description
api_ref	string	API reference (api_name:api_version).
product_ref	string	Product reference (product_name:product_version).
app_name	string	The name of the registered application.
catalog_name	string	The name of the catalog.
space_name	string	The name of the space, if spaces are enabled.
gateway_service_name	string	The name of the DataPower API gateway service that is configured by the Cloud Admin user when registering the gateway service. Only available on DataPower API Gateway v10.5.3 or higher.
plan_id	string	The plan identifier.
status_code	string	The status code set on the outbound response.
bytes_received	number	The number of bytes received from the consumer in the request.
bytes_sent	number	The number of bytes sent to the consumer in the response.
time_to_serve_request	number	The time elapsed (in milliseconds) between the gateway received the request and sent a response.

Config sync

Reference table and example use cases to monitor the use of config sync based engagement rules for artifact replication.

- An API Provider can use Engagement to get notified:
  - If the number of config sync records in a given period was less than expected, indicating that the sync failed to execute correctly.
  - If the number of config sync records in a given period was more than expected, indicating that the customers on call based licensing would be charged more.

The following table shows the list of fields available for the config sync datasource. These fields are used as filters in the Rule definition list and you can select an option based on the data that is used to trigger the rule.

Table 1. Config sync data

Field	Type	Description
apis	integer	The number of apis
catalog_name	string	The name of the catalog.
catalog_id	string	The catalog ID.
consumer_orgs	number	The number of consumer organizations synchronized.
members	number	The number of members synchronized.
users	number	The number of users synchronized.
applications	number	The number of applications synchronized.
credentials	number	The number of credentials synchronized.
subscriptions	number	The number of subscriptions synchronized.
Total items	number	The total number of items synchronized.
products	integer	The number of products

Working with Catalogs

Products must be staged to a Catalog and then published; application developers are able to access the APIs in a Product by being members of consumer organizations to which the Product is made available.

When you create a provider organization, API Connect creates a sandbox catalog by default. The characteristics of the sandbox catalog are:

- The sandbox catalog is designed for API development and testing.
- The sandbox catalog cannot be deleted and does not have production mode or Spaces options under catalog settings.
- A sandbox catalog includes a default application and a consumer organization.

In API Connect, you can create multiple Catalogs. Catalogs are useful for separating Products and APIs for testing before you make them available to consumer organizations. The syndication feature in API Connect means that you can also publish a Product to a Space in a Catalog.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
A Catalog is a staging target, and behaves as a logical partition of the gateway and the Developer Portal. The URL for API calls and the Developer Portal are specific to a particular Catalog. In a typical configuration, an API provider organization uses a development Catalog for testing APIs under development and a production Catalog for hosting APIs that are ready for full use. A common approach is to have a development cloud with a development Catalog, a few test Catalogs and a production cloud that might have its own test Catalog.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a sub-catalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in API Connect.

Note:
Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **`A user already exists with this email address`**.

For more information on using the Developer Portal, see Developer Portal: Socialize your APIs.

- **Creating and configuring catalogs**
  How to create and configure catalogs in IBM API Connect.
- **Configuring Product visibility at a Catalog or Space level**
  How to set a limit on the visibility for all Products that are published to a Catalog or Space.
- **Configuring sub paths for Developer Portal sites**
  You can increase the specificity of a IBM API Connect Developer Portal site URL by using sub paths.
- **Consumer Catalog and Developer Portal considerations**
  A customer can have either a Developer Portal or a Consumer Catalog to test and subscribe to the APIs published in the Catalog.
- **Managing Catalog membership**
  Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.
- **Importing a user-defined policy into a Catalog**
  You can make your user-defined policy available to API developers by importing it into an IBM API Connect Catalog, or a Space in a Catalog.
- **Importing an OpenAPI extension into a Catalog**
  You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.
- **Retaining Version 5 vanity endpoint behavior in a Catalog**
  The behavior of vanity endpoints in a Catalog has changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.
- **Protecting catalog properties**

Creating and configuring catalogs

How to create and configure catalogs in IBM® API Connect.

Before you begin

You must have catalog create permissions to complete this task. For more information about permissions, see API Connect user roles.

- As the user who creates the catalog, you are automatically the catalog owner and have all catalog permissions.
- If you configure a new user registry for authenticating users to the Developer Portal, you must also complete the onboarding section in the catalog, to make the registry available to Developer Portal users. See Step 10 for details.
- Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.

Procedure

To create and configure your catalog, complete the following steps:

1. Log in to API Manager and click Manage.
2. Create the catalog.
   You can create the catalog in either of the following ways:
   Specify the owner, then configure the catalog:
   a. Click Add > Create catalog.
   b. In the Catalog Owner field, select the owner of the catalog; by default, you are the owner. You can specify any user who is a member of the provider organization.
   c. Continue from step 3 to configure the catalog.
   Send an invitation email, with an activation link, to the intended catalog owner:

   a. Click Add > Invite catalog owner.
   b. Enter the email address of the catalog owner, then click Invite.
   c. On receipt of the email, the catalog owner must activate the catalog and configure it:
      i. Open the activation link, complete the sign up form, and sign in to the API Manager UI.
      ii. Click Manage Catalogs, click the catalog name that was provided on the sign up form, then click the Catalog settings tab.
      iii. Continue from step 6 to configure the catalog.
3. Enter the catalog Title. A Name is entered automatically and cannot be changed.
   Note: The value in the Name field is a single string that is used to identify the catalog in developer toolkit CLI commands. The Title is used for display; you can change the title but the name does not change.
   To view the CLI commands to manage catalogs, see the toolkit CLI reference documentation.

4. Click Create.
   Your new catalog is displayed on the Manage page.
5. To continue to configure your catalog, select the catalog on the Manage page, then click the Catalog settings tab.
6. To configure the general settings for the catalog, click Overview, then proceed with the following steps:
   a. By default, the new catalog is a development catalog. To use the catalog in production, set the Production Mode slider control to the On position, then click Confirm.
   In a development catalog, all publish operations are forced, and any conflicts are resolved automatically. If you republish a previously published product version it is overwritten without warning, allowing you, for example, to repeatedly republish the same product version during testing. If spaces are enabled in a development catalog and you republish a previously published product version to a different space, it is removed from the previous space.

   However, if the catalog has been configured to require approvals, a development catalog behaves the same as any other catalog with regard to requiring approval for staging and publishing actions.

   Note: In a production catalog, the following conditions apply:
   - You cannot publish a product to the catalog if there is already a product in the catalog with the same name and version. Instead, you must create a new version of the product for publication; see Creating a new version of your product . If spaces are enabled in a production catalog, you cannot publish a product with the same name and version to more than one space in the catalog.
   - If this new product contains one or more modified APIs, you **must** create new versions of the APIs for inclusion in the product; see Creating a new version of an API definition. If the product contains a modified API and there is already a published API of the same name and version, the changes will **not** be published.

   b. To enable the partition of this catalog into spaces, set the Spaces slider control to the On position, then click Confirm.
   For more information, see Using syndication in IBM API Connect.
   c. If the catalog is the default staging catalog, move the Default slider control to the On position, then click Confirm. Then, calls to APIs that are published to the catalog can use a shorter URL that does not include the catalog name.
   Note: You can enable Default for only one catalog. If another catalog is already set as the default catalog, you will be unable to enable the setting on this catalog without first disabling the setting on the other catalog.
   d. To enable application lifecycle for applications that are created in the Developer Portal that is associated with this catalog, set Application Lifecycle to On, then click Confirm.
   When application lifecycle is enabled, any application that an application developer creates in the Developer Portal has Development status by default. When application testing is complete, the application developer can request to upgrade the application to production status. For more information, see Managing the application lifecycle.
7. To configure the gateway service settings for the catalog, click Gateway Services, then proceed with the following steps:
   Note: If spaces are enabled in the catalog then you configure the gateway settings for the spaces, not for the catalog as a whole.
   a. Click Edit.

b. Select the gateway services that you want to use with this catalog.
Gateway services are configured by the using the Cloud Manager UI. For details, see Registering a gateway service. If any catalog default gateway services have been configured, they will already be selected when you create a new catalog; see Configuring default gateway services for catalogs.
The TYPE column indicates the gateway type for each gateway service listed, DataPower® Gateway (v5 compatible), DataPower API Gateway, or Event Gateway Service. For more information, see API Connect gateway types.

c. Click Save to save your changes.
The UI for creating or importing AsynchAPIs from Event Endpoint Management is disabled for catalogs that do not have the Event Gateway service available. If you want to work with AsynchAPIs in the catalog, you must add an Event Gateway service to the catalog.

You publish APIs by adding them to a product and then publishing the product to a catalog. To be able to publish products to a catalog, the catalog must be assigned at least one gateway service so that the APIs in the product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a catalog, and they can be of mixed types, DataPower API Gateway and DataPower Gateway (v5 compatible).

A product is gateway type specific, either DataPower API Gateway or DataPower Gateway (v5 compatible). By default, when you publish a product to a catalog, it is published to all the assigned gateway services of the same gateway type as the product, but you can choose to publish the product only to selected gateway services, of that type, at publish time; see Publishing a draft product for more information. The APIs in the product will be available to be called at all the specified gateway service endpoints.

If you select two or more Gateway services then, for analytics data to be available in the Developer Portal for this catalog, the Gateway services must all be associated with the **same** analytics service. If the set of associated analytics services for the selected gateway services includes two or more different analytics services then the Developer Portal does **not** display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see Associating an analytics service with a gateway service.
Note: You can also configure the gateway service settings for the catalog by using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

8. To specify the product lifecycle state changes for which you want to enforce approval, complete the following steps:
   a. Click Lifecycle Approvals in the catalog settings navigation pane, then click Edit.
   b. Select the required state changes, then click Save when done.
   For example, if you select Publish and leave the other check boxes cleared, approval is required when anyone attempts to publish a product, but no approval is required for any of the other lifecycle state changes.
   Note: Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   c. To allow the originator of a product lifecycle change to approve it themselves, move the Task self approval slider control to the On position.
   Note: In a development catalog, the originator of a product lifecycle change can always approve it themselves. In a production catalog, the originator of a product lifecycle change can approve it themselves only if the catalog setting Task self approval is enabled.
   d. Click Save when done.
9. To configure the permissions that each role in API Manager has, complete the following steps:
   a. Click Roles in the catalog settings navigation pane.
   To see the current permissions for a role, expand the role.
   b. Click the options icon ⋮ alongside the role that you want to work with, then click Edit.
   c. Select or clear the permissions check boxes as required.
   To ensure a role can manage user-defined policies, select Manage for the Settings permission.

   To grant a role the permission to approve a specific lifecycle state change, select the state change in the Product-Approval section.

   Note: You cannot remove a permission that has been assigned to the role at the provider organization level. However, you can add permissions that haven't been assigned at the provider organization level.
   d. Click Save when done.
10. To manage the onboarding of API consumers into this catalog, complete the following steps:
    a. Click Onboarding in the catalog settings navigation pane.
    b. To select the registries that are used to authenticate users of the Developer Portal associated with this catalog, click Edit in the Catalog user registries section, select the required registries, then click Save.
    For details on how to configure a user registry, see Authenticating by using your enterprise user registry.
    Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

    c. To set a default registry, locate the required registry and click ⋮ Set default.
    When an API consumer signs up to the Developer Portal, the specified registry is used by default, with the option to select another registry.

    d. To allow API consumers to complete their own sign-up process to the Developer Portal, set Self service onboarding to On.
    If this option is disabled, an API consumer cannot sign-up without an invitation from a consumer organization owner.
    e. To require approval for all new self service onboarding to the Developer Portal, set Self service onboarding approval to On.
    If this option is enabled, then any attempt by an API consumer to sign-up to the Developer Portal results in an approval request being sent. This request is displayed in the Task tab in the catalog for the associated Developer Portal, from where the request can be approved or declined.
    Note that Self service onboarding approval is honored whenever a consumer organization is created. So, even if an API consumer has already been approved to access a Developer Portal with a specific consumer organization, if they then try to create another consumer organization in the same Developer Portal, their request will still go through the approval process.

    Note: To enable self-service onboarding approval, you must also complete the following tasks:
    - Configure the user registry to require the user's email address.
    - Configure the OIDC apps to send the user's email address for approval.

    f. To edit the timeout period for the self service onboarding task, click Edit in the Self service onboarding task timeout section, specify the timeout period required, and click Save. The timeout period for this task covers both the email activation link and, if Self service onboarding approval is enabled, the approval process. The default timeout period for the self service onboarding task is 72 hours.
    Note that expired self service onboarding tasks are cleared only once per day in the Developer Portal. Therefore, any API consumers with expired onboarding tasks have to wait until these tasks are cleared before attempting to sign-up again.
    g. To configure the ability for API consumers to invite collaborators and assign them to roles, click Edit in the Consumer invitation and roles section, select the options required, and click Save.
    h. To configure the timeout for activation links that are sent in email invitations to application developers, click Edit in the Invitation Timeout section, specify the timeout length, then click Save. The default timeout period for the invitation link is 48 hours.

i. To override the timeouts set by consumer organization invitations, set Override consumer organization's invitation timeout with catalog invitation timeout to On.
The catalog's own timeout setting will be used instead.

Note: The Onboarding catalog settings applies to both the Consumer Catalog and Developer Portal.

11. To specify the user registries that are used to secure access to APIs in this catalog, and to add the user registry to the Sandbox catalog, complete the following steps:
    a. Click the Catalog settings tab, and then select API User Registries.
    b. Click Edit and select the user registries you want to use.
    For details on how to configure a user registry, see Authenticating by using your enterprise user registry.
    c. Click Save when done.

    Note:
    - Only LDAP and Authentication URL registries can be used to secure access to APIs; therefore, only registries of these types are listed and available for selection.
    - If spaces are enabled in the catalog then you specify the user registries for the spaces, **not** for the catalog as a whole. If you specify a user registry in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
      For more information about enabling and managing spaces, see Using syndication in API Connect

    .

12. To specify the OAuth Providers that can be used to secure access to APIs in this catalog, complete the following steps:
    Note:
    - If you want to specify an OAuth provider for a catalog, ensure that the Sandbox catalog is configured to use the same OAuth provider
    - Any resources that the OAuth provider references, such as API user registries or TLS client profiles, must also be enabled in the catalog
    - If spaces are enabled in the catalog then you specify the OAuth providers for the spaces, **not** for the catalog as a whole. If you specify an OAuth provider in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
      For more information about enabling and managing spaces, see Using syndication in API Connect.

    a. Click OAuth Providers in the catalog settings navigation pane.
    b. Click Edit, then select the OAuth providers that you want to use.
    To configure an OAuth provider, see either Configuring a native OAuth provider using Cloud Manager or Configuring a native OAuth provider using API Manager.

    c. Click Save when done.
13. To configure the TLS client profiles that are used with this catalog, complete the following steps:
    Note: If spaces are enabled in the catalog then you configure the TLS client profiles for the spaces, **not** for the catalog as a whole. If you configure a TLS client profile in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
    For more information about enabling and managing spaces, see Using syndication in API Connect.

    a. Click TLS Client Profiles in the catalog settings navigation pane.
    b. Click Edit, then select the TLS client profiles that you want to use with this catalog.
    For details on how to create a TLS client profile, see Creating a TLS client profile.
    c. Click Save when done.
14. You have two options for sharing your APIs with the application developers. Use the default Consumer Catalog for a lightweight consumer experience; no customization, basic functionality, and ideal for small API catalogs, and internal users. You do not need Portal service to configure the Consumer Catalog. For more details on choosing between Developer Portal and Consumer Catalog, see Consumer Catalog and Developer Portal considerations.
    To enable the Consumer Catalog, complete the following steps:
    a. Click Portal in the catalog settings navigation pane, then set Consumer Catalog to On. The Consumer Catalog URL is displayed.
    By default, the Consumer Catalog is set to On.
    b. Click the URL to access the Consumer Catalog.

    If you require a complete content management system for your catalog, create a Developer Portal; fully customizable, full functionality, and ideal for large API catalogs and business users. You need a Portal service to configure the Developer Portal. To configure the Developer Portal, complete the following steps:
    a. Click Portal in the catalog settings navigation pane, then click Create.
    b. Select the portal service that you want to use with this catalog.
    Portal services are configured by using the Cloud Manager UI. For details, see Registering a portal service.
    c. Optionally, override the default generated portal URL.
    The URL must have the following format:

    ```
    https://host_name.portal.com
    ```

    where *host_name.portal.com* must resolve to the IP address of the Developer Portal machine.
    For example:

    ```
    https://myhost.mydomain.com
    ```

    Important:
    - The URL must be unique across all catalogs.
    - Mixed-case names are supported for resource names; however, portal endpoint URLs can support only lower-case. If a provider organization is created with a mixed-case name, you must edit the default-generated portal URL to make the provider organization name lower-case in the URL.

    To use sub paths in your site URL, see Sub paths for Developer Portal sites.
    d. Click Create to save your changes.
    For more information on using the Developer Portal, see Developer Portal: Socialize your APIs.

    If you want to edit the portal service or URL, return to this portal settings page and click Edit. To delete the portal site, click the options icon ⋮, and click Delete.
    Note: The account profile for the owner of the catalog must have an email address specified to receive the creation notification, otherwise the Developer Portal creation operation will fail. To check whether your account profile has an email address, and specify a value, complete the following steps:

    a. Click the User icon, and then select My Account.
    b. Check the contents of the Email field, and specify a value if necessary, then click Save.
15. To define catalog properties, complete the following steps:
    a. Click Properties in the catalog settings navigation pane, then click Create.
    b. Enter the property Name and Value.
    c. Select the Protected checkbox to encrypt the property.

Note: After the property is created as protected, it remains as encrypted. If you want to make it unencrypted, delete the property and create it again without selecting the protected option.

d. Click Create.

The properties that you define can be referenced in any of the API definitions in this catalog. It is also possible to define properties that are specific to an API definition; see Setting API properties. For information on how to reference a property in an API definition, see Variable references in API Connect.

Note:

- If you define a catalog property of the same name as an API property, the API property takes precedence over the catalog property.
- If you change the value of a catalog property, any API that references that property must be republished for it use the new value.

16. Optional: To configure the visibility of products that are published to a catalog or a space, see Configuring Product visibility at a Catalog or Space level.

What to do next

Additional catalog options

You can also configure the following settings for your catalog:

- Transfer ownership - To transfer ownership of the Catalog to a different user.
- Publish validations - Configure the publish validations that are performed when a Product is published.
- Configure vanity API endpoints - Configure vanity API endpoints, so that you can publish endpoints that are different to these gateway endpoints. A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API. If you do not configure vanity endpoints, these two endpoints are the same, and point to the gateway endpoint at which an API is invoked.

Import policies

Import your own policies into the Catalog. For details, see Importing a user-defined policy into a Catalog.

Note: When you import a policy, its implementation is imported into all Gateway devices associated with the Gateway service that hosts the Catalog. Additionally, API Connect modifies some object names and file locations to mark them with the appropriate Catalog name and policy version.
For more information about how to create and manage user-defined policies, see User defined policies.

- **Additional catalog options**
  The additional configuration options for your Catalog.

Additional catalog options

The additional configuration options for your Catalog.

Transferring the catalog ownership

To transfer ownership of the Catalog to a different user, perform the following steps:

1. Click Catalog settings and select Overview.
2. Click Edit.
3. From Select owner user, select the user who will become the new owner.
4. If Spaces are enabled in the Catalog then to also have the ownership of all Spaces in the Catalog transferred to the new Catalog owner, select Also transfer ownership of owned Spaces.
5. Click Save to save the changes.

Note:

- To have permission to change the Catalog owner, you must be either the Catalog owner, or the owner of the provider organization that contains the Catalog.
- When the ownership changes, the new owner is assigned administration privileges for the Catalog, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Managing Catalog membership.
- The ownership can be transferred only to a user who is already a member of the Catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the Catalog, as described in Managing Catalog membership.

Configuring the publish validations

To configure the publish validations that are performed when a Product is published, perform the following steps:

1. Click Catalog settings and select Publish validations.
2. Click Edit, and select or clear the validation check boxes as required.
   Note: The following validation options can be selected:
   - Publishing APIs with empty paths is not allowed.
   - Validate custom policy schema in assembly.
   - Validate the references inside the API and perform additional OpenAPI validations.
   - Publishing APIs with duplicate base paths is not allowed.
3. Click Save to save the changes.

Configuring the vanity API endpoints

For any API, there are two possible endpoints to consider:

- The gateway endpoint at which the API is invoked.
- The endpoint that is visible to the consumer in the Developer Portal.

If you do not configure vanity endpoints, these two endpoints are the same, and point to the gateway endpoint at which an API is invoked.

To have an endpoint visible to the consumer that is different to the gateway endpoint, you configure a vanity endpoint. A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API. The way in which the gateway endpoints for an API are determined depends on the OpenAPI version of the API, as follows:

(OpenAPI 2.0): For any enforced API in API Connect, the gateway endpoint formats for the API are as follows:

- If the OpenAPI definition has no **host** field, the API endpoint has the following format:

  https://*gateway_service_host*/*provider_organization*/*catalog*/*basepath*

- If the OpenAPI definition has a **host** field (for example, **petstore.com**), the host is appended to the path after the *provider_organization*/*catalog* segments, and the API endpoint has the following format:

  https://*gateway_service_host*/*provider_organization*/*catalog*/*host_field_value*/*basepath*

  Note: This is a change in behavior from IBM® API Connect Version 5.0, where the **host** field is not included in the API endpoint.

In these endpoint URLs, the variables are as follows:

- *gateway_service_host* is the host name of the gateway service on which the API is running.
- *provider_organization* is the value of the **name** field of the provider organization that contains the Catalog in which the API is published.
- *catalog* is the value of the **name** field of the Catalog in which the API is published.
- *basepath* is the value of the **basepath** field in the OpenAPI definition for the API.
- *host_field_value* is the value of the host field in the OpenAPI definition for the API.

For details on configuring the host server URL in an OpenAPI 2.0 API definition, see Specifying the host for an API.

API Gateway only **(OpenAPI 3.0):** If the API is enforced by the DataPower® API Gateway, the value specified for the first **url** entry in the **servers** array in the OpenAPI definition of the API is used to determine the **basepath** element of the API endpoint, as follows:

1. If a relative URL is specified for the server URL, that value is used as-is for the **basepath**, and the API endpoint has the following format:

   https://*gateway_service_host*/*provider_organization*/*catalog*/*basepath*

2. If a full URL is specified for the server URL, the scheme (**http://** or **https://**) is ignored by the DataPower API Gateway, and the remaining host name and **basepath** are used to form the API endpoint as follows:

   https://*gateway_service_host*/*provider_organization*/*catalog*/*host_name*/*basepath*

In these endpoint URLs, the variables are as follows:

- *gateway_service_host* is the host name of the gateway service on which the API is running.
- *provider_organization* is the value of the **name** field of the provider organization that contains the Catalog in which the API is published.
- *catalog* is the value of the **name** field of the Catalog in which the API is published.
- *host_name* is the value of the host name in the server URL.
- *basepath* is the value of the **basepath** derived from the server URL.

For details on configuring the server URL in an OpenAPI 3.0 API definition, see Defining servers for an API, Defining servers for a Path, and Defining servers for an operation.

Note: You can change your Catalog settings to use the IBM API Connect Version 5.0 endpoint behavior, including support for a feature known as *host to catalog mapping*, whereby an API can be invoked without having to include the provider organization or Catalog in the URL path; see Retaining Version 5 vanity endpoint behavior in a Catalog.

To configure vanity API endpoints, so that you can publish endpoints that are different to these gateway endpoints, complete the following steps:

1. Click API Endpoints in the Catalog settings navigation pane. The Vanity API Endpoint page opens.
2. Click Edit.
3. To display the current API base endpoint settings, select Display vanity endpoint.
4. Select the required Preference setting. Choose one the following settings:
   - Catalog priority: Any host defined in the OpenAPI definition of the API is ignored and all API endpoints always point to the endpoints that you define here. For example, suppose you define a vanity API endpoint, with Catalog priority preference, to be **https://prod.acme.com/**. Then the API endpoint will be **https://prod.acme.com/*basepath***.
     The way in which the **basepath** is determined depends on the OpenAPI version of the API, as follows:
     - **(OpenAPI 2.0):** The **basepath** is taken from the **basepath** field in the OpenAPI definition.
     - API Gateway only **(OpenAPI 3.0):** The **basepath** is taken from the first **url** entry in the **servers** array in the OpenAPI definition, ignoring any scheme (**http://** or **https://**) and host name.
   - API priority: The host defined in the OpenAPI definition for the API takes precedence. For example, suppose you define a vanity API endpoint, with API priority preference, to be **https://api.acme.com/**. Then the following rules determine the endpoint that is used when an API is called:
     - If the OpenAPI definition has a host defined, **test.acme.com** for example, then that value is used to determine the API endpoint. For example: **https://test.acme.com/*basepath***.
     - If the OpenAPI definition has no host defined, the API endpoint will be **https://api.acme.com/*basepath***, as determined by the vanity API endpoint setting.

     The way in which any defined host is determined depends on the OpenAPI version of the API, as follows:
     - **(OpenAPI 2.0):** The host is taken from the **host** field in the OpenAPI definition.
     - API Gateway only **(OpenAPI 3.0):** The host is taken from the host name in the first **url** entry in the **servers** array in the OpenAPI definition.
5. Supply one or more endpoints, as follows:
   - If you selected Catalog priority, click Add to enter one or more endpoints URLs, and an optional summary for each. Any of the endpoint URLs can be used to invoke an API.
   - If you selected API priority, enter the endpoint URL, and an optional summary.

Note: After configuring your Catalog to support your vanity URL, you must configure your external network to map the vanity endpoints to the corresponding gateway endpoints. This typically includes the following:

- A DNS mapping to ensure that the vanity host resolves to the gateway.
- Additional URL routing for the API as required.

For example, if your gateway has a default domain name of **apigw.dc.zone.mycompany.com** and an IP address of **29.12.141.150**, then the generic DNS configuration might look like:

```
api.acme.com. CNAME apigw.dc.zone.mycompany.com.
```

or

```
api.acme.com. A 29.12.141.150
```

Consult your network administrator and the DNS provider's documentation to do this configuration.

Configuring Product visibility at a Catalog or Space level

How to set a limit on the visibility for all Products that are published to a Catalog or Space.

Before you begin

To configure Product visibility at the Catalog or Space level, you must be assigned to a role that has the Settings > Manage permission for that Catalog or Space. For more information on assigning Catalog permissions to a role, see Creating and configuring catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

About this task

The availability of a Product to users is determined by both the visibility setting (that covers which users can view the Product), and the subscribability setting (that covers which users can subscribe to the Product). When you create a draft Product, you typically define the visibility and subscribability in the Product document; see Specifying the visibility of your Product, and Creating a draft Product for details.
Note: After a Product is published, its visibility and subscribability can be changed in the Catalog in the API Manager UI. For more information, see Changing the availability of a Product.
You can define a Catalog or Space setting to control the visibility of all of the Products that are published to that Catalog or Space, as described in the following instructions. When this Catalog or Space setting is enabled, it can be used for the following two purposes:

- The setting can ensure that any Product published to that Catalog or Space, cannot have a visibility setting that exceeds the visibility limit set at the Catalog or Space level.
- The setting can also be used as the default visibility setting for all Products that are published to that Catalog or Space.

When you're publishing a Product, the visibility setting can come from the following four places:

1. Product override; set during the API Manager UI sequence to publish a Product. If this setting is used, it supersedes any visibility setting in the draft Product.
2. Product document; set in the draft Product.
3. Catalog or Space setting. If Product visibility is enabled in the Catalog or Space, and the visibility is not set by a Product override or in the Product document, then the Catalog or Space visibility setting is used as the default setting. This setting can also be used as a limiter, to ensure that any Product that is published cannot exceed the Catalog or Space visibility setting.
4. Default setting. If there are no other visibility settings, then the following default visibility and subscribability settings are used:

```
visibility: {
    view: {
        enabled: true,
        type: 'public',
        orgs: []
    },
    subscribe: {
        enabled: true,
        type: 'authenticated',
        orgs: []
    }
}
```

The following table shows which Product level visibility settings are allowed, if the Catalog level visibility setting is enabled.

Table 1. Relationship between the Catalog level visibility settings, and the Product level visibility settings.

Catalog level visibility setting	Product level visibility setting
Public.	Public, Authenticated, or Custom.
Authenticated.	Authenticated, or Custom.
Custom.	Custom. Note that the Product level visibility organization and group URLs are limited by the Catalog level organization and group URLs.

Note:

- Even if you restrict the product visibility to a smaller audience, the product will still appear under Forums in the Developer Portal.
- If you want to disable a Forum module in the Developer Portal, click Extend > Disable module. For more information, see Turning off forums in the Developer Portal.

The following table shows how the Product subscribe setting is limited by the Product visibility level. The basic premise to remember, is that if a Product is to be available for subscription, it must be visible. For example, if you want the subscription audience to be `authenticated`, the visibility audience cannot be `custom`.

Table 2. Relationship between the Product visibility settings, and the Product subscribe settings.

Product visibility level	Product subscribe setting
Public.	Authenticated, or Custom.
Authenticated.	Authenticated, or Custom.
Custom.	Custom. Note that the Product subscribe organization and group URLs are limited by the Product visibility organization and group URLs.

Note:

- Changes to the Catalog visibility setting affects only future Product publishes. There is no change to Products that are already published.
- Any updates to the visibility of a Product are always verified against the Catalog visibility setting, as the Catalog visibility setting sets the maximum visibility level that is allowed. Therefore, if Product visibility is enabled in a Catalog, and the visibility setting of a Product is less restrictive than is set in the Catalog, then the Product publish to that Catalog will fail. For example, if the Catalog visibility setting is **authenticated**, then any Products that are published to that Catalog cannot have a visibility setting of **public**.
- You can also modify the Catalog visibility settings by using the API Connect REST APIs; see the API Connect REST API documentation.

Procedure

- To modify the Catalog or Space visibility settings by using the API Manager UI, complete the following steps.
  1. Open the Catalog that you want to work with.
  2. Click the Catalog settings tab.
  3. Click Product visibilty in the side navigation bar.
  4. Set the Enable product visibility toggle to On.
  5. Select the organization or groups that you want the Products in the Catalog to be visible to.
     You can select from the following options:
     - Public - Products are visible to all users.
     - Authenticated - Products are visible only to users who have successfully authenticated.
     - Custom - Products are visible only to the consumer organizations and groups that you specify.
  6. Click Save.
- To modify the Catalog or Space visibility settings by using the developer toolkit CLI, complete the following steps.
  1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

     ```
     apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
     ```

     Where:
     - *mgmt_endpoint_url* is the platform API endpoint URL.
     - *user_id* is the user ID that you want to log in with. The user ID must be a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
     - *password* is the password that is associated with the supplied user ID.
     - *identity_provider* is the identity provider that is used to authenticate the supplied user ID.

     For example:

     ```
     apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
     ```

     You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

     ```
     apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
     ```

     For example,

     ```
     apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
     total_results: 2
     results:
       - title: API Manager User Registry
         realm: provider/default-idp-2
       - title: Corporate LDAP user registry
         realm: provider/corporate-ldap
     ```

     The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
     For full details on how to log in to your management server from the CLI, see Logging in to the management server.

  2. Define your visibility settings by creating a YAML file with the following structure:

     ```
     allowed_product_visibility: {
         view: {
             enabled: true_or_false,
             type: 'visibility_type',
             org_urls: [],
             group_urls: []
         },
         subscribe: {
             enabled: false,
             type: 'authenticated'
         }
     }
     ```

     Where, in the **view** section of the **allowed_product_visibility** property:
     - **enabled** - can be set to **true** or **false**. The default setting is **false**.
       If set to **true** then any Product that is published to that Catalog or Space can have only a visibility that is the same or more restrictive than is configured in the **type** setting. If no visibility is set in the Product document, then the Catalog or Space setting is used as the default for the publish. If you want to always use the Catalog or Space setting as the default, then you must ensure that a Product visibility is not set.
       Note: If you are creating draft Products, and no visibility is set, then the value from the **allowed_product_visibility** field in the Sandbox Catalog is used as the default.
       If set to **false**, the feature is disabled, and the Product visibility settings that are defined in the Product document are used.
     - **type** - if **enabled** is set to **true**, then this property specifies the maximum visibility of the Products that are published to this Catalog or Space. Valid settings are:
       - **public** - Products are visible to all users.
       - **authenticated** - Products are visible only to users who have successfully authenticated.
       - **custom** - Products are visible only to the consumer organizations and groups that are specified in **org_urls** and **group_urls**.
     - **org_urls** - if **type** is set to **custom**, then this property specifies the URLs of the consumer organizations that you want the Products to be visible to. Otherwise, leave empty.

- **group_urls** - if **type** is set to **custom**, then this property specifies the URLs of the consumer organization groups that you want the Products to be visible to. Otherwise, leave empty.

The **subscribe** section cannot be edited at the Catalog or Space level. Subscribability is defined in the Product document **subscribe** section, and must be at least as restrictive as **authenticated**. For more information, see Specifying the visibility of your Product.

3. Modify your Catalog settings by using the following command:

   ```
   apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename
   ```

   Where ***filename*** is the name of the YAML file that you created in step 2.

   Note: If Spaces are enabled for the Catalog, then the visibility settings must be set at the Space level by using the **--space** option.
4. Confirm your updated Catalog settings by using the following command:

   ```
   apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -
   ```

Related tasks

- Creating and configuring catalogs

Configuring sub paths for Developer Portal sites

You can increase the specificity of a IBM® API Connect Developer Portal site URL by using sub paths.

By adding additional text to the URL of a Developer Portal site, you can create more site permutations for an organization. Developer Portal site URLs must be unique across all Catalogs.

Important:

- Sub paths are case-sensitive.
- The Developer Portal host name must contain only **lowercase** characters.

You can create a Developer Portal in the following format:

```
https://host_name.portal.com/sub_path_1/sub_path_2/.../sub_path_n
```

Where *sub_path* can be any text that you want to implement to specify your site URL. There is no limit to the number of sub paths that you can have for the first site that you want to create.
However, you must not create overlaps in the naming of your URLs. A URL of one site must not be able to be confused with pages belonging to another site. For example, if you create the following site URL:

```
https://host_name.portal.com/bank/safe/dollar
```

Then, you cannot have the following site URL permutations:

```
https://host_name.portal.com/bank/safe
```

or

```
https://host_name.portal.com/bank/safe/dollar/cent
```

However, you can lengthen or shorten a site URL if you change a single sub path value, or the *host_name.portal.com* value. For example, if you created the following site URL:

```
https://host_name.portal.com/bank/safe/dollar
```

Then, you can create the following site URL permutations:

```
https://host_name.portal.com/bank/euro
```

and

```
https://host_name.portal.com/bank/euro/vault/cent
```

Important: If you already have a site URL that ends in *sub_path* texts, you cannot create a new site URL with the sub path text at the start.
For example, if you create the following site URL:

```
https://host_name.portal.com/bank
```

then, you cannot create the following site URL:

```
https://bank.host_name.portal.com
```

Consumer Catalog and Developer Portal considerations

A customer can have either a Developer Portal or a Consumer Catalog to test and subscribe to the APIs published in the Catalog.

Consumer Catalog

The Consumer Catalog is a non-customizable, web-based site for application developers to test and subscribe to the API published in your Catalog. The site uses less resources when compared to the Developer Portal and offers quick and basic credential access. The Consumer Catalog is ideal for smaller API catalogs and internal users,

who are looking for a lightweight consumer experience with basic functionality.

You can enable or disable the Consumer Catalog in the API Manager under Catalog settings. By default, the Consumer Catalog is enabled. For more information, see Configuring Consumer Catalogs on API Manager.

The Consumer Catalog site supports the following key features:

- Create consumer accounts
- Delete consumer accounts
- Create new applications
- View analytics for an application
- View the available API products
- Local user registry, OIDC user registry, or LDAP registry
- Test the API
- Subscribe to the API

Attention:
It is not possible to modify the Consumer Catalog settings except for the options provided in the Catalog settings. For example, the self-service feature of the Consumer Catalog depends on your catalog settings. If the Self service onboarding option is not enabled for your catalog, the user cannot sign up to the Consumer Catalog. If you want to control the user experience, configure a Developer Portal for your site.

Known limitations

If your catalog has more than one user registry, the default user registry is used. Furthermore, the Consumer Catalog does not support the following options:

- Does not support Twitter OIDC user registries
- Content or documentation update after the API or Product publish
- Consumer organization management:
  - Changing the consumer organization ownership
  - Viewing users
  - Editing users
  - Adding users
  - Removing users
- Custom consumer catalog URL
- Branding
- Customization
- Configuration options
- Monetization

Note: If you have any suggestions to enhance the Consumer Catalog in future releases, you can raise your ideas in the IBM Ideas portal.

Developer Portal

The Developer Portal is a fully customizable, web-based portal site for application developers to explore, discover, test, and subscribe to the APIs published in your Catalog. The portal also provides extra features, such as application and consumer organization analytics, forums, blogs, and ratings, for socialization and collaboration. The default configuration supports consumer organization management, content management, user registry management, and other options. The Developer Portal is ideal for larger API catalogs and external users, who are looking for complete developer experience.

You can create the Developer Portal in the API Manager under Catalog settings. For more information, see Creating Developer Portal.

Important: Each portal site created, even if unused, uses resources in the portal service that's associated with the catalog, and more infrastructure might be required. If you do not want to modify your portal site, you can consider configuring a Consumer Catalog.

Managing Catalog membership

Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.

Before you begin

To manage Catalog members in the API Manager, you must be assigned to a role that has the Member > Manage permission for that Catalog. For more information on assigning Catalog permissions to a role, see Creating and configuring catalogs.

About this task

The Catalog owner can invite members of the provider organization work with the Catalog in the API Manager. The invited users are called "Catalog members" and are different from consumer users who are members of consumer organizations.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Members tab.
3. To add an existing user, click Add > Add member. To add a new user, click Add > Invite member.
   If you are using the Add member option, you can add any user who is already a member of another Catalog, or of a Space, in the provider organization, and is neither currently a member of this Catalog, nor the Catalog owner.
4. Enter the email address of a new user, or search for, and select, an existing user.
5. Select the roles that you want to assign to the user.

For details of the roles and the default permissions assigned to them, see API Connect user roles. For details on how to create your own roles, see Creating custom roles.

If Spaces are enabled in the Catalog, any role that you assign to the user at the Catalog level is assigned automatically to the user in all Spaces in that Catalog. Furthermore, if a user had originally been assigned a role only in a specific Space in a Catalog and you subsequently assign the user that role at the Catalog level, the Space specific role assignment is lost and the user now has that role in all Spaces in the catalog.
Note: You can subsequently change the roles assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members tab. If a user was originally added to the provider organization, rather than to the Catalog itself, the following conditions apply:

- Any role assigned to the user at the provider organization level is assigned automatically to the user in all Catalogs, and cannot be removed at the Catalog level.
  For details on adding a user to a provider organization, see Adding provider organization users and assigning roles.
- In the Catalog, the user has the permissions that are configured for the role at the Catalog level.
- Any role that hasn't been assigned to the user at the provider organization level can be assigned to the user at the Catalog level.

6. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Importing a user-defined policy into a Catalog

You can make your user-defined policy available to API developers by importing it into an IBM® API Connect Catalog, or a Space in a Catalog.

About this task

For instructions, see Defining, packaging, and publishing a catalog-scoped policy for the API Gateway.

Importing an OpenAPI extension into a Catalog

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.

Before you begin

You must possess Catalog edit permissions to complete this task.

About this task

This task describes how to import an OpenAPI extension into a Catalog by using the browser based API Manager user interface. Alternatively, you can use the developer toolkit CLI; see Working with OpenAPI extensions.

For an example of an extension schema file, see Referring to an extension in an API definition.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
3. Click the Catalog settings tab if you are working in a Catalog, or the Space settings tab if you are working in a Space.
4. Click Gateway services.
5. Alongside the Gateway service that you want to work with, click the options icon and then click View extensions.
6. Click Upload then upload the extension file as indicated, either by dragging and dropping the file, or by browsing and selecting it. The extension schema file will be either a JSON or YAML file.
7. Click Upload when done.

Results

The user-defined extension is now imported into a Catalog or Space, and can be used when developing an API by using the API editor in either the API Designer or the API Manager user interface.

What to do next

Add the OpenAPI extension to your APIs as required; see Adding an OpenAPI extension to an API.

Retaining Version 5 vanity endpoint behavior in a Catalog

The behavior of vanity endpoints in a Catalog has changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.

About this task

A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API.

You can modify your Catalog settings to define vanity endpoints that retain the API Connect Version 5 behavior.

Note: Vanity endpoints for APIs function as expected. Vanity URLs for OAuth providers in Version 10 support the same functionality as in Version 5 when legacy vanity behavior is enabled for a catalog. This behavior supports flat hostname URLs (for example, https://www.myvanityhostname.com/) but does not extend to full URLs with a URI path (for example, https://www.myvanityhostname.com/mypath).
You can modify the Catalog settings in either of the following ways:

- Use the API Manager user interface.
- Use the developer toolkit CLI.

You can also use the API Connect REST APIs; see the API Connect REST API documentation.

Procedure

- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the API Manager user interface, complete the following steps:
  1. Click API Endpoints in the Catalog settings navigation pane. The Vanity API Endpoint page opens.
  2. Click Edit, then select v5 legacy behavior.
  3. To use the API Connect URLs, select Use gateway URLs. To configure a vanity endpoint, select Display vanity endpoint then provide the following information:
     - Endpoint: The URL of your vanity endpoint.
     - Gateway Uri: The URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint; select from the list provided.
     - Summary: An optional description of the vanity endpoint.
- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the developer toolkit CLI, complete the following steps:
  1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

     ```
     apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
     ```

     where:
     - *mgmt_endpoint_url* is the platform API endpoint URL.
     - *user_id* is the user ID that you want to log in with. The user ID must be a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
     - *password* is the password associated with the supplied user ID.
     - *identity_provider* is the identity provider that is used to authenticate the supplied user ID.

     For example:

     ```
     apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
     ```

     You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

     ```
     apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
     ```

     For example,

     ```
     apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
     total_results: 2
     results:
       - title: API Manager User Registry
         realm: provider/default-idp-2
       - title: Corporate LDAP user registry
         realm: provider/corporate-ldap
     ```

     The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
     For full details on how to log in to your management server from the CLI, see Logging in to the management server.

  2. Define the configuration for your vanity endpoint by creating a YAML file with the following structure:

     ```
     legacy_endpoint_behavior: enabled
     v5_endpoint_substitution_behavior:
       base_endpoints:
         - endpoint: vanity_endpoint_url
           description: description
           gateway_service_url: gateway_service_url
       unenforced_api_base_endpoint: unenforced_api_base_endpoint
     ```

     where:

     - the `legacy_endpoint_behavior: enabled` setting specifies that the Catalog retains API Connect Version 5 behavior. A Catalog can support either Version 5 behavior or Version 10 behavior but not both.
     - *vanity_endpoint_url* is the URL of your vanity endpoint.
       Note: API Connect Version 5 supports only the host name in a vanity endpoint URL; a URL of the form `https://host_name/path` is not supported. Therefore the vanity endpoint URL that you supply here must contain only a host name; for example, `https://vanity.com`.
     - *description* (optional) is a description of your vanity endpoint.
     - *gateway_service_url* is the URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint.
       Note: You can determine the gateway service URL by using the following command:

       ```
       apic configured-gateway-services:list --scope catalog --catalog catalog_name --server mgmt_endpoint_url --org organization_name
       ```

       where:

- *gateway_service_name* is the name of the gateway service.
- *catalog_name* is the name of the Catalog.
- *organization_name* is the name of the provider organization that contains the Catalog.

The command output lists all the gateway services that are enabled in the Catalog, together with their gateway service URLs.

- *unenforced_api_base_endpoint* (optional) is a custom API URL that specifies the URL for APIs that are deployed to a third party gateway.

Note: `base_endpoints:` is an array. You can configure multiple vanity endpoints by defining multiple `endpoint:` entries.

3. Modify your Catalog settings by using the following command:

```
apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename
```

where *filename* is the name of the YAML file that you created in step 2.

4. Confirm your updated Catalog settings by using the following command:

```
apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -
```

Protecting catalog properties

You can protect a catalog property so that its data is returned as redacted in the response to an API call.

Catalog administrator access is required to protect a property. When a property is marked as protected, you cannot unprotect it. However, you can delete the property and then create it newly as an unprotected property.

You can update the value in a protected property; the property remains protected. The protection feature applies only to catalog-level properties and does not affect spaces or API properties.

The API invoke call returns the property in clear text, all other calls returns the property as redacted and display only asterisks as in: ******.

To protect a catalog property, complete the following action:

1. Log in to IBM® API Connect as the catalog administrator and navigate to the catalog.
2. Create or edit a property.
   a. To create a protected property, complete the following action:
      i. Click Create.
      ii. Provide the name and value for the new property.
      iii. Click Protect.
      Note: When you protect a property, its value is displayed as *****.
   b. To edit a property, complete the following action:
      i. Select a property and click Edit.
      ii. Update the property's value.
      Note: The value for a protected property displays as ***** but you can replace the value.
      iii. If the property is not already protected, click Protect.
      Note: When you protect the property, its value displays as *****.
      iv. Click Save to update the property.

To unprotect a catalog property, complete the following action:

1. Log in to IBM API Connect as the catalog administrator and navigate to the catalog.
2. Delete the protected property.
3. Add the property again and do not mark it as protected.
4. Save your changes.

Managing the application lifecycle

By using the application lifecycle capability in IBM® API Connect, the applications that are created in the associated Developer Portal initially has Development status, and can make API calls through the Development endpoints. When application testing is complete, the application developer can request to upgrade the application to Production status. After the request is approved, the application is upgraded can make API calls through Production endpoints.

Note: The Development and Production endpoints must be configured in the API by using the *Switch* policy.

Configuring API Connect to use the application lifecycle

To configure API Connect to use the application lifecycle capability, you must enable Application Lifecycle in the Catalog settings. For more information, see step 6.d in Creating and configuring catalogs.

Using application lifecycle in the Developer Portal

If application lifecycle is enabled for the Catalog, any application that an application developer registers in the associated Developer Portal initially has Development status, and when you subscribe the application to use an API, it can make API calls only to Development endpoints.

When you have completed your application testing, you can request to upgrade your application to Production status; For more information, see Upgrading a Development application to Production status. After the application upgrade request has been approved, the application can make calls to Production endpoints.

Creating an API that uses switch policy for different endpoints

You can configure the *switch* policy to create an API that will invoke a different endpoint depending on whether your application is set to Development or Production status. The following example shows how you can create a conditional API using the *switch* policy:

```
assembly:
           execute:
             - switch:
                 version: 2.1.0
                 title: switch
                 case:
                   - condition: $apiCtx().client.app.lifecycle-state = 'PRODUCTION'
                     execute:
                      - invoke:
                          version: 2.0.0
                          title: invoke
                          backend-type: detect
                          header-control:
                            type: blocklist
                            values: []
                          parameter-control:
                            type: allowlist
                            values: []
                          timeout: 60
                          verb: GET
                          chunked-uploads: true
                          persistent-connection: true
                          cache-response: protocol
                          cache-ttl: 900
                          target-url: https://backend.server.example.com/v1/stores/{id}
                   - condition: $apiCtx().client.app.lifecycle-state = 'DEVELOPMENT'
                     execute:
                      - message-template:
                          version: 2.0.0
                          title: message-template
                          template: |-
                            {
                               "id": "12345",
                               "status": "closed"
                             }
```

For more information on configuring the *switch* policy to create an API, see Built - in policies.

Approving an application upgrade request

A request to upgrade a Development application to the Production status is approved or declined in the API Manager UI. For more information, see Approving application upgrade requests.
Note: To place the upgrade request, the API must be configured to use two different endpoints depending on the application lifecycle state.

Related information

- Registering a gateway service
- Applications in the Developer Portal
- Exploring APIs and Products in the Developer Portal

Approving application upgrade requests

To approve or decline requests by application developers to upgrade a Development application to Production status, use the Approvals tab in the Catalog that is associated with the IBM® API Connect Developer Portal from which the application upgrade request was submitted.

Before you begin

To approve application upgrade requests in a Catalog, you must either be the owner of the associated API provider organization, or you must be assigned a user role that has Subscription and Application Approvals > Manage permission in the Catalog. For information on configuring permissions for a Catalog, see Creating and configuring catalogs. For information on assigning user roles, see Managing Catalog membership.

About this task

If application lifecycle is enabled for a Catalog, any application that an application developer registers in the associated Developer Portal initially has Development status. When application testing is complete, the application developer can request to upgrade the application to Production status.

Procedure

To approve application upgrade requests, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. Click the Tasks tab, The Approval tasks page opens. You can find the application upgrade requests here. Locate the application upgrade request that you want to deal with.
   An application upgrade request has an Application Lifecycle label.
3. Click Approve or Decline as required. If you decline the request, a Reason for declining window is displayed, giving you the option to supply the reason why you declined the request. Click Decline and send when done.

A notification email is sent to the originator of the request.

Using syndication in API Connect

With the API Connect syndication feature, you can partition your catalogs into *Spaces*. Each space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that space, enabling each team to manage their APIs independently.

When you stage or publish an API to a catalog that has spaces enabled, you specify the space within that catalog that you want to stage or publish to. However, application developers that access the Developer Portal for the catalog are unaware of the space partitioning of the catalog and see the APIs as a coordinated offering.

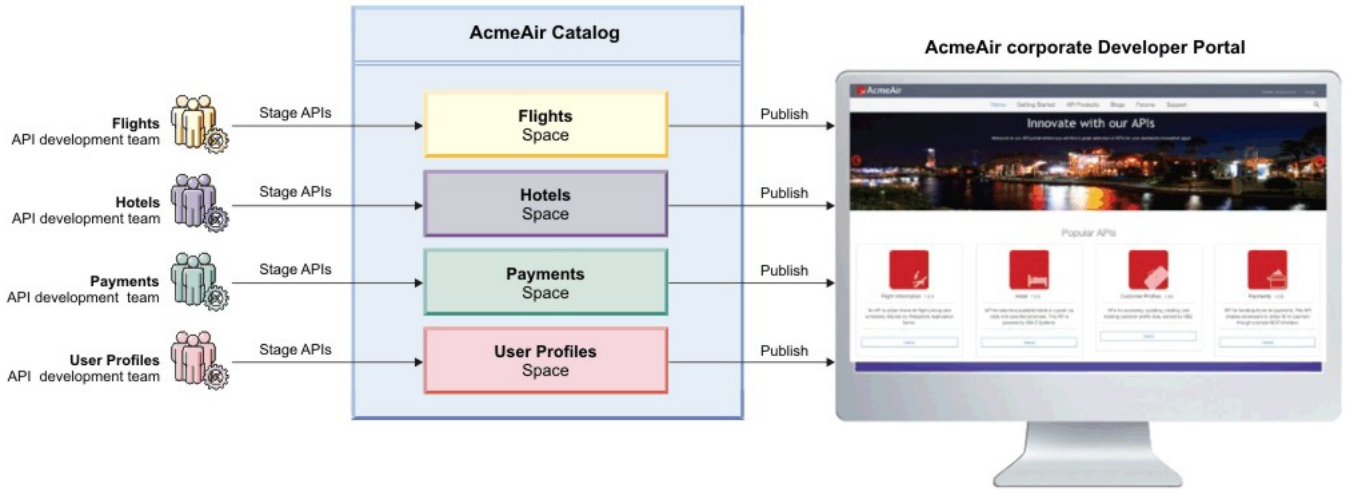
Each space has its own product lifecycle management, subscription approvals, and analytics data. You use space specific access control to restrict user access to each space; for example, a developer in the Flights team is able to stage APIs only to the Flights space.

Example

A travel company, AcmeAir, has separate API provider development teams for each of the following areas of their business:

- Flights
- Hotels
- Payments
- User Profiles

They have an AcmeAir corporate catalog, with its associated corporate Developer Portal. They partition their catalog into separate spaces, one for each development team.



Spaces are described in detail in the following sections:

- **Enabling Spaces in a Catalog**
  To use the syndication feature in IBM API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.
- **Creating, modifying, and deleting Spaces**
  You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.
- **Working with Spaces**
  If Spaces are enabled in an IBM API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Enabling Spaces in a Catalog

To use the syndication feature in IBM® API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.

Before you begin

If Spaces are enabled for a Catalog, Products (and their associated APIs) can be published only to a Space within that Catalog. For information about publishing, see Staging a Product for publishing by using the API Designer, and see Publishing APIs for publishing by using the developer toolkit.

Note: You cannot enable Spaces in a Catalog to which one or more Products have already been staged or published. If the Catalog does contain staged or published Products, first complete the following steps for each Product in the Catalog:

1. Remove all staged Products.
2. Retire, then remove, all published Products.

After enabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

About this task

By default, Spaces are disabled in a Catalog. You enable Spaces by modifying the Catalog settings. After Spaces are enabled for a Catalog, a default Space is automatically created that inherits all of the configuration settings from the Catalog.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

Procedure

To enable Spaces in a Catalog, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Catalog settings tab.
3. Set the Spaces slider control to the On position.
4. In the Enable Spaces window, click Enable.

Results

Spaces are enabled for your Catalog, and a default Space is created that automatically inherits all of the configuration settings from the Catalog. The Catalog owner is also the owner of the default Space.

What to do next

You can modify Space settings, and create more Spaces; see Creating, modifying, and deleting Spaces and Working with Spaces for more information.

Creating, modifying, and deleting Spaces

You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.

Before you begin

Navigate to the Spaces page of the Catalog containing the Space you want to work with, by completing the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

Procedure

- To create a new Space, complete the following steps:
  1. Click Add > Add a new Space.
  2. In the Space Details window, enter the Title of the Space and, optionally, a descriptive summary. A Name is entered automatically.
     Note: The value in the Name field is a single string that is used to identify the Space in developer toolkit CLI commands. The Title is used for display.
     To view the CLI commands to manage Spaces, see the toolkit CLI reference documentation.
  3. Click Create to create the Space.

  Note:
  - As the user who creates the Space, you are automatically the Space owner and have all Space permissions.
  - When you create a new Space, it does not automatically inherit all of the configuration settings from the Catalog. So you should check and modify the settings as necessary.
- To modify the details of a Space, complete the following steps:
  1. On the Spaces page, select the Space whose details you want to modify, then click Space settings.
  2. Use the options in the navigation pane to modify the details as required.
     The following types of resource can be enabled in a Space:
     - Gateway services
     - API user registries
     - OAuth providers
     - TLS client profiles

     Note:
     - If you enable a resource of any of the following types in one Space in a Catalog, it is deployed to the gateway services across all Spaces in that Catalog:
       - API user registries
       - OAuth providers
       - TLS client profiles
     - If you deploy any of the following types of resource to a gateway in a Space, it is actually deployed to the gateway at Catalog scope:
       - Custom policy
       - Global policy
       - Global policy pre-hook
       - Global policy post-hook
       - Gateway extension
- To change the owner of a Space, complete the following steps:
  1. On the Spaces page, select the Space whose details you want to modify.
  2. Click the Space settings tab to open the Space details page, then click Edit.
  3. From the Select owner user drop-down menu, select the user who will become the new owner.
  4. Click Save when done.

  Note:

- To have permission to change the Space owner, you must be either the Catalog owner, the Space owner, or the owner of the provider organization that contains the Space.
- When the ownership changes, the new owner is assigned administration privileges for the Space, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Managing Space membership.
- The ownership can be transferred only to a user who is already a member of the Space or Catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the Space, as described in Managing Space membership, or to the Catalog, as described in Managing Catalog membership.

- To delete a Space, complete the following steps:

  1. On the Spaces page, click the Manage icon ⋮ for the Space that you want to delete.
  2. Click Delete, then click Confirm to confirm deletion.

  Note:
  - You cannot delete a Space to which one or more Products have been staged or published.
  - If there is only one Space in a Catalog, you cannot delete it, but you can disable Spaces for the Catalog.
    However, you cannot disable Spaces in a Catalog to which one or more Products have already been staged or published. If any of the Spaces in the Catalog do contain staged or published Products, first complete the following steps for the Products in each of the Spaces:
    1. Remove all staged Products.
    2. Retire, then remove, all published Products.

    Then, to disable Spaces for the Catalog, complete the following steps:
    1. Click the Catalog settings tab in the Catalog.
    2. Set the Spaces slider control to the Off position.

    After disabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

Working with Spaces

If Spaces are enabled in an IBM® API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Procedure

To work with a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.

What to do next

For details of the Space management tasks, see the following subtopics:

- **Managing Products in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.
- **Managing subscription requests in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.
- **Managing application subscriptions in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.
- **Managing Space membership**
  If Spaces are enabled in an IBM API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.
- **Managing user access in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.
- **Managing Gateways in a Space**
  If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM API Connect Catalog.

Managing Products in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.

Before you begin

To manage Products in a Space in the API Manager UI, a user must be assigned a role that has the Products > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

To manage the Products that are staged or published to a specific Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.

What to do next

For details of the management tasks that you can perform on the Products in the Space, see Working with Products.

Managing subscription requests in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.

Before you begin

To manage Space subscription requests in the API Manager UI, a user must be assigned a role that has the Subscription Approvals > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

To manage the subscription requests in a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Tasks tab.
   The Tasks page lists only the subscription requests for the selected Space.

What to do next

For details on how to manage approvals, see Approving Product lifecycle and subscription requests.

Managing application subscriptions in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.

Before you begin

To manage application subscriptions in the API Manager UI, a user must be assigned a role that has the Subscriptions > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. In the navigation pane of the API Manager UI, click the Applications tab.
   All applications that have been registered in the Developer Portal associated with this Space are listed.
5. Click the options icon ⋮ alongside the application you want to work with, then click View Subscriptions.

What to do next

For details of the management tasks that you can perform on application subscriptions in a Space, see Working with application subscriptions.

Managing Space membership

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.

Before you begin

To manage Space members in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For more information on assigning Space permissions to a role, see Managing user access in a Space.

About this task

Note: You can add the same user to two or more Spaces and assign different roles in each, allowing a user to have differing levels of access in different Spaces.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Members tab.
5. To add an existing user, click Add > Add member. To add a new user, click Add > Invite member.
   If you are using the Add member option, you can add any user who is already a member of another Space, or of a Catalog, in the provider organization, and is neither currently a member of this Space, nor the Space owner.
6. Enter the email address of a new user, or search for, and select, an existing user.
7. Select the roles that you want to assign to the user.
   For details of the roles and the default permissions assigned to them, see API Connect user roles. For details on how to create your own roles, see Creating custom roles.

   If a user was originally added either to the provider organization, or to the Catalog that contains the Space, rather than to the Space itself, the following conditions apply:
   - Any role assigned to the user at the provider organization or Catalog level is assigned automatically to the user in all Spaces, and cannot be removed at the Space level.
     For details on adding a user to a provider organization, see Adding provider organization users and assigning roles.

     For details on adding a user to a Catalog, see Managing Catalog membership.
   - In the Space, the user has the permissions that are configured for the role at the Space level.
     For details on configuring role permissions for a Space, see Managing user access in a Space.
   - Any role that hasn't been assigned to the user at the provider organization or Catalog level can be assigned at the Space level

   Note: You can subsequently change the roles assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members page.
8. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Managing user access in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.

Before you begin

To manage Space permissions in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see Managing Space membership.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Space settings tab.
5. Click Roles, click the options icon ⋮ alongside the role whose permissions you want to modify, then click Edit.
6. Select the required permissions, then click Save.

Related tasks

Managing Gateways in a Space

If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM® API Connect Catalog.

Before you begin

To manage Space Gateway settings in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see Managing Space membership.

About this task

Note: If Spaces are enabled in a Catalog then you configure the Gateway settings for each Space separately, **not** for the Catalog as a whole.

Procedure

To manage the Gateway settings for a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Space settings tab.
5. Click Gateway services.
   The Gateway services that are currently enabled for the Space are listed.
6. To change the Gateway service configuration for the Space, click Edit, then select which Gateway services you want the Space to use.
7. Click Save to save your changes.

Related information

- Configuring the initial Gateway service

Working with Products

In IBM API Connect, Plans and APIs are grouped together in Products.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
Information about managing Products in the API Manager UI can be found in the following topics.

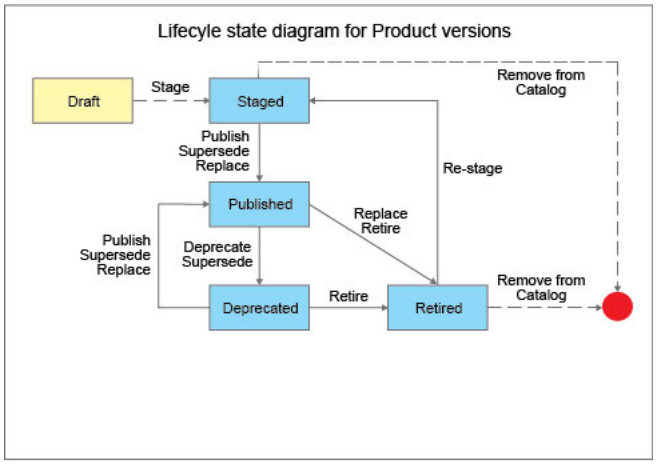
- **The Product lifecycle**
  When you manage your Product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.
- **Monetizing your Products**
  In addition to offering free Plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM API Connect.
- **Managing your Products**
  You can manage your products in API Manager by using the Products page of the associated catalog. In this view, you can move the products through their lifecycle, display analytics information, and control who can see or subscribe to the products. The syndication feature in IBM API Connect means that products can also be managed by using the Products tab of the associated space.

The Product lifecycle

When you manage your Product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM® API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.

Product lifecycle state diagram

The following diagram shows the possible lifecycle states for a Product version, and the Product management operations that move a Product version from one lifecycle state to another. For example, the Retire operation moves a Product version from the Published to the Retired state.



Note: The same Product lifecycle states apply irrespective of whether your Product is managed within a Catalog, or within a Space in a Catalog. For more information about the syndication feature, see Using syndication in API Connect.
If approval is required for a Product management operation, an approval request is sent and the Product version moves to the pending state. When the request is approved, the operation is completed and the Product version moves to the next lifecycle state. If approval is not required, the operation is completed immediately.
Note: Approval is not required for the following lifecycle state transitions:

- Retired to Staged.
- Deprecated to Published.

For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
Note:

- Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- To view the subscription tasks history, complete the following steps:
  - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
  - Click Tasks tab.
  - Click Approvals history from the navigation pane.
- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

The following sections describe the various lifecycle states for a Product version.
Note: All references in this topic to a Catalog, can also be applied to a Space in a Catalog, unless specified otherwise.

Draft

The draft state for a Product or API is when a Product or API definition is not deployed and is not associated with any Catalog.

Staged

When you stage a Product, a copy of the Product version is deployed to the target Catalog. Staged is the initial state when you publish a Product. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. For more information about staging a Product, see Staging a Product.

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests. For information on publishing a Product, see Publishing a Product.

Published

When you publish a Product, a fixed copy of the Product version is deployed to the target Catalog. The Product version is visible to, and subscribable by, the targeted developers or communities. When a Product is published in a Catalog, the visibility and subscription settings can be changed for the published version of that Product. Any further changes require a new version of the Product to be staged and published before they take effect.

If you replace a Published Product with a Staged or Deprecated Product, the replacement Product is published, and the replaced Product is retired.

If you supersede a Published Product with a Staged or Deprecated Product, the superseding Product is published, and the superseded Product is deprecated.

For more information about publishing a Product, see Publishing a Product.

Note: If you want to update a Product, you must republish it. The `products:update` command only updates a Product's metadata.

Deprecated

When you deprecate a Product, the Product version is visible only to developers whose applications are currently subscribed. No new subscriptions to the Plans in the Product are possible. For more information about deprecating Products, see Deprecating a Product.

A Product is also deprecated if you supersede it with another Product. For more information, see Superseding a Product with another Product.

Retired

When you retire a Product, the Product version can neither be viewed nor can its Plans be subscribed to, and all of the associated APIs are taken offline. For more information about retiring Products, see Retiring a Product.

A Product is also retired if you replace it with another Product. For more information, see Replacing a Product with another Product.

Replace product

Use the replace product option when you want to replace product A with product B and migrate all subscriptions. This action retires the source product and publishes the destination product. For more information, see Replacing a Product with another Product.

Migrate Subscriptions

Use Migrate Subscriptions to perform the same function as Replace Product, except it does not retire the source product, and the destination product must already be published.

You can also use Migrate Subscriptions to migrate individual subscriptions between different products or between plans within the same product. For more information, see Migrating application subscriptions to another Product and Migrating application subscribers to new Product versions.

Supersede product

Use Supersede Product to replace product A with product B and migrate all subscriptions at a later time. This option deprecates the source product and publishes the destination product.

When a product is deprecated, new subscriptions are not allowed, but existing subscriptions continue to function until they are migrated. Consumers can migrate all subscriptions or individual subscriptions at a time that suits them. For more information, see Superseding a Product with another Product.

Set migration target

Use Set Migration Target option to perform the same function as the Supersede option. It prepares subscriptions for migration to the destination product but does not deprecate the source product. The destination product must already be published. For more information, see Migrating application subscribers to new Product versions.
Note:
Both Supersede Product and Set Migration Target assume that the source product will no longer be used after all subscriptions are migrated and that it will not be used as a migration target in the future.

These options are typically used when a new version of product A supersedes an older version of the same product. The source and destination products are labeled with the attributes **`superseded_by`** and **`supersedes`**, respectively.

Execute Migration Target

Use Execute Migration Target to force the migration of all subscriptions from a superseded product before retiring it. For more information, see Migrating application subscribers to new Product versions.
Note:
Supersede Product and Set Migration Target prevent setting the migration target to an older product version to avoid circular dependencies, where two products point to each other as migration targets.

To reset the migration target to an older version, first clear the **`superseded_by`** and **`supersedes`** settings created by Supersede Product or Set Migration Target. Then, run Execute Migration Target to migrate all subscriptions to the destination product.

After all subscriptions are migrated, retire the source product. To reuse it, restage and republish it before using Set Migration Target with the older version.

Monetizing your Products

In addition to offering free Plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM® API Connect.

API Connect includes a subscription billing feature that allows API providers to define pricing Plans in their API Products, and monetize their API offerings. If a Product contains a pricing Plan, API consumers must enter their payment information into the Developer Portal before they can subscribe to that Plan.

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

You can define both free Plans and paid Plans within the same Product. To charge your customers more for greater access to your APIs, you can create multiple Plans with different tiers of prices and rate-limits. For example, an introductory Plan might have a low monthly price and restrictive rate-limiting, while a higher tier Plan might couple a higher monthly price with less restrictive rate limiting controls. Your customers can then select the Plan that is appropriate for their usage rates. As your customers have different needs for the use of your Products, so you can offer different levels of service. For example, a smaller customer might need a rate of only 5 API calls per hour, whereas a larger company might need a rate of 1000 API calls per hour. You can create the Plans that are appropriate for your customers, and they can subscribe to the service and pricing Plan that is appropriate for them.

Restriction: The following limitations apply to the subscription billing feature:

- Billing and monetization requirements vary by country, where IBM and the independent cloud billing provider, Stripe, cannot guarantee every country requirement is supported. Country requirements change, and are out of scope for this document. Some limitations on storing and passing fields to the Stripe billing provider might exist, when fields are unique to a subset of countries. For example, the passing of a billing address from API Connect to Stripe, which is required by some EU countries due to GDPR and taxation laws, is not currently supported.
- Two data center disaster recovery configurations including the optional billing microservice are not supported at this time.
- After a configured billing resource is in use by a Catalog, it might not be possible to remove it. Do not add your Stripe test keys to production Catalogs. If you want to prototype with your non-production Stripe keys, create a separate temporary Catalog.
- If an API consumer deletes their payment method, or their credit card expires, or their card is out of credit after they have initially subscribed and prepaid for their first month, there is no mechanism to alert the provider organization or suspend API access automatically in response. Provider organizations can monitor their Stripe dashboards for non-payment events and, if necessary, notify the consumer, suspend the application for that subscription, or cancel the API Connect subscription manually. The URL of the API Connect subscription is saved in the metadata of the Stripe subscription object, to assist in reverse lookups.
- Suspending an application does not automatically pause the billing cycles of the subscriptions for that application.
- You can republish a Product that includes billing only when the Catalog Production mode is set to On.

Though much of the procedure is the same for setting up a paid Plan and a free Plan, there are some extra actions that are needed before you can start defining paid Plans. See the following topics for more information:

1. First, you must configure a billing integration resource for your provider organization; see Adding a billing integration resource.
2. Before you can publish a Product Plan with pricing to a Catalog, you must add your billing integration resource to that Catalog; see Adding a billing integration resource to a Catalog.
3. Also before you can publish to a Catalog, an administrator must enable the Stripe payment method module in the Developer Portal for that Catalog; see Configuring Stripe in the Developer Portal.
4. After the Catalog and Developer Portal are configured, you can create Products that include pricing Plans; see Defining a Product with billing integration.

Note:

- Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on VMware and Configuring monetization on Kubernetes for more information.
- You can also create and manage billing integration resources by using the developer toolkit CLI. For more information, see the toolkit CLI reference documentation.

Adding a billing integration resource

To enable the monetization of your Product Plans, you must add a billing integration resource in your IBM® API Connect provider organization that defines the configuration data needed to synchronize with an external subscription billing system.

Before you begin

To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.

Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on VMware and Configuring monetization on Kubernetes for more information.

You must either be the provider organization owner, or have `Settings: Manage` permissions, to complete this task.

You must have an account with Stripe to be able to complete this task. If you do not already have a Stripe account, you can set one up at: www.stripe.com.

About this task

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, you must first specify your Stripe account information by creating a billing integration resource. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that you provide as the API provider.

Important: Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from

another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To create a billing integration resource, complete the following steps:

1. In the API Manager, click Resources.
2. Ensure that you are in the provider organization to which you want to add the billing integration.
3. Select Billing, and then click Add.
   The Add billing integration page for Stripe integration is displayed.
4. Enter a Title for your billing integration.
5. The Name is auto-generated based on the Title that you enter, and is a single string that can be used in developer toolkit CLI commands.
6. Enter the Publishable key and Secret key for your Stripe account.
   Refer to your Stripe dashboard to get your publishable key and secret key; see https://dashboard.stripe.com/apikeys.
7. Click Add to create your billing integration resource.

Results

Your new billing integration resource is listed in the table on the Billing dashboard. The table also displays the state of the job queue for the billing integration. Any issues with the job queue are displayed in this table. See Billing integration resource job queues for more information.

What to do next

To be able to publish monetized Product Plans, you must add the billing integration resource to your Catalog, and to the Sandbox Catalog. See Adding a billing integration resource to a Catalog for details.

Related tasks

- Defining a Product with billing integration

Related reference

- Troubleshooting your billing configuration

Billing integration resource job queues

Billing integration resources use job queues to manage the bulk Product lifecycle operations in IBM® API Connect.

Subscription billing systems such as Stripe, typically provide APIs that support updating a single resource at a time. However, IBM API Connect has Product lifecycle operations that can modify many resources in a single transaction, such as migrating a set of subscriptions from one Product to another Product. In order to bridge the mismatch between these two APIs, API Connect adds a job queue to each billing integration resource in your provider organization. Jobs on this queue are responsible for mapping bulk operations to a series of API calls against the subscription billing system. Jobs run one at a time, in the order that they were created. When a job completes it's deleted from the queue, and the next job runs. When all of the jobs in the queue complete running and the queue is empty, the data model of the subscription billing system should be up-to-date with the changes made in API Connect.

There are potential issues when moving this type of synchronization to background jobs. Network connectivity, outages at the billing provider, or rolling of the API keys of the billing system, could all cause the job queue to be blocked if the root issue does not resolve by itself in the span of an hour. If a job encounters an error, such as a network connectivity error, the job is retried up to five times over the course of 70 minutes, before changing the state of the job from Running to either Blocked or Failed. Only when the state of the head job is blocked or failed, will the Retry Blocked Jobs action appear in the options menu. So if an error is shown but the job is still attempting to run, you need to wait up to 70 minutes before the Retry Blocked Jobs action appears.

The job queue status can be viewed in the table on the Billing dashboard. The table lists any blocked jobs, and the error that is blocking them. If the error indicates that your API keys are no longer valid, you must update your billing resource to contain the correct values. After the root cause is resolved, you can click the options menu on the row of the billing integration resource, and click Retry Blocked Jobs. This action retries the jobs on the job queue. After a few minutes the number of jobs should go down. Note that you can click the Refresh icon to refresh the results from the server.

- Monetizing your Products

Adding a billing integration resource to a Catalog

To be able to publish monetized Product Plans, you must add a billing integration resource to your Catalogs.

Before you begin

You must have created a billing integration resource. See Adding a billing integration resource for details.

You must either be the provider organization owner, or have `Settings: Manage` permissions, to complete this task.

About this task

Before you can publish any Products that include pricing Plans, you must add the billing integration resource to the Catalog where you will create the monetized Products. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, after you have specified your Stripe account in a billing integration resource, you must then apply that resource to your Catalogs. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that is provided in the billing integration resource.

Note:

- Before you can publish a monetized Product Plan to a Catalog, the Stripe payment method module in the Developer Portal must also be enabled; see Configuring Stripe in the Developer Portal.
- Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To add a billing integration resource to a Catalog, complete the following steps:

1. In the API Manager, click Manage.
2. Select the Catalog tile on the Manage page that you want to update, then click the Catalog settings tab.
3. Select Billing, and then click Edit.
4. Select the billing integration resource that you want to apply to the Catalog, and click Save. You should apply only one billing integration resource to each production Catalog.
   The billing integration resource is now listed in the Billing section.
   Note: More than one billing resource can be applied to the Sandbox Catalog.

Results

The billing integration resource is added to the Catalog.

What to do next

The Stripe payment method module must be enabled in the Developer Portal for that Catalog; see Configuring Stripe in the Developer Portal for details.

After both the Catalog and the Developer Portal are configured, you can create Products with pricing Plans. See Defining a Product with billing integration for more information.

- Troubleshooting your billing configuration

Defining a Product with billing integration

To monetize your APIs, you must create Product Plans with pricing information that allow API consumers to subscribe to your Plans with integrated billing.

Before you begin

You must have a billing integration resource, and this resource must be added to the Catalog that you want to publish your Product to, as well as to the Sandbox Catalog. See Adding a billing integration resource, and Adding a billing integration resource to a Catalog for details.

Also, the Stripe payment method module must be enabled in the Developer Portal for the Catalog; see Configuring Stripe in the Developer Portal for details.

About this task

When you decide to charge customers to use your API Products, your customers have different requirements for the number of API calls that they are willing to pay for. You can solve this issue by defining Plans at different levels of service, and at different costs.

Within your Product, you can define free Plans as well as Plans that contain billing integration. The following instructions guide you through defining a Plan with pricing information. For more detailed information about creating Products, see Creating a draft Product and Editing a draft Product.

Important: Products that contain a billing integration cannot be re-staged into non-production Catalogs. To experiment with billing on the Sandbox Catalog, or any other non-production Catalogs, you must publish new versions of your monetized Product. This practice aligns with how you have to work with production Catalogs currently, as they also don't support the re-staging of existing versions of the same Product.

Procedure

To add pricing information to a Product Plan, complete the following steps:

1. In the API Manager, click Develop.
2. Select the Products tab.
3. Select the Product that you want to add billing integration to, or create a new draft Product by clicking Add > Product and following the wizard.
4. With the Product open and the Design tab selected, select Billings in the navigation menu.
5. In the Billing integration section, select the billing integration resource that you want to apply to the Product.
   In the Plans section, you can then either edit the Default Plan to add pricing information, or create a new Plan with pricing information.
6. If this is a new Plan, enter a Title, and if you require approval for someone to subscribe to this Plan also select the Approval check box.
7. In the Plan pricing section, complete the following steps to add the pricing information:
   a. Change the toggle to On for Plan pricing.
      The Plan pricing definition section is displayed.
   b. Optional: If you want to include any free trial days in your Plan, select Include free trial days, and then enter the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.
   c. Select the Currency for the billing process use.
   d. Enter the Price per month to bill the subscriber for.
      If the selected currency supports fractional units, enter the price including any fractional units, such as cents.
8. Optional: In the Plan rate limits section, set the rate limits by entering the number of calls that are allowed per unit of time.
   Remember that this rate limit applies only to this Plan. You can set multiple rate limits, at second, minute, hour, day, and week time intervals. You can override this Plan rate limit for specific endpoints if you prefer, adding a different rate limit or enabling unlimited calls to it. You can also create more Plans with different rate limits. For more information about rate limits, see Understanding rate limits for APIs and Plans.
9. Optional: Select the Hard limit checkbox if you want the gateway to reject any calls beyond the specified rate, rather than adding them to a queue to be resolved when the limits reset.
10. Optional: Add more burst limits, GraphQL limits, and assembly limits, as appropriate for your APIs.
11. Complete the Plan APIs section if you want to customize the APIs and operations that are available in this Plan.
12. If you want to add more Plans to the Product, repeat the process from Step 6.
13. Click Save to save the Product.

Results

Your Product with billing integration and a pricing Plan is listed in the Products dashboard of the Develop area. If your Product doesn't appear, click the Refresh icon to refresh the results from the server.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

Managing your Products

You can manage your products in API Manager by using the Products page of the associated catalog. In this view, you can move the products through their lifecycle, display analytics information, and control who can see or subscribe to the products. The syndication feature in IBM® API Connect means that products can also be managed by using the Products tab of the associated space.

Before you begin

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

For more information about the product lifecycle, see The Product lifecycle.
For more information about the syndication feature, see Using syndication in API Connect.

For information on viewing analytics that can provide insight into product and API usage and performance, see API Analytics.

For information about product billing, see Monetizing your Products.

Procedure

To manage your product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Expand a product to see details of the APIs and plans in that product.

   Manage options are also available, depending on the state of the product. To view the manage options, click the options icon and select the options that you require.
4. To manage the lifecycle of a version of a product, click the options icon alongside the product version, and select the required lifecycle action.
5. To set the migration target of a version of a product, click the options icon alongside the product version, and select Set migration target. In the Set migration target window, select the product that you want to set as the migration target, and select Next. Then map the migration source plans to the migration target plans, and click OK.
   Restriction: If the plan is part of a product that is contained within a space in the catalog, and the migration action is being made at the space level, the plan that you are migrating subscriptions from must be located in the same space as the plan you are migrating to. If the migration action is being made at the catalog level, subscriptions can be migrated across spaces. For more information about the Space feature, see Using syndication in API Connect.

- **Considerations when changing a Product lifecycle with billing integration**
  There are special considerations for lifecycle operations for Products that contain a billing integration in IBM API Connect.
- **Publishing a Product**
  APIs become accessible when a Product is published and made visible on the IBM API Connect Developer Portal for use by application developers. A Product can be published to selected communities of application developer organizations, and the Plans within the Product can be used to tailor access and visibility further.
- **Migrating application subscriptions to another Product**
  By using the Products view within a Catalog in API Manager, you can migrate application subscriptions between Products. The syndication feature in IBM API Connect means that you can also use the Products view within a Space in a Catalog to migrate application subscriptions. Use the Migrate Subscriptions option to perform the same function as Replace Product, except it does not retire the source product. The destination product must already be published. You can also use Migrate Subscriptions to migrate individual subscriptions between different products or between plans within the same product.
- **Migrating application subscribers to new Product versions**
  When new versions of Products are created in IBM API Connect, there are a number of ways that subscribers can be moved to the Plans of the new Product.
- **Changing the availability of a Product**
  You can change the availability of a Product and the associated Plans by using the Products view within a Catalog or Space in API Manager. The availability of a Product covers both the visibility of that Product to users, and which users can subscribe to it.
- **Deprecating a Product**
  You can deprecate a published Product by using the Manage Products page within a Catalog in API Manager. When you deprecate a Product, application developers that are already subscribed to the Product can continue to use it, but no new developers can subscribe to the Product. The syndication feature in IBM API Connect means that you can also use the Manage Products page within a Space in a Catalog to deprecate a published Product.
- **Retiring a Product**
  You can retire a published or deprecated Product by using the Manage Products page within a Catalog in API Manager. When a Product is retired, all associated APIs are taken offline, and any subscriptions are deleted. The syndication feature in IBM API Connect means that you can also use the Manage Products page within a Space in a Catalog to retire a Product.
- **Re-staging a Product**
  If a Product in a Catalog has been retired, you can re-stage the Product so that it can re-enter the Product lifecycle. A re-staged Product moves to the Staged state, from where it can be published. The syndication feature in IBM API Connect means that you can also re-stage a Product within a Space in a Catalog.
- **Working with the subscriptions in a Product**
  You can work with the subscriptions to the Plans in a specific Product. Plan subscriptions are created by application developers in the Developer Portal.
- **Updating the gateway services for a Product**
  When you stage or publish a draft Product to a Catalog, you specify the gateway services at which the APIs in the Product are to be made available. However, you can later update the selected gateway services after a Product has been stage or published.
- **Removing a Product from a Catalog**
  You can remove a Product from a specific Catalog by using the Products view within a Catalog in API Manager. The syndication feature in IBM API Connect means that you can also use the Products view within a Space to remove a Product from a Catalog.
- **Approving Product lifecycle and subscription requests**
  To approve or decline requests to change the lifecycle state of a Product, and requests by application developers to subscribe to a Plan, use the Tasks page in the Catalog that contains the associated Product in API Manager. The syndication feature in IBM API Connect means that you can also use the Tasks page within a Space in a Catalog to approve or decline requests.

Considerations when changing a Product lifecycle with billing integration

There are special considerations for lifecycle operations for Products that contain a billing integration in IBM® API Connect.

For example, if you release new versions of your Product that contain pricing changes, you will need to define the upgrade pathways for your existing subscribers. The following scenarios detail the special considerations for Product lifecycle changes:

Deprecating
: Preparing an existing Product to be removed from production. You can define a replacement Product by using the Set Migration Target option in the Catalog. API consumers will then see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the

upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a free Plan to a paid Plan are supported. For more information about deprecating Products, see Deprecating a Product.

Migrating
: Moving subscriptions from one Product to a different Product, and from a free Plan to a paid Plan, is not supported. Instead, see the superseding scenario.

Replacing
: Replacing a Product with a newer version of the same Product, and automatically upgrading all existing subscribers to the new Product. You must map which Plans from your new Product correspond to which Plans in your old Product. You cannot map a free Plan to a paid Plan in the replace operation. For more information about replacing Products, see Replacing a Product with another Product.

Retiring
: Removing a Product or Plan from production, and canceling all of the existing subscriptions and their billing cycles. For more information about retiring Products, see Retiring a Product.

Superseding
: Deprecating the old Product, and at the same time defining its migration target to a newer version of itself. Retaining the existing Product and Plan for subscribers who would like to keep it, but offering a different Product and Plan for the updated version of a Product. API consumers will then see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a free Plan to a paid Plan are supported. For more information about superseding Products, see Superseding a Product with another Product.

Note: You can use the Set Migration Target option in the Catalog on a Product that isn't being deprecated. For example, if you wanted to give customers the option to move to a different Product without affecting the original Product.
While these follow the same basic procedures that are described in Managing your Products for Products and Plans without billing, there are some considerations that only apply to Products that contain paid Plans.

You cannot migrate a customer directly from a free Plan to a Plan with billing

Customers who subscribe to Plans with billing must set up their billing information in the Developer Portal. If they subscribe only to free Plans, they don't have billing accounts.

There are two ways to migrate customers from a free Plan to a paid Plan:

- Supersede the free Product Plan and provide a migration target to a paid Product Plan. This deprecates the free Product Plan so no new users can subscribe to it, and gives the customer a Migrate this subscription message in the Developer Portal to move to the new Product Plan.
- Set a migration target to a paid Product Plan. In this case the free Product Plan is not deprecated, but it still gives the customer the Migrate this subscription message in the Developer Portal for moving to the new Product Plan. With this method, new customers can still subscribe to the free Product Plan.

Both of these methods require action from the customer before they move from the free Product Plan to the paid Product Plan.
Note: Free trial days do not apply to customers when they migrate. They are available only for new customers.

You must map the existing Plans to the new Plans when you supersede or replace a Product

When you replace or supersede a Plan with billing with another Plan, you must map the Plans from the Product that is being removed to the Plans that are in the new Product. It is convenient if there are the same number of Plans for each, but you can map more than one Plan from the existing Product to one Plan in the new Product.

Billing charges are prorated when subscriptions are migrated

When customers change their subscriptions to a Plan that has a different price, their next monthly invoice will contain prorated charges, depending on how long they spent on different billing Plans. For more information about how Stripe handles proration, see https://stripe.com/docs/billing/subscriptions/prorations.

Publishing a Product

APIs become accessible when a Product is published and made visible on the IBM® API Connect Developer Portal for use by application developers. A Product can be published to selected communities of application developer organizations, and the Plans within the Product can be used to tailor access and visibility further.

Before you begin

You must stage a Product before it can be published. For more information about staging Products, see Staging a Product.
Note:
If you want to publish a project, you must publish both the APIs (by publishing the Products that contain the APIs) and the associated applications so the project can be run. For more information about publishing applications, see Publishing APIs and applications.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

A community is a collection of consumer organizations, used to control which organizations have access to Products and Plans without having to assign access on an individual basis. A Product can be published to selected communities, which means that only application developers within those organizations contained within the community can see the Product on the Developer Portal and obtain application keys to access it. A Product can alternatively be published to all communities. Communities are used to restrict the visibility and accessibility of APIs, for example to particular business partners, internal organizations, or other groups of application developers.

Note: If you want to update a Product, you must republish it. The `products:update` command only updates a Product's metadata.

Procedure

You can publish a product in any of the following ways:

- Publish a new Product.
- Replace a Product with another Product.
- Supersede a Product with another Product
  For details of the ways in which you can publish a Product, see the following subtopics:

- **Publishing a new Product**
  Publish a Product from within its containing Catalog in API Manager. The syndication feature in IBM API Connect means that you can also publish a Product from within its containing Space in a Catalog.
- **Replacing a Product with another Product**
  You can replace a published Product in IBM API Connect with another Product, and migrate all subscriptions at the same time, by using the API Manager. This action retires the source product and publishes the destination product.
- **Superseding a Product with another Product**
  You can use the supersede option to supersede product A with product B and migrate all subscriptions at a later time. This action deprecates the source product and publishes the destination product, by using the API Manager. A deprecated product does not allow new subscriptions, but existing subscriptions continue to function until they are migrated. Consumers can migrate all subscriptions at once or individually, at a time that suits them.

Publishing a new Product

Publish a Product from within its containing Catalog in API Manager. The syndication feature in IBM® API Connect means that you can also publish a Product from within its containing Space in a Catalog.

Before you begin

The Product that you are publishing must be in the Staged or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

If you publish a Product to a non-development Catalog, the Product that is published is an independent and fixed copy of the version of the Product that you chose to stage. Editing the Product through the Products page will not affect the published Product. For this reason, it is recommended that when you stage a Product, you then create a new version of the Product to edit in future, so as to avoid confusion regarding the properties of the published Product. For more information on creating new versions of your Product, see Creating a new version of your Product.

An exception is that if you publish a Product to a development Catalog, editing it through the Products page will enable you to re-stage and publish the same version of the Product. For information on how to create a development Catalog, see Creating and configuring Catalogs.

Although you can publish to a development Catalog, the development Catalog should be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

Procedure

To publish a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click Publish.
   The Confirm Visibility Settings page opens.
4. Specify the following options:

- The users that the Product is visible to
  You can choose Public users, Authenticated users, or Custom.
  - Custom - You can use the Type to add... field to search for organizations or communities that you want your Product to be visible to.
- Who can subscribe to the Product
  You can add or remove one or more consumer organizations or communities.
  - Custom - You can use the Type to add... field to search for organizations or communities that you want to allow to subscribe to your Product.

5. Click Publish, then click Confirm to proceed with the publish operation.
   If approval is required to publish Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is published when the request is approved. If approval is not required, the Product version is published immediately, and moves to the Published state. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Published state.

Your Product is published to your Catalog and available to your specified organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Replacing a Product with another Product

You can replace a published Product in IBM® API Connect with another Product, and migrate all subscriptions at the same time, by using the API Manager. This action retires the source product and publishes the destination product.

Before you begin

The Product to be replaced must be in the Published state, and the replacement Product must be in the Staged, Published, or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you replace a Product with another Product, the following actions are taken:

- The replacement Product is published.
- If the visibility and subscribability settings in the replacement Product are such that access is the same as, or less restrictive than, the original Product, the settings in the replacement Product are used. If the settings in the replacement Product are more restrictive, meaning that fewer consumer organizations can see or subscribe to the Product, the replace operation fails. For more information on visibility and subscribability settings, see Changing the availability of a Product.
- The subscribers to the original Product are migrated to the replacement Product.
  Note: Customers cannot be migrated automatically from a free Plan to a paid Plan. To move your customers from a free Plan to a paid Plan, you can supersede the product with a new product and set a migration target to the paid Plan. The customers then select a button to migrate and must enter their credit card information before the process is complete. For more information, see Considerations when changing a Product lifecycle with billing integration.
- The original Product is moved to the Retired state. Products in the Retired state are removed from the Developer Portal; they are no longer visible to the application developers, and any subscriptions to them are canceled. However, the Product can be staged again later if required.

Although you can publish to a development Catalog, the development Catalog should be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog, can also be applied to a Space in a Catalog, unless specified otherwise.

Procedure

To replace a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to replace, click the options icon, then click Replace.
   The Replace window opens.
4. Select the replacement Product, then click Next.
5. From the drop-down list, select which Plans from your new Product correspond to Plans in your old Product.
6. Click Replace.
   If approval is required to replace Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is replaced when the request is approved. If approval is not required, the Product is replaced immediately. For information on configuring product lifecycle approvals for a catalog, see Creating and configuring catalogs. For information on approving requests, see Approving product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your new Product is in the Published state, and the original Product is in the Retired state.

Your new Product is published to your preferred organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Superseding a Product with another Product

You can use the supersede option to supersede product A with product B and migrate all subscriptions at a later time. This action deprecates the source product and publishes the destination product, by using the API Manager. A deprecated product does not allow new subscriptions, but existing subscriptions continue to function until they are migrated. Consumers can migrate all subscriptions at once or individually, at a time that suits them.

Before you begin

The Product to be superseded must be in the Published state. The superseding Product must be in the Staged, Published, or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you supersede a Product with another Product, the following actions are taken:

- The superseding Product is published.
- If the visibility and subscribability settings in the superseding Product are such that access is the same as, or less restrictive than, the original Product, the settings in the superseding Product are used. If the settings in the superseding Product are such that access is more restrictive, meaning that fewer consumer organizations

can see or subscribe to the Product, the supersede operation fails. For more information on visibility and subscribability settings, see Changing the availability of a Product.

- The original Product is moved to the Deprecated state.
- The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product. In the Developer Portal the application developers will see a Migrate this subscription message, which they can click to upgrade their subscription to the migration target.
- The deprecated product can be published again if required.

Although you can publish to a development Catalog, the development Catalog should be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog, can also be applied to a Space in a Catalog, unless specified otherwise.

Procedure

To supersede a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to supersede, click the options icon and then click Supersede.
4. Select the superseding Product and then click Next.
5. From the drop-down list, select which Plans from your new Product correspond to Plans in your old Product.
6. Click Supersede.
   If approval is required to supersede Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is superseded when the request is approved. If approval is not required, the Product is superseded immediately. For information on configuring product lifecycle approvals for a catalog, see Creating and configuring catalogs. For information on approving requests, see Approving product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your superseding Product is in the Published state.

The Product that was superseded is in the Deprecated state.

Your superseding Product is published to your preferred organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product. The original Product is deprecated.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Existing customers remain subscribed to the deprecated product, and any billing cycles for subscriptions to paid plans continue uninterrupted. For more information, see Considerations when changing a Product lifecycle with billing integration.

Migrating application subscriptions to another Product

By using the Products view within a Catalog in API Manager, you can migrate application subscriptions between Products. The syndication feature in IBM® API Connect means that you can also use the Products view within a Space in a Catalog to migrate application subscriptions. Use the Migrate Subscriptions option to perform the same function as Replace Product, except it does not retire the source product. The destination product must already be published. You can also use Migrate Subscriptions to migrate individual subscriptions between different products or between plans within the same product.

Before you begin

Your Product that you are migrating subscriptions from must be in one of the following states:

- Published
- Deprecated

To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for Products in the Catalog that contains the Product. If you have View permission for Products in this Catalog, you will have read-only access to the Product management page. For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

Application developers initially subscribe their applications to one or more Plans in Products by using the Developer Portal. For more information, see Exploring APIs and Products in the Developer Portal. However, by using API Manager, for a chosen Product you can migrate one or more of its application subscriptions from one Plan to a Plan in another Product.

Procedure

To migrate Product subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click Migrate Subscriptions.
4. Select the Plan from which you want to migrate subscriptions, then click Next.
5. Select the subscriptions that you want to migrate, then click Next.
6. Select the Product that you want to migrate the subscriptions to, then click Next.
7. Select the Plan that you want to migrate the application subscriptions to, and then click Migrate.

Results

The target Product has the migrated subscriptions, and those subscriptions are removed from the Product from which they were migrated.

Related tasks

- Working with Spaces

Migrating application subscribers to new Product versions

When new versions of Products are created in IBM® API Connect, there are a number of ways that subscribers can be moved to the Plans of the new Product.

About this task

You can move users to the new Plans in different ways, depending on your Product strategy, by using the options icon alongside the Product in the associated Catalog in the API Manager UI.

Procedure

To automatically migrate all existing subscribers to a new Product, for example, when you are applying fixes to a Product:

- You should Replace the original version of the Product with a new version of the Product.
  - The replacement Product is Published.
  - The original Product is Retired.
  - The subscribers to the original Product are automatically migrated to the replacement Product.
    Note: Customers cannot be migrated automatically from a free Plan to a paid Plan. To move your customers from a free Plan to a paid Plan, you can supersede the product with a new product and set a migration target to the paid Plan. The customers then select a button to migrate and must enter their credit card information before the process is complete. For more information, see Considerations when changing a Product lifecycle with billing integration.

  For more information about replacing Products, see Replacing a Product with another Product.

To encourage subscribers to move to a new Product, and stop new users from subscribing to the original Product, for example, if an enhancement or new feature is added:

- You should Supersede the original version of the Product with a new version of the Product.
  - The superseding Product is Published.
  - The original Product is Deprecated.
  - The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product. In the Developer Portal the subscribers will see a Migrate this subscription message, which they can click to upgrade their subscription to the migration target.
  - If the migration target is a paid Plan, subscribers must enter a payment method before they can upgrade. Upgrades by subscribers from a free Plan to a paid Plan are supported.

For more information about superseding Products, see Superseding a Product with another Product.

To prepare a Product to be removed from production, but leave the existing subscriptions as they are:

- You should Deprecate the original Product.
  - The Product is Deprecated.
  - The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product.
  - You can define a replacement Product by using the Set Migration Target option in the Catalog. Application developers will then see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a free Plan to a paid Plan are supported.
  - Use Set Migration Target option to perform the same function as the Supersede option. It prepares subscriptions for migration to the destination product but does not deprecate the source product. The destination product must already be published.
    Note:
    Both Supersede Product and Set Migration Target assume that the source product will no longer be used after all subscriptions are migrated and that it will not be used as a migration target in the future.

    These options are typically used when a new version of product A supersedes an older version of the same product. The source and destination products are labeled with the attributes **`superseded_by`** and **`supersedes`**, respectively.

  - Use Execute Migration Target to force the migration of all subscriptions from a superseded product before retiring it.
    Note:
    Supersede Product and Set Migration Target prevent setting the migration target to an older product version to avoid circular dependencies, where two products point to each other as migration targets.

    To reset the migration target to an older version, first clear the **`superseded_by`** and **`supersedes`** settings created by Supersede Product or Set Migration Target. Then, run Execute Migration Target to migrate all subscriptions to the destination product.

    After all subscriptions are migrated, retire the source product. To reuse it, restage and republish it before using Set Migration Target with the older version.

  For more information about deprecating Products, see Deprecating a Product.

To give subscribers the option to move to a different Product, but without affecting the original Product:

- You can use the Set Migration Target option in the Catalog on a Product that isn't being deprecated or superseded. For more information, see Managing your Products.

Changing the availability of a Product

You can change the availability of a Product and the associated Plans by using the Products view within a Catalog or Space in API Manager. The availability of a Product covers both the visibility of that Product to users, and which users can subscribe to it.

Before you begin

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

Procedure

To change the availability of a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon , then click Edit visibility.
   The Visibility page opens.
4. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization groups, see Working with consumer organizations.

   Use the Temporarily disable visibility check box to toggle whether the Product is or is not visible, without having to change other visibility settings.

5. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe

to the Plans in the Product.
If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Working with consumer organizations.

Use the Temporarily disable subscribability check box to toggle whether the Product can or cannot be subscribed to, without having to change other subscription settings.

6. Click Save when done.
The Product version is configured with the modified availability settings.
Note:
   - Changing who can view or subscribe to a Product does not affect the settings of the draft Product. The change applies only in the Catalog that was selected in Step 1.
   - Changing who can view or subscribe to a Product does not affect existing subscriptions.
   - Any updates to the visibility of a Product are always verified against the Catalog visibility setting, as the Catalog visibility setting sets the maximum visibility level that is allowed. Therefore, if Product visibility is enabled in a Catalog, and the visibility setting of a Product is less restrictive than is set in the Catalog, then the Product publish to that Catalog will fail. For example, if the Catalog visibility setting is `authenticated`, then any Products that are published to that Catalog cannot have a visibility setting of `public`.

Results

Your Product remains in the same lifecycle state, but now with new availability settings.

What to do next

You can also set Product visibility at the Catalog or Space level. For more information, see Configuring Product visibility at a Catalog or Space level.

Related tasks

- Working with Spaces
- Configuring Product visibility at a Catalog or Space level

Deprecating a Product

You can deprecate a published Product by using the Manage Products page within a Catalog in API Manager. When you deprecate a Product, application developers that are already subscribed to the Product can continue to use it, but no new developers can subscribe to the Product. The syndication feature in IBM® API Connect means that you can also use the Manage Products page within a Space in a Catalog to deprecate a published Product.

Before you begin

The Product that you are deprecating must be in the Published state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To deprecate a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Deprecate.
The Deprecate Product window opens.
4. Click Confirm to deprecate the Product.
If approval is required to deprecate Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is deprecated when the request is approved. If approval is not required, the Product is deprecated immediately. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.

- Click Approvals history from the navigation pane.

- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Deprecated state.

Retiring a Product

You can retire a published or deprecated Product by using the Manage Products page within a Catalog in API Manager. When a Product is retired, all associated APIs are taken offline, and any subscriptions are deleted. The syndication feature in IBM® API Connect means that you can also use the Manage Products page within a Space in a Catalog to retire a Product.

Before you begin

The Product that you are retiring must be in the Published or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To retire a Product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon ⋮ and then click Retire. The Retire Product window opens.
4. Click Confirm.
   If approval is required to retire Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is retired when the request is approved. If approval is not required, the Product is retired immediately. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.

   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Retired state. It is also removed from the Developer Portal, is no longer visible to the application developers, and any subscriptions to it are deleted. You can stage the Product again later if required; for details, see Staging a Product.
If the Product has any monetized Plans, the billing cycles for any subscriptions are canceled as well. For more information, see Considerations when changing a Product lifecycle with billing integration.

Re-staging a Product

If a Product in a Catalog has been retired, you can re-stage the Product so that it can re-enter the Product lifecycle. A re-staged Product moves to the Staged state, from where it can be published. The syndication feature in IBM® API Connect means that you can also re-stage a Product within a Space in a Catalog.

Before you begin

The Product that you are re-staging must be in the Retired state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests. For information on publishing a Product, see Publishing a Product.

Procedure

To re-stage a Product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click Re-stage. The Re-stage Product window opens.
4. Click Confirm.
   If approval is required to stage Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is re-staged when the request is approved. If approval is not required, the Product is re-staged immediately. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - To view the subscription tasks history, complete the following steps:
     - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
     - Click Tasks tab.
     - Click Approvals history from the navigation pane.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Staged state, from where it can be published; see Publishing a new Product.

Working with the subscriptions in a Product

You can work with the subscriptions to the Plans in a specific Product. Plan subscriptions are created by application developers in the Developer Portal.

Procedure

To work with the Plan subscriptions in a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Alongside the Product version that you want to work with, click the options icon and then click View Subscriptions.
   A window opens listing all subscriptions to the Plans in the selected Product.
4. Alongside the subscription that you want to work with, click the options icon .
   You can then select from the following options:
   - View Consumer Organization: a window opens listing the consumer organization that the subscribing application belongs to. If required, you can click the options icon to work with the consumer organization For details of the available options, see Working with consumer organizations.
   - View Application: a window opens listing the subscribing application. If required, you can click the options icon to work with the application. For details of the available options, see Working with developer applications.
   - View Plan: a window opens listing the Plan that the application is subscribed to. If required, you can click the options icon to work with the Plan. For details of the available options, see Working with Plans.
   - View Product: a window opens listing the Product that contains the Plan that the application is subscribed to. If required, you can click the options icon to work with the Product. For details of the available options, see Managing your Products.
5. To display the Client ID's for a particular Product subscription, click the information icon in the Application column for the subscription that you require.

Updating the gateway services for a Product

When you stage or publish a draft Product to a Catalog, you specify the gateway services at which the APIs in the Product are to be made available. However, you can later update the selected gateway services after a Product has been stage or published.

Before you begin

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you stage or publish a draft Product to a Catalog, you can either choose to make the APIs in the Product available at all the gateway services that match the gateway service type of the Product, either DataPower® API Gateway or DataPower Gateway (v5 compatible), or can you select specific gateway services of that type. The APIs in the Product can then be called at those gateway service endpoints.

However, after a Product has been staged or published you can later update the gateway services to change the selections.

For more information on staging and publishing a Product, see Staging a draft Product and Publishing a draft Product.

For more information on the gateway service types, see API Connect gateway types.

Procedure

To update the gateway services for a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon , then click Update gateway services.
   The Select Gateway Services window opens.
4. Select the required gateway services, then click Save.

Removing a Product from a Catalog

You can remove a Product from a specific Catalog by using the Products view within a Catalog in API Manager. The syndication feature in IBM® API Connect means that you can also use the Products view within a Space to remove a Product from a Catalog.

Before you begin

The Product that you are removing from the Catalog must be in the Staged or Retired state. For more information, see Staging a Product or Retiring a Product.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To remove a Product from a Catalog, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Delete.
   The Delete Product window opens.
4. Click Confirm to delete the Product.

Results

Your Product is removed from the Catalog. You can stage the Product again if required; for details, see Staging a Product.
If your Product was contained within a Space in a Catalog, your Product is removed from both the Space and the Catalog.

Approving Product lifecycle and subscription requests

To approve or decline requests to change the lifecycle state of a Product, and requests by application developers to subscribe to a Plan, use the Tasks page in the Catalog that contains the associated Product in API Manager. The syndication feature in IBM® API Connect means that you can also use the Tasks page within a Space in a Catalog to approve or decline requests.

Before you begin

To see lifecycle change requests for a Product, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or manage Products in the Catalog that contains the Product. For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

The syndication feature in API Connect means that Products can be contained within a Space in a Catalog. In this case, to see lifecycle change requests for a Product, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or manage Products in the Space that contains the Product. For information on configuring Product management permissions for a Space, see Managing user access in a Space.

About this task

If approvals for Product lifecycle changes are enabled for a Catalog, then an attempt to change the lifecycle state of a Product results in an approval request being sent. This request is displayed in the Tasks page in the Catalog, from where the request can be approved or declined. The authority to approve Product lifecycle state changes is restricted to users in specified roles. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs.
Note:

- Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- To view the subscription tasks history, complete the following steps:
  - In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
  - Click Tasks tab.
  - Click Approvals history from the navigation pane.

- You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

If a Product is set to require approval for subscription by application developers, then an attempt by an application developer to subscribe to the Product results in an approval request being sent. This request is displayed in the Approvals tab in the Catalog that contains the associated Product in API Manager, from where the request can be approved or declined.

Procedure

To work with a Product lifecycle change request, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Click the Tasks tab, then locate the Product lifecycle change request that you want to deal with.
4. Click the Approve or Decline as required.
   Note: You can approve or decline lifecycle change requests only if you have a user role that has permission to approve Product publish requests in the Catalog in which the changes will take place.
   For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

To work with a subscription request, complete the following steps.

5. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
6. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
7. Click the Tasks tab, then locate the subscription requests that you want to deal with.
   Note: To see subscription approvals, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or approve subscription requests. For information on creating and assigning user roles, see Administering user access.
8. Click the Approve or Decline as required.
   Note: The options to approve or decline a subscription request are available only if you are assigned a user role that has permission to approve subscription requests. For information on configuring permissions for a Catalog, see Creating and configuring catalogs For information on assigning user roles, see Managing Catalog membership.

Results

For a subscription request, an email is sent confirming whether you approved or declined the request. For a request to change the lifecycle state of a Product, no email is sent.

Working with APIs

For a specific Product, you can work with the APIs that are contained in the Plans in that Product.

Procedure

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
To work with the APIs in a Product, complete the following steps:

1. List the Plans in the Product:
   a. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   b. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
      i. Click the Spaces tab.
      ii. Select the space that you want to work with.
   c. If the Products page is not already displayed, click the Products tab.
   d. Alongside the Product version that you want to work with, click the options icon , then click View Plans.
   A window opens listing the Plans in the Product.

2. Alongside the required Plan, click View APIs.
   A window opens listing the APIs in the Plan.
3. Alongside the required API, click the options icon ⋮.
   You can then select from the following options:
   - Take Offline: if you take an API offline, the API is no longer available to be called. When required, you can make the API available again by selecting Online.
   - View Products: a window opens listing all the Products that contain the API. If required, you can click the options icon ⋮ alongside a Product to work with that Product. For details of the available options, see Managing your Products.
   - View Plans: a window opens listing all Plans, across all Products, that contain the API. If required, you can click the options icon ⋮ alongside a Plan to work with that Plan. For details of the available options, see Working with Plans.

Working with Plans

After a Product has been published to a Catalog, you can work with the Plans in that Product.

Before you begin

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
For details on configuring a Plan in a Product, see Editing a draft Product.

For details on Publishing a Product to a Catalog, see Publishing a Product.

To complete the tasks that are described in this topic, you must either be the owner of the API provider organization, or you must be assigned a role that has either the Product > Manage or the Product > View permission for the Catalog. For more information, see Adding provider organization users and assigning roles and Managing Catalog membership. For information on configuring Product management permissions for a Catalog, see Creating and configuring Catalogs.

Procedure

To work with Plans in a Catalog, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon ⋮ and then click View Plans.
   A window opens listing all the Plans in the selected Product.
4. Alongside the Plan that you want to work with, click the options icon ⋮.
   You can then select from the following options:
   - View Product: a window opens listing the Product that contains the Plan. If required, you can click the options icon ⋮ to work with the Product. For details of the available options, see Managing your Products.
   - View APIs: a window opens listing the APIs in the Plan. If required, you can click the options icon ⋮ alongside an API to work with that API. For details of the available options, see Working with APIs.
   - View Subscriptions: a window opens listing the subscriptions to the Plan. If required, you can click the options icon ⋮ alongside a subscription to work with that subscriptions. For details of the available options, see Working with application subscriptions.

Working with consumer organizations

Manage the consumer organizations that access your APIs and Plans when their users sign up to use the IBM® API Connect Developer Portal.

About this task

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
Application developers in consumer organizations access the Developer Portal and sign up to use the Plans in the Products you create in the API Manager. You can create more than one consumer organization and each organization has one owner. Application developers are added through the Developer Portal UI.

You can also create groups of consumer organizations. A consumer organization group is an efficient way of grouping application developers together to publish Products to, making it easier to control who has access to the Plans in the Products.

Use the following tasks to administer your consumer organizations and consumer organization groups:

- **Creating a consumer organization**
  If you have permission to manage developers, you can create new consumer organizations in a Catalog. consumer organizations contain the application developers that subscribe to use the APIs that are published to the Catalog
- **Editing a consumer organization**
  You can change the title of an IBM API Connect consumer organization, and also transfer ownership to a new organization owner.
- **Deleting a consumer organization**
  When you delete a consumer organization, all of the resources in that organization are removed from the cloud. However, the account of the organization owner remains in IBM API Connect.
- **Working with the applications in a consumer organization**
  You can work with the developer applications that have been registered in a consumer organization.
- **Working with the subscriptions in a consumer organization**
  You can work with the Plan subscriptions that have been created by the developer applications registered in a consumer organization.
- **Working with consumer organization groups**
  A *consumer organization group* is a collection of consumer organizations, and provides an efficient way of controlling who can see, and subscribe to, the APIs in your Products. By using a consumer organization group, you can define this access for all the developers in the organizations in that group in a single operation, rather than having to define access for the organizations separately.
- **Sending messages to consumer organization owners**
  You can send email messages to the owners of consumer organizations. You can also style the email to match your business theme.

Creating a consumer organization

If you have permission to manage developers, you can create new consumer organizations in a Catalog. consumer organizations contain the application developers that subscribe to use the APIs that are published to the Catalog

Before you begin

Your IBM® API Connect Developer Portal must be enabled to perform this task. For more information, see Creating and configuring Catalogs.
To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

About this task

You can create a consumer organization in either of the following ways:

- Invite a user to be a consumer organization owner, in which case they receive an invitation email with an activation link, and can complete the creation of the consumer organization and specify the title.
- Create the consumer organization yourself, specifying the owner and title. There are two ways you can specify the owner:
  - Specify the user ID of an existing user.
  - If you are using a Local User Registry, specify a new user ID; the user is added to the registry and becomes the owner of the consumer organization.

If Spaces are enabled in your Catalog, when you create a consumer organization, it is added to the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. To invite a user to be a consumer organization owner, complete the following steps:
   a. Click Add > Invite organization owner.
   b. Enter the email address of the organization owner.
   c. Click Invite.
   The new consumer organization is added to the list, and an email invitation is sent to the owner; by using the activation link, the owner specifies the title of the organization. The status is shown as `Pending` until the recipient of the email clicks the link in the email to complete the creation of their Developer Portal account, after which the status changes to `Enabled`.
5. To create the consumer organization yourself, complete the following steps:
   a. Click Add > Create organization.
   b. Enter the organization Title. A Name is entered automatically.
   The value in the Name field is a single string that is used to identify the consumer organization in developer toolkit CLI commands. The title is used for display.
   To view the CLI commands to manage consumer organizations, see the toolkit CLI reference documentation.
   c. Select the required user registry.
   d. Specify the organization owner; complete one or other of the following steps, either to specify an existing user, or to create a new user:
      - To specify the user ID of an existing API Connect user who is in the selected user registry, complete the following steps:
        - For the Type of user, select Existing.
        - In the Username field, enter the user ID of the organization owner
          After the consumer organization is created, the specified user can immediately log in to the Developer Portal associated with the Catalog.
      - If you selected a Local User Registry, then to specify a new user ID, complete the following steps:
        - For the Type of user, select New User.
        - In the Username field, enter the new user ID.
        - Enter the Email, First Name, Last Name, and Password.

After the consumer organization is created, the new user will have been added to the selected registry and can immediately log in to the Developer Portal associated with the Catalog, by using the specified user ID and password.

e. Click Create to complete the creation of the consumer organization.

Editing a consumer organization

You can change the title of an IBM® API Connect consumer organization, and also transfer ownership to a new organization owner.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

About this task

If you transfer ownership, the new organization owner can be an existing user, or you can create a new user. When the ownership changes, the new owner is assigned administration privileges for the organization, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Administering members and roles.

If Spaces are enabled in your Catalog, when you edit the details of a consumer organization, the updates are applied to the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

To change the title of a consumer organization, or to transfer ownership to a new organization owner, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.

   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the name of the consumer organization that you want to work with.
5. To change the title, enter a new title in the Title field, then click Save.
6. To transfer ownership, select the user registry for the consumer organization owner you want to transfer ownership to.
   The remaining procedure varies according to the type of the selected user registry, as follows:
   - Local User Registry
     - Select whether the user is an Existing user or a New User.
       - For an existing user, complete the following steps:
         - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
         - Click Save.
       - For a new user, complete the following steps:
         - Enter a unique user name for the new user.
         - Supply an email address, name details, and a password.
         - Click Save.
   - LDAP
     - Enter the name of a user that exists in the selected user registry.
     - Click Save.
   - Authentication URL and OIDC
     - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must ensure they have been invited to the organization first.
     - Click Save.

Results

If the title of the consumer organization is changed, all application developers that are members of that consumer organization will see the title change reflected in the Developer Portal user interface.

Related tasks

- Publishing a Product

Deleting a consumer organization

When you delete a consumer organization, all of the resources in that organization are removed from the cloud. However, the account of the organization owner remains in IBM® API Connect.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

Important: If you delete a consumer organization, client IDs and secrets associated with applications that were registered by users in the consumer organization can no longer be used to call APIs. However, the account of the organization owner remains in API Connect.

About this task

When you delete a consumer organization, it is removed permanently and users can no longer access that organization.
If Spaces are enabled in your Catalog, when you delete a consumer organization, it is deleted from the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

To delete a consumer organization, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon ⋮ alongside the consumer organization you want to work with, then click Delete.
5. Click Confirm to delete the consumer organization.
   Note: If the consumer organization is the only one specified in the custom visibility settings for a published Product, the deletion operation will fail. For more information, see Changing the availability of a Product.

Working with the applications in a consumer organization

You can work with the developer applications that have been registered in a consumer organization.

Procedure

To work with applications, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon ⋮ for the consumer organization that you want to work with, then click View Applications.
   A window opens listing all the developer applications that have been registered in the consumer organization
5. To view and edit the details of an application, click the title of the application.
6. Further options are available by clicking the options icon ⋮ alongside the application you want to work with. For details, see Working with developer applications.

Working with the subscriptions in a consumer organization

You can work with the Plan subscriptions that have been created by the developer applications registered in a consumer organization.

Procedure

To work with Plan subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon ⋮ for the consumer organization that you want to work with, then click View Subscriptions.
   A window opens listing all the Plan subscriptions that have been created by the developer applications registered in the consumer organization. If required, you can click the options icon ⋮ alongside a subscription to work with that subscription. For details of the available options, see Working with application subscriptions.

Working with consumer organization groups

A *consumer organization group* is a collection of consumer organizations, and provides an efficient way of controlling who can see, and subscribe to, the APIs in your Products. By using a consumer organization group, you can define this access for all the developers in the organizations in that group in a single operation, rather than having to define access for the organizations separately.

About this task

A consumer organization group might represent particular business partners, internal organizations, or other groups of application developers.

When you create a Product, you can define which application developers can access the APIs in that Product. You can configure the following types of access:

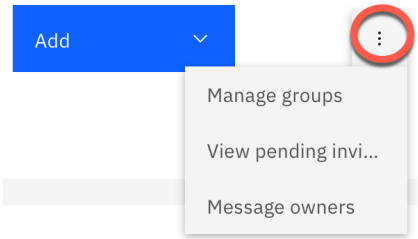
- Visibility, which specifies the application developers who can see the APIs in the Developer Portal.
- Subscribability, which specifies the application developers who can create subscribe to use the APIs.

You configure this access by selecting the required consumer organizations, and Consumer organization groups. You can also change the visibility and subscribability settings for a Product after it has been published. For more information, see Creating a draft Product and Changing the availability of a Product.

Procedure

To work with consumer organization groups, you first navigate to the Consumer organization groups page. You then create new groups, send an email to the owners of the consumer organizations in a group, and edit or delete existing groups.

- Navigating to the required consumer organization groups page.
  1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
  2. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
     a. Click the Spaces tab.
     b. Select the space that you want to work with.
  3. Click the Consumers tab, then click the options menu in the page header and select Manage Groups.



- Creating a consumer organization group.
  1. Click Add.
  2. Enter a Title for the new group and, optionally, a Summary. A Name is entered automatically. The title is used for display.
  3. Use the Search orgs/groups field to search for, and select, the consumer organizations that you want to add to the group.
     Note: To prevent excessive search results lists, only the first 10 matches are displayed when you begin typing in the field; lengthen your search string to shorten the list for locating the required consumer organization.
  4. Click Save to create the group.
- Editing a consumer organization group.
  1. Click the options icon for the consumer organization group that you want to work with, then click Edit.
  2. Make the required updates, then click Save.

  Note: If you remove a consumer organization from a group, and that group is specified in the custom visibility settings for a Product, applications in that consumer organization can no longer subscribe to the Product. However, any existing subscriptions are not affected. For information on managing visibility and subscribability settings, see Editing a draft Product.
- Deleting a consumer organization group.
  1. Click the options icon for the consumer organization group that you want to work with, then click Delete.
  2. Click Confirm to delete the group.
- Sending an email to the owners of the consumer organizations in a consumer group
  1. Click the options icon for the consumer organization group that you want to work with, then click Message owners.
     The Send message window opens, and the email addresses of the consumer organization owners are displayed as the recipients.
  2. Enter the subject of the message in the Subject field.
  3. Enter the content of the message in the Message field, then click Send.

Sending messages to consumer organization owners

You can send email messages to the owners of consumer organizations. You can also style the email to match your business theme.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

Email messages contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see tbc.

Note: You can also send email messages by using the developer toolkit CLI, or by using the API Connect REST APIs. See API development and management commands, or API Connect REST APIs, for more information.

Procedure

To send a message, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. You can either send a message to the owner of a specific consumer organization, or to the owners of multiple selected consumer organizations.
   - To send a message to the owner of a specific consumer organization, click the options icon alongside the consumer organization you want to work with, then click Message owner. The Send Message window opens, and the email address of the consumer organization owner is displayed as the recipient.
   - To send a message to the owners of multiple selected consumer organizations, complete the following steps:
     - Click the options icon alongside the Add button, then click Message owners.
     - Select the required consumer organizations, then click Next. The Send Message window opens, and the email addresses of the selected consumer organization owners are displayed as the recipients.
5. Enter the subject of the message in the Subject field.
6. Select the Content type that you want to use for the entering the content of the message, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 1. List of allowed HTML tags and their attributes

HTML tag	Attribute
`<a>`	`"class", "href", "hreflang", "style"`
`<em>`	`"class", "style"`
`<strong>`	`"class", "style"`
`<cite>`	`"class", "style"`
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

   If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
   Images can be used by adding a `<img src="https://path/to/image.png"/>` tag in the template. The `src` attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.
7. Enter the content of the message.
8. Click Send.

Working with developer applications

You can work with the applications that have been registered in the Developer Portal associated with a Catalog.

About this task

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Procedure

To work with developer applications, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Click the Applications tab.
   All applications that have been registered in the Developer Portal associated with this Catalog are listed.
4. To view and edit the details of an application, click the title of the application.
5. Further options are available by clicking the options icon alongside the application you want to work with, as follows:
   - Client ID: lists the Client IDs for the application. You can add new client ID/client secret credentials; you can copy the client secret only at creation time. An option is provided for deleting any of the credentials from the application.
   - Create Subscription: subscribe the application to a Plan in a Product; select the required Plan and Product, then click Create Subscription.
   - View Subscriptions: a window opens listing summary details of all the Plan subscriptions for the application. If required, you can click the options icon alongside a subscription to work with that subscriptions. For details of the available options, see Working with application subscriptions.
   - View Consumer Organization: a window opens listing the consumer organization that the application belongs to. If required, you can click the options icon to work with the consumer organization. For details of the available options, see Working with consumer organizations.

Working with application subscriptions

You can work with the subscriptions to the Plans in all the Products in a specific Catalog. Plan subscriptions are created by application developers in the Developer Portal.

Procedure

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
To work with application subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage catalogs, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Click the Subscriptions tab.
   A window opens listing all subscriptions to the Plans in all the Products in the Catalog.
4. Alongside the subscription that you want to work with, click the options icon .
   You can then select from the following options:
   - View Consumer Organization: a window opens listing the consumer organization that the subscribing application belongs to. If required, you can click the options icon to work with the consumer organization For details of the available options, see Working with consumer organizations.
   - View Application: a window opens listing the subscribing application. If required, you can click the options icon to work with the application. For details of the available options, see Working with developer applications.
   - View Plan: a window opens listing the Plan that the application is subscribed to. If required, you can click the options icon to work with the Plan. For details of the available options, see Working with Plans.
   - View Product: a window opens listing the Product that contains the Plan that the application is subscribed to. If required, you can click the options icon to work with the Product. For details of the available options, see Managing your Products.

Security and authentication

In API Manager, you can use TLS profiles to secure the transmission of data between the management server and other API Connect subsystems and external services, and also configure user registries to securely authenticate your catalogs and APIs.

For details of authentication in IBM API Connect, see the following subtopics:

- **Creating a TLS client profile**
  Create a TLS client profile to secure communication within your API Connect deployment and to external services.
- **Authenticating by using your enterprise user registry**
  IBM API Connect supports a variety of user registry types for authenticating users and securing APIs.
- **Configuring a native OAuth provider**
  Native OAuth providers are configured and managed by you within your cloud.
- **Configuring a third-party OAuth provider**
  Enter the secure endpoints to provide OAuth authentication from a third party.
- **OAuth concepts for API Connect**
  OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Creating a TLS client profile

Create a TLS client profile to secure communication within your API Connect deployment and to external services.

Before you begin

One of the following roles is required to configure TLS profiles:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

About this task

API Connect provides pre-configured TLS client profiles that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new client profiles with your own TLS certificates. For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.

Note: If you update a TLS profile that is associated with a Gateway service, the updates are not automatically propagated to Gateway servers. For instructions on configuring the toolkit command-line tool to use TLS certificates when connecting to API Manager, see Configuring the command-line tool to use TLS certificates.

Procedure

To create a TLS profile, complete the following steps:

1. In the API Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the TLS client profile table.
4. Enter the fields to configure the TLS client profile:

Field	Description
Title	Enter a title for the profile.

Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
	To view the CLI commands to manage a TLS client profile, see the toolkit CLI reference documentation.
	
	Important: The name of the TLS client profile as saved on the DataPower® Gateway, depending on the gateway type, is as follows:
	• DataPower API Gateway:
	`provider-org-name_catalog-name_tlsp-tls-profile-nameV1.0.0`
	• DataPower Gateway (v5 compatible):
	`provider-org-name-tls-profile-nameV1.0.0`
	
	where
	• *tls-profile-name* is the value of the auto-generated name field for the TLS client profile in API Connect.
	• *provider-org-name* is the name of the provider organization that contains the TLS client profile.
	• *catalog-name* is the name of the catalog, in that provider organization, that contains the TLS client profile.

Version	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, **`MyProfile 1.0`** and **`MyProfile 1.1`**.
Summary	Enter a description of the profile.
Protocols	Select one or more supported TLS protocol versions. The default is 1.2 and 1.3
Server Connection	Specify whether to support weak or insecure credentials. • Allow insecure server connections - Insecure server connections can mean connections that use self-signed, expired, corrupted, or are from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections. • Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates that are presented on the same IP address using different hostnames. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.
Keystore	The keystore is a repository containing public and private key pairs. Select the keystore where you store the certificates for the profile. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your uploaded certificates before they expire.
Truststore	The truststore is a repository containing verified public keys. Truststores contain the list of certificates that your TLS client profile trusts. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your uploaded certificates before they expire.
Ciphers	Cipher suites are encryption algorithms that are used to secure TLS communication. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, all the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are not added to the list of ciphers supported by the profile.

5. Click Save.

Results

Important: If a third-party OAuth provider references a TLS client profile, that profile must be explicitly configured in the catalog (or space) where the OAuth provider is used. If the required TLS client profile is not present in the catalog, attempting to update or save the OAuth provider configuration fails with the following error:

```
400 Bad Request
The OAuth Provider '<name>' requires the following TLS client profile that is not configured in the catalog: <profile-name>
```

- **Creating a keystore**
  Keystores contain matched pairs of public certificates and private keys that are used to secure TLS connections.
- **Creating a truststore**
  Create a truststore that contains a list of certificates that your TLS client profile trusts.
- **Using OpenSSL to generate and format certificates**
  Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.
- **Viewing certificate details and adding certificates to a keystore or truststore**
  You can view details for the certificates in an existing keystore or truststore and add more certificates.
- **Defining elliptic curve cryptographic schemes for a TLS client profile**
  You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

Related tasks

- Working with user registries

Creating a keystore

Keystores contain matched pairs of public certificates and private keys that are used to secure TLS connections.

Before you begin

Your private and public keys must be in PEM or P12 format files.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure keystores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

Procedure

Complete the following steps to create a keystore:

1. In the API Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the keystore table.

Field	Description
Title	Enter a title for the keystore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Private key & public key: Step 1: Upload private key	Upload the file that contains the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).
Private key password	If the private key has a password, then enter it here.
Private key & public key: Step 2: Upload public key	If the public key is contained in a separate file, upload it in Step 2. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).

4. Click Save.
   Note: Uploaded keys and certificates cannot be download from API Connect.

Related tasks

- Creating a TLS client profile
- Creating a truststore

Creating a truststore

Create a truststore that contains a list of certificates that your TLS client profile trusts.

Before you begin

Your public keys must be in PEM or P12 format files.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure truststores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

Procedure

1. In the API Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the truststore table.

Field	
Title	Enter a title for the truststore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Upload truststore certificates	Upload the file that contains the public key certificate.

4. Click Save.

Using OpenSSL to generate and format certificates

Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.

OpenSSL is an open source toolkit that can be used for generating and validating TLS certificates.

This topic covers how to generate a self-signed TLS certificate by using the OpenSSL toolkit, and how to convert certificates in PEM format to P12 format.

Creating a self-signed certificate with OpenSSL

Use the following command to create a private key and public certificate with OpenSSL:

```
openssl req -newkey rsa:2048 -nodes -keyout private_key.pem -x509 -days 365 -out public_certificate.pem
```

The OpenSSL command asks for the following information to create your private key and public certificate (example values shown):

- Country Name (2 letter code) []: US
- State or Province Name (full name) []: California
- Locality Name (eg, city) []: Sacramento
- Organization Name (eg, company) []: exampleorganization
- Organizational Unit Name (eg, section) []:
- Common Name (eg, fully qualified host name) []: gateway.exampleorganization.com
- Email Address []:

Common Name must be set to the fully qualified domain name of the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example. **192.16.183.131** or **gateway.exampleorganization.com**).

To review the generated public certificate run:

```
openssl x509 -text -noout -in public_certificate.pem
```

To combine the generated private_key and public_certificate PEM files into a password protected P12 file, run:

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12
```

To validate a P12 file, run:

```
openssl pkcs12 -in certificate.p12 -noout -info
```

Creating PKCS#12 (P12) certificate from PEM files

PKCS#12 (P12) defines an archive file format for storing cryptographic objects as a single file. Use OpenSSL to create a password protected P12 file from your PEM files.

Prerequisites:

- Private key file. For example: private_key.pem.
- CA signed certificate. For example: public_certificate.pem.
- If you have intermediate certificates from your CA, concatenate them into a single .pem file to create a ca_chain.pem file:

  ```
  cat ca1.pem ca2.pem ca3.pem > ca_chain.pem
  ```

  the ca_chain.pem file should look like this:

  ```
  -----BEGIN CERTIFICATE-----
  MIIEpjCCA46gAwIBAgIQEOd26KZabjd+BQMG1Dwl6jANBgkqhkiG9w0BAQUFADCB
  ...
  lQX7CkTJn6lAJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
  -----END CERTIFICATE-----
  -----BEGIN CERTIFICATE-----
  MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NUmXJTANBgkqhkiG9w0BAQUFADBv
  ...
  -----END CERTIFICATE-----
  ```

```
-----BEGIN CERTIFICATE-----
MIIENjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQQGEwJTRTEU
...
-----END CERTIFICATE-----
```

- If you have multiple end-entity (leaf) certificates in one file, then split them into separate files and create separate P12 files for each certificate.

Create the P12 file with the following OpenSSL command (if you don't have CA certificates to include, then omit **`-CAfile <filename> -chain`**):

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

Viewing certificate details and adding certificates to a keystore or truststore

You can view details for the certificates in an existing keystore or truststore and add more certificates.

Before you begin

One of the following roles is required to edit keystores and truststores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

Procedure

To work with existing keystores and truststores:

1. In the API Manager, click Resources.
2. Select Crypto Material.
3. Click the name of the keystore or truststore.
4. Edit the name and summary if needed.
5. The Subject, Finger Print, and Expiration date are shown for each certificate in the keystore or truststore. Click > to view the certificate details.
6. Add additional private or public keys if needed.
7. Click Save.
   Note: Uploaded keys and certificates cannot be download from API Connect.

Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include **`elliptic_curve_auto_negotiation`** and **`elliptic_curve`** properties in a YAML file definition for the TLS client profile. The **`elliptic_curve`** property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When **`elliptic_curve_auto_negotiation`** is set to **`true`**, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any **`elliptic_curve`** property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The **elliptic_curve_auto_negotiation** option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

  Table 1.

API enforcement on the gateway	API Connect server access security
secp192r1	prime192v1
secp256r1	prime256v1

  Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
        .
        .
        .
  - secp256r1
  - prime256v1
        .
        .
        .
```

Procedure

Complete the following steps to create a TLS client profile with elliptic curve cryptographic schemes defined:

1. Create a YAML file definition for your TLS client profile, with the required **elliptic_curve** property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see Logging in to a management server.
3. Create the TLS client profile by using the following command:

   ```
   apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
   ```

   where:
   - *mgmt_endpoint_url* is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
   - *organization_name* is either **admin**, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
   - *tls_client_profile_yaml_file* is the name of the YAML file that contains the definition for your TLS client profile.

   Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.
   For reference details of all the **apic tls-client-profiles** commands, see the toolkit CLI reference documentation.

   You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Authenticating by using your enterprise user registry

IBM® API Connect supports a variety of user registry types for authenticating users and securing APIs.

You can use your enterprise user registry for authentication in API Connect if it is of one of the following types:

LDAP directory
: If your user registry uses Lightweight Directory Access Protocol (LDAP), you can use it in API Connect for both user authentication and API security.

Authentication URL User Registry
: You can configure a non-LDAP user registry by using an authentication URL user registry. An authentication URL user registry enables integration with third-party authentication providers. You can use an authentication URL user registry in API Connect for both user authentication and API security.

Local User Registry
: You can authenticate users with a local user registry. A local user registry is an internal registry stored within API Connect.

OpenID Connect
: You can authenticate users through an identity provider that supports the OpenID Connect (OIDC) authentication protocol.

- **Working with user registries**
  To secure the APIs that are published to your IBM API Connect Catalogs, you authenticate with user registries.
- **Modifying the configuration details for a user registry**
  You modify the configuration details for a user registry by using the User Registries page in the API Manager user interface of IBM API Connect.
- **Password lockout criteria**
  You can be locked out of your account if you attempt to log in and fail consecutively.

Related tasks

- Working with user registries

Working with user registries

To secure the APIs that are published to your IBM® API Connect Catalogs, you authenticate with user registries.

About this task

Create user registry resources to secure your APIs, and authenticate with users.

Procedure

To configure a user registry, complete the following steps:

1. In the API Manager user interface, select Resources.
2. On the Resources page, select User Registries > Create.
3. Select the tile for the user registry type you want, and continue to the instructions for configuring user authentication for your selection.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

   Authentication URL User Registry
   : For more information, see Creating an Authentication URL user registry.

   Custom user registry
   : For more information, see Creating an organization-specific custom user registry.

   LDAP User Registry
   : For more information, see Creating an LDAP user registry in API Manager.

   Local User Registry
   : For more information, see Creating a Local User Registry

   OIDC User Registry
   : For more information, see Creating an OIDC user registry in API Manager.

Results

The user registry information is added to API Manager.

What to do next

You can now use API Manager to chart and manage your Catalogs.

- **Creating an Authentication URL user registry**
  An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- **Creating an organization-specific custom user registry**
  You can configure an organization-specific custom user registry to provide user authentication for the Developer Portal.
- **Creating an LDAP user registry in API Manager**
  You can use the API Manager UI to configure an organization-specific LDAP user registry to provide user authentication and onboarding for the Developer Portal. APIs can also be secured with an LDAP user registry.
- **Creating a Local User Registry**
  A Local User Registry (LUR) can be created to provide user authentication for API Manager.
- **Creating an OIDC user registry in API Manager**
  Create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

Creating an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

About this task

This topic describes how to create a new Authentication URL user registry as a Resource in your organization. After the user registry is created, the user registry must be added to the Sandbox catalog.

One of the following roles is required to configure user registries:

- Administrator
- Organization Owner
- Custom role with the `Settings: Manage` permissions

Note:

API Connect issues an HTTP **GET** call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as **https://myauthurl.example.com/user/authenticate**:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of **200**, the user authenticates successfully. An HTTP status code other than **200** indicates a failed login attempt. API Connect forwards any HTTP Header starting with **X-** (with the exception of **X-Client-Certificate**), and Cookie to the Authentication URL identity provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
 X-Forwarded-For: 8.8.9.9
 X-Custom-Header-From-Customer: special
 Cookie: MyCookie=VGhpc0lzV2lja2VkQWlhemluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- **username**
- **email**
- **first_name**
- **last_name**

If the **username** field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The **Content-Type** must be **application/json**.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "username":"myuser",
  "email":"myuser@example.com",
  "first_name":"My",
  "last_name":"User"
}
```

Procedure

1. In the API Manager, click Resources.
2. Select User Registries to see the list of current user registries in your organization.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Authentication URL User Registry and enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary (optional)	Enter a brief description.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **Title** of the User Registries when rendering them at the login page, rather than the **Display Name**.
URL (required)	Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either `200 OK` or `401 Unauthorized` will be returned.
TLS Client Profile (optional)	Select a TLS Client Profile to allow secure authentication with a specific web server. Note: You cannot configure a user registry to a catalog if the TLS client profile is not configured.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.

Field	Description
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.
6. Add the user registry to the Sandbox catalog. See Creating and configuring Catalogs.

Results

The user registry can be used for Basic Authentication in the Security Definition for an API. For more information, see Defining basic authentication security schemes.

Creating an organization-specific custom user registry

You can configure an organization-specific custom user registry to provide user authentication for the Developer Portal.

Before you begin

Custom user registries can be used for authenticating users to the Developer Portal, but cannot be used to secure APIs.

To configure a custom user registry as a resource in API Manager, the external user directory must be created and available to use with your API Connect ecosystem.

Also, a custom user registry definition for your external user registry must already have been created on the Cloud Manager, as you will need the information from this definition to set up the custom user registry. See Configuring a shared custom user registry for information.

One of the following roles is required to configure a custom user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create a custom user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure an organization-specific custom user registry. If you want to create a shared registry, see Configuring a shared custom user registry for more information.
Note:

- You can also create and manage custom user registries by using the API Connect REST APIs; see the API Connect REST API documentation.

You can use the following instructions to create a writable or a read-only custom user registry.

API Connect provides two methods for creating a custom user registry in the API Manager, as described in the following sections:

- Creating a custom user registry by using the API Manager UI
- Creating a custom user registry by using the developer toolkit CLI

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

Creating a custom user registry by using the API Manager UI

You configure a custom user registry by creating a new custom user registry resource, which references the custom user registry type that is defined in the Cloud Manager. To make the custom user registry available to the Developer Portal for user authentication, you must enable the registry in the associated Catalog. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the custom user registry type.

Creating a custom user registry resource

Use the following instructions to create a new custom user registry resource in the API Manager UI.

1. Click Create in the User Registries section of Resources.
2. Click the Custom user registry tile.
3. Enter the following information:

Property	Description
Custom type	The name of the custom user registry type. For example, *my-custom-user-registry-type*. Use the drop-down arrow to select different custom user registry types. The custom user registry type is defined in the Cloud Manager.
Title	A descriptive name to display in the UI.
Name	The name of the custom user registry. This name is auto-generated, and is used in CLI commands.
Summary	A brief description of the custom user registry.
Endpoint	Optional endpoint information.

Property	Description
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: • The Developer Portal does not support case sensitive usernames. • After at least one user has been onboarded into the registry, you cannot change this setting.
User registry managed	Determines whether API Connect manages your user registry. Valid values are: • `true` - select the checkbox • `false` - clear the checkbox
User managed	Determines whether your user registry is writable or not. Select the checkbox to set to `true` for writable. Clear the checkbox for the non-writable option.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Create. The new user registry is displayed in the User registries list.

Adding your custom user registry to the Developer Portal login

To make the custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Catalog settings > Onboarding. In the Catalog User Registries section, click Edit, select the custom user registry, and click Save. For more information, see Creating and configuring Catalogs.

Creating a custom user registry by using the developer toolkit CLI

You configure an organization-specific custom user registry by creating a new custom user registry resource that references the integration document that exists on the Cloud Manager. You use developer toolkit CLI commands to create the custom user registry, and to make the registry available to the Developer Portal, you must enable the registry in the associated Catalog. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the integration document.

Logging in to the management server CLI

Before you can define the custom user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your custom user registry

You define the configuration of your custom user registry in a *`custom_config_file`*`.yaml` file, as shown in the following example.

```
name: 'custom_registry_name'
title: 'display_title'
registry_type: 'custom_user_registry'
integration_url: custom_integration_url
case_sensitive: true_or_false
user_managed: true_or_false
user_registry_managed: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: 'provider_title'
configuration:
```

```
  custom_config1: 'value1'
  customize: true
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the custom user registry. This name is used in the CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`registry_type`	The registry type that is configured in the `name` property in the integration document, for example `custom_user_registry`.
`integration_url`	The custom integration URL in your API Connect configuration. You can determine the custom integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable. Set to `false` if you don't want the registry to be writable.
`user_registry_managed`	Determines whether API Connect manages your user registry. Valid values are: • `true` • `false`
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your custom server, where: • `name` - is the name of the custom server and is the name that is used in CLI commands • `title` - is the display name of the custom server
`configuration`	The user-defined configuration based on the `configuration_schema` that is defined in the integration document.

Save your `custom_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section.

Creating your custom user registry

To create your organization-specific custom user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org organization_name custom_config_file.yaml
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `--org organization_name` means that the registry will be created in your provider organization.
- `custom_config_file` is the name of the YAML file that defines the configuration of your custom user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The `registry_name` is derived from the `name` property in the custom user registry YAML file. The `registry_url` is the URL with which the custom registry resource can be accessed.
Your organization-specific user registry is now created; see the following section for instructions on how to make the registry available to users.

Configuring your custom user registry in a Catalog

To make your custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_registry_url: custom_registry_url
   ```

   where ***custom_registry_url*** is the URL of your custom user registry, obtained in step 1.
4. Press `CTRL D` to terminate the input.

Creating an LDAP user registry in API Manager

You can use the API Manager UI to configure an organization-specific LDAP user registry to provide user authentication and onboarding for the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in API Manager, the LDAP directory must be created and populated for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Organization Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure an organization-specific LDAP user registry. If you want to create a shared registry, see Configuring an LDAP user registry in the Cloud Manager for more information.
Note:

- You can also create and manage LDAP user registries by using the developer toolkit CLI. For more information, see Using the CLI to create an organization-specific LDAP user registry.
- The API Connect REST APIs can also be used to create and manage LDAP user registries; see the API Connect REST API documentation.
- You can map external LDAP groups to API Connect user roles to enable greater control of user access, but this configuration can be done only by using the developer toolkit CLI; see Using the CLI to create an organization-specific LDAP user registry for details.

You create an LDAP user registry by configuring a set of properties in the API Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see LDAP authentication.

Procedure

Follow these steps to configure a new LDAP user registry as a Resource in the API Manager UI.

Note: If you are using an **`Active Directory`**, you must indicate this by using the property **`"directory_type": "ad"`** in the LDAP config.

1. In the API Manager, click Resources.
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select LDAP User Registry for the user registry type, and enter the following information:

Field	Description
Title	Enter a descriptive name to display on the screen.

Field	Description
Name	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Address	Enter the IP address or host name of the LDAP server.
Port	Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, `389`.
Select a TLS Client Profile (optional)	Select the TLS Client Profile that the LDAP server requires. Note: You cannot configure a user registry to a catalog if the TLS client profile is not configured.
Select a protocol version	Select the version number for the LDAP protocol that you are using.
Remote directory is Microsoft Active Directory	Select this option if you use Active Directory.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** select Case sensitive if your backend LDAP server supports case-sensitivity. • Do **not** select Case sensitive if your backend LDAP server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
   - Compose DN - Select this format if you want users to login with a username that is also part of their LDAP Distinguished Name (DN). For example, using `uid` for user login where the user's LDAP DN is: `uid=<username>,ou=People,dc=company,dc=com`. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator.
   - Compose UPN - Select this format if your LDAP directory supports binding with User Principal name such as **`john@acme.com`**. This is applicable if you are using Microsoft Active Directory as your LDAP directory. If you are unsure whether your LDAP directory supports binding with LPNs, contact your LDAP administrator.
     Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
   - Search DN - Select this format if you want users to login with a username that is not part of their LDAP DN. For example, if the user's LDAP DN was: `uid=<username>,ou=People,dc=company,dc=com` and you want them to login with the email. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator. Optionally select a scope to specify which part of the directory information tree is examined:
     Optionally select a scope to specify which part of the directory information tree is examined:
     - Whole subtree (default)
     - Base object
     - Single level

   For all of the authentication methods:

   If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the DN of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the DN that comes before the username for binding or authentication. For example, `bind_prefix: 'uid='`.
Suffix	Part of the DN that follows the username, specifying the user's location in the LDAP tree. For example, `bind_suffix: ',ou=users,dc=apic,dc=com'`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

6. For authentication method Compose UPN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the DN of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Suffix	Part of the DN that follows the username for constructing the UPN. For example, `@domain.com`.

Field	Description
Use group authentication (optional)	Enter the Filter condition for the group.

7. For authentication method Search DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the DN of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the search filter that comes before the username. The last attribute must be the one you chose to use for login. For example, `'(&(uid='`.
Suffix	Part of the search filter that follows the username. For example,`'))(objectClass=organizationalPerson)'`. Notice how it always begins with a `'))'` which is meant to close the attribute filter for the last attribute specified in `search_dn_filter_prefix`.
Base DN	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.
9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:
   - LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
   - API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.

   The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

LDAP ATTRIBUTE NAME	API Connect VALUE
`dn`	`uid=[username],ou=users,dc=company,dc=com`
`cn`	`[first_name] [last_name]`
`sn`	`[last_name]`
`mail`	`[email]`
`userPassword`	`[password]`

   You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
10. Click Create.
    Your new LDAP registry is shown in the list of User Registries on the Resources page.

What to do next

If you use DataPower® API Gateway, your cloud administrator can optionally update the service and enable LDAP connection pooling to improve performance as explained in Registering a gateway service.

If you want to make the LDAP user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Click the relevant Catalog, then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring catalogs .

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Defining basic authentication security schemes.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

- **Using the CLI to create an organization-specific LDAP user registry**
  You can use the developer toolkit CLI to configure an organization-specific LDAP user registry to provide user authentication for the Developer Portal. APIs can also be secured with an LDAP user registry.

Using the CLI to create an organization-specific LDAP user registry

You can use the developer toolkit CLI to configure an organization-specific LDAP user registry to provide user authentication for the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in API Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, The STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.

Note: If you are using an **`Active Directory`**, you must indicate this by using the property **`"directory_type": "ad"`** in the LDAP config.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure an organization-specific LDAP user registry. If you want to create a shared registry, see Using the CLI to configure a shared LDAP user registry for more information.
Note:

- You can also create organization-specific LDAP user registries by using the API Manager UI; for more information see Creating an LDAP user registry in API Manager.
- In addition, you can create and manage LDAP user registries by using the API Connect REST APIs; see the API Connect REST API documentation.
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable more control of user authorization by using the developer toolkit CLI. The following instructions explain how to set the **`external_group_mapping_enabled`** configuration on your LDAP user registry resource. For information about how to set external role mapping on your API Connect user roles, see Configuring LDAP group mapping on Cloud Manager user roles.

You create an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see LDAP authentication.

Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **`default-idp-2`**.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your LDAP configuration

You define the configuration of your LDAP user registry in an ***`ldap_config_file`*`.yaml`** file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.
Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
user_managed: true_or_false
user_registry_managed: false
directory_type: ad
external_group_mapping_enabled: true_or_false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
```

```
configuration:
  authentication_method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
  admin_password: admin_password
  search_dn_base: "search_dn_base"
  search_dn_scope: search_dn_scope
  search_dn_filter_prefix: prefix
  search_dn_filter_suffix: suffix
  attribute_mapping:
    dn: "distinguished_name"
    cn: "common_name"
    sn: "last_name"
    mail: "email_address"
    userPassword: "password"
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the registry. This name is used in CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`integration_url`	The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable LDAP. You can change this setting to `false` if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
`user_registry_managed`	Must be set to `false` for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.
`directory`	Specify one of the of following values for the directory type: • `ad` - Indicates that the LDAP is Microsoft Active Directory • `standard` - (Default value) Indicates any other LDAP
`external_group_mapping_enabled`	Determines whether your user registry supports LDAP group mapping. Valid values are: • `true` • `false` The default value is `false`.
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your LDAP server, where: • `name` - is the name of the LDAP server and is the name that is used in CLI commands • `title` - is the display name of the LDAP server
`endpoint`	The endpoint of your LDAP server, made up of the url and port, for example: `"ldap://server.com:389"`
`tls_profile`	Optionally set the TLS Client Profile that the LDAP server requires.
`protocol_version`	Optionally set the version number for the LDAP protocol that you are using. Valid values are: • `2` • `3` Defaults to `3` if not explicitly set.

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- `compose_dn` - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the

correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, **compose_dn** is not supported with the DataPower API Gateway.

- **compose_upn** - Set this format if your LDAP directory supports binding with User Principal Names such as **john@acme.com**. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
  Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- **search_dn** - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method **compose_dn**, set the following configuration properties:

Properties	Description
authentication_method	**compose_dn**
authenticated_bind	The bind method. Valid values are: • **"true"** - authenticated bind • **"false"** - anonymous bind If specific permissions are not needed to search the registry, select **"false"**. If specific permissions are necessary, select **"true"**.
admin_dn	If **authenticated_bind** is set to **"true"**, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: **"cn=admin,dc=company,dc=com"**
admin_password	If **authenticated_bind** is set to **"true"**, enter the user password for the **admin_dn**.
search_dn_base	Optionally set a base DN, for example: **"dc=company,dc=com"**
bind_prefix	Set the prefix to the DN, for example: **(uid=**
bind_suffix	Set the suffix to the DN, for example: **)**
attribute_mapping	If **user_managed** is set to **true**, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows: ***ldap_registry_attribute_name*: "*apic_ldap_attribute_value*"** Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in **[ ]** with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are **username**, **first_name**, **last_name**, **email**, and **password**. The following extract shows an example of an attribute mapping: **attribute_mapping:** **dn: "uid=[username],ou=users,dc=company,dc=com"** **cn: "[first_name] [last_name]"** **sn: "[last_name]"** **mail: "[email]"** **userPassword: "[password]"**

For authentication method **compose_upn**, set the following configuration properties:

Properties	Description
authentication_method	**compose_upn**
authenticated_bind	The bind method. Valid values are: • **"true"** - authenticated bind • **"false"** - anonymous bind If specific permissions are not needed to search the registry, select **"false"**. If specific permissions are necessary, select **"true"**.
admin_dn	If **authenticated_bind** is set to **"true"**, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: **"cn=admin,dc=company,dc=com"**
admin_password	If **authenticated_bind** is set to **"true"**, enter the user password for the **admin_dn**.
bind_suffix	Enter the domain part of the user principal name. For example: **@acme.com**

Properties	Description
attribute_mapping	If **user_managed** is set to **true**, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows: ***ldap_registry_attribute_name*: "*apic_ldap_attribute_value*"** Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in **[ ]** with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are **username**, **first_name**, **last_name**, **email**, and **password**. The following extract shows an example of an attribute mapping: **attribute_mapping:** **dn: "uid=[username],ou=users,dc=company,dc=com"** **cn: "[first_name] [last_name]"** **sn: "[last_name]"** **mail: "[email]"** **userPassword: "[password]"**

For authentication method **search_dn**, set the following configuration properties:

Property	Description
authentication_method	**search_dn**
authenticated_bind	The bind method. Valid values are: • **"true"** - authenticated bind • **"false"** - anonymous bind If specific permissions are not needed to search the registry, select **"false"**. If specific permissions are necessary, select **"true"**.
admin_dn	If **authenticated_bind** is set to **"true"**, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: **"cn=admin,dc=company,dc=com"**
admin_password	If **authenticated_bind** is set to **"true"**, enter the user password for the **admin_dn**.
search_dn_base	Optionally set a base DN, for example: **"dc=company,dc=com"**
search_dn_scope	Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are: • **base** • **one** • **sub** (default value)
search_dn_filter_prefix	Set the prefix to the DN, for example: **(uid=**
search_dn_filter_suffix	Set the suffix to the DN, for example: **)**
attribute_mapping	If **user_managed** is set to **true**, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows: ***ldap_registry_attribute_name*: "*apic_ldap_attribute_value*"** Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in **[ ]** with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are **username**, **first_name**, **last_name**, **email**, and **password**. The following extract shows an example of an attribute mapping: **attribute_mapping:** **dn: "uid=[username],ou=users,dc=company,dc=com"** **cn: "[first_name] [last_name]"** **sn: "[last_name]"** **mail: "[email]"** **userPassword: "[password]"**

Save your ***ldap_config_file*.yaml** so it can be accessed by the **user-registries:create** command in the following section. See the Example section for an example configuration file.

Creating your LDAP user registry

To create your organization-specific LDAP user registry, run the following CLI command:

apic user-registries:create --server *mgmt_endpoint_url* --org *organization_name* *ldap_config_file*.yaml

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the **name** property of your provider organization.
- *ldap_config_file* is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The *registry_name* is derived from the **name** property in the configuration YAML file. The *registry_url* is the URL with which the registry resource can be accessed.
Your LDAP user registry is now created; see the following section for instructions on how to make the registry available in the Developer Portal.

Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Log in to the management server as a member of a provider organization; enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
   For full details of the **apic login** command, see Logging in to a management server.

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: ldap_registry_url
   ```

   where *ldap_registry_url* is the URL of your LDAP registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the **user_managed** property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

   The command returns a list of all the user registries for that organization, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example **https://company.com/api/user-registries/x-x-x-x-x/*registry_id***.
2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registries:update --server mgmt_endpoint_url --org organization_name registry_name_or_id -
   ```

   where ***registry_name_or_id*** is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

   ```
   Reading USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_managed: true_or_false
   ```

   where **true** makes the registry writable, and **false** makes the registry read-only.
4. Press **CTRL D** to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the **attribute_mapping** configuration, as described in the previous registry property tables.

Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
directory_type: standard
case_sensitive: false
identity_providers:
  - name: ldap
    title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

Creating a Local User Registry

A Local User Registry (LUR) can be created to provide user authentication for API Manager.

About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can use API Manager to create additional Local User Registries for use with your provider organization.

One of the following roles is required to configure user registries:

- Administrator
- Organization Owner
- Custom role with the `Settings: Manage` permissions

Procedure

Follow these steps to configure a new LUR:

1. In the API Manager, click Resources.
2. Select User Registries to see the list of current user registries in your organization.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Local User Registry as the type for the user registry and enter the following information:

Field	Description
Title (required)	Enter a descriptive name for use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.

Field	Description
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the `Title` of the User Registries when rendering them at the login page, rather than the `Display Name`.
Summary (optional)	Enter a brief description.
Case sensitive	Select this setting if user names are case-sensitive. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.
6. Add the user registry to the Sandbox Catalog. See Creating and configuring Catalogs.

Results

New local user registry is now available in API Manager.

Creating an OIDC user registry in API Manager

Create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create an organization-specific registry. For information on how to create a shared registry, see Configuring an OIDC user registry in Cloud Manager.

Important: If you are using X (formerly known as Twitter) as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your X application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.
API Connect provides two methods for creating an OIDC user registry in API Designer, as described in the following sections:

- Using the UI to create an OIDC user registry
- Using the CLI to create an OIDC user registry

Using the UI to create an OIDC user registry

Use the API Designer user interface to create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

1. In the API Designer navigation pane, click Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create.
   Many of the registry settings are preconfigured to simplify the configuration steps.

   Provider Type
   Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

Field	Description
Provider Type	OIDC provider. Select one of the following supported OIDC providers: • Facebook • GitHub • Google • LinkedIn • Slack • X (formerly known as Twitter) • Windows Live • Standard OIDC (default value allows you to specify another provider)
Title	Provide a descriptive name for display purposes.

Field	Description
Name	Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary	Provide a brief description of the new registry.
Email required	Select this option if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this option if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

Provider Endpoint

Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

Token Endpoint

Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.
TLS	Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

UserInfo Endpoint

Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint. For LinkedIn, the endpoint changed and now uses the following value: `https://api.linkedin.com/v2/me` If you previously configure the OIDC registry using the legacy LinkedIn OIDC protocol, you do not need to specify this endpoint.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Email Endpoint

Required for the legacy LinkedIn OIDC protocol.

Due to changes in LinkedIn, the configuration settings for the OIDC registry in API Connect also changed. If you are configuring a new OIDC registry for LinkedIn, you can leave the Email Endpoint field blank.

If you previously configured an OIDC registry for use with the legacy LinkedIn OIDC protocol, update your configuration by providing the Email endpoint settings as described in Table 4. The new setting is required for the legacy LinkedIn OIDC protocol.

Table 4. Email Endpoint settings

Field	Description
URL	For the legacy LinkedIn OIDC protocol, this field defaults to the following value: `https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))` You can override the setting by typing in a new value.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

JWKS Endpoint

Fill in the settings as described in Table 5.

Table 5. JWKS Endpoint settings

Field	Description
URL	Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Logout

You can configure either of the following types of logout support, but not both:

- Logout redirect:
  Allows you to specify what the user sees after logging out of API Connect; for example, you might want to "redirect" the user to the OIDC provider's logout endpoint, or to another address. When the user logs out of API Connect, the browser is redirected to the specified URL for further processing by the specified URL.

- RP-initiated logout:
  Provides a more secure form according to the OpenID Connect RP-Initiated Logout 1.0 Profile. When the user logs out of API Connect, API Connect issues a POST request to the specified endpoint URL to clear the user's session. With this option, you can optionally provide an RP logout redirect endpoint URL as well.

Fill in the settings as described in Table 6.

Table 6. Logout options

Field	Description
Logout redirect URL	Optional. Provide a URL to redirect the browser when the user logs out of API Connect. If you use this option, do not enable the OIDC RP logout.
Enable OIDC RP logout	Select this option to use the RP-initiated logout instead of the conventional logout redirect. If you use this option, do not provide a Logout redirect URL. With the RP-initiated logout, you can optionally specify an RP-logout redirect URL.
URL endpoint that the RP will issue a POST request	Provide the URL to the endpoint where the POST request will be executed; for example, the authorization endpoint of the OpenID provider.
TLS	Select the TLS profile to use when sending the POST request to the OpenID provider endpoint.

Field	Description
RP logout redirect endpoint URL	Optional. Provide a URL where the OIDC provider can redirect after the logout operation. The URL functions as the **post_logout_redirect_uri**, as described in the OpenID Connect RP-Initiated Logout 1.0 Profile.
Include refresh_token in logout	Optional. Allow the refresh_token to be included, in addition to the id_token_hint, per the OpenID Connect RP-Initiated Logout 1.0 Profile.

Client Information

Fill in the settings as described in Table 7.

Table 7. Client Information settings

Field	Description
Client ID	Provide the client ID of the application that is registered with the selected OIDC provider.
Client Secret	Provide the client secret of the application that is registered with the selected OIDC provider. This field is optional when you create an OIDC directory of type Standard and set the Client Authentication Method to Data encoded form body. If you are not using the Client Secret, ensure that mutual TLS is configured with the OIDC provider. To enable mutual TLS, create a TLS profile and include it in the OIDC user registry setup.
Response Type	Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.
Scopes	Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.
Client Authentication Method	Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: • HTTP Basic authentication schema • Data encoded form body

Additional Support

Optional. Select the additional security parameters described in Table 8.

Table 8. Additional security options

Security parameter	Setting name for CLI	Description
NONCE	**nonce**	Enable the NONCE extension to prevent compromised requests from being used again (replayed).
Proof Key for Code Exchange (PKCE)	**pkce**	Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted.

Advanced Features

Optional. Select the advanced features described in Table 9.

Table 9. Advanced features

Feature / UI Label	Setting name for CLI	Description
Auto onboard	**auto_onboard**	Allow users to executes calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. Note: Does not apply to consumer organizations.
Always use the userinfo endpoint	**userinfo**	Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.
Use Portal as Endpoint for external OIDC provider traffic	**proxy_redirect**	When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager. When enabled, the redirect URI for the Developer Portal should be set to **/ibm_apim/oidcredirect**. For details, see the Redirect URI.
Return third-party access token	**proxy_access_token**	Include the third-party OIDC access token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party id_token	**proxy_id_token**	Include the third-party OIDC id_token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party access_token and id_token as separate claims	**proxied_token_as_separate_claim**	Include the third-party OIDC tokens (the **proxy_access_token** and **proxy_id_token**) in the response as separate claims instead of adding them to the access_token issued by API Connect. To use this feature, you must enable at least one of the Return third-party access token and Return third-party id_token options. Separating the third-party tokens prevents them from affecting the size of the access_token issued by API Connect.
Token Relay	**token_relay**	Allow **access_token/refresh_token** to send in 302 redirect for logout
Userinfo POST	**post_userinfo**	If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint. Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.
Use IBM APIC token expiration setting from cloud	**override_provider_ttl**	Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see Configuring timeouts for access tokens and refresh tokens.
Disable hash verification (CLI only)	**disable_hash_verification**	Disable **at_hash**, **c_hash**

User Mapping

Fill in the settings as described in Table 10.

Note: The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 10. User mapping settings

Field	Description
Username	The name of the field in the response token that contains the user's user name. Note: The Username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed.
Email	The name of the field in the response token that contains the user's email address.
First name	The name of the field in the response token that contains the user's given name.
Last name	The name of the field in the response token that contains the user's surname.

Redirect URI

The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.
Note: If the Developer Portal is publicly accessible and you select the **`proxy_redirect`** option, you must configure your OIDC provider to use the following redirect URI:

- URI path: **`/ibm_apim/oidcredirect`**
- Full URL example: **`https://<your-developer-portal-domain>/ibm_apim/oidcredirect`**

Where:
`<your-developer-portal-domain>` is the actual hostname of your public-facing Developer Portal; for example, **`developer.example.com`**.

This configuration ensures that the OIDC provider can correctly redirect authenticated users back to the Developer Portal as part of the login flow.

Enabling the OIDC user registry

Complete the following steps to enable the new user registry for a specific catalog in the Developer Portal. Repeat this procedure for each catalog that will use the new registry.

1. On the navigation pane, click Manage.
2. Select the catalog for which you will enable the new OIDC user registry.
3. On the navigation pane, click the Catalog settings tab.
4. On the Settings page, click Onboarding.
5. On the Onboarding page, click Edit in the Catalog User Registries section.
6. On the Edit User Registry page, select the new OIDC user registry to enable for your catalog.
7. Click Save.

Using the CLI to create an OIDC user registry

Use the developer toolkit CLI to create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
Configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated catalog.
Note:

- An OIDC registry cannot be used to secure APIs on the gateway.
- If you are using an OIDC user registry for login, The Management server handles the interaction with the third-party OIDC provider. The management server is considered the application from the perspective of the third-party OIDC provider. Therefore, your OIDC redirect endpoint on the management server, which the third-party authorization server uses to send the token, must be accessible to the OIDC provider. To ensure login functions, you must allow access if your API Connect environment is secured behind a firewall. This is true for user login on both API Manager and Cloud Manager.
- If OIDC user registry is used for consumer login at the Developer Portal and Developer Portal is in the DMZ, you can use the **`proxy_redirect`** property. This allows the Developer Portal to act as the endpoint for proxying communication between the OIDC provider and API Connect.
- When you register your application with the third-party OIDC provider, you are required to supply the associated OIDC redirect URI, https://consumer.mycompany.com/consumer-api/oauth2/redirect for example. However, you cannot access this information until you create your OIDC user registry in API Connect. First, register your application without this information and then update it later, as detailed in the instructions on this page.

Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time.

The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

Defining your OIDC registry configuration

Define the configuration of your OIDC user registry in a YAML file. At a minimum, the YAML file must include the settings from the following list. For additional settings, see the tables provided with the UI version of the procedure in this topic.

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type
```

where:

- *registry_title* is your chosen descriptive title for the user registry.
- *oidc_integration_url* is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

  ```
  apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
  ```

- *case_sensitivity_setting* determines whether your user registry is case-sensitive. Valid values are:
  - **true**
  - **false**

  To ensure proper handling of user name capitalization, ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:
  - Only set **case_sensitive** to **true** if the backend OIDC provider supports case-sensitivity.
  - Set **case_sensitive** to **false** if the backend OIDC provider does not support case-sensitivity.

  Note: After at least one user has been added to the registry, you cannot change this setting.
- *email_required* determines whether an email address is required as part of the user onboarding process. Valid values are:
  - **true**
  - **false**

  If set to **true**, the source identity provider must supply the email address as part of the authentication process during onboarding.
  Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
- *email_unique_if_exist* determines whether email addresses must be unique within the user registry. Valid values are:
  - **true**
  - **false**

  Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
- *app_client_id* is the client ID of the application that is registered with the OIDC server, and must be in string format.
- *my-client-secret* is the client secret of the application that is registered with the OIDC server, and must be in string format.
- *oidc_provider_type* is the type of OIDC provider; specify one of the following values:
  - **facebook**
  - **github**
  - **google**
  - **linkedin**
  - **slack**
  - **twitter**
  - **windows_live**
  - **standard**

  Note:
  - Use the **twitter** provider type if your OIDC provider is X (formerly known as Twitter).
  - Use the **standard** provider type for any OIDC provider that is compliant with the OIDC standard.
    If the provider type is **standard**, you must include the following additional properties in the **configuration** section of your YAML file:

    ```
    authorization_endpoint: 'oidc_auth_endpoint'
    token_endpoint:
      endpoint: 'oidc_token_endpoint'
    ```

    where:
    - *oidc_auth_endpoint* is the authorization endpoint on the OIDC server, and must be in string format.
    - *oidc_token_endpoint* is the token endpoint on the OIDC server, and must be in string format.

Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file.

Note: Endpoints are subject to change; when you create a registry you must verify the default endpoint provided by API Connect.
API Connect makes the best effort to update endpoints for the known OIDC user registry types. However the OIDC provider can change the endpoint at any time. It is the customer's responsibility to confirm that the endpoints provided by API Connect are supported by the OIDC provider and to update the OIDC configuration as needed.

The default configurations are as follows:

- Facebook

  ```
  authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
  token_endpoint:
    endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
  userinfo_endpoint:
    endpoint: 'https://graph.facebook.com/me'
  scope: email public_profile
  field_mapping:
    username: email
  ```

```
  email: email
  last_name: last_name
  first_name: first_name
```

- GitHub

```
authorization_endpoint: 'https://github.com/login/oauth/authorize'
token_endpoint:
  endpoint: 'https://github.com/login/oauth/access_token'

field_mapping:
  username: email
  email: email
  last_name: family_name
  first_name: given_name
```

- LinkedIn
  Some settings differ between the legacy configuration and the newer configuration. Be sure to use the correct settings for the LinkedIn protocol that you are using.

  - New OIDC protocol:

    ```
    authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
      credential_location: form_body
      field_mapping:
        email: email
        username: name
        first_name: given_name
        last_name: family_name
      scope: openid profile email
      token_endpoint:
        endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
      userinfo_endpoint:
        endpoint: 'https://api.linkedin.com/v2/me'
    ```

  - Legacy OIDC protocol:

    ```
    authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
    token_endpoint:
      endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
    userinfo_endpoint:
      endpoint: 'https://api.linkedin.com/v2/me'
    email_endpoint:
      endpoint: 'https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))'
    scope: r_liteprofile r_emailaddress
    field_mapping:
      username: emailAddress
      email: emailAddress
      last_name: localoizedLastName
      first_name: localizedFirstName
    credential_location: form_body
    ```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'
token_endpoint:
  endpoint: 'https://slack.com/api/oauth.access'
userinfo_endpoint:
  endpoint: 'https://slack.com/api/users.identity'
scope: identity.basic identity.email
field_mapping:

  email: user.email
  last_name: user.name
  first_name: user.name
```

- X (formerly known as Twitter)

```
request_endpoint: https://api.x.com/oauth/request_token'
authorization_endpoint: https://api.x.com/oauth/authenticate'
token_endpoint:
    endpoint: 'https://api.x.com/oauth/access_token'
userinfo_endpoint:
    endpoint: 'https://api.x.com/1.1/account/verify_credentials.json'
oauth_signature_method: 'HMAC-SHA1'
field_mapping:
    email: email
    first_name: name
    last_name: name
    username: screen_name
```

- Windows Live

```
authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
  endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
scope: openid offline_access profile email
field_mapping:
  email: email
  username: preferred_username
  first_name: name
  last_name: name
```

- Standard

```
response_type: code
scope: openid
field_mapping:
  username: sub
  email: email
  last_name: family_name
  first_name: given_name
credential_location: auth_header
```

Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org organization_name oidc_config_file
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the **name** property of your provider organization.
- *oidc_config_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the *registry_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry_url* is an internal URL that API Connect assigns to the registry.
After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc_redirect_uri** value is in the **consumer:** section; for example:

```
consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect
```

Enabling your OIDC registry in a Catalog

To make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_registry_url: oidc_registry_url
   ```

   where *oidc_registry_url* is the URL of your OIDC registry, obtained in step 1.
4. Press **CTRL D** to terminate the input.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Modifying the configuration details for a user registry

You modify the configuration details for a user registry by using the User Registries page in the API Manager user interface of IBM® API Connect.

About this task

If you want to authenticate an API Connect Catalog with a user registry that is not yet defined in API Connect, you define the registry when you configure the Catalog; for details, see Working with user registries.
Note: User registries shared from the Cloud Manager cannot be edited.
To modify the configuration details for a user registry that is already defined, you use the User Registries page.

Procedure

To modify the configuration details for a user registry, complete the following steps:

1. In the API Manager, click Resources, and then select User Registries.
2. On the User Registries page, click the options icon for the user registry that you want to edit, then click Edit.
   The details of the registry are displayed.
3. Modify the configuration details as required, then click Save to save your changes.

Password lockout criteria

You can be locked out of your account if you attempt to log in and fail consecutively.

Note: Account lock out applies only for local user registries.
The length of time that you are locked out of using the account is based on the number of consecutive attempts that you fail. The length of time increases as the number of consecutive failed attempts increases.

For example, you can be locked out for 15 seconds if you have five consecutive failed attempts, or 32 minutes for 12 consecutive failed attempts.
Note: External user registries, such as LDAP, might enforce their own lockout criteria.

Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client_id checks:
If you are calling an OAuth endpoint, the sequence of `client_id` checks in the token request is as follows:

1. Check both body and query.
   - If found in only the body, validate and return a `200` or appropriate return code.
   - If found in only the query, return a `wrong location` error.
   - If found in both the body and the query, return a `more than one location` error.
2. When not found in the body or the query, check the `Authorization` header.
   - If found in this header, validate and return a `200` or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the `client_id` is in the request body.
One of the following roles is required to configure a native OAuth provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

Note:

- The OAuth provider logs analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

Procedure

1. In the API Manager, click Resources.
2. Click OAuth Providers > Add > Native OAuth provider.

a. Complete the following parameters for the first screen, then click Next.

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
Gateway Type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

b. In the next screen, enter the following additional configuration parameters, then click Next.

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

d. Enter the parameters for User Security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application grant type. Click Next when done.

Field	Description

Identity Extraction	Determines how the user credential is extracted:
	• Basic Authentication - HTTP basic authentication (requires no additional configuration)
	• Default HTML Form - Use default login form for user name and password
	• API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables
	Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible).
	• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security.
	• Redirect - If you select Redirect , enter the following parameters:
	  • End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL
	  • Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark symbol (?), usually consisting of key-value pairs separated by ampersand symbol (&).
	  Note: To ensure the query parameters that you entered is applied to the gateway, republish your OAuth provider.
	  • Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements.
	• API Gateway only Disabled - do not collect the user credential
	Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the **`state_nonce`** query parameter, otherwise the authorization fails.

Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.
Authorization	The following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML authorization form for user security. • API Gateway only Disabled - Disable authorization.

3. Review the Summary for the native OAuth provider configuration.
4. Click Back to make changes.
5. Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.
   If you want to specify the native OAuth Provider in your Catalog, see Specifying the OAuth Providers.

Results

You can use the OAuth Provider to secure the APIs in catalog.

- **Configuring basic settings for a native OAuth provider**
  You can update the identification details and basic configuration settings for a native OAuth provider.
- **Configuring scopes for a native OAuth provider**
  Access tokens contain authorization for specific scopes.
- **Configuring user security for a native OAuth provider**
  Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- **Configuring tokens for a native OAuth provider**
  Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- **Configuring token management and revocation for a native OAuth provider**
  Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.
- **Configuring introspection for a native OAuth provider**
  Define an introspection path to allow the metadata for an access token to be examined.
- **Configuring metadata for a native OAuth provider**
  Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Configuring the OIDC parameters for a native OAuth provider**
  Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.
- **Editing a native OAuth provider by using the API Editor**
  You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. To modify the identification details, click Info in the sidebar menu, then update the following fields as required:

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Field	Description

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
	
	Tip: If you plan to configure OpenID Connect (OIDC) for a Native OAuth provider, include at least one of the following grant types: Implicit, Access code.

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:

a. Click User Security in the sidebar menu, then click Edit.
b. Update the user security settings as required; for more details, see Configuring user security for a native OAuth provider.
c. Click Save when done.

3. Click Save when done.

Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

About this task

The client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see The OAuth 2.0 Authorization Framework.

One of the following roles is required to configure scopes for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.
If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

2. Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are invoked after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and will overwrite any previous scopes.

Field	Description
Application scope check	Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS Profile to use for an application scope check.
Owner scope check	Further refine the scope with an additional check. Enter the endpoint and an optional TLS Profile to use for an owner scope check.

For more information about scope, see Scope

3. Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

Field	Description
Enabled	Select the check box to enable the advanced scope check after token validation. Enter an optional default validator endpoint.
Use endpoint from API	Select the check box to use the endpoint from the API, or clear the check box to override the endpoint from the API.

For more information about scope, see Scope

4. Click Save when done.

Results

You can use the OAuth Provider with these scopes to secure the APIs in catalog.

Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click User Security in the sidebar menu.
2. Specify the following parameters for User Security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

Field	Description

Identity Extraction	Determines how the user credential is extracted:
	• Basic Authentication - HTTP basic authentication (requires no additional configuration)
	• Default HTML Form - Use default login form for user name and password
	• API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables
	• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security.
	• Redirect - If you select Redirect , enter the following parameters:
	  • End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL
	  • Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark (?) symbol, usually consisting of key-value pairs separated by ampersand symbol (&).
	  Note: To ensure the query parameters that you entered is applied to the gateway, republish your OAuth provider.
	  • Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements.
	• API Gateway only Disabled - do not collect the user credential
	Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.

Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry.
Authorization	Various methods may be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. • API Gateway only Disabled - Disable authorization.

3. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in catalog.

Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Tokens in the sidebar menu.
2. Define the settings to configure tokens.

Field	Description
Access tokens time to live	Enter the expiration time period in seconds for access tokens.
API Gateway only One time use access token	Click the check box to enable one time use for the access token. Access tokens are multiple use by default which allows them to be used for multiple requests. When one time use is enabled, the access token will be consumed after one use. The OAuth flow will need to be repeated to obtain another access token. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Refresh tokens	Click the check box to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.
One time use refresh token	Clear the check box to disable one time use for the refresh tokens. Refresh tokens are one time use by default which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Maximum consent	Click the check box to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.
API Gateway only Token secret	Click the check box to select the Shared Secret which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter an key name and key value to use as the token secret.
API Gateway only Proof Key for Code Exchange	Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. You can enable this extension when deploying with the DataPower® API Gateway. For more information, see RFC 7636. Select the options for your OAuth Providers: • Enable proof key for code exchange If selected, enforces PKCE when submitted in Authorization Code grant requests. • Always required If selected, requires PKCE in all Authorization Code grant requests. • Allow plain Select this check box to allow the plain challenge method in Authorization Code grant requests.

3. Click Save when done.

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 OAuth 2.0 Token Revocation.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the check box.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.
   Note: If you are using the API Manager user interface then, for the External option to be available, you must be using DataPower® API Gateway Version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see Creating and configuring Catalogs
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
   - Resource owner revocation path - Uses the standard OAuth revocation path to allow the resource owner (end user) to revoke the application permission.
   - Client revocation path - Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.

   For more information about managing tokens with the Native DataPower Gateway, see Token management with the native DataPower Gateway.
5. For External, the settings depend on the gateway type, as follows:
   DataPower API Gateway:
   - Endpoint - the URL of the external management endpoint.
   - TLS Client Profile (optional) - the TLS client profile to secure connections.
   - Security - how to secure connections. The only supported method is basic authentication.
   - Basic authentication username (optional) - the user name for authentication.
   - Basic authentication password (optional) - the password for authentication.
   - Basic authentication request header name (optional) - the request header that contains the authentication string; if you supply both a request header name and user name/password, the request header authentication method is used.
   - Custom header pattern (optional) - the name pattern of the headers to use for sending additional information to the external management service.
   - Cache type - the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
   - Fail on error - if selected, processing is stopped if the connection to the external management service fails.

   Note: For details of the JSON format that is required when exchanging messages with the external management service, see JSON format to exchange messages with the external management service.
   DataPower Gateway (v5 compatible):
   - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see Token revocation.
   - TLS Client Profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

About this task

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See OAuth 2.0 Token Introspection.

One of the following roles is required to enable introspection for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Introspection in the sidebar menu.
2. Select the check box to enable Introspection. The OAuth standard path for introspection, /oauth2/introspect is automatically entered. This path will be used when another entity inspects the token contents.
3. Click Save when done.

Results

Tokens will be queried using the /oauth2/introspect path. You can use the OAuth Provider to secure the APIs in a catalog.

Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

About this task

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see OAuth external URL and authentication URL.

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see Authentication URL user registry.
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5. API Gateway only If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as `metadata`.
6. API Gateway only If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as `miscinfo`.
7. Save the OAuth Provider.
8. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the System > Manage permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see Configuring basic settings for a native OAuth provider.
You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click OpenID Connect.
2. Select Enable OIDC and then enter the following parameters as appropriate:

Field	Description
Support hybrid response types	Optional. Select the response types for the OpenID Connect hybrid flow to be supported by this OAuth provider.
Auto Generate OIDC API Assembly	Optional. Select this option to generate the full OIDC assembly. Leave this option unselected to simply enable OIDC support in the OAuth provider, and allow developers to implement their own assemblies.
ID token issuer	Descriptive text to indicate the source of the key.
ID token signing crypto object	The cryptographic object to use to sign the token.
ID token signing key	The JSON Web Key (JWK) to be used to sign the ID token.
ID token signing key identifier	The key ID used for signing the token.
ID token signing algorithm	The algorithm used to sign the token.
OpenIDConnect Discovery path	A URL that is exposed by the provider and allows a client to send a request for information about the provider's publicly visible configuration.

3. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog. You can edit the policies using the API Editor.

Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click API Editor.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag and drop editor to add additional policies to the OIDC behavior.
   Note: If you add a policy that references a TLS profile, an **`invoke`** policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For details on how to enable a TLS profile in a Catalog, see Creating and configuring Catalogs.
4. Save the edits.
5. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

About this task

One of the following roles is required to configure OAuth Providers:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

Procedure

1. In the API Manager, click Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
   a. Complete the following parameters for the first screen and click Next.

Field	Description
Title	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name	This field is auto-populated by the system and used as the internal field name.

Supported grant types	Select from the following options:
	• Implicit: An access token is returned immediately without an extra authorization code exchange step.
	• Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require User Security.
	• Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code.
	• Resource owner - Password: The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.
	• API Gateway only Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).

Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. Specify configuration settings for the endpoints, and then click Next.

Field	Description
Authorization URL	An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example: **`https://example.com/oauth2/authorize`**
Token URL	A token request URL where the client application exchanges an authorization grant for an access token. Example: **`https://example.com/oauth2/token`**

Field	Description
Introspect URL	The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example: `https://example.com/oauth2/introspect` For more information on integrating third party OAuth providers for introspection, see OAuth introspection for third-party OAuth providers.
API Gateway only Introspect cache type	The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: • No cache (default): Responses are not cached. • Protocol: Defined by the `cache-control` header in the provider response. • Time to live: Defined by the provider.
API Gateway only Cache Time to Live	The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.
TLS Profile (optional)	Select an optional TLS profile for communicating with the third party provider.
Security	Default is Basic Authentication.
Basic authentication request header name	The `x-introspect-basic-authorization-header` is available to provide a user-configured HTTP Basic authorization header.
API Gateway only Basic authentication username (optional)	The default user name for HTTP Basic authentication.
API Gateway only Basic authentication password (optional)	The default password for HTTP Basic authentication.
API Gateway only Token validation	Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: • Connected: The query is successful if the status return code is `200`. • Active (default): The query is successful if the status return code is `200` and the response JSON body includes the property `active: true`.
API Gateway only Custom header pattern (optional)	A regular expression for request headers that are to be passed to the third-party provider; for example, `x-Introspect-*`.
API Gateway only Authorization header pass through	Select this check box if you want to retain the `Authorization` header for a bearer token. The default behavior is to remove this header.

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
sample_scope_2	Scope for token
additional scopes	Scope for token

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.

OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **OAuth user scenario**
  Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- **OAuth introspection for third-party OAuth providers**
  OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.
- **OAuth external URL and authentication URL**
  You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Scope**
  Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- **Tokens**
  Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- **Authentication URL user registry**
  You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.
- **Custom forms for user security**
  You can create custom forms for the authorization and identity extraction phase of OAuth.
- **Securing an API with a JSON Web Token**
  There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated

external to IBM API Connect.

- **Troubleshooting OAuth**
  You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

- The OAuth 2.0 Framework

OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.

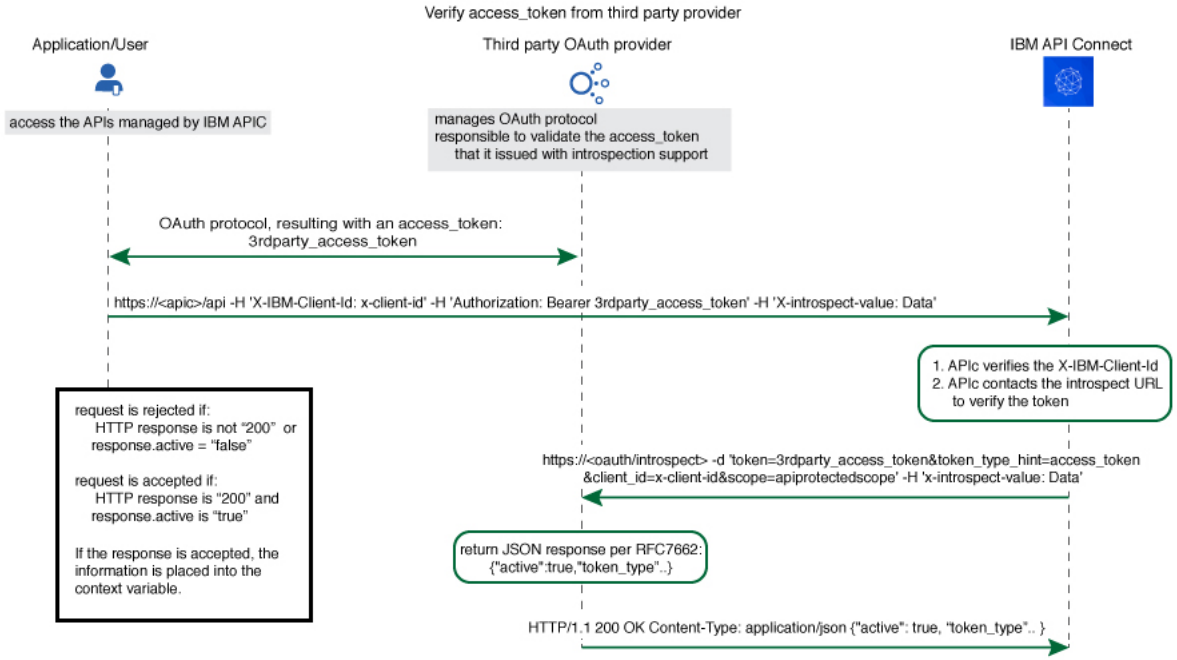
OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in RFC 7662. In addition to the specification, the **`x-Introspect-`** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.



The Introspect URL is configured in the Third Party OAuth provider configuration. See Configuring a third-party OAuth provider.

When an API is protected by a third-party OAuth provider, API Connect will extract the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as **`x-introspect-*`**.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider. The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be **`x-Introspect-`**.

API Connect will issue this POST request to the introspection endpoint specified in **`x-tokenIntrospect`**, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider will respond with `HTTP 200` indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
 Content-Type: application/json;charset=UTF-8
 Cache-Control: no-store
 Pragma: no-cache
```

```
 { "active":true,
    "token_type":"bearer",
    "client_id":"xxx-xxx",
    "username":"John Smith",
    ...
 }
```

If the value of the active claim is `false`, the token is treated as invalid.

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
```

```
{
  "active":false
}
```

A response code other than **`HTTP 200`** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see API Connect context variables.

When contacting the introspection endpoint, API Connect uses **`client_id`**/**`appId`** and **`client_secret`**/**`appSecret`** to construct the HTTP Basic authorization header.

By default, if **`x-introspect-basic-authorization-header`** exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcnR5LWNsaWVudF9pZDozcmQtcGFydHlfY2xpZW50X3NlY3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format ***`user:password`***, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and user name and password details are not supplied in the third party OAuth provider configuration, but **`client_id`** and **`client_secret`** values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider.
If either, or both, of scope and **`scope validate url`** are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect will further enforce the scope validation in the following order:

1. If **`scope`** is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If **`scope validation url`** is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see Creating an OAuth security definition.

For more information, see Scope.

DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a **`suppress-parameters`** header as follows:

  `suppress-parameters: client_id`

  `suppress-parameters: scope`

  or

  `suppress-parameters: client_id scope`

  depending on which parameters you want to suppress.
- Define an API property called **`suppress-parameters`** in the API definition itself, with one of the following string values:

  `client_id`

  `scope`

  or

  `client_id scope`

  depending on which parameters you want to suppress. For information on how to define API properties, see Setting API properties.

OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL - When you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL - When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.
  See: Authentication URL.

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

  X-API-OAUTH-METADATA-FOR-PAYLOAD

  X-API-OAUTH-METADATA-FOR-ACCESSTOKEN

  Note: These are the default header names for the DataPower API Gateway but you can override them; see Configuring metadata for a native OAuth provider.
- DataPower Gateway (v5 compatible):

  API-OAUTH-METADATA-FOR-PAYLOAD

  API-OAUTH-METADATA-FOR-ACCESSTOKEN

The response header value from **X-API-OAUTH-METADATA-FOR-PAYLOAD** or **API-OAUTH-METADATA-FOR-PAYLOAD** is placed in the response payload and indicated as **metadata**.

The response header value from **X-API-OAUTH-METADATA-FOR-ACCESSTOKEN** or **API-OAUTH-METADATA-FOR-ACCESSTOKEN** is placed within the access token and indicated as **miscinfo**.

The two metadata response headers are case insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
"token_type":  "bearer",
"access_token":  "AAEkNzhjDHYyyYy...cL0Mv6ctl37w7ZU",
"metadata":  "m:metadata-for-payload_content"
"expires_in":  3600,
"scope":  "read",
"refresh_token":  "AAEnj5SynCMybF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with **"miscinfo"** containing the metadata information.

```
{
"active":  true,

Input to the External URL

The following request headers are sent to the External URL.
Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **x-existing-metadata-for-payload** and **x-existing-metadata-for-access-token**. The Metadata URL can make use of this information to create a new set of metadata values.
The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload     payload-from-auth-url
X-existing-metadata-for-access-token     token-from-auth-url
X-URI-in     /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in     POST
X-POST-Body-in     client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP     IP_address
X-X-Global-Transaction-ID     ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **X-POST-Body-in** header is not supported.

Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **miscinfo** field can be accessed in the Assembly with the **oauth.miscinfo** context variable, as in the example.

```
apim.setvariable('message.body',apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

Refresh tokens and metadata

The Authentication URL (if configured for authentication) is invoked first, during authentication of the resource owner. The External URL is invoked as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not invoked. The metadata from the refresh token is retained and then copied into the newly generated access token.

Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with **`m:`**
- Metadata from the Authentication URL is prefixed with **`a:`**

Note: When revocation is enabled, some internal details are also stored in the **`miscinfo`** field, in brackets within the access token as shown in the following example:

`"miscinfo": "[tlsprofile@https://`*`api-revoke-url`*`:443/server/revocation-url]m:`*`metadata-for-accesstoken_content`*`"`

Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in following sections.

Characters are not allowed in metadata in certain scenarios

When you use the Authorization code grant type, or when a consent form is used for implicit grant type, there is a temporary state or code where the metadata from the authentication URL is stored. API Connect internally uses two prefixes - **`!ma`** and **`!mp`** to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - **`!ma`** and **`!mp`** should not be used as the metadata itself.

Grant types and metadata

The OAuth grant types described in the following sections include **`authorization code (access code)`**, **`implicit`**, and **`client credentials (application)`**.

Authorization code grant type

- When metadata is included from an Authentication URL for an Authorization code grant type, as it is a three legged flow, both the content and the payload are stored within the **`dp-state`** and carried on to the authorization code and to the access token. Note that around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the **`dp-state`**. In addition, if revocation is enabled, that will also be part of the token metadata. Hence the combined size of the token metadata, the payload metadata (including the 10 characters of internal data), and internal revocation details, cannot exceed 512 bytes in total.

  If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "`metadata too large`" as shown in the example.

  ```
  "metadata":"m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
  "miscinfo":"[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
  ```

  This size restriction can be overcome when the metadata is sent from the Metadata URL and not from the Authentication URL, because the metadata is not stored in **`dp-state`** or in the authorization code.

  Example of the **`authorization code (access code)`** grant type:

  ```
   $ curl -k -d
  "grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
  https://9.70.153.90/fei/sb/introspectp1/oauth2/token
  { "token_type":"bearer",
  "access_token":"AAEkOThlZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ20ZN5Tl_TqYFeIfB7BFf6HFgibEoOjWXXEA84oFsWuE4NY-
  RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_lYKm3ahrfhR5kI3sPO0uADEoseIP5-O9anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
  PHBialoRkBD5qca6kO0fV2M", "metadata":"a:[Authorization Code-Test-auth-url-payload]", "expires_in":3600,
  "scope":"scope_introspect", "refresh_token":"AAFAg1EVMbwicr_L0fTZ4q6HZ-
  RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNGl5C1GbIe3dwhXJdiWA0Go-
  dduhVtCbG26sJRRXyYrMeRxWnJsylBETPI8HQEN4a_D7fmxKcTVRZBvq86byg95qe1ZKyERi0Lhxdd_O4Nvss" }
  ```

  ```
  $ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
  "token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
  { "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746", "username":"anyuser",
  "sub":"anyuser", "exp":1484766368, "expstr":"2017-01-18T19:06:08Z", "iat":1484762768, "nbf":1484762768,

Test-auth-url-token]", "client_name":"oauth_app" }
```

Client credentials grant type
: Authentication URL will not be invoked when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL will be included as metadata.

Behavior when retrieving metadata with both an External URL and an Authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "`error on metadata url`" is written for metadata in both the payload and the access token.

If an External URL is configured and the connection is successful, but the remote server does not send any of the specified HTTP response headers, a blank value is written for metadata in both the payload and the access token.
Attention: An External URL overwrites existing values from Authentication URL. This includes blank values.
If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.
Note:

- An OAuth Provider must have at least one scope.
- An OAuth token will not be granted unless a default scope is configured at the provider, or one or more predefined scopes are included in the grant request.
- If no default scope is defined, and the request does not contain a scope, an invalid scope error is returned for the request.

OAuth provider

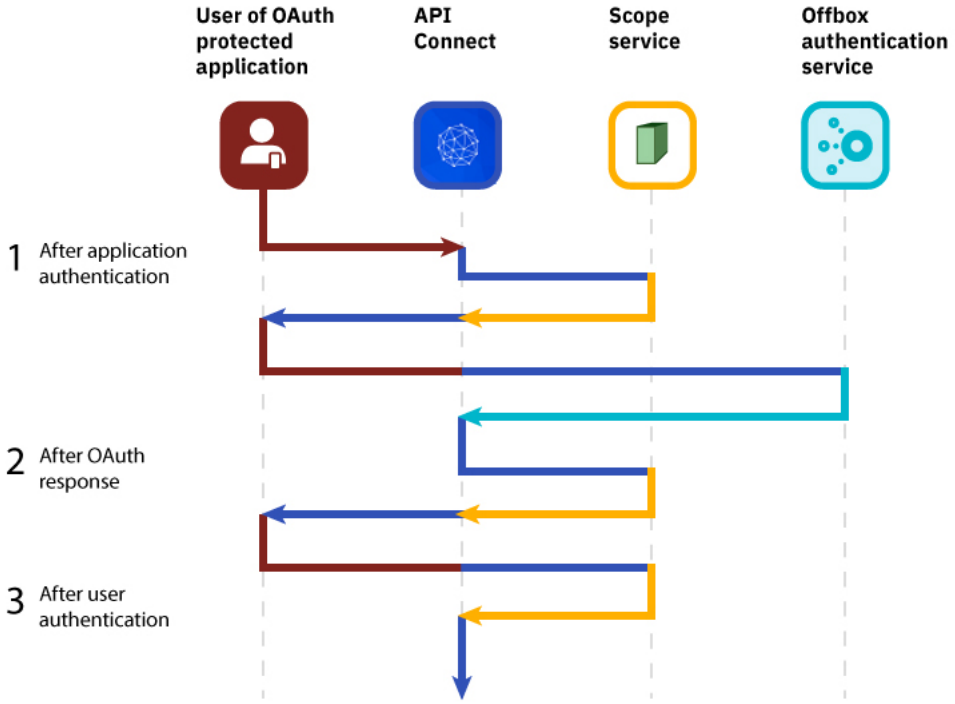
To provide more refined support for the OAuth scope handling, API Connect allows the Authentication URL user registry extension to modify the scope value.

When you define an OAuth provider, the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.

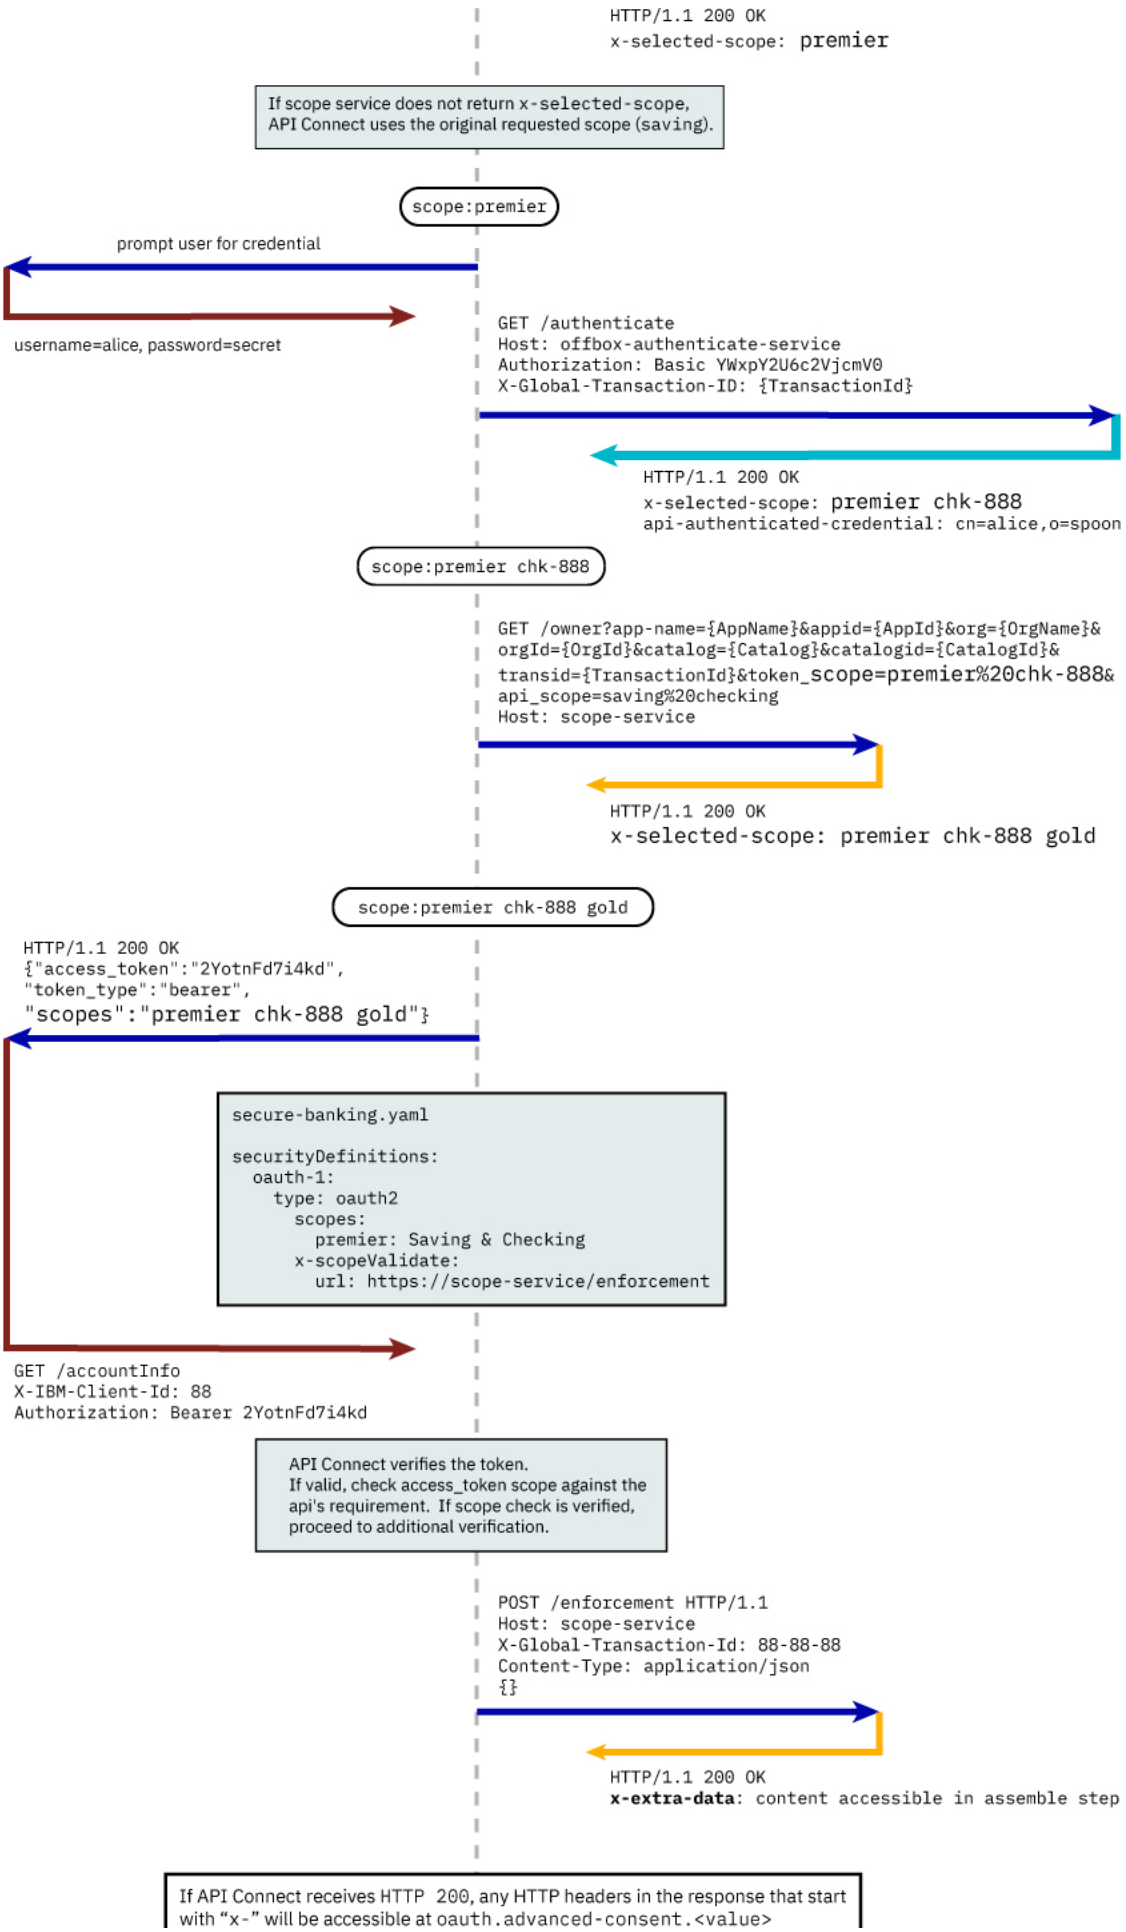
1. After the application successfully authenticates, and if OAuth Native provider > Advanced scope check > Application scope check is configured, API Connect makes a call to allow extra verification and uses the contents of **`x-selected-scope`** to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.
2. If OAuth Native provider > User Security > Authentication is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in Authentication URL user registry. When the response code is `HTTP 200`, and the response header **`x-selected-scope`** is present, the value that is configured in **`x-selected-scope`** is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, **`x-selected-scope`** is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider > Advanced scope check > Owner scope check is enabled and configured with a valid URL, API Connect makes a call to allow the content of **`x-selected-scope`** to refine the scope value. When Owner scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.

Figure 1. OAuth advanced scope overview



The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. Figure 2 shows a more detailed view of the transaction flow with examples that show when **`x-selected-scope`** provides a new scope value.

Figure 2. OAuth advanced scope detail



HTTP/1.1 200 OK
x-selected-scope: premier
If scope service does not return x-selected-scope, API Connect uses the original requested scope (saving).
scope:premier
prompt user for credential
username=alice, password=secret
GET /authenticate
Host: offbox-authenticate-service
Authorization: Basic YWxpY2U6c2VjcmV0
X-Global-Transaction-ID: {TransactionId}
HTTP/1.1 200 OK
x-selected-scope: premier chk-888
api-authenticated-credential: cn=alice,o=spoon
scope:premier chk-888
GET /owner?app-name={AppName}&appid={AppId}&org={OrgName}&
orgId={OrgId}&catalog={Catalog}&catalogid={CatalogId}&
transid={TransactionId}&token_scope=premier%20chk-888&
api_scope=saving%20checking
Host: scope-service
HTTP/1.1 200 OK
x-selected-scope: premier chk-888 gold
scope:premier chk-888 gold
HTTP/1.1 200 OK
{"access_token":"2YotnFd7i4kd",
"token_type":"bearer",
"scopes":"premier chk-888 gold"}
secure-banking.yaml
securityDefinitions:
oauth-1:
type: oauth2
scopes:
premier: Saving & Checking
x-scopeValidate:
url: https://scope-service/enforcement
GET /accountInfo
X-IBM-Client-Id: 88
Authorization: Bearer 2YotnFd7i4kd
API Connect verifies the token.
If valid, check access_token scope against the api's requirement. If scope check is verified, proceed to additional verification.
POST /enforcement HTTP/1.1
Host: scope-service
X-Global-Transaction-Id: 88-88-88
Content-Type: application/json
{}
HTTP/1.1 200 OK
x-extra-data: content accessible in assemble step
If API Connect receives HTTP 200, any HTTP headers in the response that start with "x-" will be accessible at oauth.advanced-consent.<value>

For the above example, `x-extra-data` is accessible at `oauth.advanced-consent.x-extra-data`.
If other than `HTTP 200` is returned, it has the same effect as if the access token does not contain neccesary permissions to access the resource.

Consumer API enforcement

Standard scope validation
To access the API /getaccount the application must send a **GET** request with an access token that contains the scope, or scopes, defined in the OAuth provider. If the request doesn't contain a scope, you must specify a default scope to use. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file secure-banking.yaml defines the scope, or scopes, that must exist in the token to be granted access to the API /getaccount.

```
secure-banking.yaml

securityDefinitions:
   scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
security:
  - scope-only:
      - checking
  - scope-only:
      - saving
      - mutual
```

In the examples, the access token **AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ** is able to access the API because it contains one, or a combination of **scope-only** that is defined in secure-banking.yaml such as:

- **checking**
- **saving mutual**
- **checking saving mutual**

Advanced Scope Check
Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes **x-scopeValidate** as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
    x-scopeValidate:
      url: 'https://advanced-scope-check.bk.com/validate-scope'
      tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an **HTTP POST** request to the **x-scopeValidate** endpoint similar to the following example. Response code `HTTP 200` from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
     POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
     Host: advanced-scope-check.bk.com
     Content-Type: application/json

   {"context-root" : checking,
    "resource" : accountinfo,
    "method" : GET,
    "api-scope-required" : [jointaccount],
    "access_token" : {"client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
                      "not_after" : 174364070,
                      "not_after_text" : "2017-07-11T02:27:50Z",
                      "not_before" : 174360470,
                      "not_before_text" : "2017-07-11T01:27:50Z",
                      "grant_type" : "code",
                      "consented_on" : 1499736470,
                      "consented_on_text" : "2059-07-11T01:27:50Z",
                      "resource_owner" : "cn=spoon,email=spoon@poon.com",
                      "scope" : "jointaccount mutual",
                      "miscinfo" : "[r:gateway]"
                     }
}
```

An example of successful response follows.

```
HTTP/1.1 200 OK
Cache-Control: no-store
Pragma: no-cache
X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "**x-**" is kept as the context variable **oauth.advanced-consent**. Based on the example successful response, **X-Custom-For-Assemble-Process: audit** becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options
You can optionally use additional fields for validation:

Request Header
: Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable
: Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format **oauth.advanced-consent.***.

Related information

- IETF RFC 6749

Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- **Refresh tokens**
  If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- **Token revocation**
  In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- **Authenticating and authorizing through a redirect URL**
  You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- **Token management with the DataPower Gateway (v5 compatible)**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- **Token management with the DataPower API Gateway**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the expires_in property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYy1hbGxlhdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens > Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see Configuring a native OAuth provider.

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management > Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted.

The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml

<?xmlversion="1.0" encoding="UTF-8"?>
<token>
   <token_type>bearer</token_type>
   <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
   <expires_in>3600</expires_in>
   <scope>3600</scope>
   <resource-owner>alice</resource-owner>
   <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

Provide token information on revocation request

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET  <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET  <revocationURL>GET  HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
```

```
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a `200 OK` response to the Gateway.

Revoking tokens issued to Alice up to and including a specific date

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Revoking all tokens issued up to and including a specific date

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
<oauth-revocation>
```

Putting it all together

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
HTTP/1.1 200 OK
Content-Type: application/xml
Cache-Control: public, max-age=120
Date: Fri, 08 May 2015 21:49:03 GMT

<?xml version-"1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The `before` attribute uses the `xs:dateTime` syntax.

Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

Before you begin

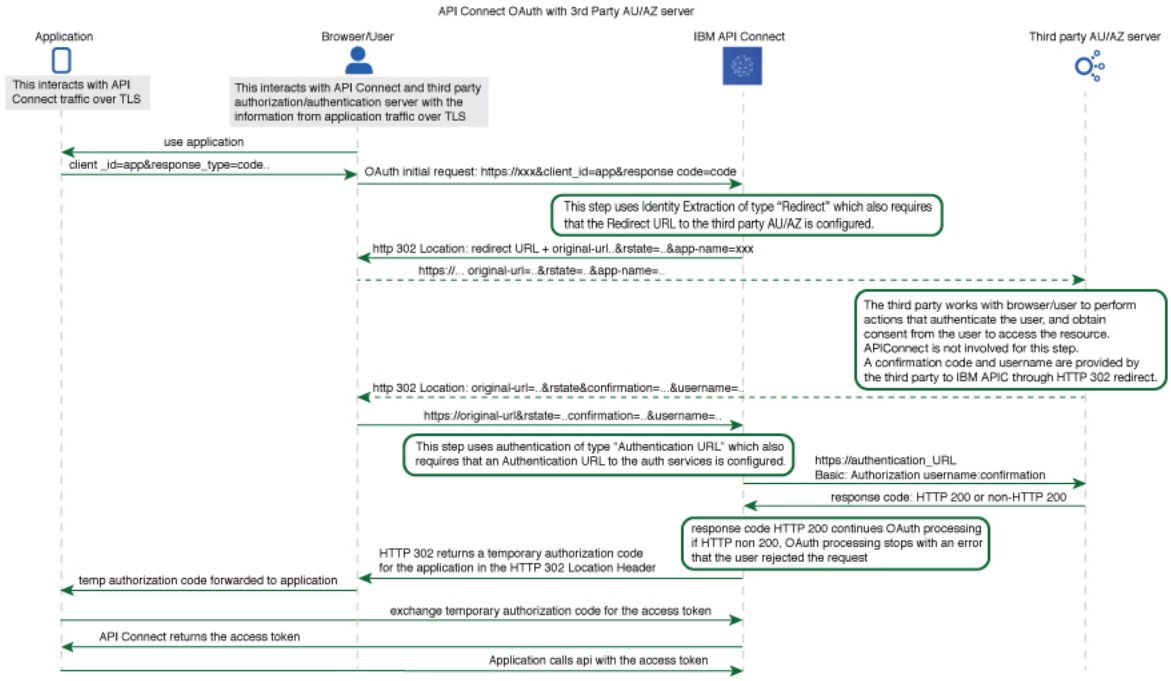
To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see Creating an OAuth security definition.

About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow



1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an **`HTTP 302`** redirect based on **`identity extraction -> redirect -> redirect-url`**, for user authentication (and optional authorization).
2. The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an **`HTTP 302`** redirect that uses the **`original-url`** from the request, with the username and confirmation code appended.
3. API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on **`authentication -> x-ibm-authentication-url`**, to confirm user identity before the request is completed.
4. An **`HTTP 200`** response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the **`grants`** type.
   - **`- accessCode`** returns a temporary code to the application.
   - **`- implicit`** returns the access token to the application.

   For any response other than HTTP 200, the request fails with a statement added to the error log.

Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

1. Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
   a. To include elements in your form that are provided by API Connect, use the following query parameters from the URL that your user is redirected to.
   Note: With the exception of **`original-url`**, none of these parameters are included in the URL automatically; you must add them as required.

   app-name
   : The name of the application requesting access, as provided through the Developer Portal.

   appid
   : The id of the application requesting access.

   catalog
   : The name of the catalog where the product is being used by the application.

   catalogid
   : The id of the catalog where the product is being used by the application.

   catalogtitle
   : User-friendly display name for the catalog.

   org
   : The name of the consumer organization that hosts the application.

   orgid
   : The id of the consumer organization that hosts the application.

   orgtitle
   : User-friendly display name for the organization.

   original-url

The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the state_nonce is appended. The state_nonce is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the **`state_nonce`** should remain unchanged.

provider
: The name of the API provider organization.

providerid
: The id of the API provider organization.

providertitle
: User-friendly display name for the provider organization.

requested-scope
: [optional] If Application Scope check is enabled and replaces the **`scope`** from the initial application request, this field holds the **`scope`** value from the initial application request, and the new replacement scope value is put into **`original-url`**.

transid
: transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

```
Redirect_URL?original-url=Original_URL&state_nonce=R_State&app-name=Application_Name
```

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

b. Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the *Original_URL* and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect.
Original URL requires the following form:

```
Original_URL&username=User_Name&confirmation=Confirmation_Code
```

where all variables are as described previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=spoon&confirmation=12345678
```

c. To send your own error responses after the authentication and authorization service, redirect the user to the *Original_URL* and append an error code. You can also append a user name. Use the following form:

```
Original_URL&username=User_Name&error=Error_Response
```

where *Error_Response* is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as `200 OK` if you want to allow access, or non-`200 HTTP` response code, such as `401 Unauthorized` to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2.
For more information on configuring an OAuth Provider, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See Quota enforcement.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:
If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.
- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure

DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see Configuring the quota enforcement server.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request

```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client_id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com
```

```
x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Note: The steps described in this topic are required if you are using the DataPower® OVA or appliance version of the gateway. For the API Connect supplied Kubernetes deployment, the API Security Token Manager is preconfigured provided that, in the gateway service custom resource file, v5 compatibility mode is disabled and the token management service is enabled:

```
      .
      .
      .
spec:
      .
      .
      .
  apicGatewayServiceV5CompatibilityMode: false
  tokenManagementService:
    enabled: true
```

```
.
.
.
```

For more information, see Installing the DataPower Gateway subsystem.
Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

In order to manage tokens with the DataPower API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Note: This setting is also required when you use a third-party OAuth provider and **`Introspect cache type`** is set to **`protocol`** or **`Time to live`**.
For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.
6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see Defining the API security token manager and Creating a gateway peering instance.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user **`cn=spoon,o=ibm`** with username **`spoon`** and password **`spoon`** using a registered administration application of **`5287fe53-8747-438a-8262-681ec75b79c5`**.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

} => delete second item

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client_id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **`cn=spoon,o=eatery`**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **`access_token`**.
- Overriding the **`scope`** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the **`scope`** value that the application receives. For example, you can provide a specific resource owner an account number within the **`scope`** header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use **`cn=spoon,o=eatery`** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.

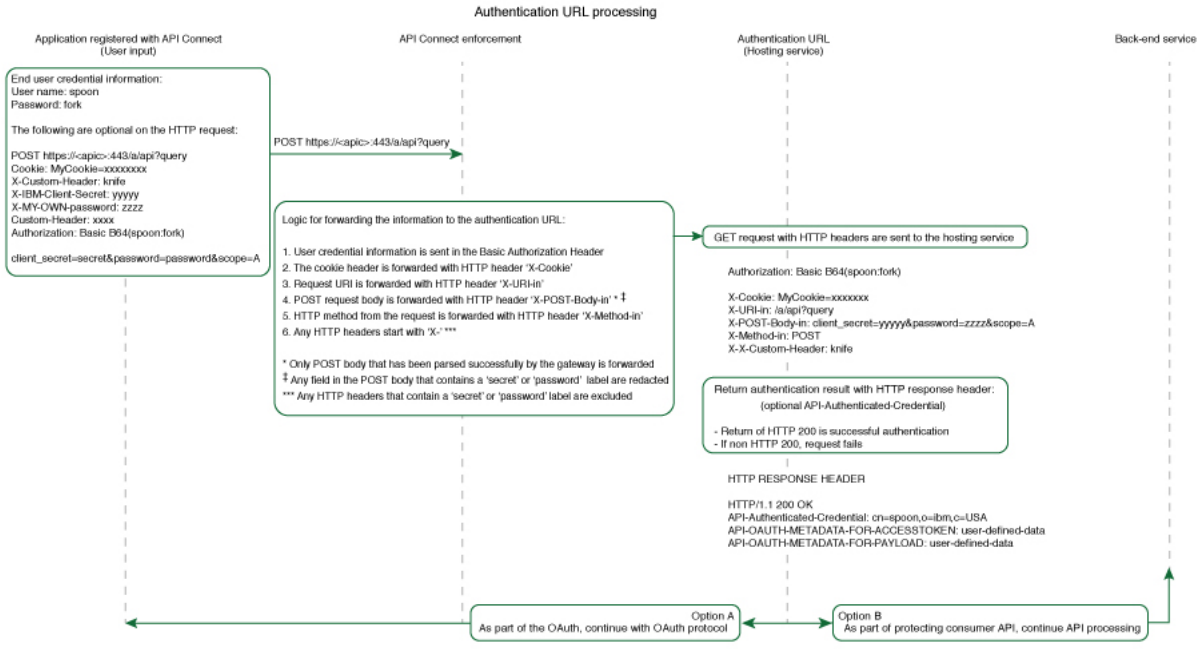
API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested **`scope`** from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```



If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

About this task

The Native OAuth provider configuration provides the capability for requiring additional authentication and authorization steps for user security. Custom HTML forms may be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- **Creating a custom HTML login form for user security**
  Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- **Creating a custom HTML authorization form for user security**
  Custom HTML forms can be created for user security during the authorization stage in OAuth.

Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. For more information, see Configuring a native OAuth provider. This topic describes how to create the Custom HTML form for identity extraction.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. Create a well formed XHTML document that will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.
   For example:

   ```
   <button
   id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.apionprem.doc_oauth_custom_login_form_2_login
   _button" type="submit" name="login" value="true">Log in</button>
   ```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing Steps 1 through to 8 results in a form similar to the following example:

    ```
    <html lang="en" xml:lang="en">
      <head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>
      <body>
        <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
          <h1>Please sign in</h1>
          <p>Username </p>
          <p ><input type="text" name="username" required="required" /> </p>
          <p>Password </p>
          <p ><input type="password" name="password" required="required" /> </p>
          <EI-INJECT-HIDDEN-INPUT-FIELDS/>
          <p > <button
    id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.apionprem.doc_oauth_custom_login_form_2_login
    _button" type="submit" name="login" value="true">Log in</button> </p>

          <EI-LOGINFIRSTTIME>
            <p>If you have forgotten your user name or password, contact your system administrator.</p>
    ```

```
      </EI-LOGINFIRSTTIME>

      <EI-LOGINFAILED>
        <p >At least one of your entries does not match our records.
          If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFAILED>

      <EI-INTERNAL-CUSTOM-FORM-ERROR/>

    </form>
  </body>
</html>
```

11. Make your form available at a URL of your choice.
12. If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to authorize application users and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. This topic describes how to create the Custom HTML form for authorization.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form through which they grant permission to an application to access their data through the API on their behalf. You can present a custom form or a default form. Your custom form must fulfill certain requirements.
Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

1. Create a well-formed XHTML document. This will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Add the line `<AZ-INJECT-HIDDEN-INPUT-FIELDS/>`. This line is a placeholder that API Connect will replace with input fields necessary for the completion of the OAuth process.
4. Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

   ```
   <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
   <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
   ```

5. Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<AZ-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
6. Optional: You can add to the form HTML elements that will load features from external sources, such as images or JavaScript.
   For example, `<script src="http://www.example.com/example.js" />`
7. Insert spacing and additional elements as you require. Completing Steps 1 through to 6 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><title>Request for permission</title></head>
  <body class="customconsent">
    <div>
      <div>
        <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
          <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
          <p>Greeting..</p><DISPLAY-RESOURCE-OWNER/>
          <p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
          <div>
            <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
            <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
```

```
          </div>
        </form>
      </div>
      <AZ-INTERNAL-CUSTOM-FORM-ERROR/>
    </div>
  </body>
</html>
```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a Custom HTML Form for authorization for User Security. Provide the URL as the endpoint at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM® API Connect.

About this task

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the **jwt-generate** command, and then augment the response payload with your generated token replacing the `id` token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

Procedure

Create a **jwt-generate** policy in the assembly.

a. In API Manager, open the Assembly tab.
b. Add a jwt-generate policy to the assembly for the API.

Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

You can use the following links to go to the topics:

- OAuth 2.0 support in the developer portal test tool
- OAuth requires quorum in a multi-node cluster

OAuth 2.0 support in the developer portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see Testing an API using the Developer Portal test tool.

OAuth requires quorum in a multi-node cluster

In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

API Analytics

You can use API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.

API analytics is built on the OpenSearch open source real-time distributed search and analytics engine.

The content of the API event data depends on the logging policy that is set for the operation. For more information about the fields that are displayed in an API event record, see API event record field reference. For information about how to configure your logging preferences for API events, see activity-log policy and Including elements in your assembly.

To monitor your API usage with API Connect analytics, see Analytics: understand your API usage.

- **Catalogs, spaces, and analytics**
  Understand how syndication and the use of catalogs and spaces affects the use of the features in API Connect analytics.

- **Accessing analytics**
  Analytics data is displayed in dashboards in the API Manager UI. Dashboards are scoped at the provider organization, catalog, and space level. To access analytics data at the cloud scope, use the Cloud Manager UI. Analytics data is also accessible by using the Toolkit CLI and REST API.
- **Analytics dashboards**
  IBM API Connect analytics provides dashboards for viewing your analytics data.

Catalogs, spaces, and analytics

Understand how syndication and the use of catalogs and spaces affects the use of the features in API Connect analytics.

The data for analytics is collated from API events that are logged when API operations are invoked. Analytics data for an API is scoped to the catalog or space where that API resides, and is only included in search results (and thus, visualizations and dashboards) for the owning catalog or space.

Access to the analytics data, and to the analytics functions in the API Manager user interface, can be managed through the use of catalogs and spaces, and the roles and permissions that are assigned to the users (or *members*) of the provider organization.

The cloud admin user can view aggregated analytics data for all catalogs, spaces, in all provider organizations, in the admin UI.

Catalogs, spaces, and permissions

Catalogs act as deployment targets through which APIs (in their containing plans and products) are staged and published to consumer organizations. API Manager users in the provider organization can be assigned the following access to the analytics component for a catalog:

- A role that has the Analytics > View permission for a catalog: These users can view the analytics data generated for the APIs in the catalog within *dashboards*, export dashboard data in its raw format or as event records, and apply filters to the data shown within the dashboards.
- A role that has the Analytics > Manage permission for a catalog: This is a legacy permission and has the same permissions as the View permission.

The IBM® API Connect syndication feature provides a way for you to partition a catalog into multiple deployment targets (or *spaces*) through which separate groupings of APIs (in their containing plans and products) can be staged and published. Each space can be allocated to a separate group of users who need to manage their products independently, and the analytics data in each space is scoped to those products only. API Manager users in the provider organization can be assigned the following access to the analytics component for a space:

- A role that has the Analytics > View permission for a space: These users can view the analytics data generated for the APIs in the space within dashboards, export dashboard data in its raw format, and apply filters to the data shown within the dashboards.
- A role that has the Analytics > Manage permission for a catalog: This is a legacy permission and has the same permissions as the View permission.

For more information about assigning catalog or space permissions to a role, see Managing Catalog membership and Managing Space membership.

For more information about the default API Manager roles and permissions, see API Connect user roles.

Accessing analytics

Analytics data is displayed in dashboards in the API Manager UI. Dashboards are scoped at the provider organization, catalog, and space level. To access analytics data at the cloud scope, use the Cloud Manager UI. Analytics data is also accessible by using the Toolkit CLI and REST API.

The ability to access analytics data at a catalog or space level depends on your assigned roles and permissions. For more information about catalogs and spaces, see Working with Catalogs and Using syndication in API Connect.

To access analytics data from the API Manager UI, select the Analytics tab when viewing a catalog. For more information about the analytics data viewable from the API Manager UI, see Accessing analytics from the API Manager UI.
Restriction: If the visualizations in your dashboards are empty or display no recent data, a possible reason might be that access to analytics data within API Connect is deactivated. Contact your administrator for confirmation.
To export your analytics data, see Export your analytics data.

To use the toolkit CLI or REST API to access your analytics data, see:

- Analytics CLI.
- Analytics REST API.

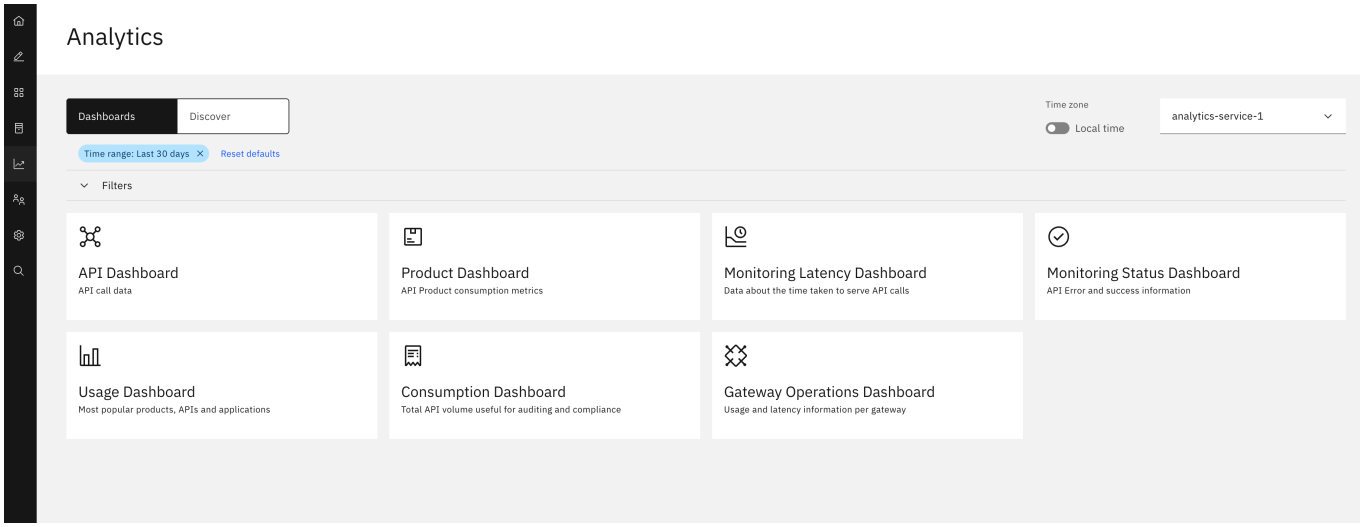
Analytics dashboards

IBM® API Connect analytics provides dashboards for viewing your analytics data.

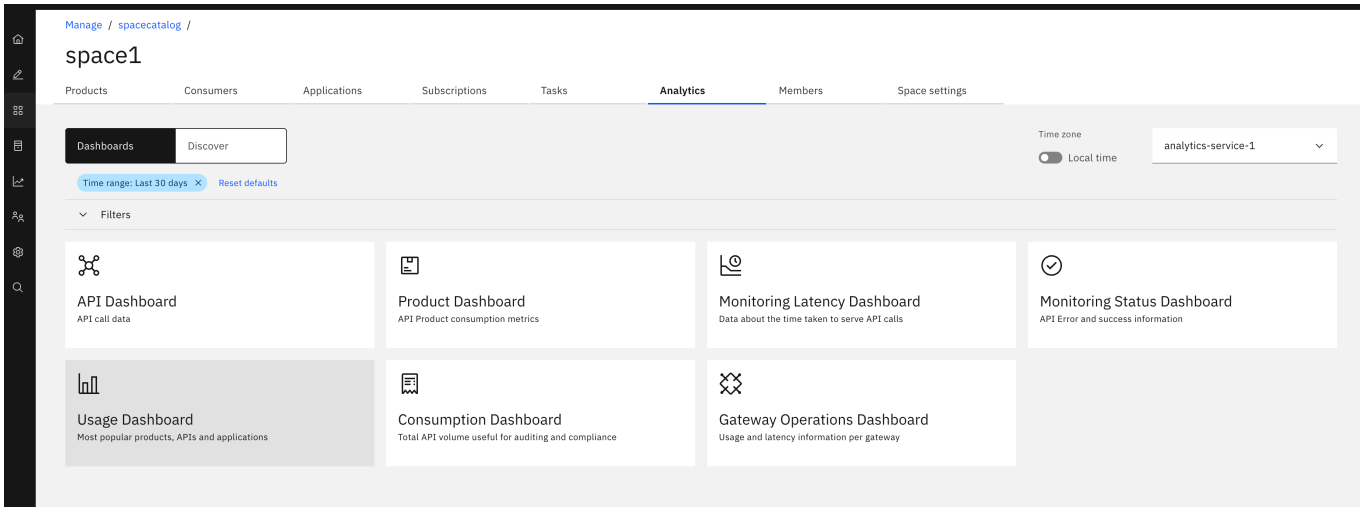
Analytics dashboards

The analytics dashboards in the API Manager UI show the API event data at the scopes of provider organization, catalog, and space. The scope of the analytics data shown depends on how you access the analytics dashboards, see: Accessing analytics.

The provider organization scoped dashboards are accessed from the settings icon in the navigation pane:



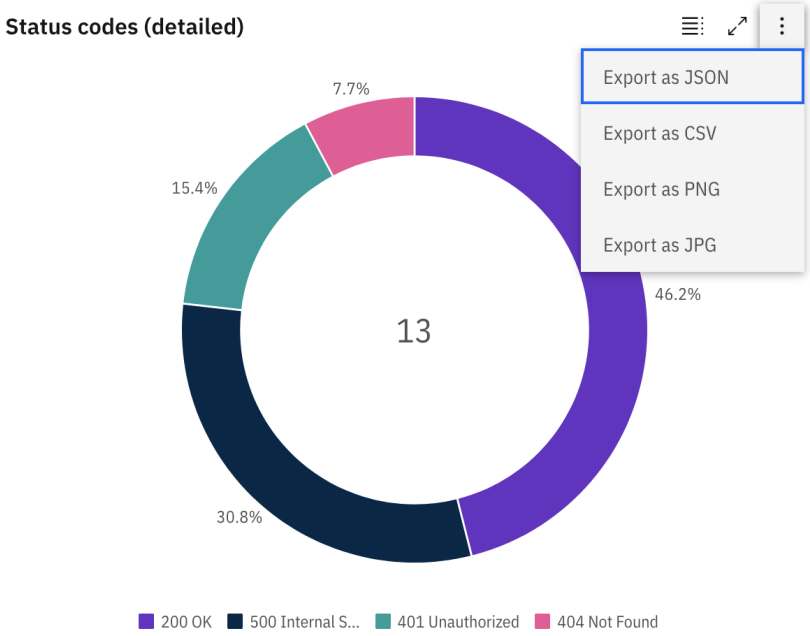
The space scoped dashboards are accessed from the Analytics tab when viewing the space:



Seven dashboards are available:

- API Dashboard- contains charts that summarize total API calls, response codes, and response times.
- Product Dashboard - contains charts that show total API calls and application subscriptions per plan.
- Monitoring Latency Dashboard - contains charts that provide response time statistics and data usage.
- Monitoring Status Dashboard - contains charts that show the response codes and success/failure rates of API calls.
- Usage Dashboard - contains charts that show the top five APIs, products, and apps.
- Consumption Dashboard - contains charts that show total API consumption in your cloud.
- Gateway Operations Dashboard - contains charts that show API usage and latency by gateway.

Each chart in the dashboards can be exported as a PNG or JPG image. The source data for each chart can be exported as a JSON or CSV file. To export a chart, click

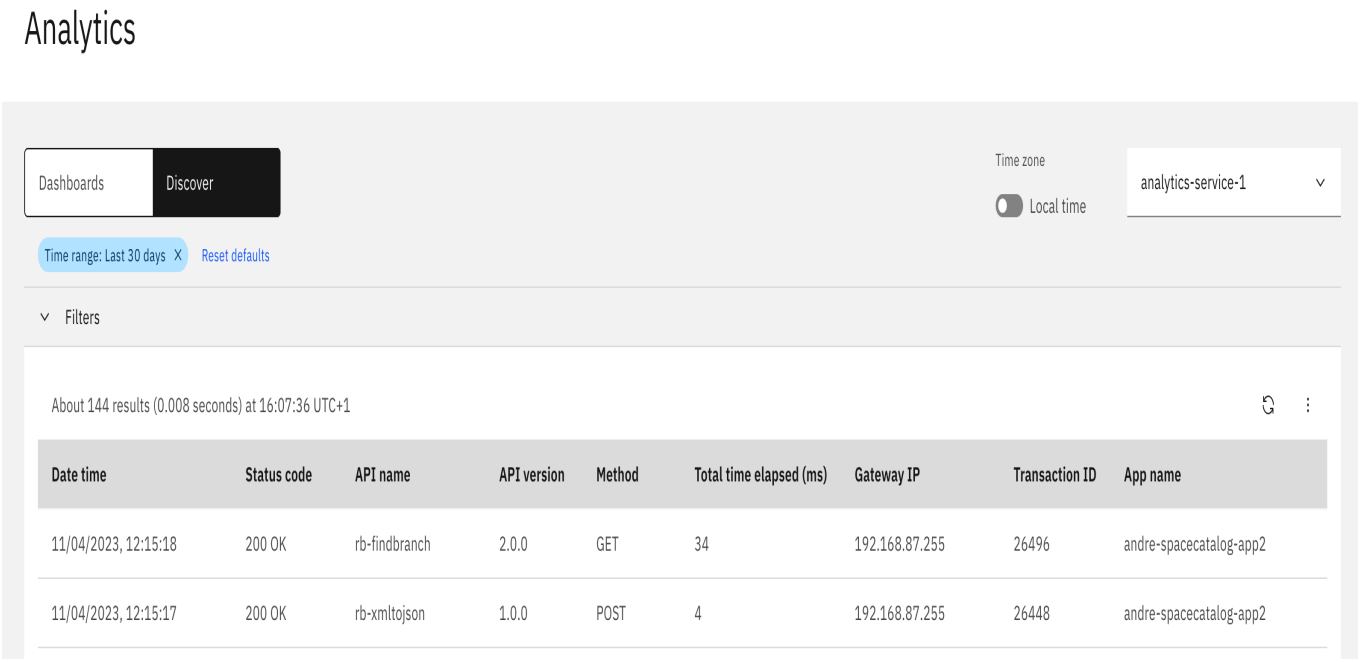


Actions at the upper right:

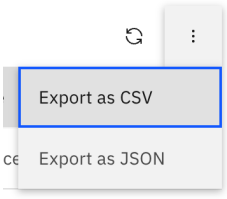
It is also possible to enlarge the chart to full-screen by clicking . To see the source data in tabular form click .

Discover view

By default the Dashboards tab is displayed. To view your API event data in tabular form, select Discover:



The maximum number of API events that can be accessed from the UI is 10,000. The maximum number of event records that can be displayed per page on the Discover view is 200.

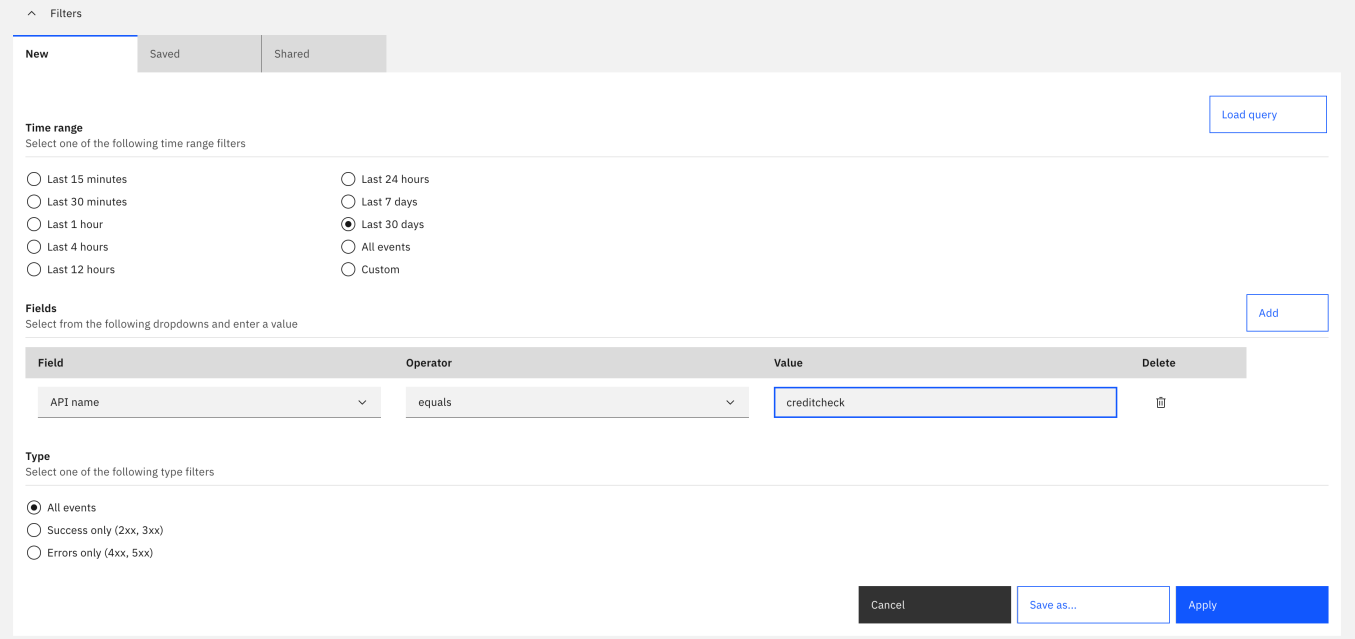


You can export the API event data from this view by clicking Actions at the upper right:

Note: When you export from the Discover view, only the data displayed on the current page of results is exported. If you want to export the data from all pages, you must export separately from each page.

Filtering displayed data

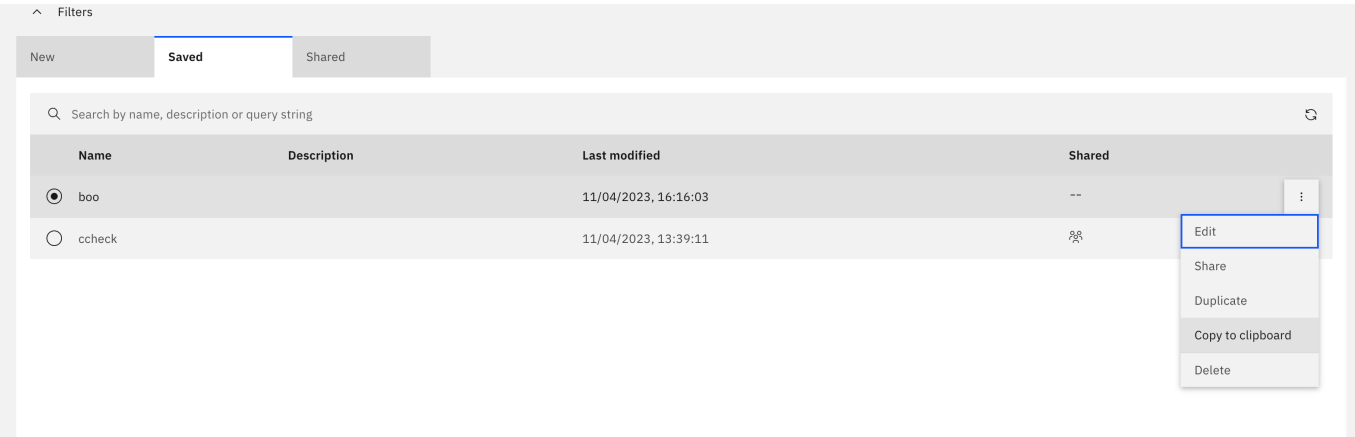
You can filter the data that is displayed in the Dashboards and Discover view by defining queries. Expand the Filters section to view, define, and apply analytics queries to your displayed data:



You can save and share the queries that you define:

- Shared queries are visible to all users at the same scope. They are not visible to users in a different scope. For example, a query that is shared by a Cloud Manager UI user is not visible to an API Manager UI user. Within the API Manager UI, a query that is created at catalog scope is not visible to users viewing analytics data at provider organization scope.
- Other users cannot edit or delete queries that you share, but they can create a duplicate query, which they can edit and share.
- All queries have a name and an optional description. The name does not need to be unique.

Saved queries can be exported as strings for use in REST API and toolkit CLI queries, for example:



copies the following string to the clipboard:

```
api_name=equals:boo&timeframe=last30days
```

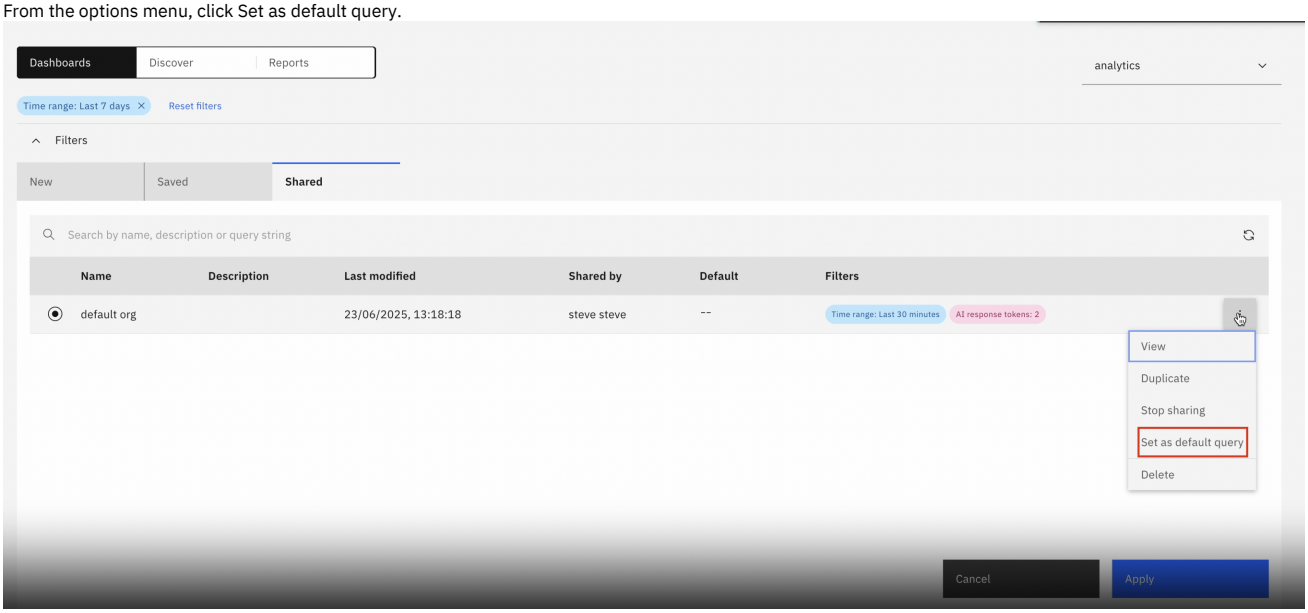
Set a default query in analytics

You can now set a default query that is automatically applied when you visit the Dashboard or Discover pages in Analytics. The default query is configured per user and per scope (organization, catalog, or space).
Note:

- Only shared queries can be set as default queries.
- Each scope can have one default query per user. A different default query can be set for each catalog and space.

1. Ensure that the query you want to set as default is saved.
2. To share the saved query, complete the following steps.
   - Click Saved tab.
   - From the options menu, click Share.
   - In Share query window, click Share.
3. Click Shared tab.

4. From the options menu, click Set as default query.



5. In Default query window, click Default.
6. To apply the default query immediately. Click Apply. The default query is applied immediately for all users in that scope. If you do not click Apply after setting the default query, it is automatically applied the next time you visit the Dashboard or Discover tabs.

Configuring governance in the API Manager

How to add custom governance rulesets to your API development process, to validate and enforce organizational governance policies and best practices in your provider organization.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. See Enabling governance on Kubernetes, and Enabling governance on VMware for more information. If governance is enabled in your deployment, the Governance icon is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

One of the following roles is required to be able to configure governance:

- Organization Administrator
- Owner
- Custom role with the **`Settings: Manage`** permission.

About this task

The governance service is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices in your API development process. You configure governance by creating one or more custom rulesets that contain a collection of rules that can then be used to check Swagger, OpenAPI, and AsyncAPI documents, as well as product documents. You can also run validation scans on your catalogs and spaces; for more information, see Scanning your catalogs and spaces.

The governance service contains the following types of rulesets:

API

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
- Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. Note that the Spectral ruleset names are prefixed with spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
- Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Tags can be added to API rulesets that, when matched with the same tag in an API, help ensure that the appropriate rulesets are preselected for your validation scans. In this way, the governance process can be run more quickly and effectively. These preselected rulesets can be deselected from the scan if required.

Note:

- Governance in API Connect supports the creation of custom rulesets that contain rules that use only the built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions. The use of custom functions, for example rules that use functions that you created yourself in JavaScript files, is not supported. Also note that the following Spectral OpenAPI rules aren't supported as they might identify false positives:
  - `oas2-unused-definition`
  - `oas3-unused-component`
- Some of the Spectral rules within the Global rulesets contain the property `recommended: false`, which means that those rules are ignored during validation. However, if you create a new ruleset from one of these rulesets by using the Save as new ruleset option, the `recommended` property isn't transferred to the new ruleset. Therefore, all the rules are used in the validation, unless you delete those rules from the ruleset. The Spectral ruleset names are prefixed with spectral-.
- Dereferencing, which means not introspecting a referenced definition within an API, is not supported in the governance service. Instead, a referenced object can be explicitly validated by using custom rules.
- You can also configure governance rulesets in the Cloud Manager. For more information, see Configuring governance in the Cloud Manager.

The following methods can be used to configure both API and product rulesets:

- Create a new ruleset by using the UI
- Import a ruleset
- Create a ruleset by using the CLI

Procedure

- To create a new API or product ruleset by using the API Manager or API Designer UI, complete the following steps.

1. In the side menu bar, click Governance.
   The Governance page is displayed.
2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
   The manage rulesets page is displayed.
3. In the Provider organization rulesets section, click Add > Create from scratch.
   The Create provider organization ruleset wizard opens.
4. Provide the following Ruleset info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the ruleset. This name is displayed in the list of global rulesets.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Version	Yes	The version number defaults to 1.0.0, but can be edited. You can have rulesets with the same name, but with different version numbers. The version number must be in the format `major.minor.patch`.	String
Description	No	An optional description of the ruleset.	String

5. Optional: For API rulesets, you can add one or more tags to your ruleset by clicking Add, and completing the tag Name and Description.
   Adding matching tags to your rulesets and APIs, means that validation scans can preselect which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags to APIs, see Adding tags to an API.
6. Click Next, and then add an initial rule to your ruleset.
7. Provide the following Rule info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the rule.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Description	Yes	A description of the rule.	String
Message	No	Provide a message to help users understand what the goal of the rule is. If no message is provided, the value of the Description property is used for the message output of the validation scan.	String
Severity	Yes	Select a severity level from the following options: • error • warn • info • hint • off error is selected by default.	String

8. In the Given section, specify one or more values for the parts of the API or product document to target. To add more values, click Add. Values must be written in JSONPath.
9. In the Then section, specify the function type and options that will be used to evaluate the target values in the API or product document. Write this section in YAML syntax.
   In the following API rule example, for a Given value of `$` (which means root level of the document), the Then section uses the Spectral core `truthy` function to check that the `info.contact` property value is not `false`, `""`, `0`, `null`, or `undefined`.

   ```
   - field: info.contact
     function: truthy
   ```

   The Then section can also contain a list of functions to be applied to the Given part of the document. In the following API rule example, for a Given value of `$.info.version` (which refers to the `version` property inside the `info` property at the root level of the document), the Then section uses both the `truthy` function, and the Spectral core `pattern` function that checks that the `info.value` matches the regex expression that is given by `functionOptions.match`.

   ```
   - function: truthy
   - function: pattern
     functionOptions:
       match: "^[0-9]+.[0-9]+.[0-9]+(-[a-z0-9+.-]+)?"
   ```

   For a complete list of the Spectral core functions that you can use in your custom API rules, along with examples of these functions, see https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
10. Click Create to create your draft ruleset.

Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon . To return to the design form view, click the Form icon .

11. You now have the following options:
    - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon alongside Rules in the navigation pane. Remember to click Save when you finish editing.
    - If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the API governance overview page.

- To import an existing API or product ruleset, complete the following steps. Remember that the rules in your imported ruleset can contain only built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
  1. In the side menu bar, click Governance.
     The Governance page is displayed.
  2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
     The manage rulesets page is displayed.
  3. In the Provider organization rulesets section, click Add > Import.
     The Import ruleset wizard opens.
  4. Drag a file into the Upload file box, or click in the Upload file box to select a file to upload. The maximum file size is 100 kb, and the supported file types are YAML, YML, and JSON.
  5. Click Next.
  6. Edit the Ruleset info details as required, and click Import.
     Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon . To return to the design form view, click the Form icon .
  7. You now have the following options:
     - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon alongside Rules in the navigation pane. Remember to click Save when you finish editing.
     - If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the API governance overview page.
- To create an API or product ruleset by using the toolkit CLI, complete the following steps.
  1. Create a JSON file that contains the new ruleset.
     The following JSON shows the contents of an example API document Spectral ruleset file:

```
{
    "name": "short-draft-ootb",
    "title": "short-draft-ootb",
    "description": "short ruleset",
    "ruleset_type": "custom",
    "tags": [
      {
        "name": "general",
        "description": "general work"
      }
    ]
    "rules": [
      {
        "name": "sec-array-boundaries-2",
        "description": "Array size should be limited to mitigate resource exhaustion attacks.\nThis can be done using
`maxItems` and `minItems`, like in the example\nbelow.\n\n```\nLimited:\n  type: array\n  maxItems: 10\n  items:\n
type: string\n    format: date\n```\n\nYou should ensure that the schema referenced in  `items` is constrained
too.\n\nIf you delegate input validation to a library or framework,\nbe sure to test it thoroughly and ensure that it
verifies `maxItems`.",
        "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
        "formats": [
          "oas3"
        ],
        "severity": "warn",
        "recommended": true,
        "given": [
          "$..[?(@.type==\"array\")]"
        ],
        "then": [
          {
            "field": "maxItems",
            "function": "defined"
          }
        ]
      }
    ]
  }
```

     The following JSON shows the contents of an example product document ruleset file:

```
{
  "type": "ruleset",
  "ruleset_type": "custom",
  "api_version": "2.0.0",
  "id": "dbb5f400-e707-412e-b081-ac36f5afbbb9",
  "name": "test-product",
  "title": "Test Product",
  "description": "",
  "ruleset_version": "1.0.0",
  "ruleset_state": "draft",
  "ruleset_format_type": "2",
  "rule_urls": [
    "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b"
  ],
  "created_at": "2024-05-22T17:19:02.820Z",
  "updated_at": "2024-05-22T17:24:59.000Z",
  "url": "https://my.manager.com/governance/orgs/myorg/rulesets/dbb5f400-e707-412e-b081-ac36f5afbbb9",
```

```
  "rules": [
    {
      "api_version": "2.0.0",
      "id": "ca6ef7d9-a503-498e-8f53-4e3aa35d086b",
      "name": "subscribe",
      "version": "1.0.0",
      "title": "subscribe",
      "description": "subscribe enabled",
      "message": "subscribe not enabled",
      "given": [
        "$.visibility.subscribe.enabled"
      ],
      "severity": "error",
      "created_at": "2024-05-22T17:19:02.000Z",
      "updated_at": "2024-05-22T17:24:59.000Z",
      "url": "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b",
      "then": [
        {
          "function": "pattern",
          "functionOptions": {
            "notMatch": "/true"
          }
        }
      ]
    }
  ]
}
```

2. Log in to the toolkit as the owner or admin of the provider organization that owns the new ruleset.
   For example:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

3. Run the `rulesets:create` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:create --org <target_org> --server <server_url> RULESET_FILE
   ```

   Where:
   - *<target_org>* is the name of the organization that owns the new ruleset.
   - *<server_url>* is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and file name of the JSON file that contains the ruleset.

Results

Your draft API or product ruleset is now listed in the table of Provider organization rulesets.

What to do next

When you finish editing your ruleset, you can publish it to your provider organization. Click the options menu icon ⋮ either next to the ruleset that you want to publish, or from within the ruleset viewer. Select Publish, and then click Publish again to confirm. The status of your ruleset changes from Draft to Published, and can now be used by developers to validate their API and product documents. For more information, see Validating an API document by using governance.

To validate an API or product document by using a published ruleset, click Validate, select the APIs or products to validate, then select the rulesets and rules that you want to use, and click Validate again. If the API that you want to validate includes a tag that has a matching tag in one or more rulesets, then those rulesets are automatically selected for the scan. However, you can edit the ruleset selection to your requirements. The results of the validation are displayed in a scorecard.

You can also run validation scans on your catalogs and spaces; for more information, see Scanning your catalogs and spaces.

Note:

- After a ruleset is published, the ruleset information and rules can no longer be edited. If you need to update this information, you must create a new version by clicking the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer, and selecting Save as new ruleset.
- **The governance ruleset lifecycle in the API Manager**
  When you manage your custom governance rulesets in the API Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

- **Updating rulesets and rules with the toolkit CLI**
  Use the API Connect toolkit CLI to update a ruleset or individual rules.
- **Scanning your catalogs and spaces**
  How to use the governance service to run validation scans on your catalogs and spaces. You can run scans on both the APIs and the products within your catalogs and spaces.

The governance ruleset lifecycle in the API Manager

When you manage your custom governance rulesets in the API Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

The following sections describe the various lifecycle states for a custom governance ruleset.

Note:

- Approval is not required for any of the lifecycle state transitions.
- Global rulesets are pre-configured rulesets that contain the rules that are shared with your provider organization, and cannot be edited. These rulesets are always in the Published state.

Draft

The draft state for a ruleset is when the ruleset is not published, and isn't visible to your provider organization. The ruleset can continue to be edited, and its Status is shown as Draft.

Published

When you publish a ruleset, it is made visible to your provider organization, and cannot be changed. The ruleset Status is shown as Published. Any changes to the ruleset require a new version to be created by using the Save as new ruleset option.

Archived

When you archive a ruleset, it becomes a ready-only, fixed version of the ruleset that cannot be used for validation by your provider organization. The ruleset Status is shown as Archived.
Note: If you cannot see your Archived ruleset, ensure that the Edit filters option on the ruleset table is set to include Archived.
You can restore archived rulesets by using the Restore option, after which the Status returns to Published.

Also, you can delete Archived rulesets by using the Delete option.

Updating rulesets and rules with the toolkit CLI

Use the API Connect toolkit CLI to update a ruleset or individual rules.

Updating a ruleset

1. Create a JSON file that defines the updated ruleset.
   The following example shows an updated ruleset:

   ```
   {
       "title": "custom-ruleset-2",
       "description": "short ruleset updated",
       "ruleset_type": "custom"
   }
   ```

   where:
   - `title` is updated to a new title for the ruleset.
   - `description` is updated to a new description for the ruleset.
   - `ruleset_type` is updated to be custom for the ruleset.
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the ruleset.
3. Run the `rulesets:update` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:update --org <target_org> --server <platform_api_host_name> RULESET RULESET_FILE
   ```

   where:
   - *`<target_org>`* is the name of the organization that owns the ruleset.
   - *`<platform_api_host_name>`* is the hostname portion URL of server that hosts the API Manager(the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `RULESET_FILE` is the path and filename of the JSON file that contains the updated ruleset.
   - `RULESET` is the name or the unique ID of the updated ruleset.
     To determine the ID of a ruleset, run the following command:

     ```
     apic -m governance rulesets:list --org <target_org> --server <platform_api_host_name>
     ```

Updating a rule

1. Create a JSON file that defines the updated rule.
   The following example shows an updated rule:

```
{
  "description": "Updated the rule",
  "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
  "formats": [
    "oas3"
  ],
  "severity": "warn",
  "recommended": true,
  "given": [
    "$..[?(@.type==\"array\")]"
  ]
}
```

   where:
   - **description** is updated to a new title for the rule
   - **message** is updated to a new message for the rule
   - **formats** array is replaced to have only the format oas3 for the rule
   - **severity** is updated to the warn value for the rule
   - **recommended** is updated to have a new value for the rule
   - **given** array is replaced to have new values for the rule
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the rule.
3. Run the **rules:update** toolkit command in **governance** mode.
   There are two ways to specify the updated rule in the command, depending on whether you provide the rule name and version, or the rule ID:

   Specify the rule name and version in the update command

   ```
   apic -m governance rules:update --org <target_org> --server <platform_api_host_name> --ruleset <ruleset_name or ruleset_id> NAME:VERSION RULE_FILE
   ```

   where:
   - ***<target_org>*** is the name of the organization that owns the rule.
   - ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
   - ***<ruleset_name or ruleset_id>*** is the name or the unique ID of the ruleset to which the updated rule belongs.
   - **NAME** is the name of the updated rule.
   - **VERSION** is the version of the updated rule; increase the version when you update the rule, using the **major.minor.patch** format as in "1.0.1".
   - **RULE_FILE** is the path and filename of the JSON file that contains the updated rule.

   Specify the rule ID in the update command

   Instead of providing the rule's name and version, you can provide its unique ID instead by running the following command:

   ```
   apic -m governance rules:update --org <target_org> --server <platform_api_host_name> --ruleset <ruleset_name or ruleset_id> --id <rule_id> RULE_FILE
   ```

   where:
   - ***<target_org>*** is the name of the organization that owns the rule.
   - ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
   - ***<ruleset_name or ruleset_id>*** is the name or the unique ID of the ruleset to which the update rule belongs.
   - **RULE_FILE** is the path and filename of the JSON file that contains the updated rule.
   - ***<rule_id>*** is the value of the updated rule's unique ID.
     To determine the ID of a rule, run the following command:

     ```
     apic -m governance rules:list --org <target_org> --server <platform_api_host_name> --ruleset <ruleset_name> RULE_NAME
     ```

Scanning your catalogs and spaces

How to use the governance service to run validation scans on your catalogs and spaces. You can run scans on both the APIs and the products within your catalogs and spaces.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. See Enabling governance on Kubernetes, and Enabling governance on VMware for more information. If governance is enabled in your deployment, the Governance icon is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

One of the following roles is required to be able to run validation scans:

- Organization Administrator
- Owner
- Custom role with the **Settings: Manage** permission.

About this task

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API development process. The governance service contains the following types of rulesets:

The governance service contains the following types of rulesets:

API

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
- Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
- Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

You can create your own provider organization rulesets to validate your Swagger, OpenAPI, and AsyncAPI documents against, as well as product documents, or use any global rulesets that are provided by default. For more information about configuring rulesets, see Configuring governance in the API Manager.

Governance in API Connect is based on the open-source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Validation scanning can be run on one or more API or product documents, or on a single catalog or space. The following instructions describe how to run validation scans on a catalog or space by using the API Manager UI, or the toolkit CLI. For information about how to run validation scans on one or more API or product documents, see Validating an API or product document by using governance.

Note:

- You can select only one catalog or space to run each validation scan on. However, you can run multiple scans at the same time.
- You can also run a validation scan from within a catalog or space. Open the catalog or space that you want to scan, and then select the Governance tab. Ensure Scans is selected, click API or Product depending on what you want to scan, and then click New scan, and follow the scan wizard.
- Validation scanning by catalog or space is not available in the API Designer UI.

- Running a validation scan using the API Manager UI.
- Running a validation scan using the toolkit CLI.

CAUTION:
Scanning catalogs or spaces that contain more than a hundred API or product documents, and using a large number of rulesets for the scan, can take hours to complete, and might time out before completion depending on the workload on your server. Only one document can be scanned at a time, and the more rulesets that are applied, the longer each individual scan will take. In this scenario consider selecting only a few rulesets for each scan.

Procedure

- Running a validation scan by using the API Manager UI.

  1. In the side menu bar, click Governance.
     The Governance page is displayed.
  2. Ensure the Scans tab is selected, click API or Product depending on what you want to scan, and click New scan.
     The New validation scan wizard opens.
  3. Select the catalog that you want to scan, and click Next.
  4. Optional: If spaces are enabled on the catalog, you can then select the space that you want to scan, and click Next.
  5. Select one or more rulesets, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select one or more rules, and click Next.
  7. Enter a title for the scan, or accept the default title, and click Start scan.
     You scan is started, and appears in the list of scans in the Catalog and space validation table. The scan Status is initially set to Queued, then changes to In progress, and then changes to Complete when it's finished. Note that scans containing a lot of data can take a long time to complete.
  8. When your scan is finished, you have the following options:
     - You can see a Summary of the scan in the table. If there were findings in the report, the summary displays the number of Errors, Warnings, or Hints in the validation, and also how many Rulesets were run in the scan.
     - You can click on the scan Title, or click the options menu icon ⋮ next to the scan and select View, to view the scan dashboard. The dashboard shows a scorecard summary of the scan, as well as detailed information about any messages and their severity.

- Running a validation scan by using the toolkit CLI.

  1. Create a JSON COMPLIANCE_REQUEST_FILE that specifies the location of the catalog or space and the rulesets to use during the validation scan.
     For example:

```
{
  "collectionUrl": "https://server/api/catalogs/org/catalog",
  "config": {
    "rulesets": [
      {
        "rulesetName": "spectral-oas",
        "disabled": ["info-contact"]
      },
      {
        "rulesetName": "spectral-owasp",
        "disabled": []
      }
```

```
    ]
  }
}
```

Where:

- **collectionUrl** is the URL of the catalog or space that contains the API documents that you want to run a validation scan on, where ***server*** is the server URL, ***org*** is the name or ID of the provider organization, and ***catalog*** is the name or ID of the catalog or space. For example **https://localhost:3003/api/catalogs/alpha/sandbox**.
- **rulesets** contains a list of the rulesets to be applied to the APIs during the validation scan.
  For each ruleset in the list, you can optionally add the **disabled** property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

```
apic login --server platform_api_endpoint_url --username user_id --password password --realm
provider/identity_provider
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
total_results: 2
results:
  - title: API Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
   For full details of the **apic login** command, see Logging in to a management server.

3. In the **governance** mode, run the **compliance:scan** command:

```
apic --mode governance compliance:scan --scope org --org <target_org> --server <platform_api_host_name>
COMPLIANCE_REQUEST_FILE
```

   Where:

   - **scope** is the scope of the scan, and must be set to **org** for a catalog or space validation scan.
   - ***<target_org>*** is the name of the provider organization that contains the catalog or space that you want to scan.
   - ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
   - ***COMPLIANCE_REQUEST_FILE*** is the path and filename of the JSON file that contains the configuration details for the validation scan. For example, ./documents/validate-apis.json.

   This command runs a scan on your APIs.
   To run a scan on your products, you must add the optional parameter of **--scan_type** with a value of **product** to the command. For example:

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name
./documents/validate-products.json --scan_type product
```

   You can use the value **api** to scan only APIs, or **product** to scan only products. If omitted, only APIs are scanned.
   The following optional parameter enables you to refine the results of this command.

   - **--scantitle *scan_title*** is an optional flag that changes the retrieved scan's title to the value that you provide.

   For example:

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name
./documents/validate-apis.json --scantitle scan1
```

4. After the scan is finished, the results of the scan are printed to the screen. For more information about toolkit scan commands, see Using the toolkit CLI to scan your catalogs and spaces.

Results

Your validation scan is now listed in the Catalog and space validation table in the API Manager UI.

What to do next

When your scan is complete, the following options are available from within the dashboard UI:

- Click Export to export all of the scan data as a .csv file.
- Click Re-run scan to generate a new scan report based on the same configuration data. Each run of the same scan generates a new report.
- The date and time of each scan report is displayed at the beginning of the dashboard, and if you have run more than one scan, you can select which scan report you want to view from the Scanned date list.
- From the options menu ⋮, you can select Rename or Delete.
- You can view each of the scorecard charts in tabular form, and download that data as .csv files.
- You can use the filter options on the table of messages to display the data that you require, and you can also change the sort order of the columns.

- **Using the toolkit CLI to scan your catalogs and spaces**
  How to use the IBM API Connect toolkit CLI to run governance validation scans on your catalogs and spaces.

Using the toolkit CLI to scan your catalogs and spaces

How to use the IBM® API Connect toolkit CLI to run governance validation scans on your catalogs and spaces.

About

API governance is an API Connect service that can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your catalogs and spaces. For more information about validation scanning, see Scanning your catalogs and spaces.

The following sections detail how to run validation scan commands by using the toolkit CLI.

CAUTION:
Scanning catalogs or spaces that contain more than a hundred API or product documents, and using a large number of rulesets for the scan, can take hours to complete, and might time out before completion depending on the workload on your server. Only one document can be scanned at a time, and the more rulesets that are applied, the longer each individual scan will take. In this scenario consider selecting only a few rulesets for each scan.

Logging in to the toolkit CLI

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server platform_api_host_name --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

Running compliance:scan commands

The following commands detail how to run a compliance scan on a catalog or space.

1. Create a JSON COMPLIANCE_REQUEST_FILE that specifies the location of the catalog or space and the rulesets to use during a validation scan.
   For example:

   ```
   {
     "collectionUrl": "https://server/api/catalogs/org/catalog",
     "config": {
       "rulesets": [
         {
           "rulesetName": "spectral-oas",
           "disabled": ["info-contact"]
         },
         {
           "rulesetName": "spectral-owasp",
           "disabled": []
         }
       ]
     }
   }
   ```

   Where:
   - `collectionUrl` is the URL of the catalog or space that contains the API documents that you want to run a validation scan on, where `server` is the server URL, `org` is the name or ID of the provider organization, and `catalog` is the name or ID of the catalog or space. For example `https://localhost:3003/api/catalogs/alpha/sandbox`.
   - `rulesets` contains a list of the rulesets to be applied to the APIs during the validation scan.
     For each ruleset in the list, you can optionally add the `disabled` property with a comma-delimited list of rules to ignore during validation.

2. Run a validation scan by using the **compliance:scan** command.

   ```
   apic --mode governance compliance:scan --scope org --org <target_org> --server <platform_api_host_name>
   COMPLIANCE_REQUEST_FILE
   ```

   Where:
   - `scope` is the scope of the scan, and must be set to `org` for a catalog or space validation scan.
   - `<target_org>` is the name of the provider organization that contains the catalog or space that you want to scan.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").

Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
- ***COMPLIANCE_REQUEST_FILE*** is the path and filename of the JSON file that contains the configuration details for the validation scan. For example, ./documents/validate-apis.json.

This command runs a scan on your APIs.
To run a scan on your products, you must add the optional parameter of **--scan_type** with a value of **product** to the command. For example:

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name ./documents/validate-products.json --scan_type product
```

You can use the value **api** to scan only APIs, or **product** to scan only products. If omitted, only APIs are scanned.
The results of the scan are printed to the screen.
The following optional parameter enables you to refine the results of this command.
- **--scantitle *scan_title*** is an optional flag that changes the retrieved scan's title to the value that you provide.

For example:

```
apic --mode governance compliance:scan --scope org --org my_org --server my_platform_api_host_name ./documents/validate-apis.json --scantitle scan1
```

3. Rerun an existing validation scan by using the **compliance:rescan** command.
A scan rerun creates a new report for that scan, but uses the same configuration of catalog or space and rulesets that was used in the previous scan.

```
apic --mode governance compliance:rescan --scope org --org <target_org> --server <platform_api_host_name> --scan <scan_name_or_scan_id>
```

Where:
- **scope** is the scope of the scan, and must be set to **org** for a catalog or space validation scan.
- ***<target_org>*** is the name of the provider organization that contains the catalog or space that you want to rescan.
- ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).
- ***scan_name_or_scan_id*** is the name or ID of the existing scan that you want to run again.

The following optional parameter enables you to refine the results of this command.
- **--scantitle *scan_title*** is an optional flag that changes the title of the rescan to the value you provide.

For example:

```
apic --mode governance compliance:rescan --scope org --org my_org --server my_platform_api_host_name ./documents/validate-apis.json --scantitle scan2
```

Running scans commands

The following commands detail how to manage and update your validation scans.

1. List all validation scans that exist for a specific provider organization by using the **scans:list** command.
The return includes information about all of the validation scans, and some information about their scan reports, but if you want more detailed information about the reports, use the **scan-reports:list** command.

```
apic --mode governance scans:list --scope org --org <target_org> --server <platform_api_host_name>
```

Where:
- **scope** is the scope of the scan, and must be set to **org** for a catalog or space validation scan.
- ***<target_org>*** is the name of the provider organization that you want a list of scans for.
- ***<platform_api_host_name>*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **https://** and ending before **/manager**).

The following example shows the sample output for a list containing two scans, one of APIs, and one of products:

```
total_results: 2

```
    url: 'https://test.ibm.com/governance/orgs/6d3d9ffa-37e3-4da7-be6b-a1c34b41476f/scans/ddc5da81-0db0-425c-b74c-5fc8300934e6'
```

Where `scan_type: '1'` refers to an API scan, and `scan_type: '2'` refers to a product scan.
The following optional parameters enable you to refine the results of this command.

- `--status status_number` is a comma separated list of status codes to filter the list of scans by.

  Table 1. Table of valid status codes

Code	Status
0	Queued
1	Complete
2	In progress
-1	Error

- `--type catalog_or_space` lists the scans that are of the type `catalog` or `space`.
- `--scan_type api_or_product` is an optional flag to specifically list the scans of only APIs or only products. Use the value `api` to list only API scans, or `product` to list only product scans. If omitted, both API and product type scans are listed.
- `--collections list_of_collections` is a comma separated list of catalog or space IDs or names to filter the list of scans by.
- `--limit number_of_results` specifies how many scan results to return.
- `--fields list_of_fields` is a comma separated list of field names to return. Note that no spaces are allowed after a comma, and if you want to return only one field you must omit the comma. For example, running the following command:

  ```
  apic --mode governance scans:list --scope org --org <target_org> --server <platform_api_host_name> --fields id,title
  ```

  Returns the data in the following way:

  ```
  total_results: 2
  results:
    - id: 'e0b8afbd-e5fa-486e-8800-343e1e31faf1'
      title: 'e0b8afbd-e5fa-486e-8800-343e1e31faf2'
    - id: '436d9db5-ea45-4d91-96c4-cef5957a2c34'
      title: '436d9db5-ea45-4d91-96c4-cef5957a2c34'
  ```

For example:

```
apic --mode governance scans:list --scope org --org demo -s test.ibm.com --collections cat1 --type catalog --status 1
```

2. Get a specific scan using the **scans:get** command:

   ```
   apic --mode governance scans:get --scope org --org <target_org> --server <platform_api_host_name> SCAN
   ```

   Where:
   - `scope` is the scope of the scan, and must be set to `org` for a catalog or space validation scan.
   - `<target_org>` is the name of the provider organization that contains the scan that you want to get.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `SCAN` is the ID or name of the scan that you want to retrieve.

   The scan results are downloaded to the directory where the command was run.
3. Update the scan `title` and `summary` properties by creating a SCAN_FILE with the information to be updated, and running the `scans:update` command.

   ```
   apic --mode governance scans:update --scope org --org <target_org> --server <platform_api_host_name> SCAN SCAN_FILE
   ```

   Where:
   - `scope` is the scope of the scan, and must be set to `org` for a catalog or space validation scan.
   - `<target_org>` is the name of the provider organization that contains the scan that you want to update.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `SCAN` is the ID or name of the scan that you want to update.
   - `SCAN_FILE` is the path to a JSON file that contains the properties to be updated.

   The `SCAN_FILE` can contain the following properties:

   ```
   {
     "title": "<updated_title>",
     "summary": "<updated_summary>"
   }
   ```

4. Delete a scan by using the **scans:delete** command. This command deletes the specified scan and all of its reports.

   ```
   apic --mode governance scans:delete --scope org --org <target_org> --server <platform_api_host_name> SCAN
   ```

   Where `SCAN` is the ID or name of the scan that you want to update.
5. Delete all of the scans for a particular provider organization by using the **scans:clear** command. This command clears all of the scans and all of their reports for the specified organization.

   ```
   apic --mode governance scans:clear --scope org --org <target_org> --server <platform_api_host_name> --confirm
   organisation_confirmed
   ```

   Where `organisation_confirmed` is the name of the provider organization again, to confirm that you want to clear all of the scans from this organization.

Running scan-reports commands

The following commands detail how to manage and update your scan reports.

1. List all of the scan reports for a particular provider organization by using the **scan-reports:list** command.

```
apic --mode governance scan-reports:list --scope org --org <target_org> --server <platform_api_host_name>
```

The following optional parameters enable you to refine the results of this command.

- `--fields list_of_fields` is a comma separated list of field names to return. Note that no spaces are allowed after a comma, and if you want to return only one field you must omit the comma. For example, running the following command:

  ```
  apic --mode governance scan-reports:list --scope org --org <target_org> --server <platform_api_host_name> --fields id,title
  ```

  Returns the data in the following way:

  ```
  total_results: 2
  results:
    - id: '3e3189a3-6359-4113-9cf9-9bde9f303884'
      title: '3e3189a3-6359-4113-9cf9-9bde9f303882'
    - id: '58a975cf-a503-4297-9450-237db102cb24'
      title: '58a975cf-a503-4297-9450-237db102cb24'
  ```

- `--limit number_of_results` specifies how many scan report results to return.

2. Get a specific scan report by using the **scans:get** command.

   ```
   apic --mode governance scan-reports:get --scope org --org <target_org> --server <platform_api_host_name> SCAN_REPORT
   ```

   Where `SCAN_REPORT` is the ID or name of the scan report.
   The scan report results are downloaded to the directory where the command was run.

3. Update the scan report `summary` property by creating a SCAN_REPORT_FILE with the information to be updated, and running the `scan-reports:update` command.

   ```
   apic --mode governance scan-reports:update --scope org --org <target_org> --server <platform_api_host_name> SCAN_REPORT SCAN_REPORT_FILE
   ```

   Where:
   - `SCAN_REPORT` is the ID or name of the scan report that you want to update.
   - `SCAN_REPORT_FILE` is the path to a JSON file that contains the properties to be updated.

   The `SCAN_REPORT_FILE` can contain the following properties:

   ```
   {
     "summary": "updated_summary"
   }
   ```

4. Delete a scan report by using the **scan-reports:delete** command. This command deletes the specified scan report, and removes the reference to it from the scan. Note that you cannot delete the last report in a scan. If you want to delete all of the reports of a scan, you must delete the scan itself by using the **scans:delete** command.

   ```
   apic --mode governance scan-reports:delete --scope org --org <target_org> --server <platform_api_host_name> SCAN_REPORT
   ```

   Where `SCAN_REPORT` is the ID or name of the scan report that you want to delete.

Administering user access

If you have permission to administer users in IBM® API Connect, you can add and delete users. After users are removed from an organization through deletion, the user account remains in API Manager.

About this task

You can also authorize users to perform different roles within your organization. To make any changes to the users that can access your organizations, use the followings tasks:

- **Setting the expiration for invitations**
  Set a time-out for invitations to expire.
- **Configuring notifications**
  Specify the sender name and email address to use for email notifications. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.
- **Viewing your user information**
  You can view the users that can access your IBM API Connect organization.
- **Adding provider organization users and assigning roles**
  If you have the permissions that are required to edit users in API Connect, you can add users to your provider organization, remove users, assign roles and perform other user administration tasks.
- **Creating custom roles**
  If you have permission to edit roles in IBM API Connect, you can create custom roles, and assign permissions, in a provider organization. You can create as many custom roles as you want.
- **Removing a user from a provider organization**
  If you have permission to edit users, you can remove a user from a provider organization.
- **Configuring LDAP group mappings on API Manager user roles**
  As an API Manager administrator, you can configure LDAP group mapping on API Connect roles in a provider organization by using the developer toolkit CLI.

Setting the expiration for invitations

Set a time-out for invitations to expire.

About this task

Invitations contain a link, which expires after the specified the timeout.

Procedure

1. In API Manager, click Settings.
2. In the Settings navigation list, click Onboarding, then click Edit.
3. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
4. Click Save.

Configuring notifications

Specify the sender name and email address to use for email notifications. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

About this task

The API Manager emails are sent automatically when certain system events occur. The email templates are organized by scope, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
catalog	Activities related to Catalogs; such as application life cycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations.
space	Invitations.

Email notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see Configuring sender details for email notifications.

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Settings:Manage` permission

Note: You can also customize notifications by using the developer toolkit CLI, or by using the API Connect REST APIs. See API development and management commands, or API Connect REST APIs, for more information.

Procedure

1. In API Manager, click Settings.
2. In the Settings navigation list, click Notifications, then click Edit.
3. Specify a sender by entering a Name and Email address, then click Save.
   To configure sender details at the Space or Catalog levels, you must use the developer toolkit CLI. For more information, see Configuring sender details for email notifications.
4. Optional: To enable template customization, move the Customize notification templates slider to the On position.
   Note: You can reload all the default notifications, as configured by a cloud administrator, by disabling and re-enabling template customization. However, doing so will overwrite any customizations that have been made. For more information on customizing notifications as a cloud administrator, see Customizing email notification templates.
5. To preview the text for a template, select Preview from the options menu ⋮ alongside the template name.
6. To edit the text for the template, either click the template name, or select Edit in the options menu alongside the template name.
   When a template is opened, an attempt is made to get the language from the browser setting, but if this isn't possible the template defaults to English.

   The text includes variables; for example, `{{catalog}}`. The notification text is based on Handlebars syntax. Most variables are enclosed in double curly braces `{{ }}`, but can be enclosed in triple curly braces `{{{ }}}` to disable HTML escaping, when the variable is a URL link for example. For more information on Handlebars, see https://handlebarsjs.com/.

   To obtain the complete list of variables that are available for a particular notification template, complete the following steps:
   a. Log in to the management server from the command line as a member of a provider organization; for details, see Logging in to a management server. You can use the same management server URL, user name, and password in the login command that you use to log in to the API Manager user interface.
   b. Enter the following command:

      ```
      apic notification-templates:get template_name --server mgmt_endpoint_url --scope org --org provider_organization --subcollection template_scope --fields variables --output -
      ```

      where:
      - *template_name* is the name of the required notification template, as displayed in the Template column in the user interface.
      - *template_scope* is the scope name displayed in the Scope column alongside that template.
      - *provider_organization* is the value of the `name` field for your provider organization.

      For example:

```
apic notification-templates:get member-invitation --server https://myserver.com --scope org --org myorg --
subcollection catalog --fields variables --output -
```

The variables that are available for the template are displayed, for example:

```
variables:
  - org
  - catalog
  - activationLink
  - expiresAt
  - originator
  - originatorFirstName
  - originatorLastName
  - originatorEmail
  - username
  - email
  - firstName
  - lastName
```

The **--output -** parameter causes the command output to be written to the command line. You can specify **--output *filepath*** to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.

7. To view and edit the notification template in a different language, select one of the following supported languages from the View template in drop-down list:
   - Chinese (Simplified)
   - Chinese (Traditional)
   - Czech
   - Dutch
   - English (US English)
   - French
   - German
   - Italian
   - Japanese
   - Korean
   - Polish
   - Portuguese
   - Russian
   - Spanish
   - Turkish
8. Edit the Subject as required.
9. Select the Content type that you want to use for the template, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
10. Edit the body of the template as required.
    For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 2. List of allowed HTML tags and their attributes

HTML tag	Attribute
<a>	**"class", "href", "hreflang", "style"**
****	**"class", "style"**
****	**"class", "style"**
<cite>	**"class", "style"**
<blockquote>	**"class", "cite", "style"**
<code>	**"class", "style"**
** **	**"class", "type", "style"**
** **	**"class", "start", "type", "style"**
** **	**"class", "style"**
<dl>	**"class", "style"**
<dt>	**"class", "style"**
<dd>	**"class", "style"**
<h1>	**"class", "id", "style"**
<h2>	**"class", "id", "style"**
<h3>	**"class", "id", "style"**
<h4>	**"class", "id", "style"**
<h5>	**"class", "id", "style"**
<h6>	**"class", "id", "style"**
<p>	**"class", "style"**
** **	**"class", "style"**
** **	**"class", "style"**
****	**"class", "style"**
<img>	**"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"**
<table>	**"class", "id", "style"**
<tr>	**"class", "id", "style"**
<td>	**"class", "id", "style"**

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **** tag in the template. The **src** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

11. Click Save when done.
    Note: Edits made to a template are saved only for the specific language version that is edited.

- **Configuring sender details for email notifications**
  Understand how the hierarchical search works for the email notification sender details, and how you can configure sender details at the Space and Catalog level.

Configuring sender details for email notifications

Understand how the hierarchical search works for the email notification sender details, and how you can configure sender details at the Space and Catalog level.

Before you begin

One of the following roles is required to configure sender details for email notifications:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` or `Settings:Manage` permission

For more information about the notification templates, their scope, and how to customize them, see Configuring notifications at the Provider Organization level, and Customizing email notification templates at the Cloud Manager level.

About this task

Email notifications are sent automatically by API Connect when certain system events occur. These notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template that's being sent, the search can start at the Space level, the Catalog level, the Provider Organization level, or the Cloud level. The sender details that are used are the first set of configured details that are found during the hierarchical search.
The following table shows the starting point for the sender details hierarchical search for each email template, ordered by the scope of the template, where:

- Cloud: emails are sent from the details that are configured in the Settings > Notifications section of the Cloud Manager.
- Org: the search for sender details starts at the Provider Organization level; if not available, the Cloud details are used.
- Catalog: the search for sender details starts at the Catalog level; if not available, the Org details are used, and if they're not available, the Cloud details are used.
- Space: the search for sender details starts at the Space level; if not available, the Catalog details are used, if they're not available, the Org details are used, and if they're not available, the Cloud details are used.
- Space or Catalog: in these cases the search starts at the Space level, or at the Catalog level, depending on the user that made the request, as shown in the following list:
  - When the product lifecycle change is started by a user in a Space, the search for sender details starts at the Space level.
  - When the product lifecycle change is started by a user in a Catalog, the search for sender details starts at the Catalog level.
  - When the product lifecycle change is approved by a user in a Space, the search for sender details starts at the Space level.
  - When the product lifecycle change is approved by a user in a Catalog, the search for sender details starts at the Catalog level.

Table 1. Starting point for the sender details search for each email template

Scope	Template name	Email subject	Sender details
admin	mail-server-test-connection	Test message from IBM® API Connect.	Cloud
admin	member-invitation	Invitation to an admin organization in IBM API Connect.	Cloud
admin	password-changed	Password changed for your user account in IBM API Connect.	Cloud
admin	password-reset	Password reset request for your user account in IBM API Connect.	Cloud
provider	invitation	Invitation to create an API provider organization in IBM API Connect.	Cloud
provider	member-invitation	Invitation to an API provider organization in IBM API Connect.	Org
catalog	app-lifecycle-cancelled	Request withdrawn to *{{action}}* app *{{appName}}*.	Catalog
catalog	app-lifecycle-request	Request for approval to *{{action}}* app *{{appName}}*.	Catalog
catalog	invitation	Invitation to create an API catalog in IBM API Connect.	Org
catalog	member-invitation	Invitation to an API catalog in IBM API Connect.	Catalog
catalog	task-consumer-onboard-request	Consumer onboarding request in the *{{catalog}}* developer portal.	Catalog
catalog	task-product-lifecycle-approved	Request approved to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-cancelled	Request withdrawn to *{{action}}* an API product in the *{{catalog}}* catalog.	Space or Catalog
catalog	task-product-lifecycle-denied	Request denied to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-pending	Request received to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-request	Request for approval to *{{action}}* an API product in the *{{catalog}}* catalog.	Space or Catalog
catalog	task-subscription-cancelled	Request withdrawn to subscribe to an API product in the *{{catalog}}* catalog.	Catalog
catalog	task-subscription-request	Request for approval to subscribe to an API product in the *{{catalog}}* catalog.	Catalog
space	invitation	Invitation to create an API space in IBM API Connect.	Catalog
space	member-invitation	Invitation to an API space in IBM API Connect.	Space
consumer	account-approved	*{{catalogTitle}}* developer portal account registration is approved.	Catalog
consumer	account-denied	*{{catalogTitle}}* developer portal account registration is denied.	Catalog
consumer	account-pending-approval	*{{catalogTitle}}* developer portal account registration pending approval.	Catalog
consumer	app-lifecycle-approved	Request approved to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-lifecycle-denied	Request denied to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-lifecycle-pending	Request received to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-reinstated	*{{appName}}* app reinstated in the *{{consumerOrg}}* developer portal.	Catalog
consumer	app-suspended	*{{appName}}* app suspended in the *{{consumerOrg}}* developer portal.	Catalog
consumer	invitation	Invitation to create an API consumer organization in the *{{catalog}}* developer portal.	Catalog
consumer	member-invitation	Invitation to an API consumer organization in the *{{catalog}}* developer portal.	Catalog
consumer	password-changed	Password changed for your user account in *{{portalTitle}}* developer portal.	Catalog
consumer	password-reset	Password reset request for your *{{catalog}}* developer portal account.	Catalog
consumer	sign-up	*{{catalogTitle}}* developer portal account registration.	Catalog
consumer	task-subscription-approved	API subscription request approved for app *{{appName}}*.	Catalog

Scope	Template name	Email subject	Sender details
consumer	task-subscription-denied	API subscription request denied for app *{{appName}}*.	Catalog
consumer	task-subscription-pending	API subscription request received for app *{{appName}}*.	Catalog

The sender address details can be configured at four levels: Cloud, Provider Organization, Catalog, and Space, and you can set a different sender address for each Provider Organization, Catalog, or Space, as required. The sender address for the Cloud can be configured in the Cloud Manager UI; see Setting up notifications for details. The sender address for the Provider Organization can be configured in the API Manager UI; see Configuring notifications for details. However, the sender address for Catalogs and Spaces can be configured only by using the toolkit CLI, as explained in the following steps.

Procedure

1. Log in to the management server from the command line as a member of a provider organization; for more information, see Logging in to a management server. You can use the same management server URL, username, and password in the login command that you use to log in to the API Manager user interface.
2. To update the sender address details for a Space, run the following commands.
   a. Run the **apic space-settings:get** command to read the current Space settings and output them to a json file. For example:

   ```
   apic space-settings:get --server my_mgt_server --org my_provider_org --catalog my_catalog --space my_space --format
   json
   ```

   Where:
   - ***my_mgt_server*** is your management server endpoint or URL.
   - ***my_provider_org*** is the name of your Provider Organization.
   - ***my_catalog*** is the name of your Catalog.
   - ***my_space*** is the name of your Space.

   b. Make a copy of the output file that you can then use to update the settings, for example:

   ```
   cp space-setting.json space-setting-update.json
   ```

   c. Edit the copied settings file to update the **email_sender** block. For example:

   ```
   vi space-setting-update.json
   ...
     "email_sender": {
       "custom": true,
       "name": "NO REPLY: space sender name",
       "address": "space_sender_email@nomail.com"
     },
   ...
   ```

   Where:
   - **custom** must be changed from the default setting of **false** to **true**.
   - the **name** line must be added to the file, and the ***space sender name*** details completed.
   - the **address** line must be added to the file, and the ***space_sender_email@nomail.com*** address details completed.

   Note: Ignore all of the other configuration details that are contained in this settings file.
   d. Run the **space-settings:update** command to update the Space settings with the new sender address details. For example:

   ```
   apic space-settings:update --server my_mgt_server --org my_provider_org --catalog my_catalog --space my_space space-
   setting-update.json
   ```

   Where ***space-setting-update.json*** is the name of your updated settings file.
3. To update the sender address details for a Catalog, run the following commands.
   a. Run the **apic catalog-settings:get** command to read the current Catalog settings and output them to a json file. For example:

   ```
   apic catalog-settings:get --server my_mgt_server --org my_provider_org --catalog my_catalog --format json
   ```

   Where:
   - ***my_mgt_server*** is your management server endpoint or URL.
   - ***my_provider_org*** is the name of your Provider Organization.
   - ***my_catalog*** is the name of your Catalog.

   b. Make a copy of the output file that you can then use to update the settings, for example:

   ```
   cp catalog-setting.json catalog-setting-update.json
   ```

   c. Edit the copied settings file to update the **email_sender** block. For example:

   ```
   vi catalog-setting-update.json
   ...
     "email_sender": {
       "custom": true,
       "name": "NO REPLY: catalog sender name",
       "address": "catalog_sender_email@nomail.com"
     },
   ...
   ```

   Where:
   - **custom** must be changed from the default setting of **false** to **true**.
   - **name** line must be added to the file, and the ***catalog sender name*** details completed.
   - **address** line must be added to the file, and the ***catalog_sender_email@nomail.com*** address details completed.

   Note: Ignore all of the other configuration details that are contained in this settings file.
   d. Run the **catalog-settings:update** command to update the Catalog settings with the new sender address details. For example:

   ```
   apic catalog-settings:update --server my_mgt_server --org my_provider_org --catalog my_catalog catalog-setting-
   update.json
   ```

   Where ***catalog-setting-update.json*** is the name of your updated settings file.

Results

You now understand how the hierarchical search works for the sender details for each email template, and can update the sender details at the Space and Catalog level as required.

Viewing your user information

You can view the users that can access your IBM® API Connect organization.

Procedure

To view your organization user information, complete the following steps:

In the navigation pane of the API Manager user interface, click Members.

What to do next

You can modify your user accounts; see Adding provider organization users and assigning roles. You can create custom roles; see Creating custom roles.

Adding provider organization users and assigning roles

If you have the permissions that are required to edit users in API Connect, you can add users to your provider organization, remove users, assign roles and perform other user administration tasks.

About this task

There are two ways to add a user:

- Invite member - send an invitation email with an activation link that enables the user to complete the addition operation.
- Add member - specify the user and add them as a member of the provider organization immediately.

Procedure

- To send an email invitation to a new user to register as a member of the provider organization, complete the following steps:
  1. In the navigation pane of the API Manager user interface, click Members.
  2. Click Add > Invite member.
  3. Enter the email address of the user.
  4. Select the roles that you want to assign to the user.
  5. Click Invite.
- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:
  1. In the navigation pane of the API Manager user interface, click Members.
  2. Click Add > Add member.
  3. Select the required user registry.

     Note: For a user registry to be available in the selection list, one of the following conditions must be satisfied:
     - The visibility of the user registry is set to Public.
     - The visibility of the user registry is set to Custom, and the specified list of provider organizations includes the one to which you are adding the user.

     For more information, see Setting visibility for a user registry.

     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Select the roles that you want to assign to the user, then click Add. The user is added and their membership is immediately enabled. The specified user can log in to the API Manager user interface.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Select the roles that you want to assign to the user, then click Add. The user account is created, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface with their LDAP user name.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface.

Results

The user is added to the list of provider organization members. If an email invitation was sent, the status is shown as `Pending` until the recipient of the email clicks the link in the email to complete the creation of their account, after which the status changes to `Enabled`.

What to do next

The new user can access the API Manager user interface. The user's authorization within API Manager is defined by the roles that are assigned to them.

Related tasks

- Creating custom roles

Creating custom roles

If you have permission to edit roles in IBM® API Connect, you can create custom roles, and assign permissions, in a provider organization. You can create as many custom roles as you want.

About this task

You create custom roles at the provider organization level; those roles are inherited by the Catalogs and Spaces in the provider organization. You can assign permissions at the provider organization, Catalog or Space level.

For a description of the permissions, and details of the default user roles and default permissions assigned to those roles, see API Connect user roles.

Note: In API Manager, the Organization Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

Procedure

To create a custom role, complete the following steps:

1. In the navigation pane of the API Manager user interface, click Settings
2. Click Roles, then click Add.
   The Create a Role page opens.
3. Enter a role Title and an optional Summary. A Name is entered automatically.
   Note: The value in the Name field is a single string that is used to identify the role in developer toolkit CLI commands. The Title is used for display.
   To view the CLI commands to manage roles, see the toolkit CLI reference documentation.
4. Use the check boxes to assign permissions to the new role.
5. When you are finished, click Save.
6. To delete a role, click the options icon ⋮ alongside the role that you want to delete, click Delete, then click Delete again to confirm the role deletion.
   Note:
   - You can create and delete a role only at the provider organization level. You cannot create or delete a role at the Catalog level. Nor can you create or delete a role at the Space level.
     You can, however, assign Catalog-specific permissions to the role; for details, see Creating and configuring Catalogs. You can also assign Space-specific permissions; for details, see Managing user access in a Space; for more information on Spaces, see Using syndication in API Connect.
   - If you assign Product-Drafts or Api-Drafts permissions to the role, these permissions are not inherited by the role in a Catalog or Space. These permissions apply to working with draft Products and APIs in a provider organization and are not relevant in a Catalog or Space.

Results

The custom role is created and assigned the permissions that you selected.

What to do next

Assign the custom role to a user.

Removing a user from a provider organization

If you have permission to edit users, you can remove a user from a provider organization.

About this task

After you have removed the user from your IBM® API Connect provider organization, their resources are deleted and the user cannot access any of the organization's artifacts.
Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the API Manager user interface but only information links are available; there is no access to view or manage any resources.
If you later invite the same user again, they can re-activate their account. If you are using a Local User Registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. For details on how to invite a user to join your organization, see Adding provider organization users and assigning roles.

Procedure

To remove a user from a provider organization complete the following steps:

1. In the navigation pane of the API Manager user interface, click Members.
2. Alongside the user that you want to delete, click the options icon , click Delete, the click Delete again to confirm the user deletion.
   Note: You cannot delete the owner of a provider organization.

Results

The user is removed from the provider organization, and the user account remains in API Manager.

Configuring LDAP group mappings on API Manager user roles

As an API Manager administrator, you can configure LDAP group mapping on API Connect roles in a provider organization by using the developer toolkit CLI.

Before you begin

You must have an LDAP user registry resource in the API Manager that has the **`external_group_mapping_enabled`** configuration set to **`true`**. See Using the CLI to create an organization-specific LDAP user registry for information.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Custom role with the `Settings: manage` permissions

Note: The provider organization roles apply only to API Manager users. If you want to apply LDAP group mapping to Cloud Manager users, see Configuring LDAP group mapping on Cloud Manager user roles. LDAP group mapping cannot be applied to Developer Portal users.

About this task

You can map external LDAP groups to the API Connect preconfigured user roles (except for the Owner and Member roles), as well as to any custom user roles, to reflect your business needs.

Notes:

- After LDAP group mapping is enabled on a role, user onboarding always honors the group mappings.
- Once on-boarded, user membership in API Connect is valid throughout the login period (**`access_token_ttl`**), irrespective of any changes in the external LDAP registry. Membership is updated only on the next login, when the LDAP information is fetched and refreshed.
- One or more API Connect roles can be mapped to one or more LDAP groups, and one or more LDAP groups can be mapped to a role.
- When multiple LDAP groups are mapped to a single role, it means that a user from any one of the LDAP groups can logon to API Connect.
- If a user is removed from the external LDAP user registry, to ensure quick removal from API Connect you must also delete the user membership in API Connect.
- In API Manager you can map roles at the provider organization, Catalog and, if appropriate, Space level. However, you can only map roles at the child level of Catalog, and then the Catalog's child level of Space, if the parent level also has group mapping defined. Mapping at a child level overrides the mapping for the same role at the parent level. For example:
  If the Administrator Role at the provider organization level is mapped to the LDAP group of **`cn=APIC-Administrators,ou=ibmgroups,o=ibm.com`**, and the Administrator Role at a Catalog level is mapped to the LDAP group of **`cn=APIC-Developers,ou=ibmgroups,o=ibm.com`**, then any user that is added as a Catalog member must belong to the **`cn=APIC-Developers,ou=ibmgroups,o=ibm.com`** group. Note that provider organization level members that belong to the **`cn=APIC-Administrators,ou=ibmgroups,o=ibm.com`** group can still access the Catalog due to inheritance.

You can configure LDAP group mappings using one of the following methods:

- Using the UI to configure LDAP group mappings
- Using the CLI to configure LDAP group mappings

Using the UI to configure LDAP group mappings

Use the API Manager UI to configure LDAP group mappings.

Procedure

1. Login to the API Manager as a user with the appropriate permissions.
2. Click Settings > Roles > Add a new Role or edit existing role .
3. Select the following settings:
   - Enable external group mapping - select to enable external group mapping for this role.
   - LDAP user Registry - LDAP user registry list which has external group mapping enabled. User must select one of the LDAP user registry from this list.
   - LDAP group names - add one or more LDAP group names that you want to map to the user role.
   - User group prefix - add the prefix for the LDAP user group.
   - User group suffix - add the suffix for the LDAP user group.
4. Save your changes.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the API Manager, and automatically be assigned the correct access permissions for their role.

Using the CLI to configure LDAP group mappings

Use the toolkit CLI to configure LDAP group mappings.

About this task

For detailed information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Procedure

Perform the following steps to map external LDAP groups to API Manager user roles.

1. Log in to the management server CLI.
   Before you can update the role configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   where `mgmt_endpoint_url` is the platform API endpoint URL.
   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the login command, see Logging in to a management server.

2. Run the following command to get the URL of the LDAP user registry resource in the API Manager that you want to map the user roles to:

   ```
   apic user-registries:get  ldap_user_registry --org organization_name --server mgmt_endpoint_url --output -
   ```

   where:
   - `ldap_user_registry` is the name or ID of your LDAP user registry resource.
   - `organization_name` is the value of the `name` property of your provider organization.
   - `mgmt_endpoint_url` is the platform API endpoint URL.

   This command outputs the configuration details of your LDAP user registry, and the `url:` is shown at the end of the list, for example:

   ```
   type: user_registry
   api_version: 2.0.0
   id: 35e75bad-1d89-4a65-a70f-xxxxxx
   name: ldap
   title: LDAP
   integration_url: >-
     https://server.com/api/cloud/integrations/user-registry/147b5fb1-e88e-41e3-90e9-xxxxxx
   registry_type: ldap
   user_managed: false
   user_registry_managed: false
   external_group_mapping_enabled: true
   ...
   url: >-
     https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
   ```

3. Create a role yaml file that contains the following LDAP group mapping configuration properties:

   ```
   external_group_mapping:
     user_registry_url: https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
     ldap_groups:
       - 'cn=apic-administrators,ou=ibmgroups,o=ibm.com'
       - 'cn=apic-developers,ou=ibmgroups,o=ibm.com'
     user_group_filter_prefix: (&(uniquemember=
     user_group_filter_suffix: )(objectClass=groupOfUniqueNames))
   ```

   Where:
   - `user_registry_url` is the URL of your LDAP user registry resource from Step #task_apim_role_mapping__ldap_url.
   - `ldap_groups` is a list of the LDAP group names that you want to map to the user role.
   - `user_group_filter_prefix` is the prefix for the LDAP user group.
   - `user_group_filter_suffix` is the suffix for the LDAP user group.

4. Run the following command to update the user role with the `external_group_mapping` configuration properties:

   ```
   apic roles:update role_name --scope org --org organization_name --server mgmt_endpoint_url mapping_properties_file
   ```

   Where:
   - `role_name` is the name of the user role that you want to add the LDAP group mapping to.
   - `--scope` is the organization level that you want the update to apply to. Valid values are:
     - `org` to apply the mapping at the provider organization level.
     - `catalog` to apply the mapping at the Catalog level.
     - `space` to apply the mapping at the Space level.

- ***organization_name*** is the value of the **name** property of your provider organization.
- ***mgmt_endpoint_url*** is the platform API endpoint URL.
- ***mapping_properties_file*** is the name of your mapping properties file from Step #task_apim_role_mapping__role_file, for example **role_mapping_file.yaml**.

If you prefer to enter the configuration properties interactively on the command line, you can substitute the ***mapping_properties_file*** for a terminating hyphen character **-**, and enter the information manually, followed by pressing **CTRL D** to terminate the input.
If you want to create a custom role that includes LDAP group mapping, you can include the **external_group_mapping** configuration section in the **role_file**, and then create the new role by using the **apic roles:create** command.

For more information about the **apic roles** commands, see the toolkit CLI reference documentation.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the API Manager, and automatically be assigned the correct access permissions for their role.

Changing your API Manager password

You can change your API Manager password in IBM® API Connect.

Procedure

To change your password, complete the following steps:

1. Log in to the API Manager user interface.
2. Click the User icon then click My Account.
3. In the Change password section, enter your current password and your new password, and confirm the new password.
   Passwords must satisfy the following requirements:
   - Cannot be re-used for at least 8 password cycles
   - Cannot contain more than 2 consecutive repeating characters
   - Must include at least 8 characters
   - Must include 1 or more characters from at least 2 of the following categories:
     - Lowercase letters
     - Uppercase letters
     - Numbers
     - Special characters – only the following special characters are allowed:

       ```
       !
       \"
       #
       $
       %
       &
       \
       (
       )
       *
       +
       ,
       -
       .
       /
       :
       ;
       <
       =
       >
       ?
       @
       [
       \\
       ]
       ^
       _
       `
       {
       |
       }
       ~
       ```
4. Click Change Password.

Results

Your password is changed.

Resolving login problems by increasing HTTP header size

You can resolve login problems for the API Manager UI by increasing the maximum HTTP client header size.

About this task

Login attempts to the user interface might fail with error **502 (Bad Gateway)**. This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaround this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

Procedure

1. **SSH** to your management system or appliance.
2. Enter the following commands:

```
kubectl get deployment -n namespace  | grep apim
kubectl edit deployment -n namespace management-apim
```

3. In the **env** section of the deployment configuration, change **--max-http-header-size=12000** to a larger value that works for your environment. For example:

```
 - name: NODE_OPTIONS
          value: --max-old-space-size=8094 --max-http-header-size=16000
```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `management-apim` pods are up and running.

API Gateway only

Reviewing processing status and downloading gateway logs

View and download the processing status information for the Gateway services that are enabled in your API Connect Catalogs and Spaces.

About this task

Check the status of API events processed by the gateway, and download gateway logs as needed. For example, you might want to check whether a Product was published and is available on the gateway before using one of its APIs. Or you might notice that API events are processing slowly and want to see if all events for a specific gateway service are affected.

When a user performs an action in API Manager, such as publishing, deprecating, or retiring a product. At this point, the status changes to an **in-progress** state:

- **published-in-progress**
- **deprecated-in-progress**
- **retired-in-progress**

API Manager then generates an event that corresponds to the action and sends it to the Gateway. Communication between API Manager and the Gateway is event-based and asynchronous.

After receiving the event, the Gateway attempts to apply the requested change:

- If the Gateway successfully applies the change, it sends a confirmation to API Manager. The product status then updates to a success state, such as **published-success**.
- If the Gateway fails to apply the change, it reports the failure to API Manager. The product status then updates to a failed state, such as **published-failed**.

For more information about the different statuses of a product compatible with DataPower® API Gateway, see Publishing a draft Product.
Use the API Manager user interface to view or download the processing status information for all the gateway services that are associated with a particular catalog or Space.

Notes: You can only obtain processing status information for the DataPower API Gateway. This feature is not supported for the DataPower Gateway (v5 compatible) service or the Event Gateway service.

Procedure

To check the status of API events processed by the gateway and download gateway logs, complete the following steps:

a. Log in to API Manager.
b. In the navigation pane, click Manage.
c. Select a catalog.
d. Click the Catalog settings tab or Spaces tab.
   - Catalog settings: if spaces are not enabled in your catalog, you can view the gateway processing status from the Catalog settings tab. To review the gateway processing status from the catalog settings tab, complete the following step:
     - On the Settings page, click Gateway services.
   - Spaces: If you enable the Spaces option for your catalog, you cannot see the status of gateway services in the catalog settings tab. To know the gateway services status from the Spaces tab, complete the following steps:
     - Select the space that you want to work with.
     - Click the Space settings tab.

- On the Space Settings page, click Gateway services.
- In the Event load column, you can see the current status.

e. A list of all of the gateway services for the selected catalog, including all of its Spaces, displays the gateway type and its endpoint URL. In addition, a status icon displays for each service name to provide a quick indication of that service's status:

- Normal: Between 0 and 10 events are waiting to be processed
- Increased: Between 10 and 20 events are waiting to be processed
- High: More than 20 events are waiting to be processed

You can view details about a service's status to gain insight into possible issues.

f. View the gateway status: On the Gateway services page, click ⋮ next to a service and select View status.
The Gateway processing status page displays a list of the events that were sent to the gateway. For each event, you can see the following information:

- Event type: The action performed by the event; for example, subscribing to a product, deleting an application, or creating a new consumer organization.
- Category: The feature area affected by the event; for example, subscriptions, applications, or consumer organizations.
- Time: The time when the event was processed by the gateway service.
- Status: The current event's processing status; for example, Queued (not yet sent for processing), Sent (but not processed yet), Processed (complete) or Failed (processing failed). For more information about the different statuses of a product compatible with DataPower API Gateway, see Publishing a draft Product.
  The number of events in the Queued and Sent states determine the status level for the service.

The display includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

g. To download Gateway logs, complete the following steps:

- Click ⋮ next to the gateway service and select Download logs.
- Downloads a .zip file to your computer with a name that uses the format <gateway-name>.zip for example v6gw.zip.

API gateway response codes

When an API is called, different HTTP status codes are returned by the gateway to indicate whether the request was successfully completed.

The response codes used in IBM® API Connect correspond to the registered HTTP status codes that are typically generated to provide informational (1xx), successful (2xx), redirection (3xx), client error (4xx), or server error (5xx) responses, as described at https://tools.ietf.org/html/rfc7231#section-6 and Hypertext Transfer Protocol (HTTP) Status Code Registry.

In API Connect, successful responses vary depending on the API being called. Other response codes can also be generated, depending on the implementation of the assembly and the response from the external systems. The standard reasons listed for the registered HTTP status codes are considered adequate for most responses that are returned; these response codes and their causes are therefore not listed here.

In certain cases, a client or server error response code can be caused by a condition that is specific to API Connect. The following table contains a list of these error response codes and identifies possible causes for these codes being returned. For some error codes, multiple causes are possible.

Table 1. Error codes and their causes

Error Code	Cause
401 Unauthorized	• The required client identification has not been successfully provided. • User authentication failed or did not take place.
403 Forbidden	• The application is not registered with the plan that is used. • The application is not active. • User authentication failed because multiple client IDs provided.
404 Not Found	• Information for the provider organization or environment was not found. • The API URL was not found in the organization or environment.
405 Method Not Allowed	The API URL was found, but no operation was found that supports the requested HTTP verb.
406 Not Acceptable	The API cannot produce any responses that are supported by the application.

Error Code	Cause
429 Too Many Requests	The rate limit has been exceeded for the plan or operation being used.
500 Internal Server Error	An error occurred while executing this request.
503 Service Unavailable	The status of an API was switched from online to offline, making the API unavailable across all Products in which it is contained. For more information, see Managing your Products in the API Manager UI and Managing API Products using the developer toolkit.

Context variables in the task payload

Use context variables to display the required task payload information.

You can use different context variables in the task payload to display information associated with the engagement alerts. When defining a rule for the notification task, you can add the required context variables in the task Payload section on the Define query page. The information corresponding to the context variables is displayed in the destination that is specified when creating or editing the rule. For more information, see Creating a notification task.

The following table shows the list of all context variables that are associated with the engagement alerts.

Table 1. Context variables in engagement alerts

Context variable	Description
catalogId	The catalog ID that the rules apply to.
endPeriod	The end of the time period.
field_name	To retrieve the field name used in filters. Follow the format {}{{field_name{}}}. For example, {}{{api_name{}}}, {}{{product_version{}}}.
filters	The list of filters that are used when creating the rules.
groupedData	The data grouped into buckets, each containing a key representing the following details: • The group • The number of documents in the group
isRuleEnabled	Indicates whether the rule is enabled.
operator:field_name	To retrieve the operator used in filters. Follow the format {}{{operator:field_name{}}}. For example, {}{{operator:api_name{}}}, {}{{operator:product_version{}}}.
orgId	The organization ID that the rules apply to.
periodStart	The start of the time period.
ruleEnabledTime	The timestamp when the rule is enabled.
ruleLastUpdatedTime	The timestamp when the rule was last updated.
ruleName	The name of the rule that is created or updated.
ruleSchedulePeriodInterval	The interval for the rule schedule.
ruleSchedulePeriodUnit	The unit for the schedule period.
ruleType	The type of the rule.
searchIndex	The search index used to match the data.
totalDocumentsMatched	The total number of documents that match the rule conditions.
triggerCondition	The condition that is set to activate the trigger.
triggerId	The ID of the trigger associated with the rule.
triggerName	The name of the trigger associated with the rule.
triggerSeverity	The severity level of the trigger.

Troubleshooting your billing configuration

Some issues can occur when you are setting up billing integration in IBM® API Connect.

You can use the following links to browse the issues:

1. My customer payment is not completing with Stripe, but the Product is still being accessed.
2. My Product with billing is returning an error when I try to configure it with my Stripe account.
3. My customer previously had a Stripe subscription to a Product but can't access its billing details.

My customer payment is not completing with Stripe, but the Product is still being accessed.

When payment issues occur with the credit card payment provider, the credit card subscription is canceled, but the API Connect subscription is not canceled. You can disable an application until the payment issues are resolved by completing the following steps:

1. Navigate to the Settings page in the dashboard of your Stripe account.
2. In the Billing section navigate to the Subscriptions and emails page.
3. In the Manage failed payments section, change the Subscription status to If all retries for a payment fail, mark the subscription as unpaid.
4. Navigate to the Subscriptions page, and when the subscription has moved into the unpaid state open the subscription in the Stripe dashboard.
5. In the Metadata section, copy the subscription_url value.
6. Use the developer toolkit CLI, and the UUID from the subscription_url, to set the state of the application or subscription to disabled.

My Product with billing is returning an error when I try to configure it with my Stripe account.

The most common cause of this is that your Developer Portal cluster servers or your Management cluster servers cannot communicate with Stripe.
To resolve this, ensure that the Stripe API is enabled with HTTPS communication with your Management cluster servers and the Developer Portal on port 443. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.

Other causes might be issues with the subscription billing service, network stability, or the API keys might have been rolled and not updated in API Connect and the Developer Portal.

My customer previously had a Stripe subscription to a Product but can't access its billing details.

There is more than one possible cause and resolution for this situation.

- The credit card transaction might not be completing correctly. If this situation happens, the subscription might be canceled with Stripe, but the API Connect subscription is not canceled. For instructions about how to disable a subscription, see My customer payment is not completing with Stripe, but the Product is still being accessed.
- A recent change to a Product with billing might have triggered an action that was not completed correctly. Seemingly minor changes to the Product can start a number of actions that can overload a server. For example, when you replace a version of the Product with a new version, it starts an update to the Stripe server for every account that is subscribed to that Product. If the action fails to complete, the Plan's subscription status might not be reflected correctly with Stripe.
  You can identify this situation by viewing the Billing dashboard in the Resources section of the API Manager. The table displays the state of the job queue for the billing integration resource, and any issues with the job queue are displayed here. For more information about the job queue, and how to retry blocked jobs, see Billing integration resource job queues.

API Manager tutorials

Tutorials for using the API Manager user interface in IBM® API Connect.

Prerequisites

Because you are working online, using API Manager, to complete the following tutorials you must be the Organization Manager of an API Connect account. Or, you received an invite to join API Connect as an Administrator. See Working with consumer organizations for more information.

If you have received an email inviting you to create an API Connect user account, follow the instructions in your email to create your API Connect account.

Overview

In the following tutorials, you will use API Manager to create simple SOAP API definitions that can be accessed through the Developer Portal and called through the gateway in the same manner as other API Connect API definitions.

- **Tutorial: Creating a proxy REST API definition**
  This tutorial shows you how to define and implement a REST API definition that proxies an existing service.
- **Tutorial: Creating a SOAP API**
  This tutorial shows you how to create an API definition by using a SOAP service Web Service Definition Language (WSDL). This API definition simplifies creating and managing access to the SOAP service.
- **Tutorial: Generate a JSON Web Token (JWT)**
  This tutorial shows you how to define and implement a REST API definition that generates a JSON Web Token (JWT).
- **Tutorial: Validate a JSON Web Token (JWT)**
  This tutorial shows you how to define and implement a REST API definition that validates a JSON Web Token (JWT).

Tutorial: Creating a proxy REST API definition

This tutorial shows you how to define and implement a REST API definition that proxies an existing service.

About this tutorial

In this tutorial you will complete the following lessons:

1. Creating a REST API definition
2. Testing the REST API

Before you begin

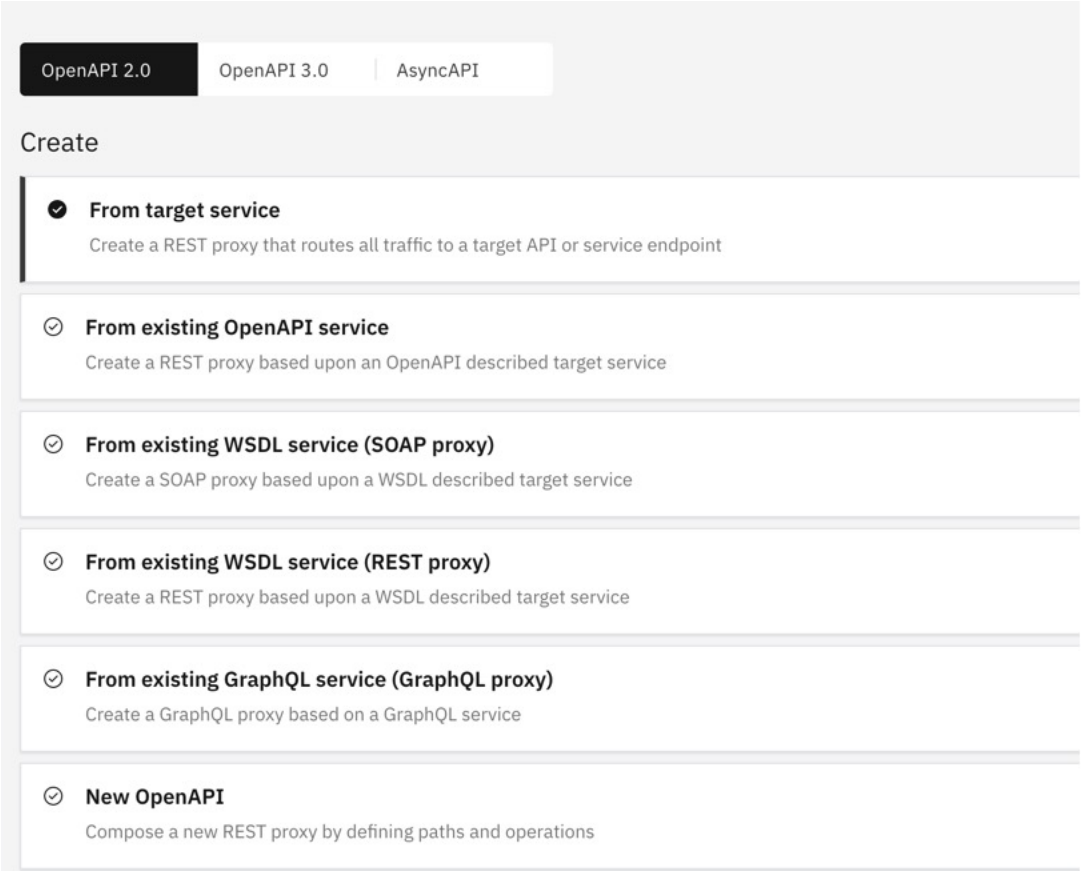
Note: The Sandbox catalog must be configured to use either a DataPower® API Gateway, or a DataPower Gateway (v5 compatible), or both. See Creating and configuring Catalogs.

Creating a REST API definition

You can create and define a REST API that returns the branch details of a fictional bank, called BankA by using the following steps.

1. Log in to API Manager.
2. On the Home page, in the left panel, either click the Develop icon, or click the Develop APIs and products tile.
3. In the Develop screen, click Add > API.

4. Ensure that OpenAPI 2.0 is selected.
5. Select From target service, and click Next.

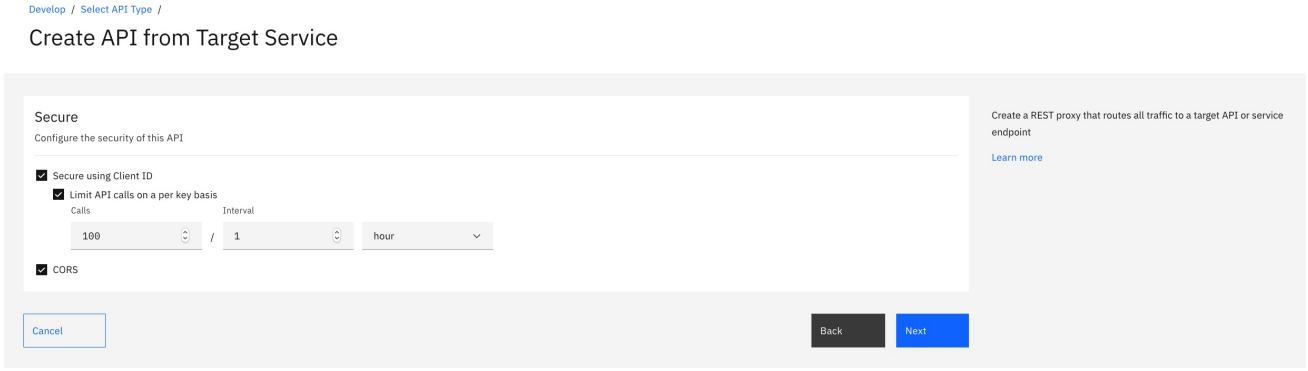


6. Enter the following information to create a REST API from a target service.
    a. In the Title field, enter `Branches`.
    b. The Name field is auto-populated with `branches`.
    c. Leave the Version field as `1.0.0`.
    d. The Base Path field is auto-populated with `/branches`.
    e. In the Target Service URL field, enter `https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches`

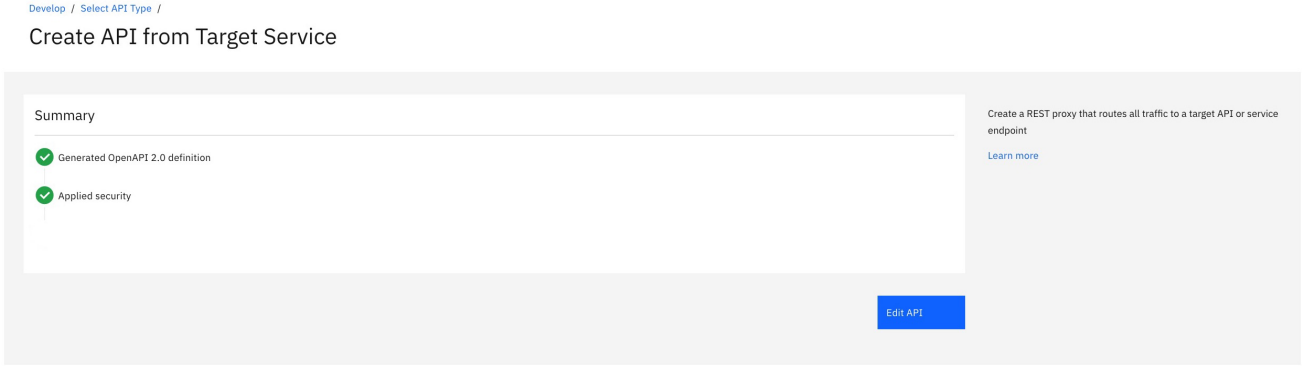
7. Click Next.
8. In the Secure dialog, make sure

- Secure using Client ID
- CORS

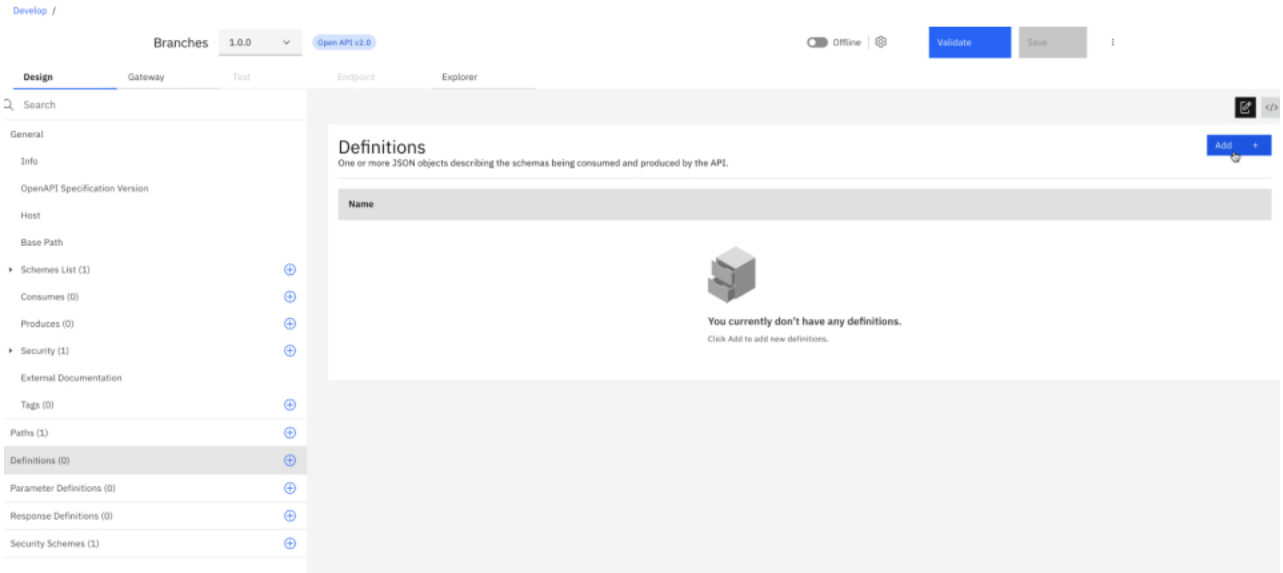
are selected and click Next.



9. The new API is created, and the Summary page is displayed. Click Edit API to continue configuring the API.



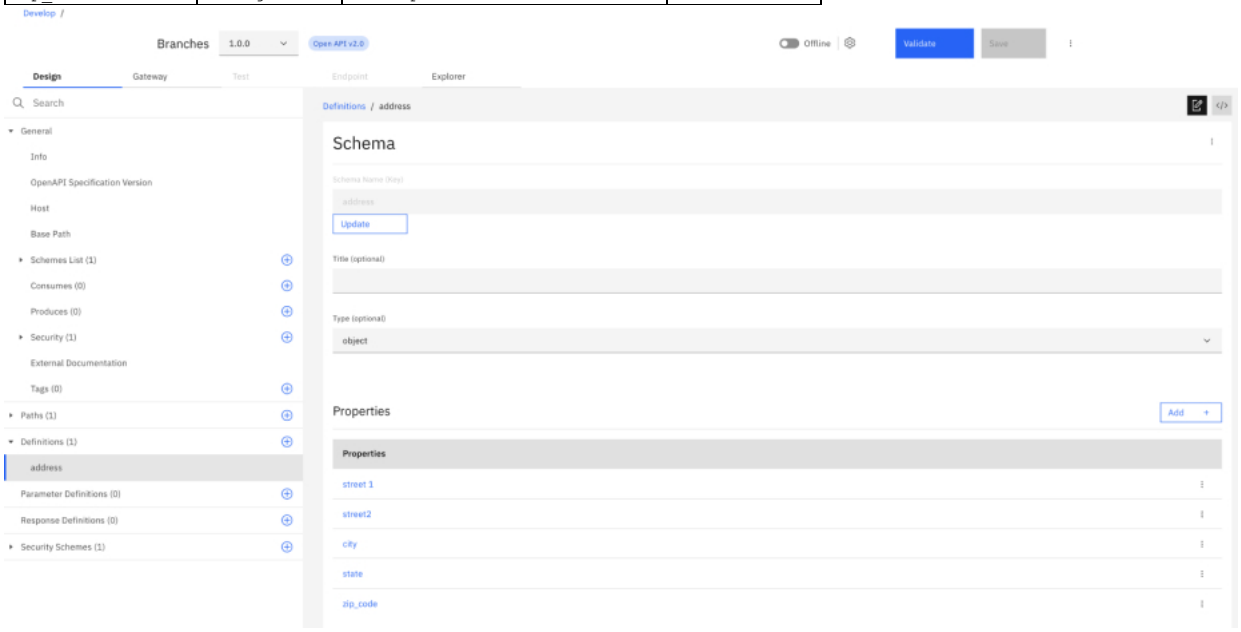
10. On the Design view, click Definitions in the side menu bar, and then click Add.



11. Enter the following information to create a new definition in the form of an object Schema.
    a. In the Schema Name (Key) field enter `address`.
    b. In the Type field select `object`.
    c. Click Add.
    d. In the Description field enter `The format of the address object`.
12. Click Save.
13. The schema for new object displays as part of the Design view under the Definitions section.
14. To create properties for the new address object, click Add in the Properties section.
15. To configure the properties, complete the following steps:
    a. In the Name field enter `street1`.
    b. In theType field select `string`.
    c. In the Description field add `The first line of the address`.
    d. Click Save.
    e. The new schema property is created, and is now displayed as part of the Design view under the Properties section. To complete it, click the ellipsis icon and select the Details option. Go to the Documentation tab and add `4660 La Jolla Village Drive` in the Example Value field.
    f. Click Save.
16. Repeat the same process for the other new schema properties by following the information provided in the Table 1.

Table 1. Address properties

SCHEMA NAME (KEY)	TYPE	DESCRIPTION	EXAMPLE VALUE
street2	string	The second line of the address	Suite 300
city	string	The city of the address	San Diego
state	string	The state of the address	CA
zip_code	string	The zip code of the address	92122



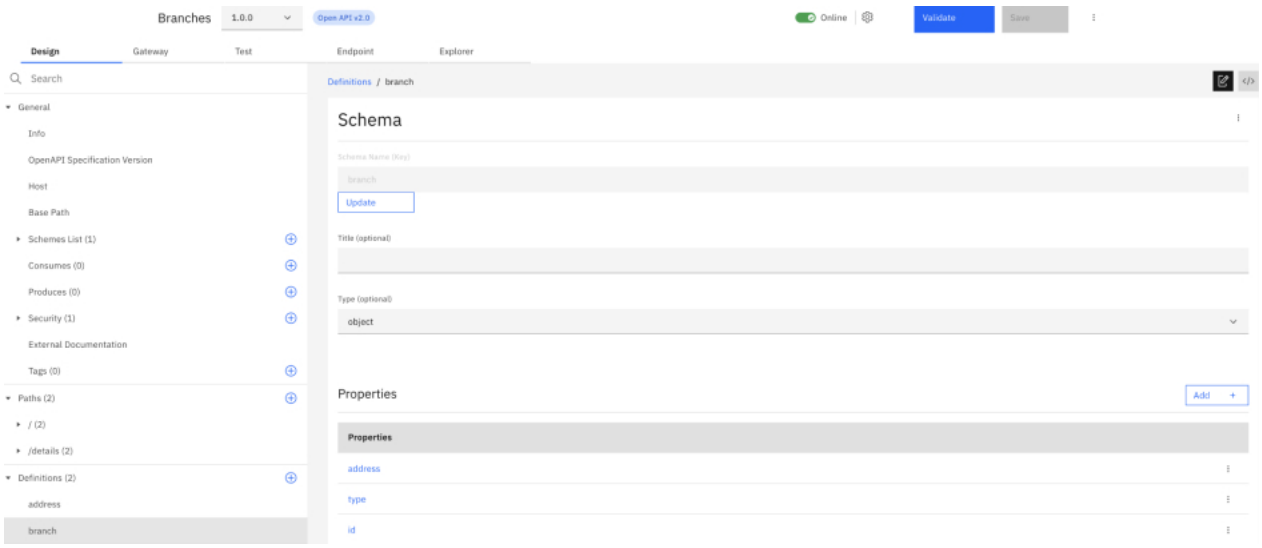
Note: The schema definitions are presented to developers in the Developer Portal to provide them with information about the type of data to expect in their response.

17. Click Save.
18. Create a second definition schema by clicking Add in the Definitions pane.
    a. In the Schema Name (Key) field enter `branch`.
    b. In the Type filed select `object`.
    c. Click Add.
    d. In the Description field enter `The format of the branch field`.
    e. Click Save.
19. Configure the Properties of the branch object according to Table 2. To generate new properties click Add, fill in information, then click Save.
    Note: To add and access the Example value of the schema definition you created, you have to finish the creation process first by clicking Save.

Table 2. Branch properties

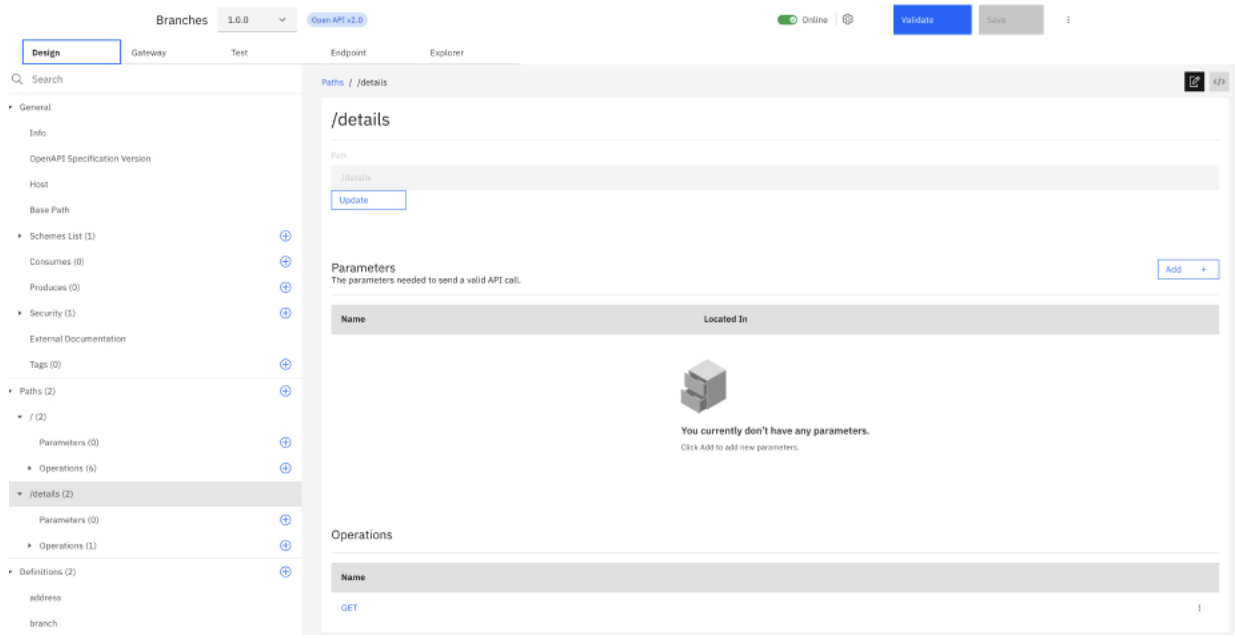
SCHEMA NAME (KEY)	TYPE	DESCRIPTION	EXAMPLE VALUE
address	address	The address of the branch	
type	string	The type of branch	atm
id	string	The ID of the branch	9d72ece0-7e7b-11e5-9038-55f9f9c08c06

Notice that for the address property, the type section refers to the definition that you created within your API, and the example is blank. In this way, you can create complex data structures.



20. Click Save.
21. On the Design view, select Paths and click the Plus button to add a new path.
22. In the Path name field, enter `/details`.
23. In the Operations section within the Design view, click the Plus.

24. Select get, and then click Add.



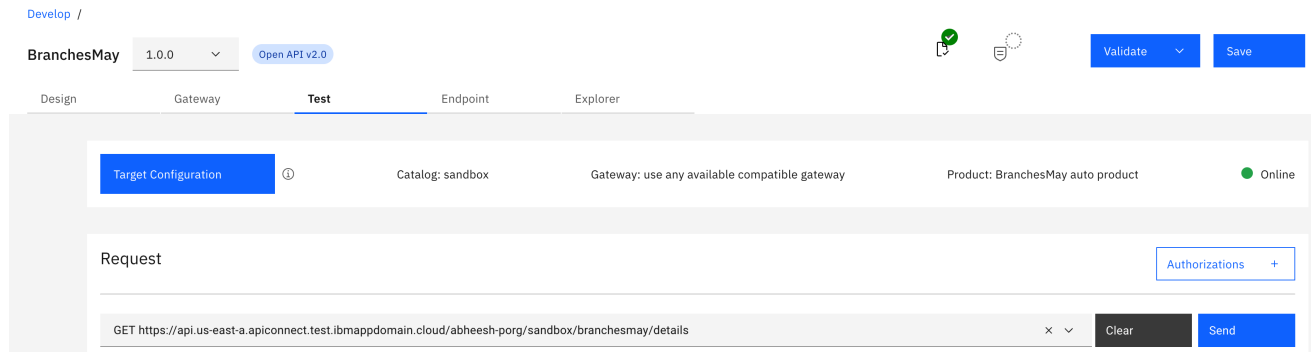
25. Click Save. The new path called /details appears in the list of available paths.
26. Click /details so you can edit the GET operation in the Path.
27. On the Design view, under Paths > Operations, click GET.
28. Scroll down to the Responses section, and edit the response as follows:
    a. Leave `200` as the Name (Key).
    b. Edit the Description field to be `200 OK`.
29. Click Save.
30. In the page banner, click Preferences .
    In the Preferences dialog box, configure the following settings:
    a. Set Auto-publish to **On**.
    b. Set a Target product rate limit.
        i. Click Edit.
        ii. In the Choose a Rate Limit dialog box, select Custom.
        iii. Set Number of Calls to **5** calls per **hour**.
        iv. Click **Choose Rate Limit**.
    c. In the Preferences dialog box, click Save Preferences.
31. Click **Save** to update the API.

Now the API is online and available for use, so you can test it.

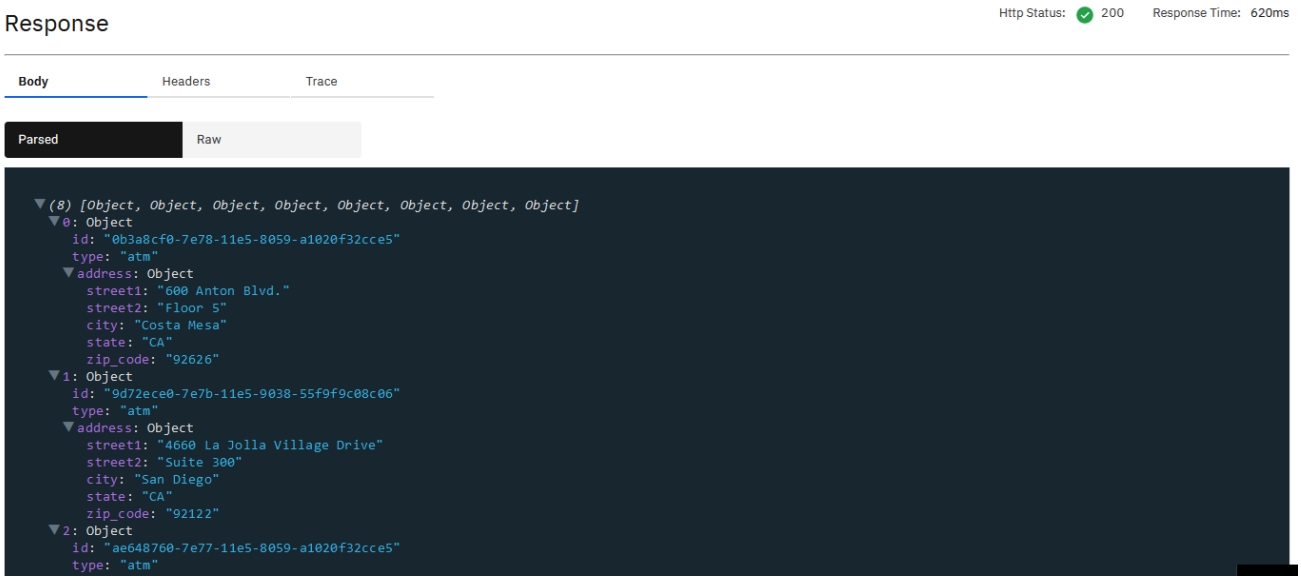
Testing the REST API

Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test the REST API, complete the following steps.

1. On the Develop page, click the API to edit it.
2. Click the Test tab.
3. In the Test page's banner, verify that the API is set to "Online".



4. Click Send in the Request section to execute an API call, which tests the API. The response displays the status code that you defined (200) and the bank branch data that the API retrieved.



5. Click Send at least 5 more times so that you exceed the defined rate limit. Now the response returns the status code 429 "Too many requests" to indicate that you exceeded the rate limit.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a REST API definition.
- Tested the REST API.

Related information

- Creating an API definition

Tutorial: Creating a SOAP API

This tutorial shows you how to create an API definition by using a SOAP service Web Service Definition Language (WSDL). This API definition simplifies creating and managing access to the SOAP service.

About this tutorial

Follow this tutorial to create an API in API Manager by importing the WSDL for an existing SOAP service. Both SOAP 1.1 and SOAP 1.2 standards are supported by API Connect. When invoked, the API takes a SOAP request from the API caller and uses it to make its own request to the SOAP service. The API then returns the response of the SOAP service. In this tutorial, the SOAP service returns the balance of a fictional bank account for a particular user.

In this tutorial you will complete the following lessons:

1. Creating a SOAP API
2. Testing your SOAP API

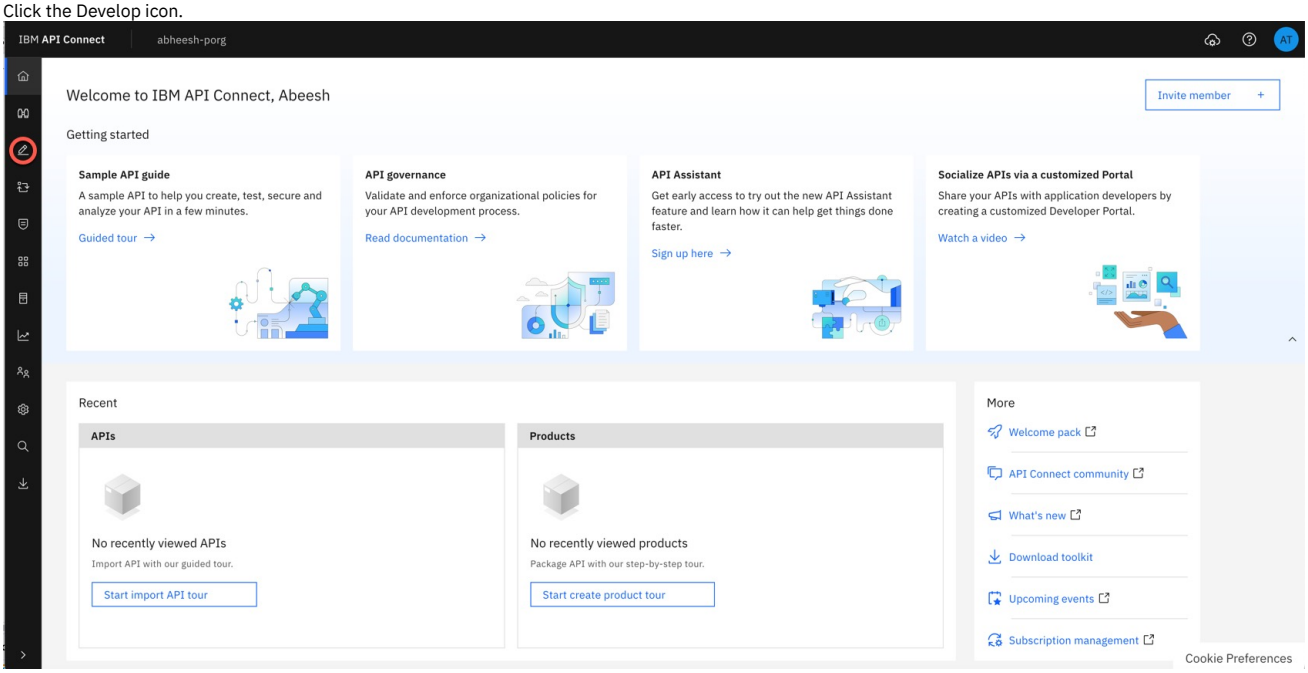
Before you begin

Note: The Sandbox catalog must be configured to use either a DataPower® API Gateway, or a DataPower Gateway (v5 compatible), or both. See Creating and configuring Catalogs.

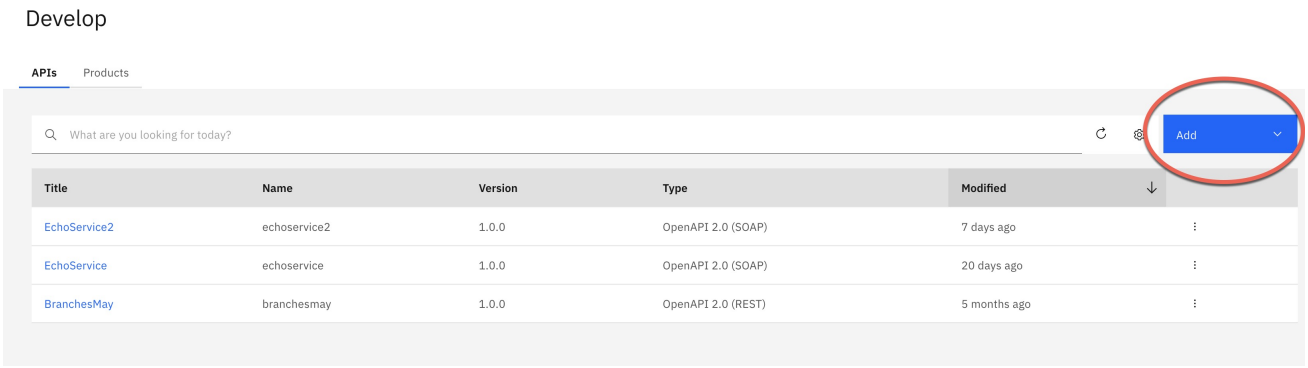
Creating a SOAP API

To create an API for an existing SOAP service, complete the following steps.

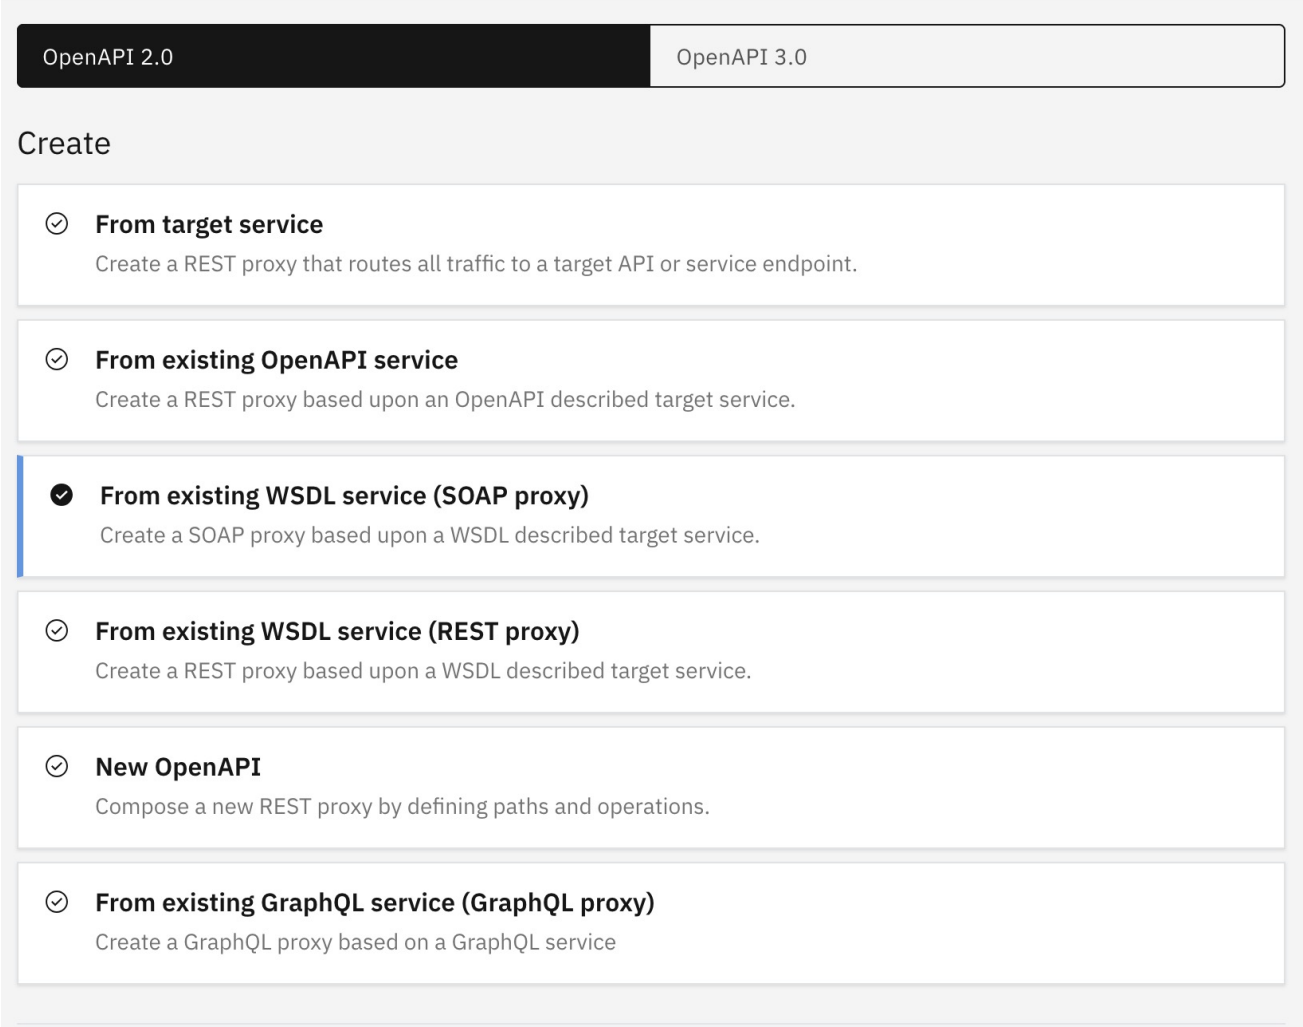
1. Download the SOAP WSDL file AccountServicing.txt. Rename this file `AccountServicing.wsdl`.
2. Log in to the API Manager UI.
3. Click the Develop icon.



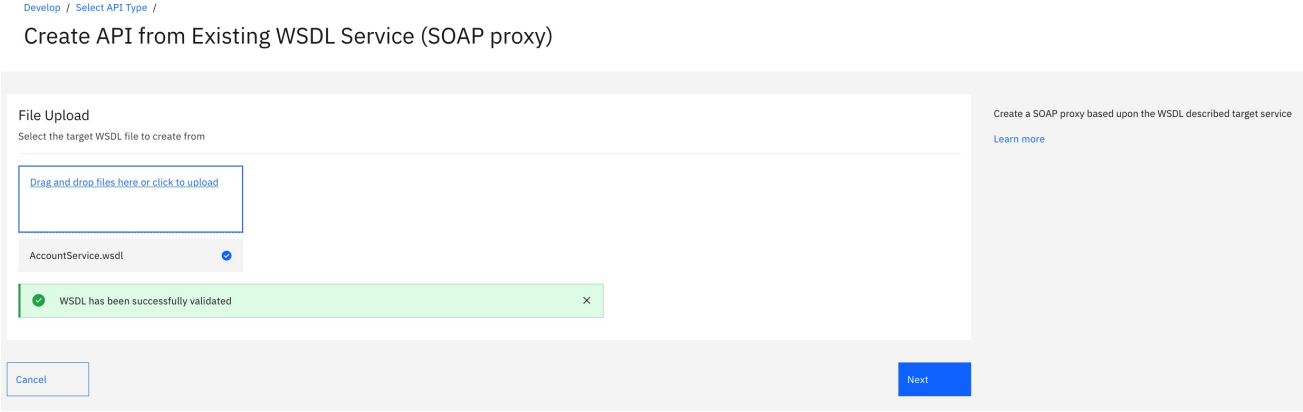
4. Click Add > API.



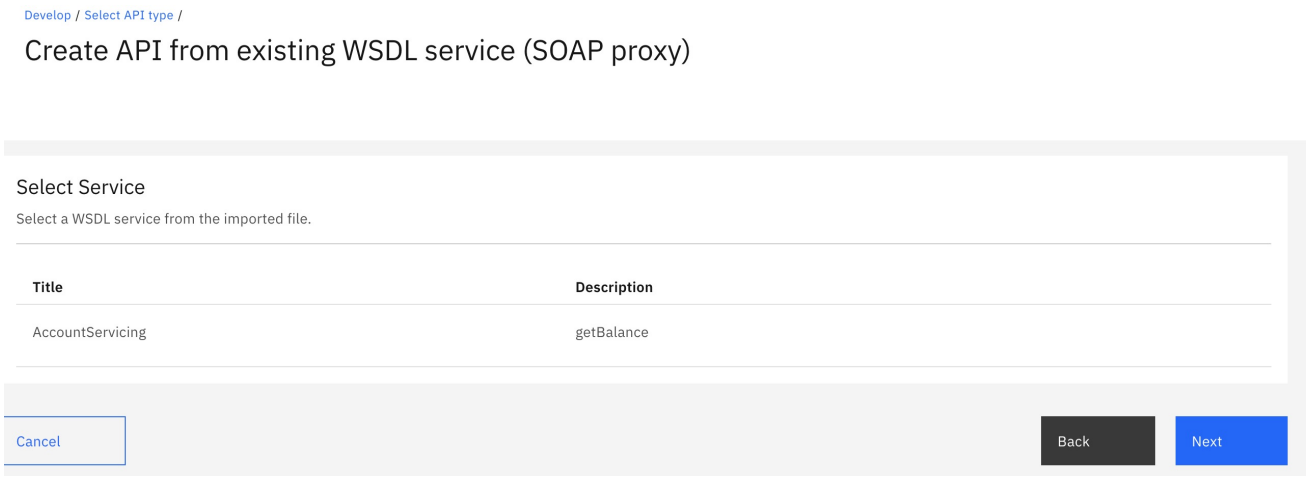
5. Ensure that OpenAPI 2.0 is selected.
6. Select From existing WSDL service (SOAP proxy). Click Next.



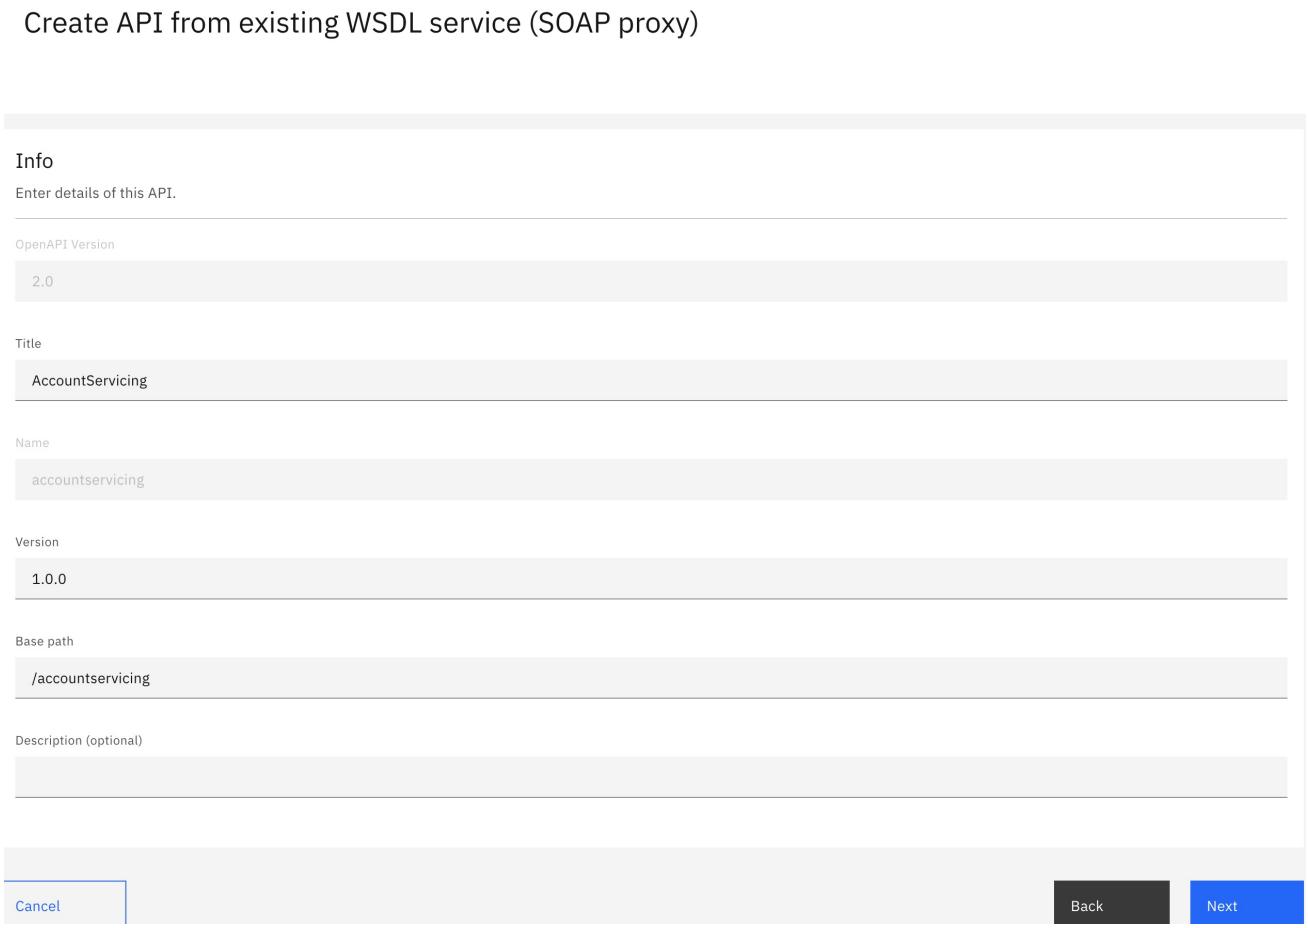
7. In the File Upload section, either drag and drop the `AccountServicing.wsdl` file, or click to upload from your filesystem.



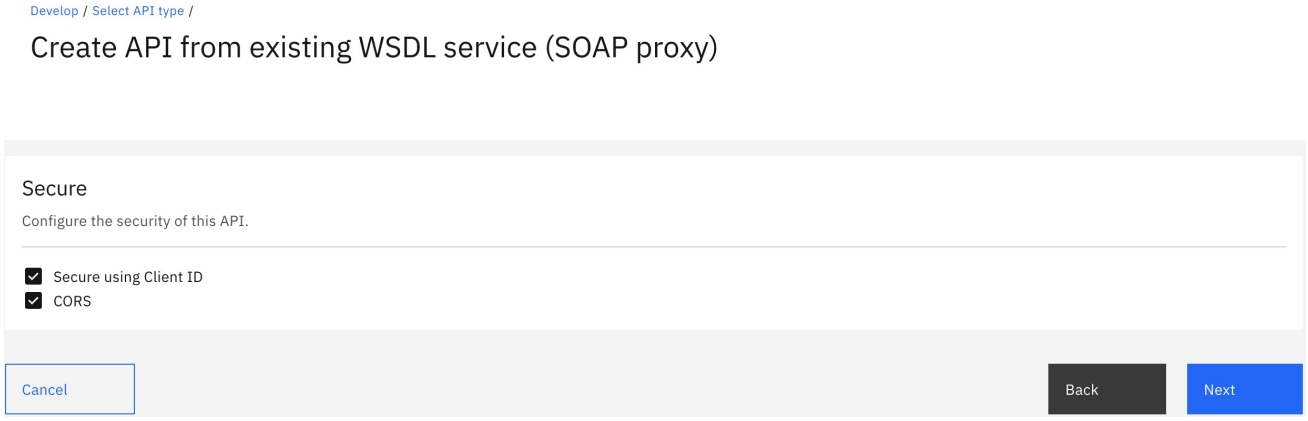
8. The file uploads, and is parsed by API Connect. A confirmation message is displayed. Click Next to continue.
9. The AccountServicing WSDL service gets selected, click Next.



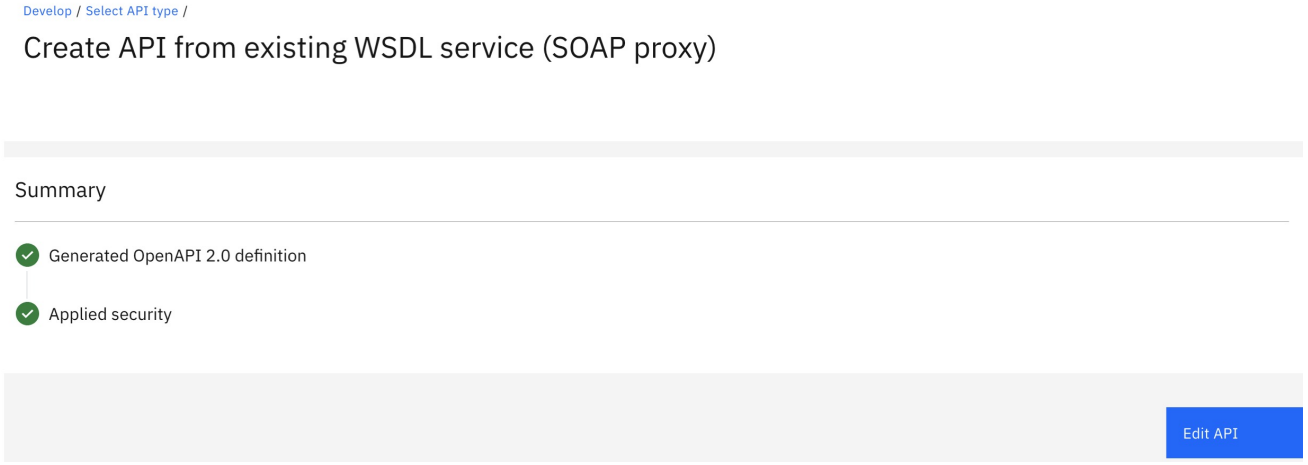
10. Leave the values unchanged in the Info section, and click Next.



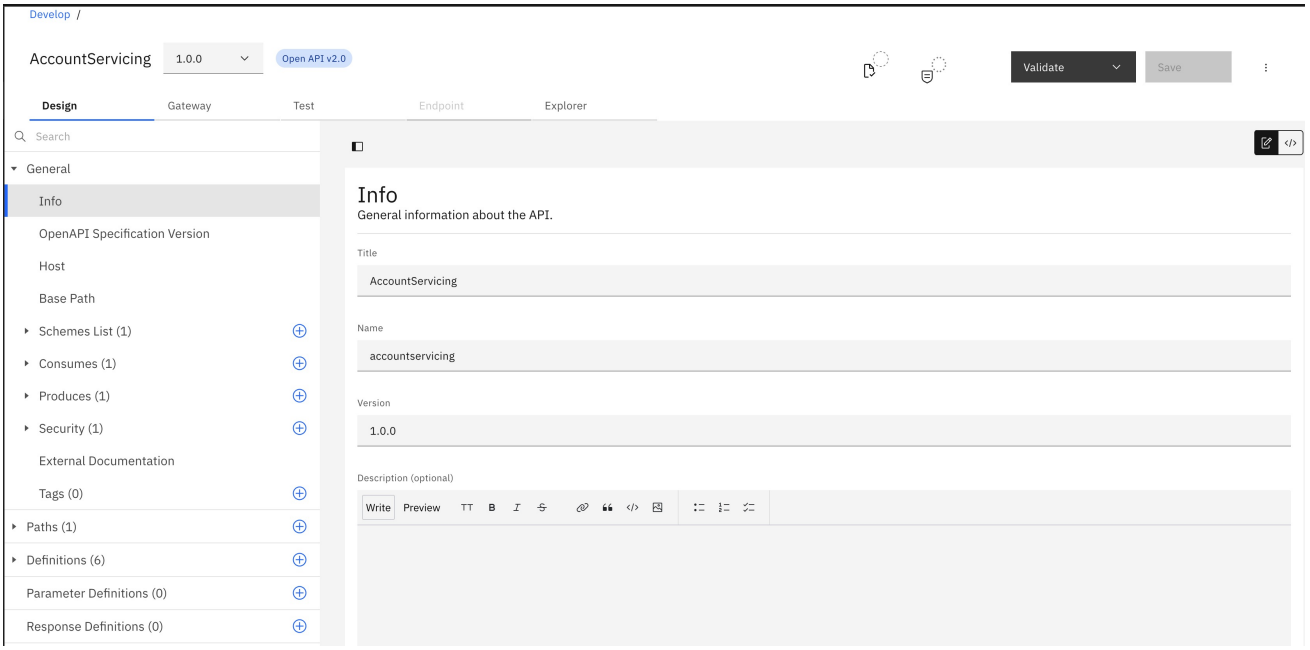
11. In the Secure section, ensure that Secure using Client ID and CORS check boxes are selected. Click Next.



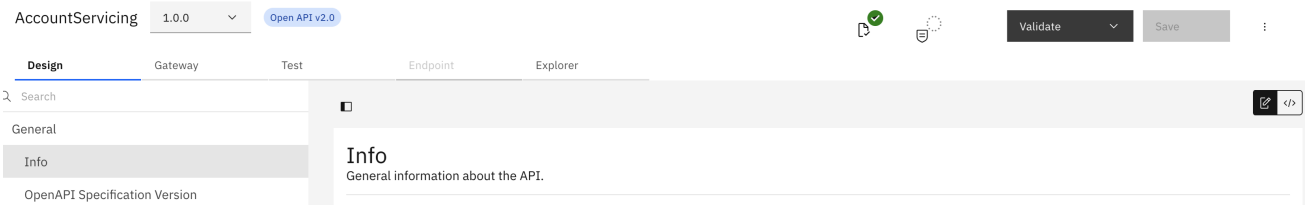
12. A Summary screen is now displayed.



13. Click Edit API.



14. Click Validate > with Specifications. Your SOAP API is now online.

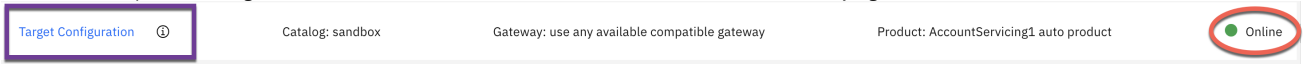


You successfully created a SOAP API. The WSDL file provided all the information that was needed to configure the API inputs and response.

Testing your SOAP API

To test your SOAP API, complete the following steps.

1. Click the Test tab of the AccountServicing API.
2. Click Target Configuration to open the Preferences dialog box.
3. Enable the Auto-publish setting and click Save Preferences. You will see the API is now online, indicated by a green marker.



4. Under Request, click Send to test the API. The API response is displayed in the Response section.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a SOAP API definition.

- Tested your SOAP API.

Related information

- Tutorial: Creating a REST API definition that invokes an existing SOAP service
- Creating an API definition

Tutorial: Generate a JSON Web Token (JWT)

This tutorial shows you how to define and implement a REST API definition that generates a JSON Web Token (JWT).

About this tutorial

In this tutorial you complete the following lessons:

1. Generate a JWT
2. Testing the REST API

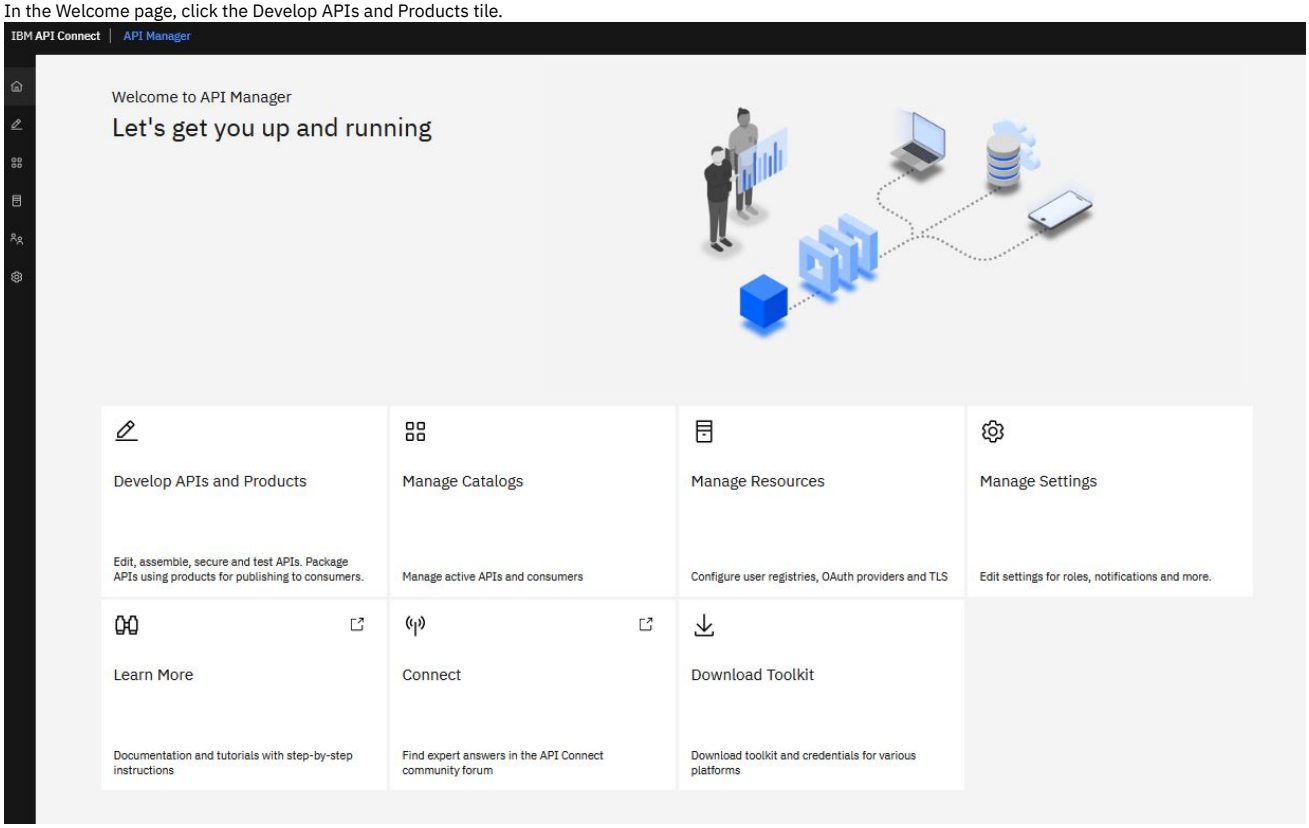
Note: The Sandbox catalog must be configured to use either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway or both. See Creating and configuring catalogs.

Generate a JWT

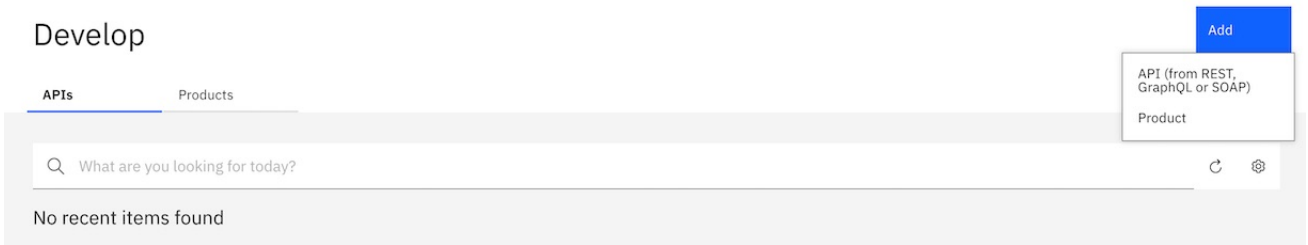
Create a REST API to generate and return a JSON Web Token (JWT).

To add and define this REST API, complete the following steps:

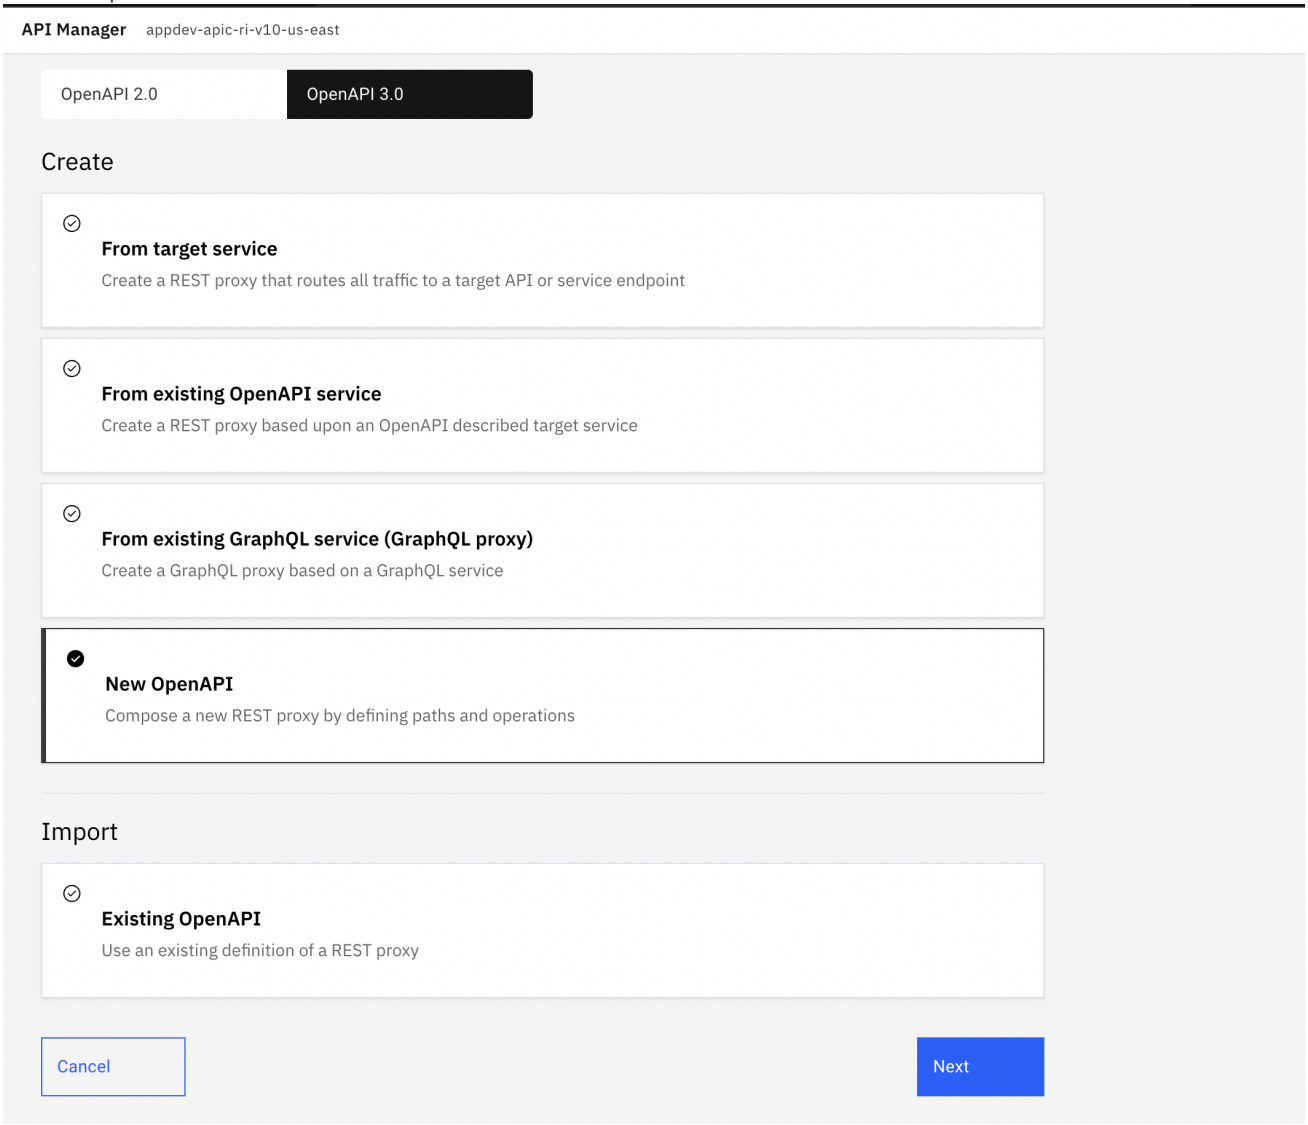
1. Log in to API Manager.
2. In the Welcome page, click the Develop APIs and Products tile.



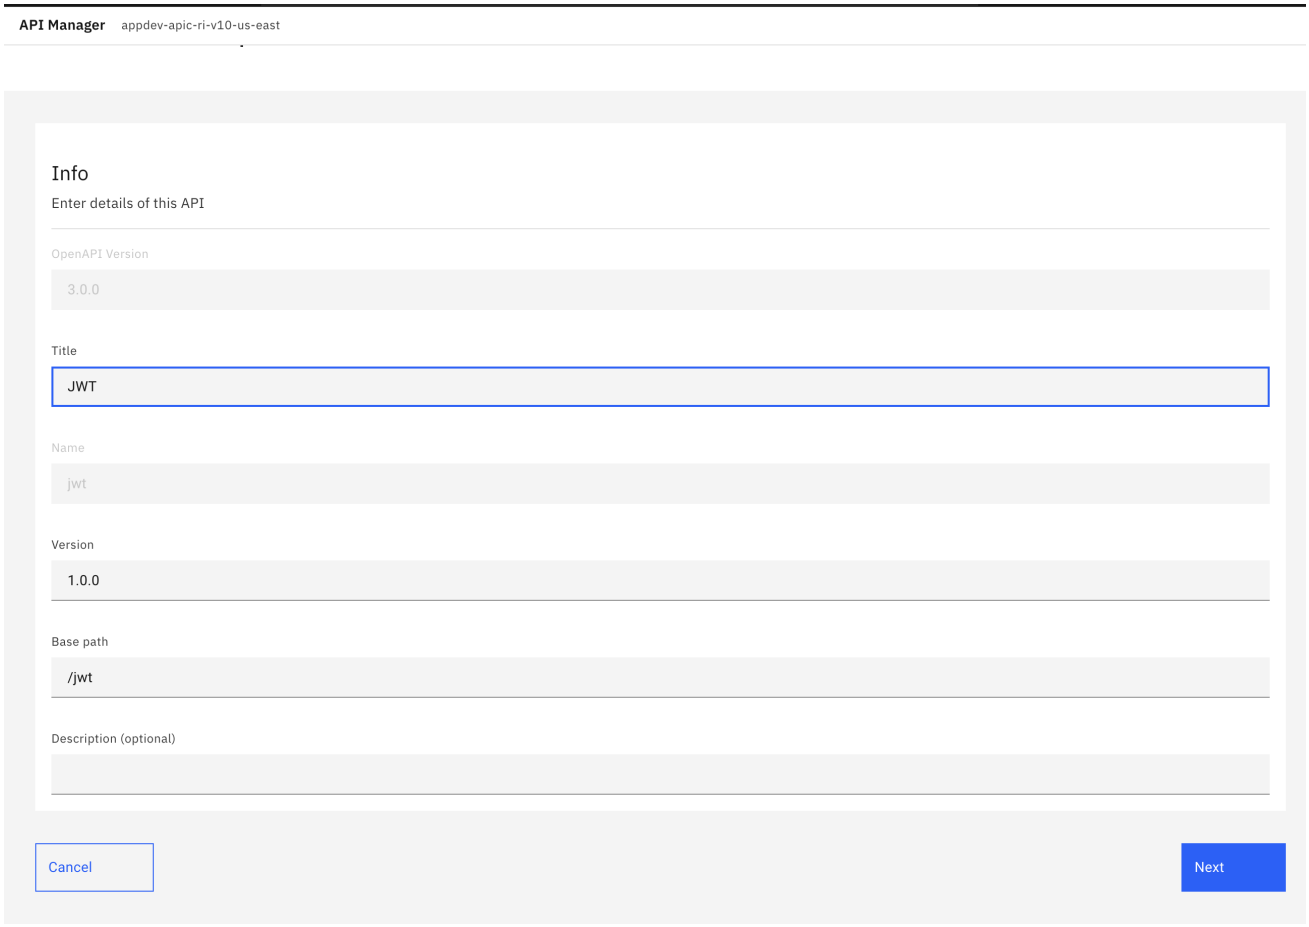
3. Click Add > API (from REST, GraphQL or SOAP).



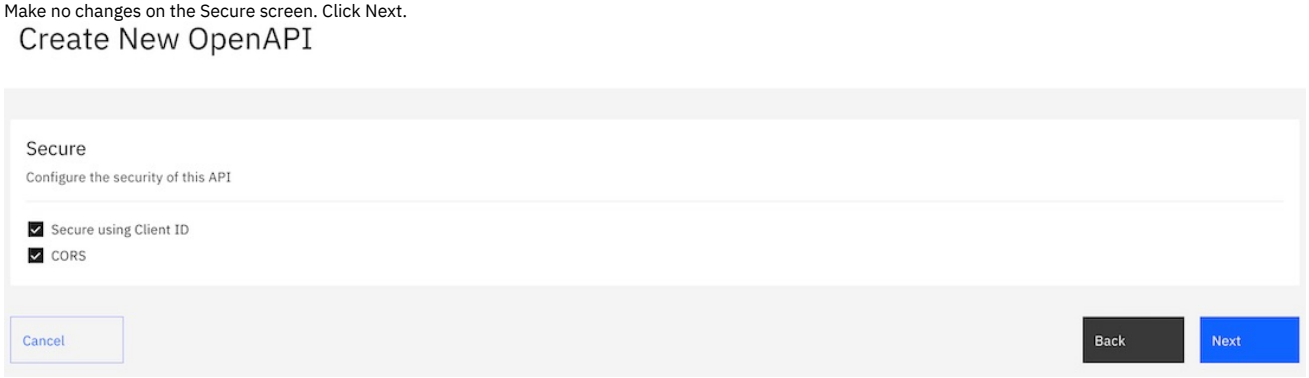
4. Ensure that OpenAPI 3.0 is selected.
5. Select New OpenAPI. Click Next.



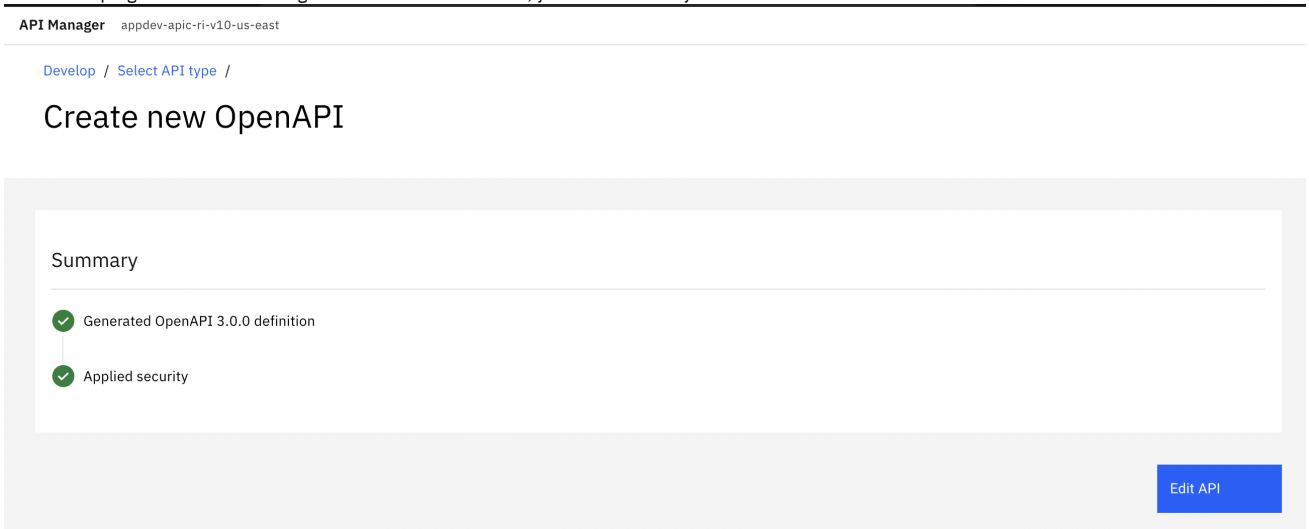
6. Enter the appropriate information to create a REST API definition.
   a. In the Title field, enter `JWT`.
   b. The Name and Base Path fields auto-populate with the terms `jwt` and `/jwt` respectively.
   c. The Version field auto-populates with `1.0.0`.



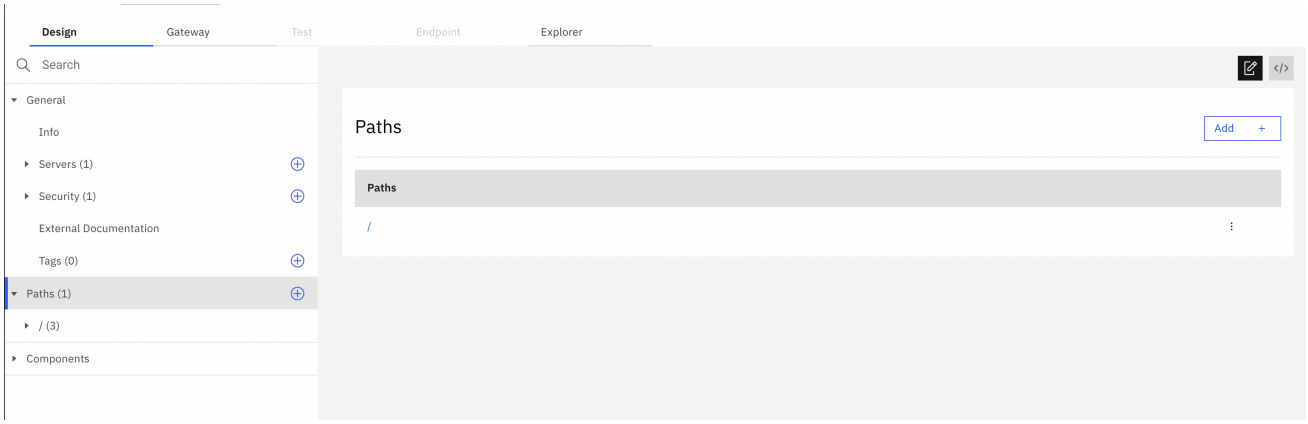
7. Click Next.
8. Make no changes on the Secure screen. Click Next.



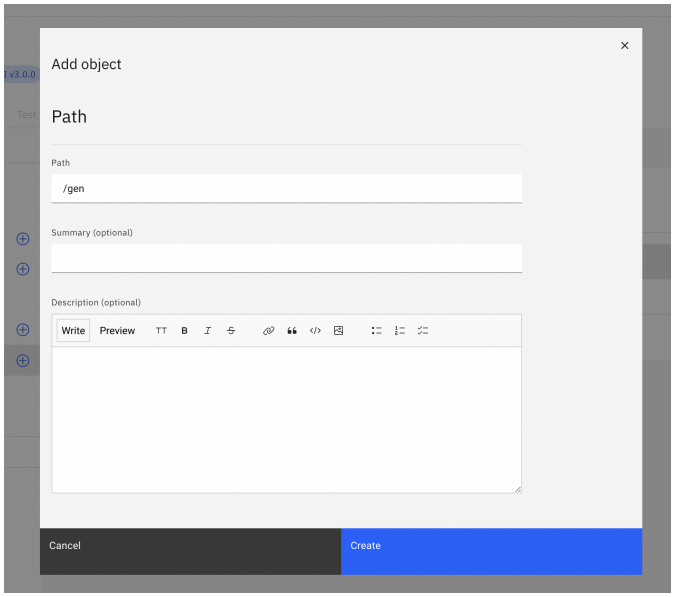
9. You see the progress as the new API gets created. When it is done, you see a Summary. Click Edit API.



10. In the side bar of the Design page, select Paths to display the Paths panel.
11. Click Add.

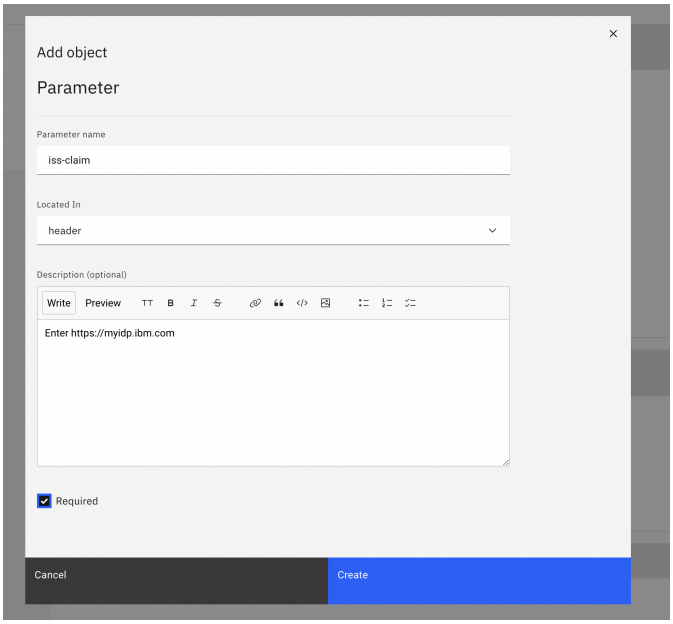


12. In the Path name field, enter /gen.
13. Click Create.



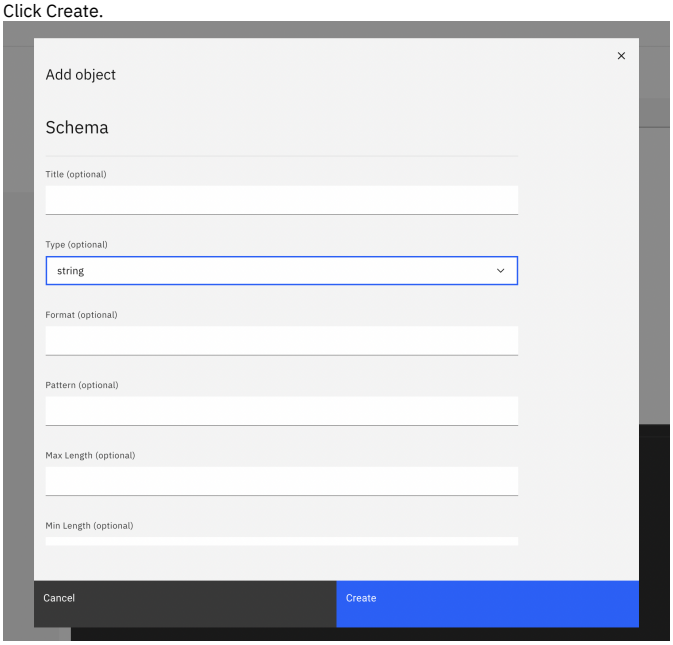
14. Scroll down. In the Parameters section, click Add.

    a. Enter `iss-claim` in the Parameter name field.
    b. Select `header` in the Located In field.
    c. Enter `Enter https://myidp.ibm.com` to match in the Description field.
    d. Select Required.
    e. Click Create.

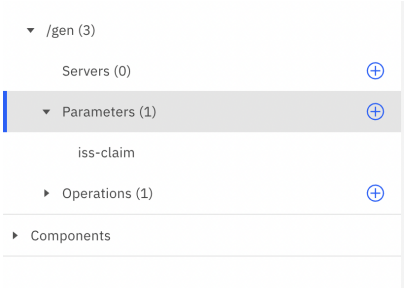


f. Scroll down. In the Schema section, click Create

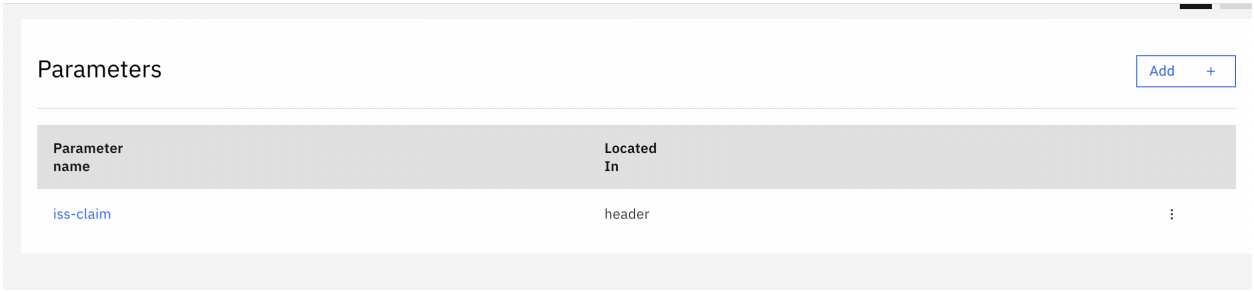
g. Select `string` in the Type field.
h. Click Create.



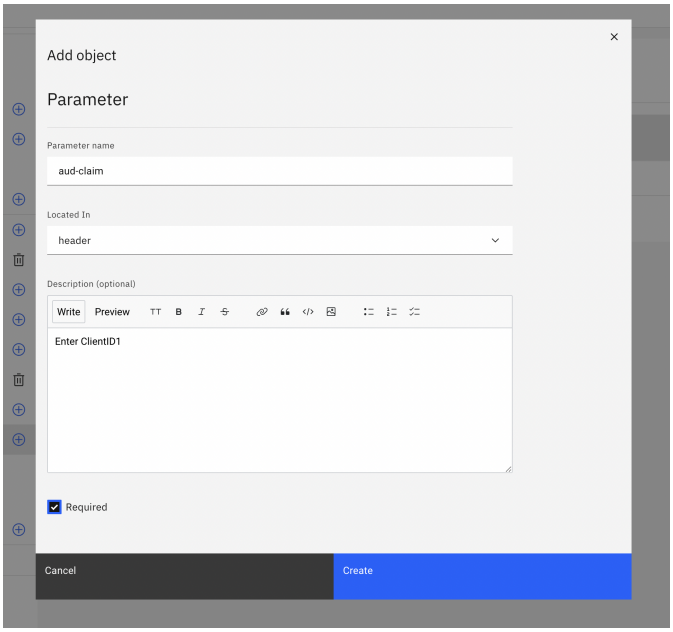
15. After you create the parameter, click Save.
16. To add a second parameter. Complete the following steps:
    a. In the side bar of the Design page, select Parameters under the newly created /gen path.



b. Click Add.

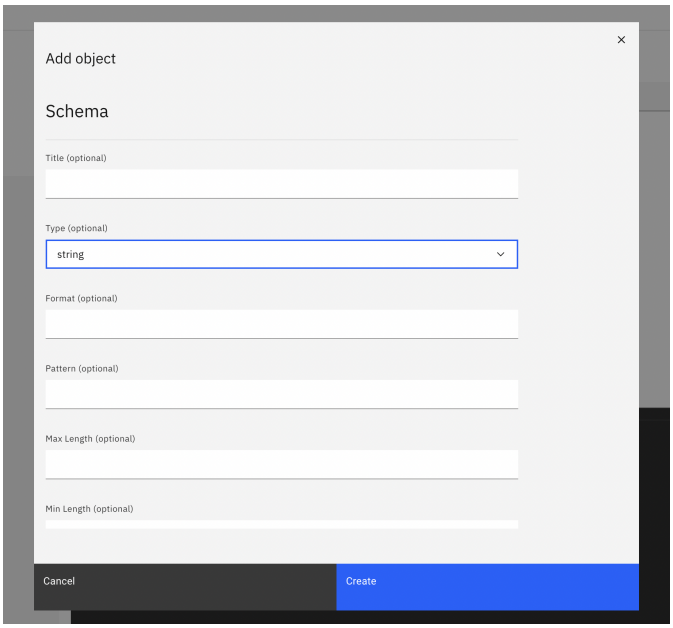


c. Enter `aud-claim` in the Parameter name field.
d. Select the `header` in the Located In field.
e. Enter `Enter ClientID1` to match in the Description field.
f. Select Required.
g. Click Create.

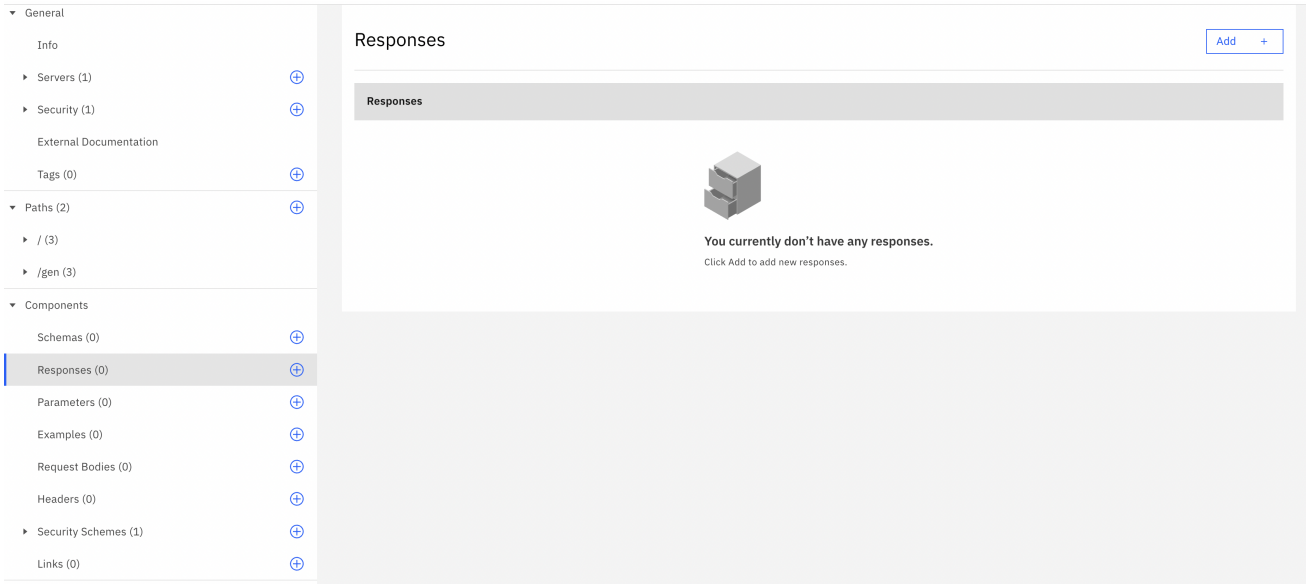


h. Scroll down. In the Schema section, click Create.

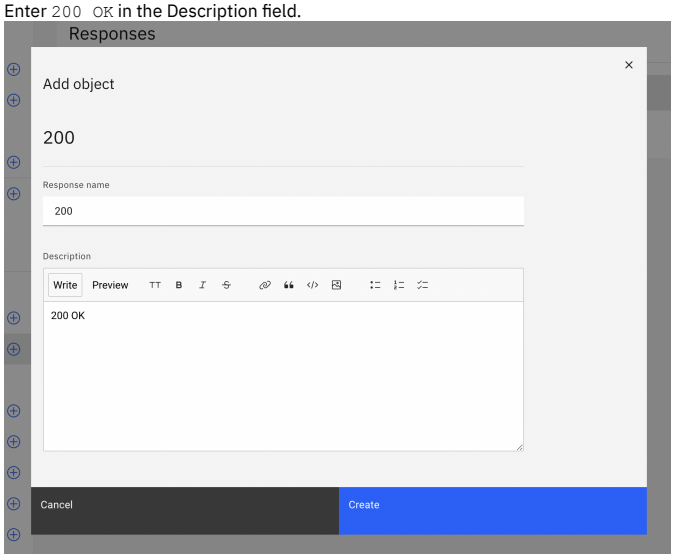
i. Select the `string` in the Type field.
j. Click Create.



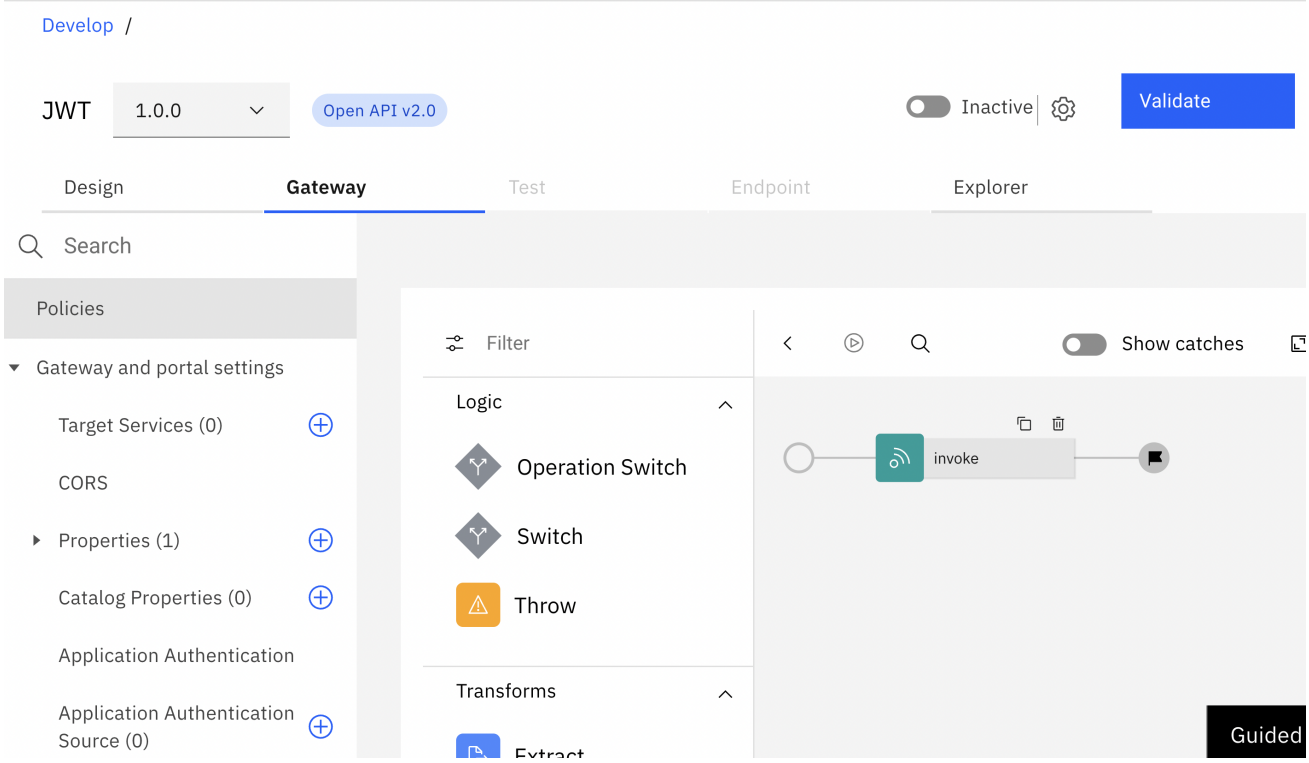
17. After you create the second parameter, click Save.
18. Click Componets > Responses.
19. Click Add.



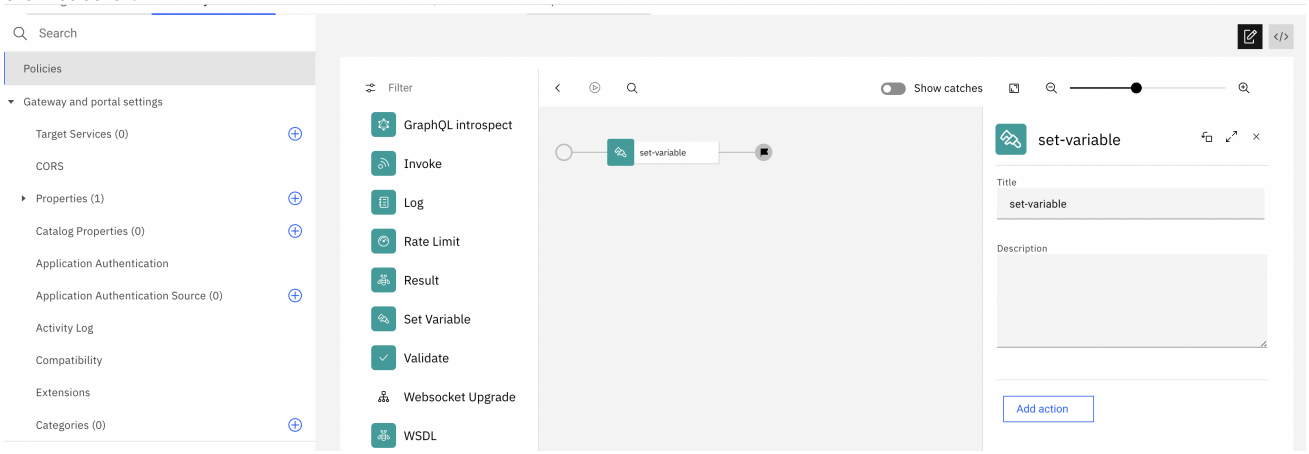
20. The Response name field auto-populates with `200`.
21. Enter `200 OK` in the Description field.



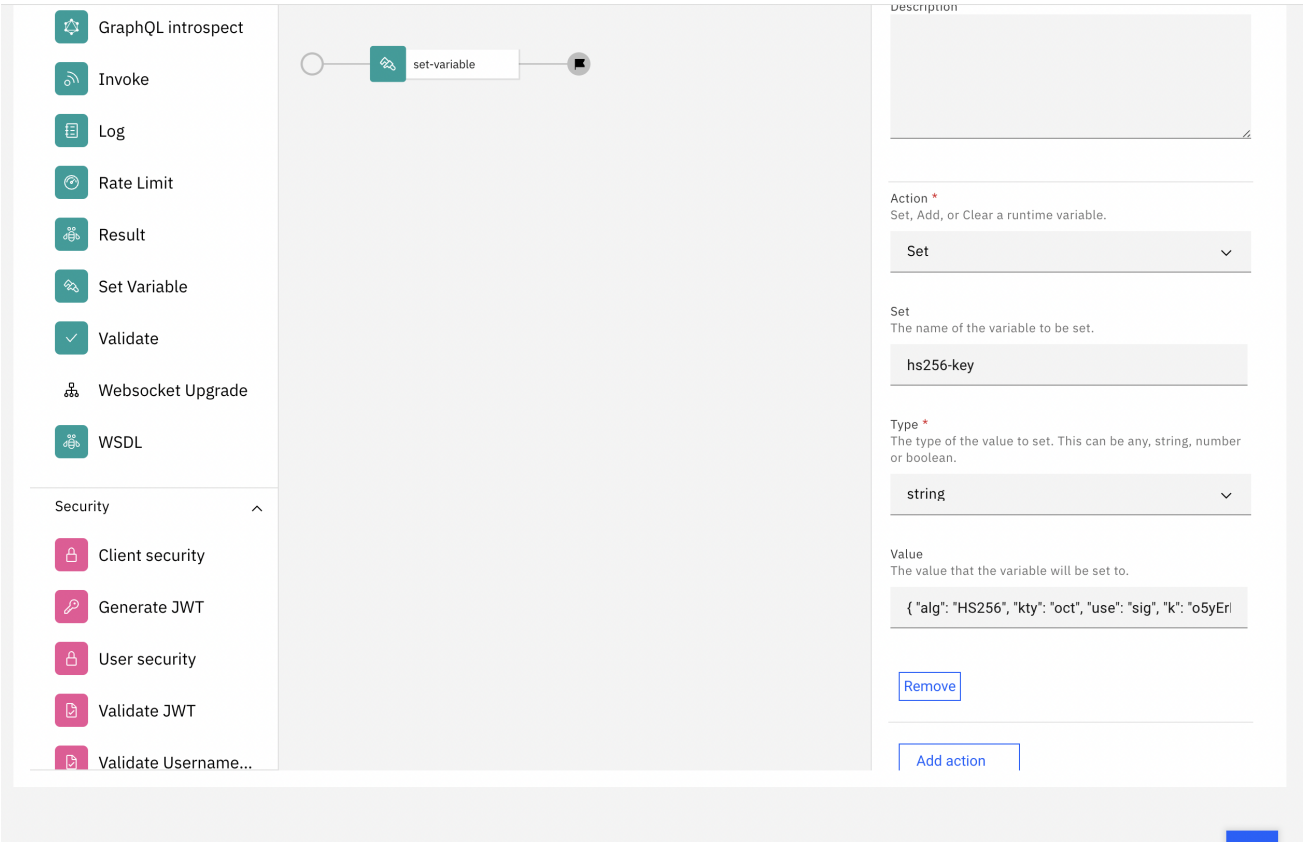
22. After you create the response, click Save.
23. Click Gateway.
24. Hover the mouse over the existing Proxy or Invoke action and click the trash can icon to delete it.



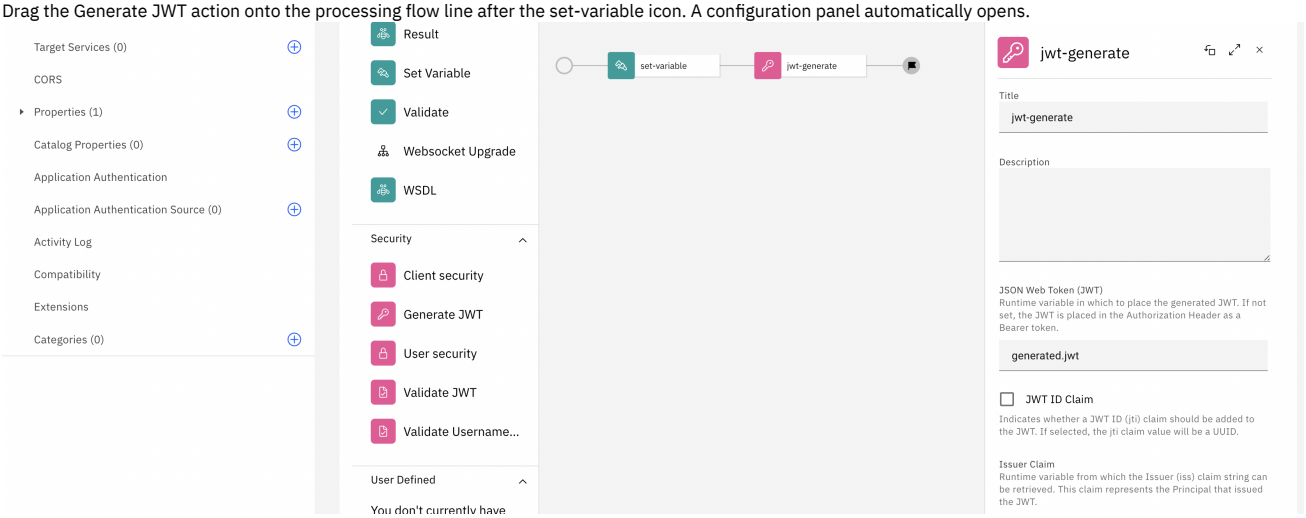
25. Drag the Set Variable action onto the processing flow line. A configuration panel automatically opens.
26. Click Add action.



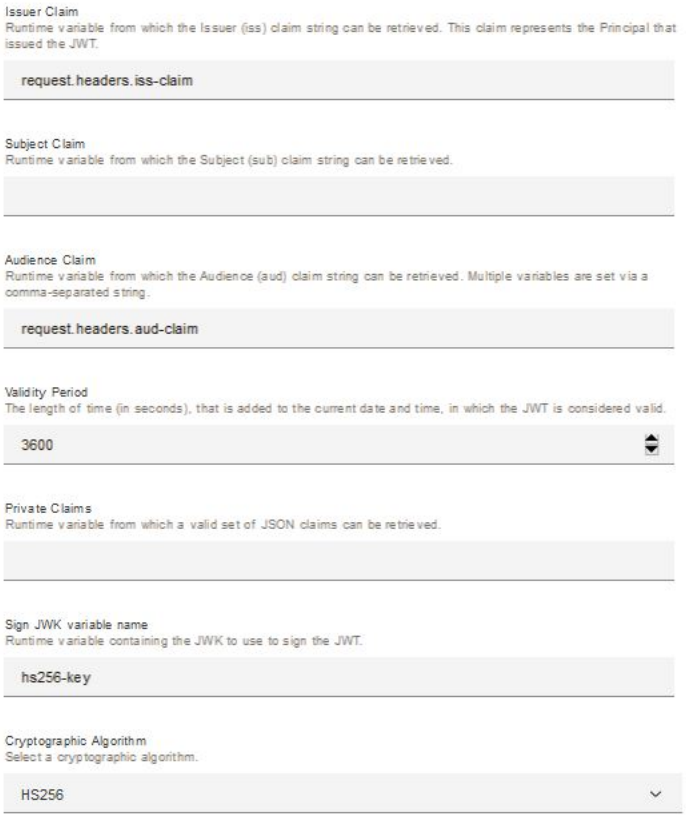
27. Enter `hs256-key` in the Set field.
28. Select `string` in the Type field.
29. Enter a JWK in the Value field. Here is an example. `{ "alg": "HS256", "kty": "oct", "use": "sig", "k": "o5yErLaE-dbgVpSw65Rq57OA9dHyaF66Q_Et5azPa-XUjbyP0w9iRWhR4kru09aFfQLXeIODIN4uhjElYKXt8n76jt0Pjkd2pqk4t9abRF6tnL19GV4pflfL6uvVKkP4weOh39tqHt4TmkBgF2P-gFhgssZpjwq6l82fz3dUhQ2nkzoLA_CnyDGLZLd7SZ1yv73uzfE2Ot813zmig8KTMEMWVcWSDvy61F06vs_6LURcq_IEEevUiubBxG5S2akNnWigfpbhWYjMI5M22FOCpdcDBt4L7K1-yHt95Siz0QUb0MNlT_X8F76wH7_A37GpKKJGqeaiNWmHkgWdE8QWDQ", "kid": "hs256-key" }`



30. Close the property panel. Click Save.
31. Drag the Generate JWT action onto the processing flow line after the set-variable icon. A configuration panel automatically opens.

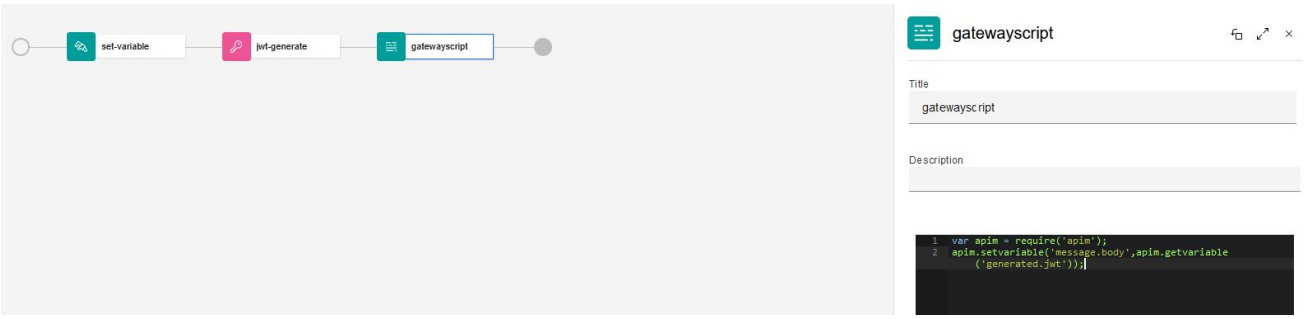


32. Enter `request.headers.iss-claim` in the Issuer Claim field.
33. Enter `request.headers.aud-claim` in the Audience Claim field.
34. Enter `hs256-key` in the Sign JWK variable name field.
35. Select `HS256` in the Cryptogrpahic Algorithm field.



36. Close the property panel. Click Save.
37. Drag the GatewayScript action onto the processing flow line after the Generate JWT icon. A configuration panel automatically opens.
38. Enter the following code:

```
var apim = require('apim');
apim.setvariable('message.body',apim.getvariable('generated.jwt'));
```



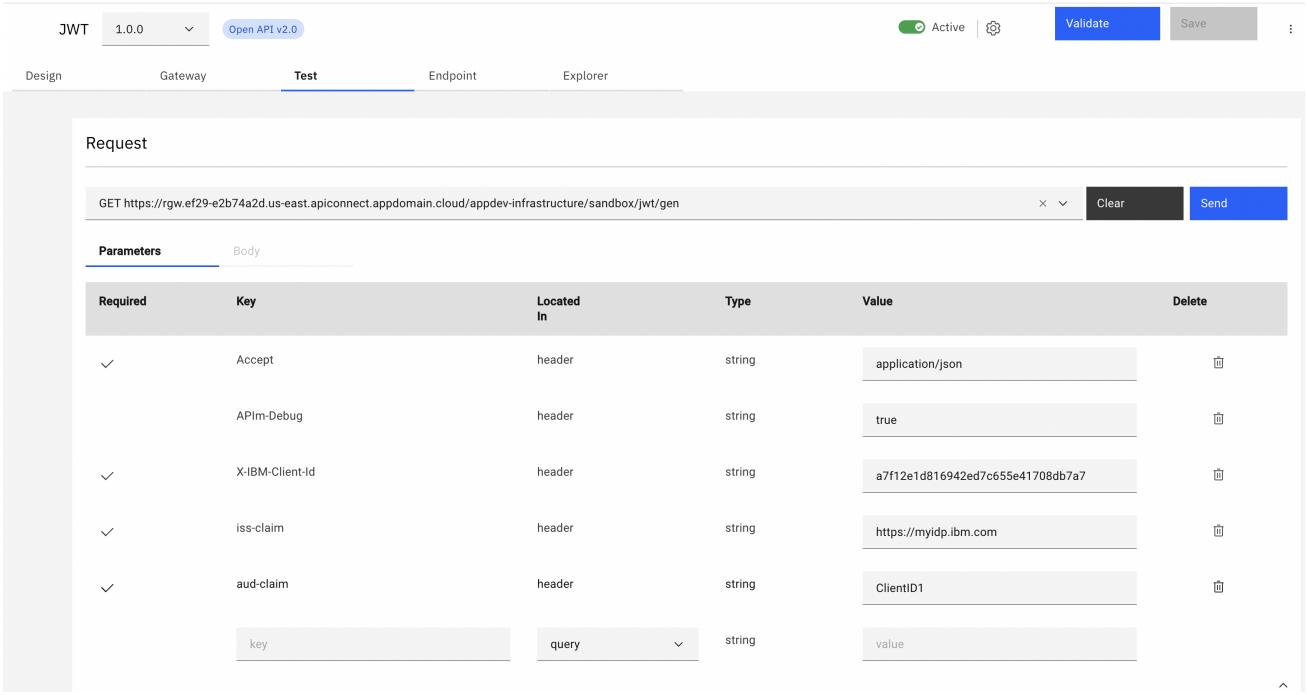
39. Close the property panel. Click Save.

Testing the REST API

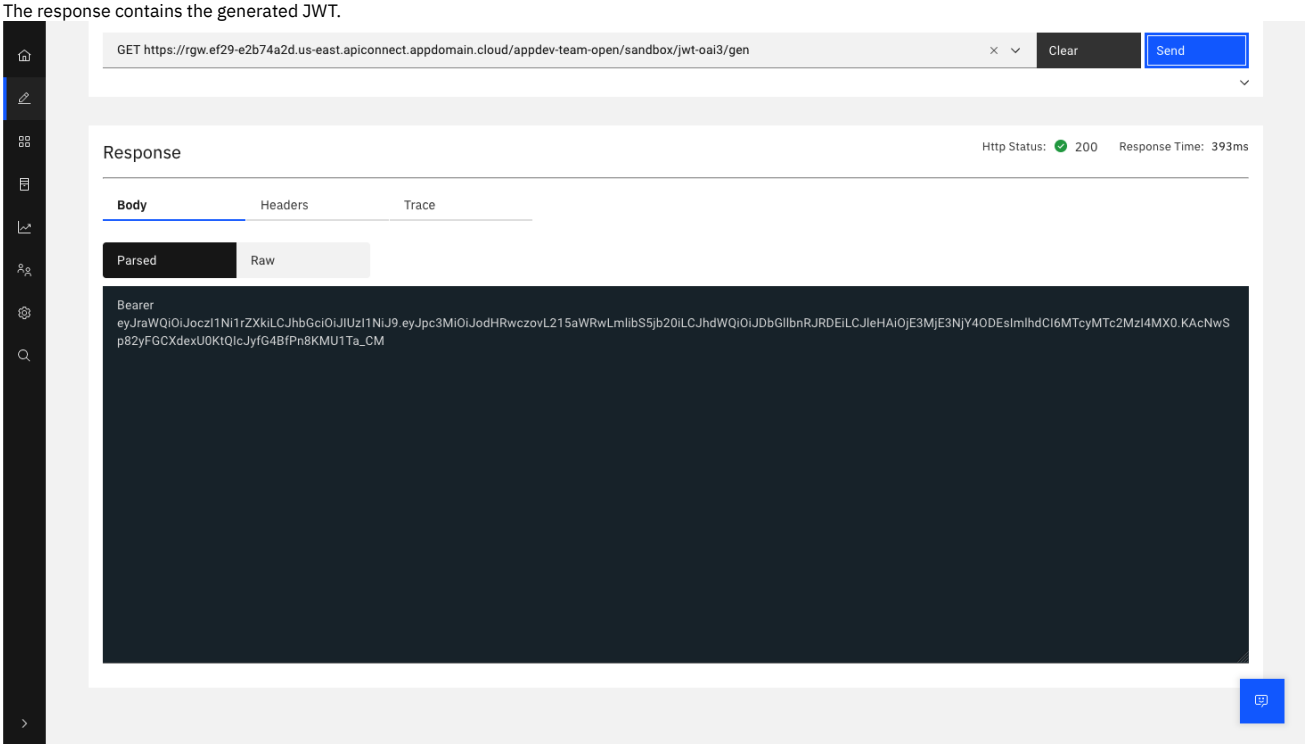
Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test the REST API, complete the following steps:

1. Turn on the activation toggle to activate the API you created.

2. Click Test.
3. Enter `https://myidp.ibm.com` in the Value field corresponding to the iss-claim parameter.
4. Enter `ClientID1` in the Value field corresponding to the aud-claim parameter.
5. Click Send.



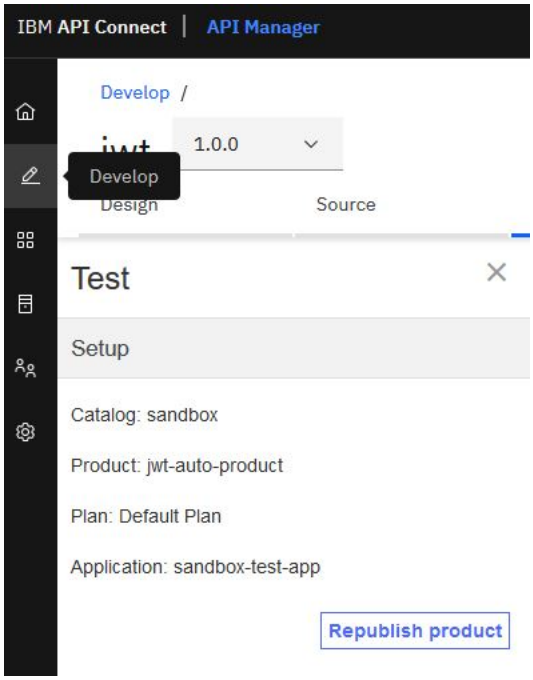
6. The response contains the generated JWT.



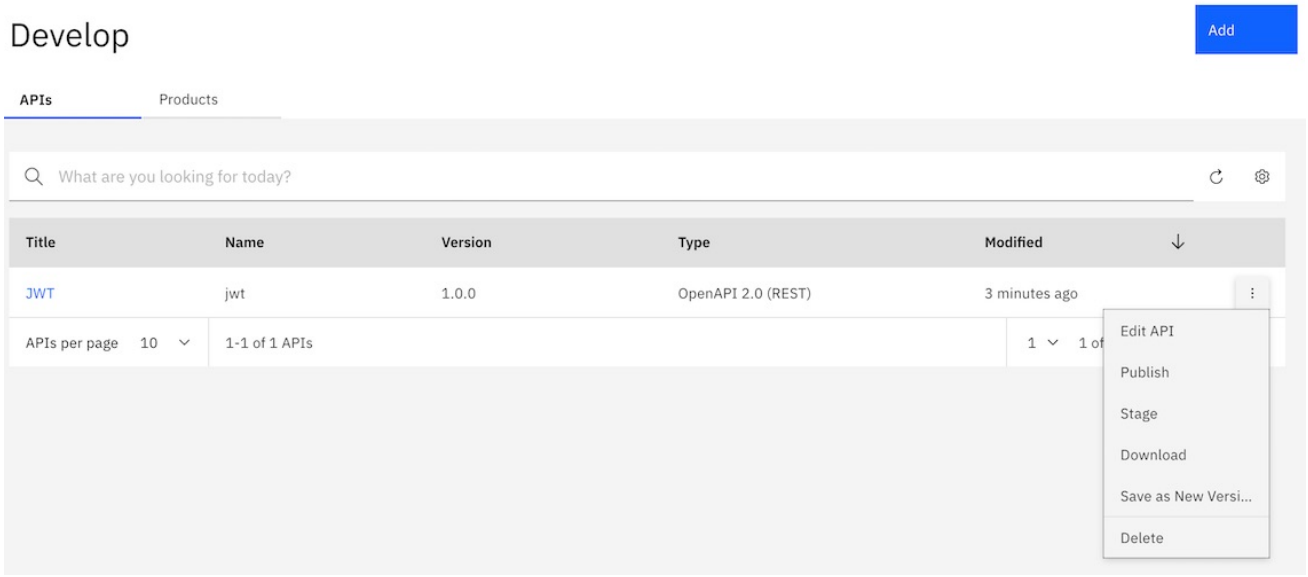
Manage your API definition

Now that your new API works correctly, you can manage this API. To see your immediate options, take the following steps.

1. Click the Develop icon on the navigation bar.



2. Click the Options icon ⋮ alongside the JWT API.



3. Select Download.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a new API definition that generates a JSON Web Token (JWT).
- Tested the new API.

Tutorial: Validate a JSON Web Token (JWT)

This tutorial shows you how to define and implement a REST API definition that validates a JSON Web Token (JWT).

About this tutorial

In this tutorial, you complete the following lessons:

1. Validate a JWT
2. Testing the REST API

Note: The Sandbox catalog must be configured to use either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway or both. See Creating and configuring catalogs.

Before You Begin

You must also do the following steps.

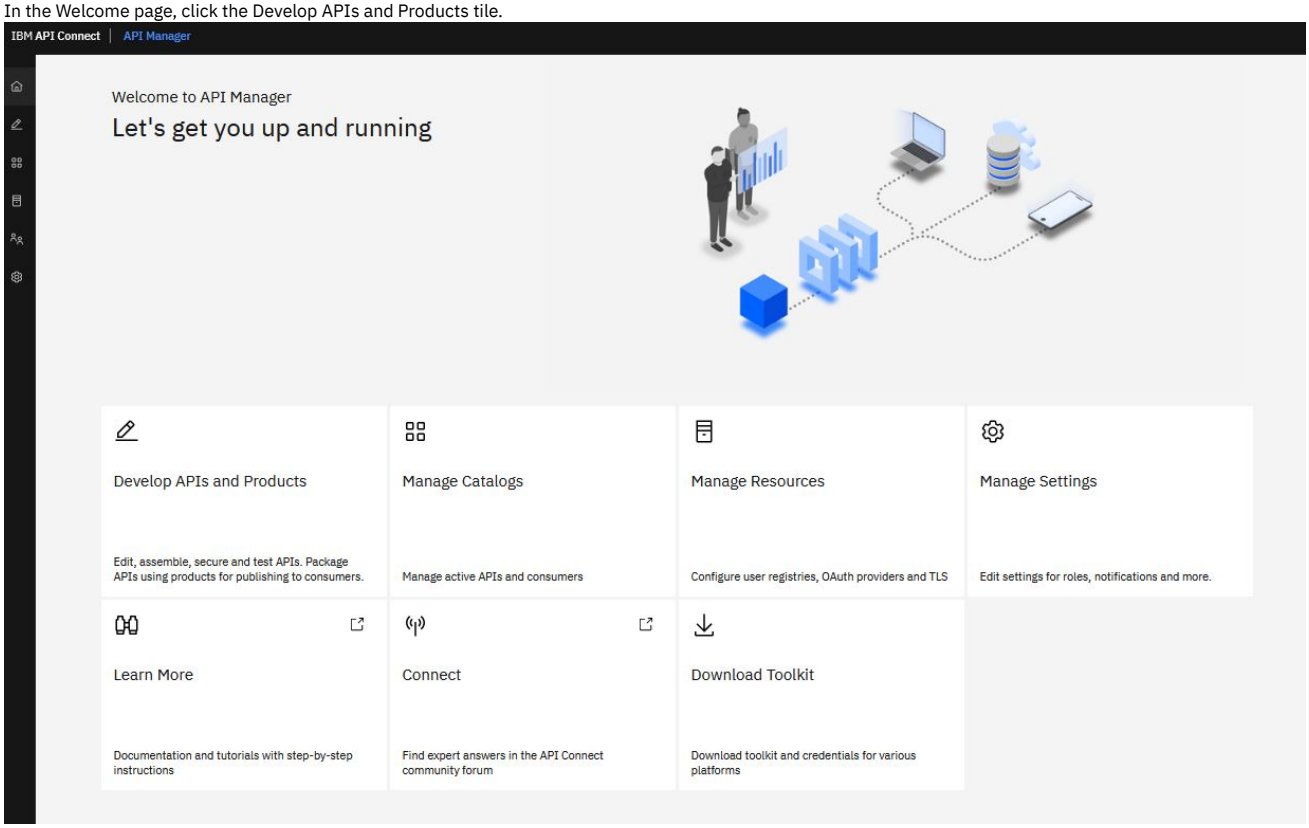
- Complete the Tutorial: Generate a JSON Web Token (JWT) tutorial. This tutorial generates a JSON Web Token that can be validated by this tutorial. You need this JWT to test this validation API.

Validate a JWT

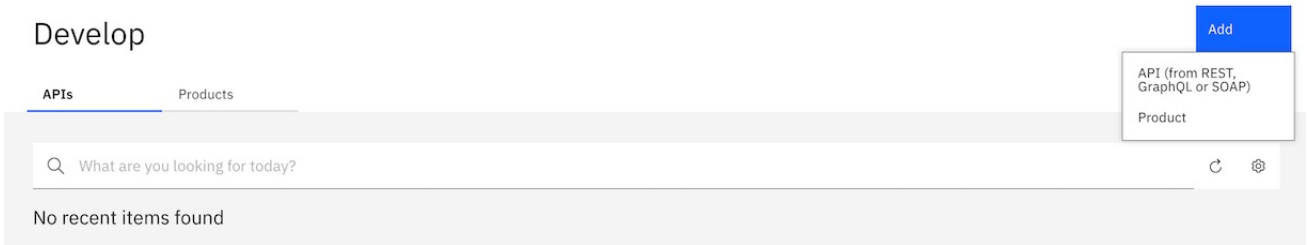
Create a REST API to validate a JSON Web Token (JWT).

To add and define this REST API, complete the following steps:

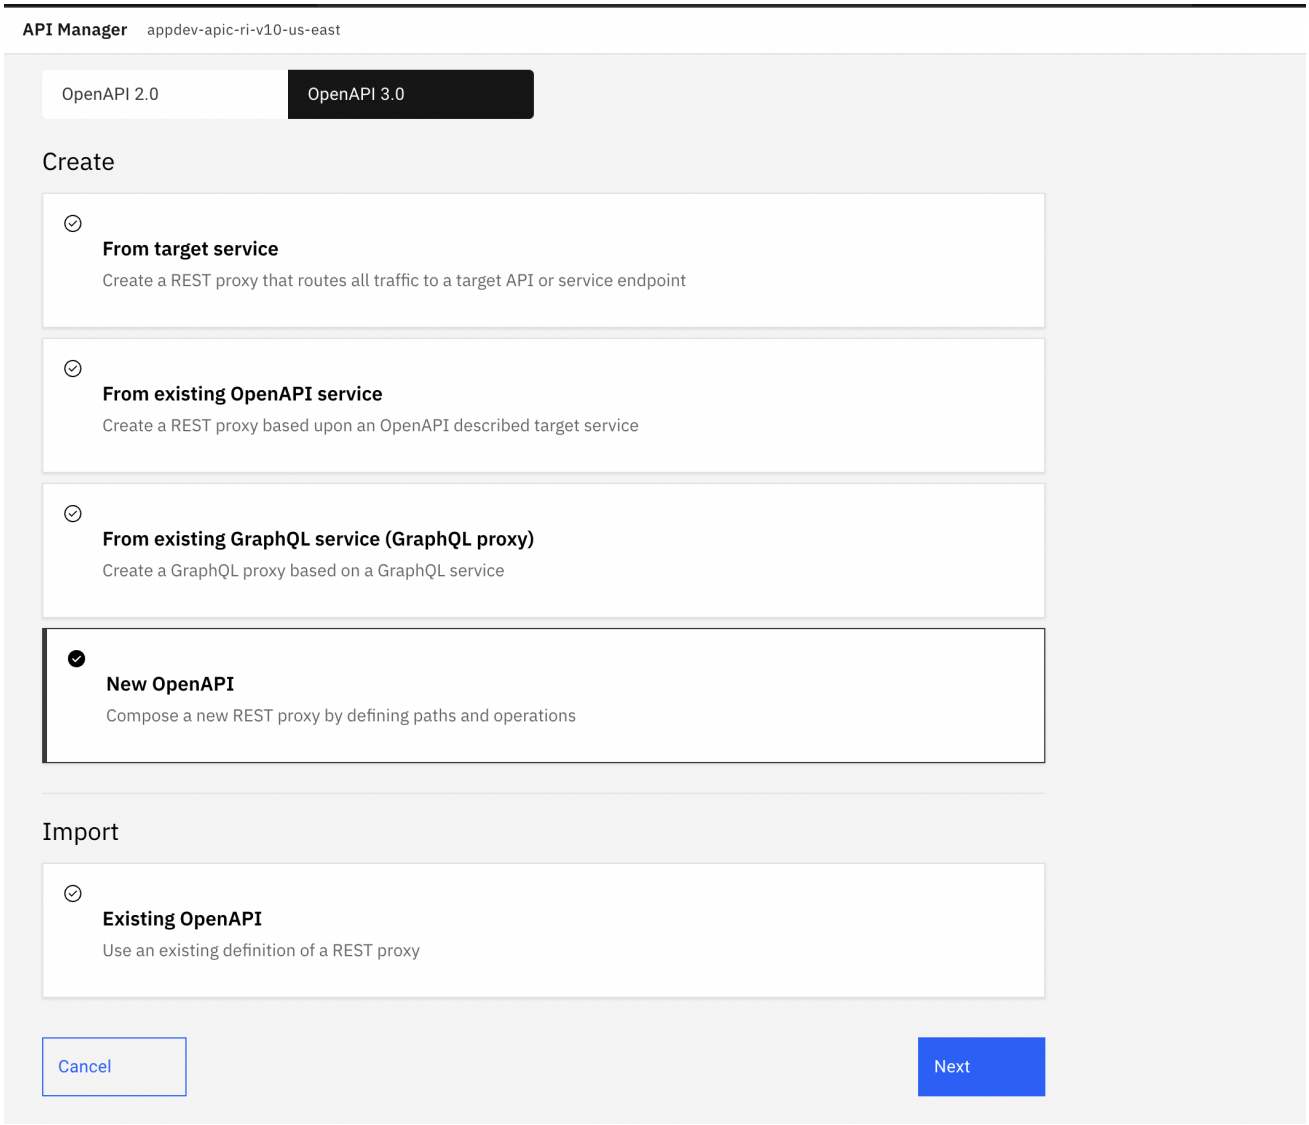
1. Log in to API Manager.
2. In the Welcome page, click the Develop APIs and Products tile.



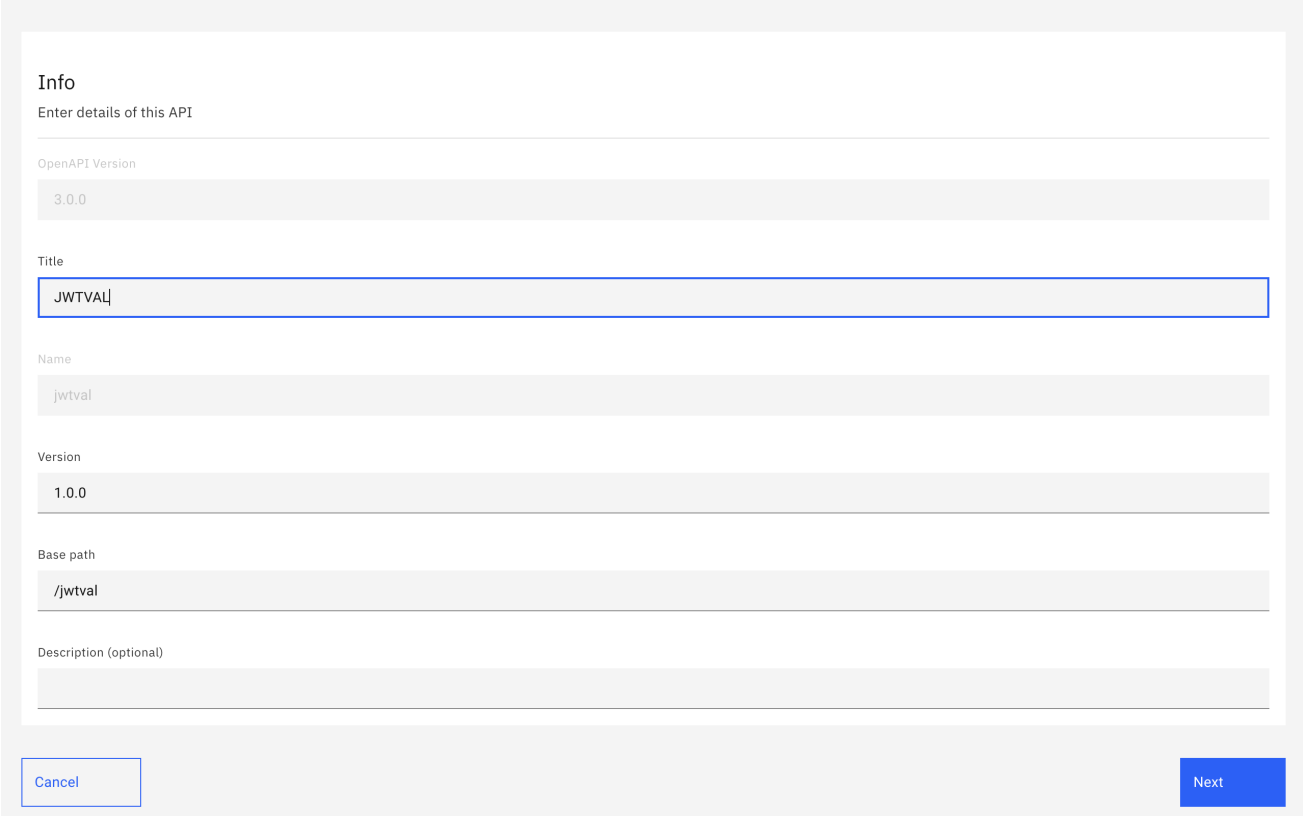
3. Click Add > API (from REST, GraphQL or SOAP).



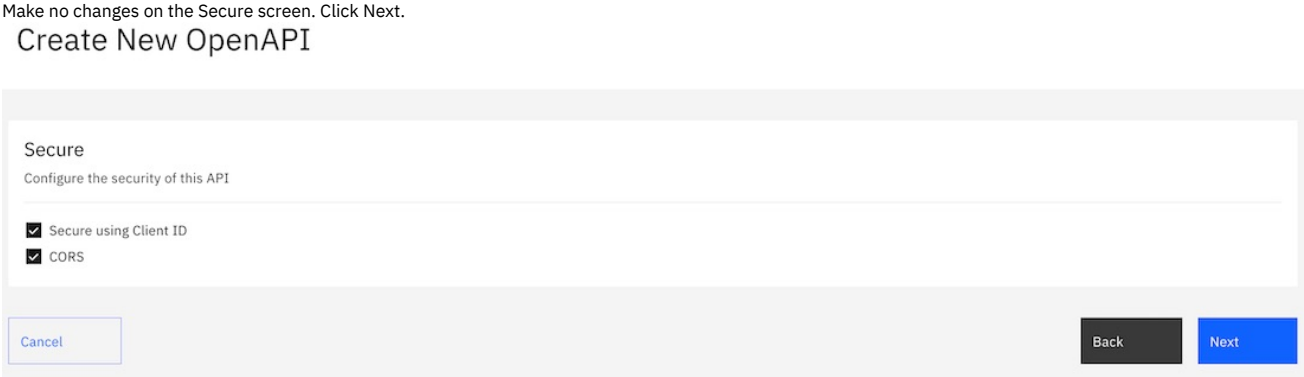
4. Ensure that OpenAPI 3.0 is selected.
5. Select New OpenAPI. Click Next.



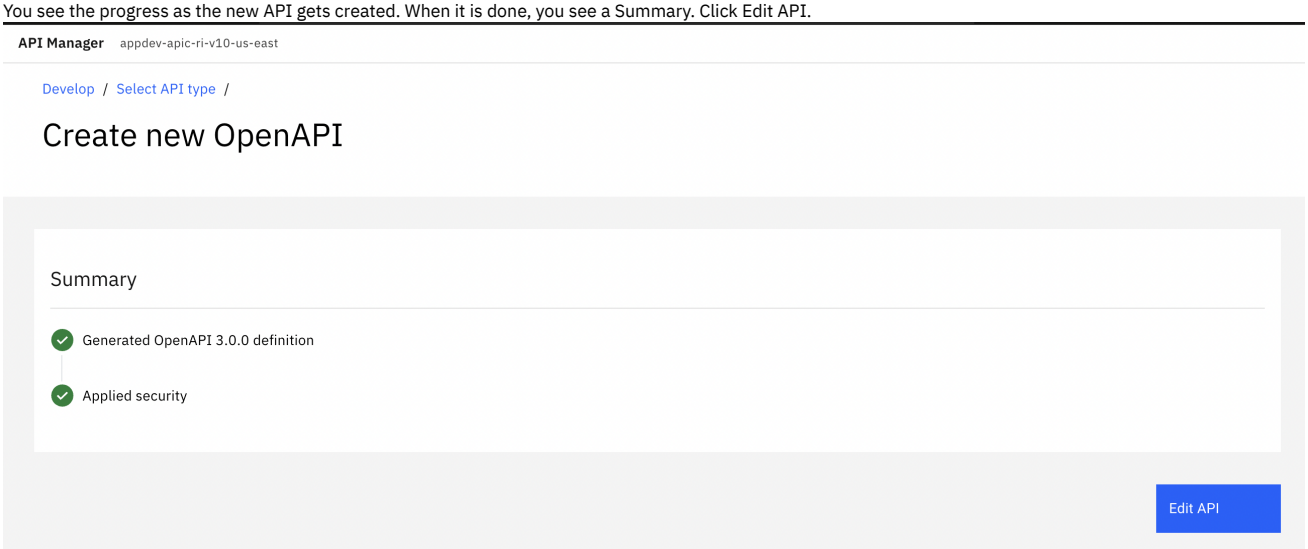
6. Enter the appropriate information to create a REST API definition.
   a. In the Title field, enter `JWTVAL`.
   b. The Name and Base Path fields auto-populate with the terms `jwtval` and `/jwtval` respectively.
   c. The Version field auto-populates with `1.0.0`.



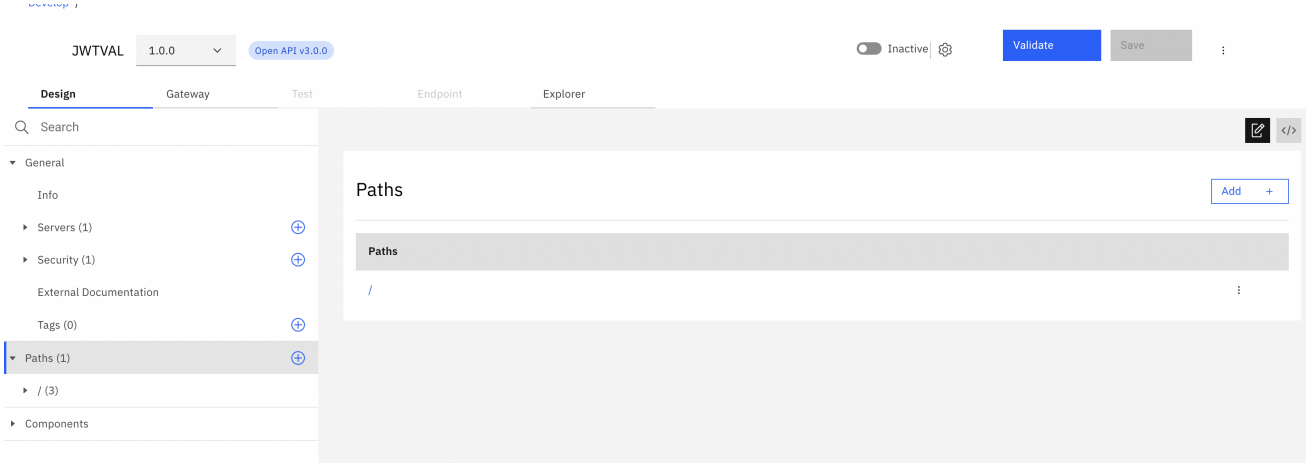
7. Click Next.
8. Make no changes on the Secure screen. Click Next.



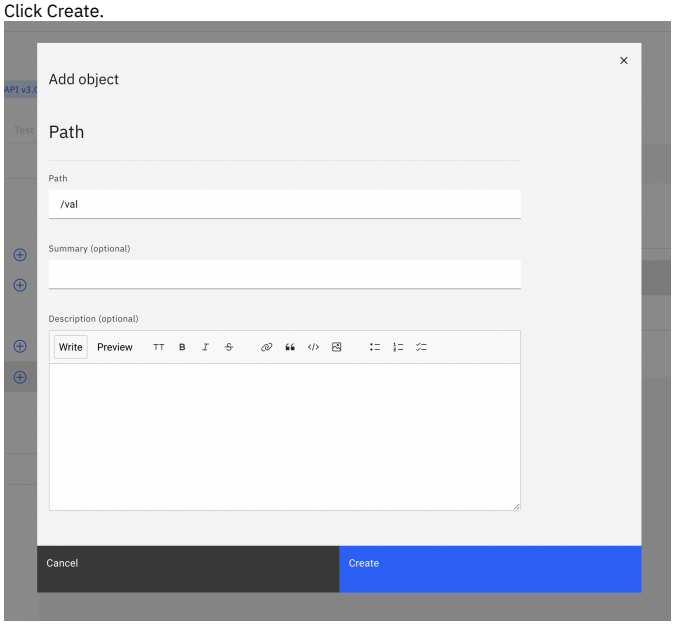
9. You see the progress as the new API gets created. When it is done, you see a Summary. Click Edit API.



10. In the side bar of the Design page, select Paths to display the Paths panel.
11. Click Add.

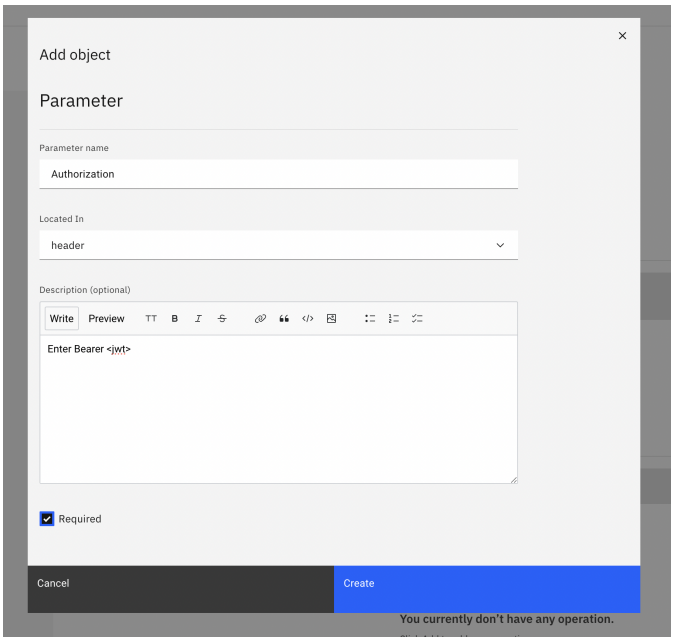


12. In the Path name field, enter /val.
13. Click Create.



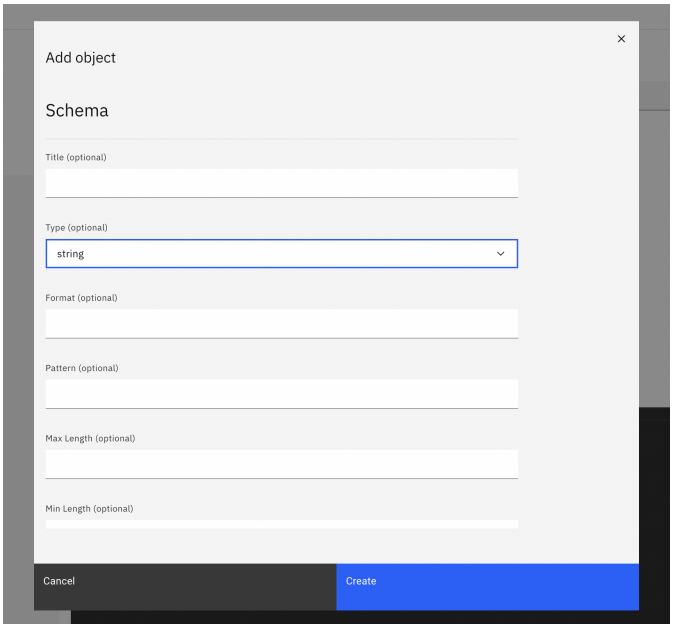
14. Scroll down. In the Parameters section, click Add.

    a. Enter `Authorization` in the Parameter name field.
    b. Select `header` in the Located In field.
    c. Enter `Enter Bearer <jwt>` to match in the Description field.
    d. Select Required.
    e. Click Create.

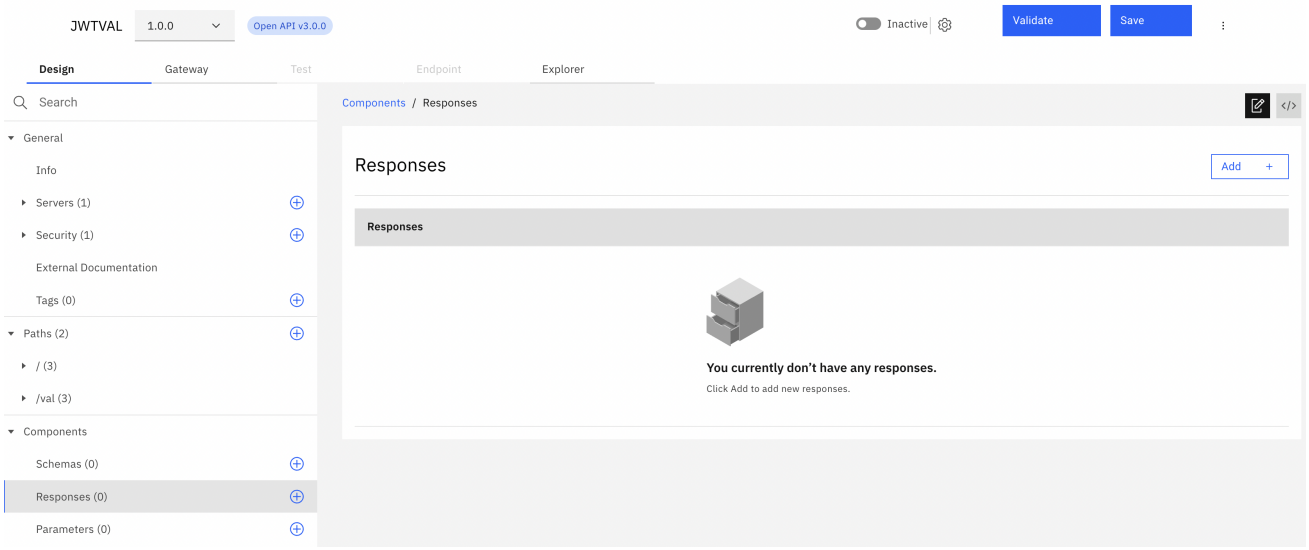


f. Scroll down. In the Schema section, click Create

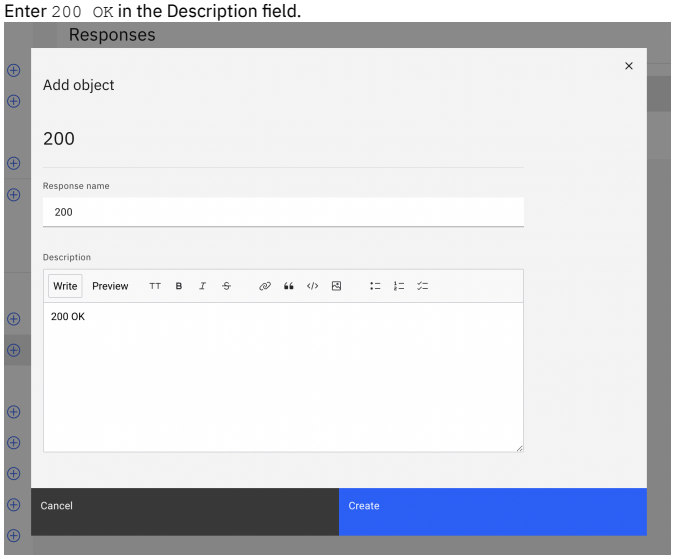
g. Select `string` in the Type field.
h. Click Create.



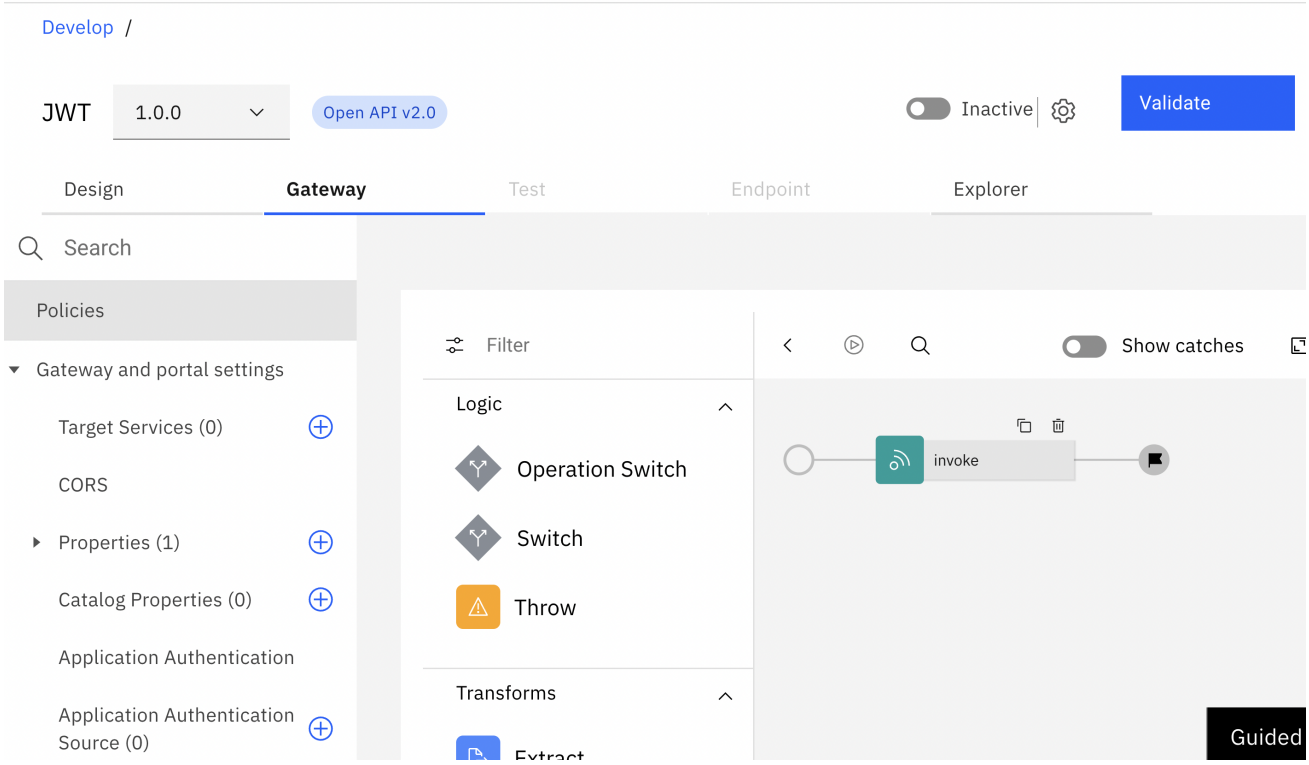
15. After you create the parameter, click Save.
16. Click Componets > Responses.
17. Click Add.



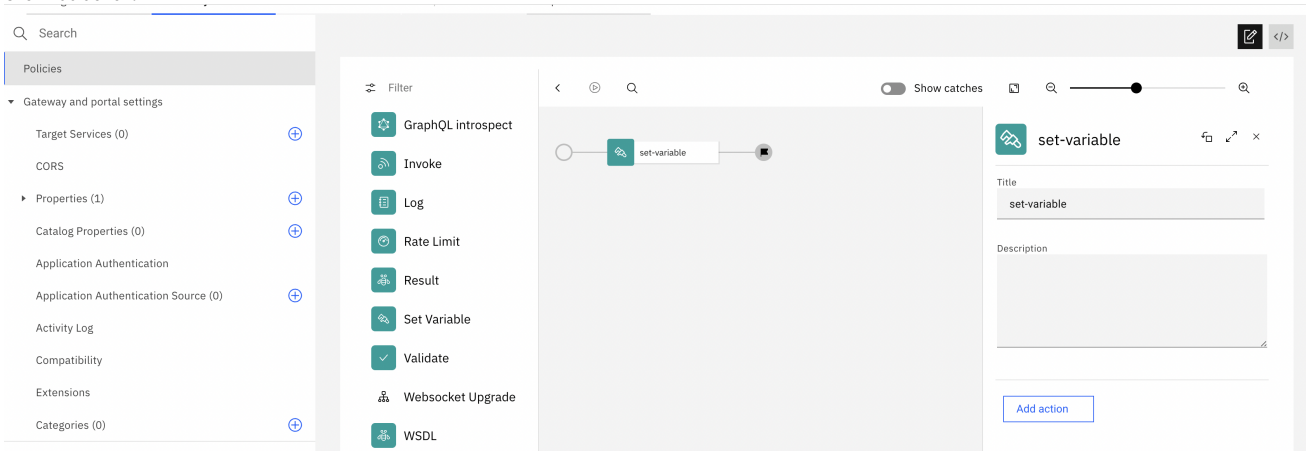
18. The Response name field auto-populates with `200`.
19. Enter `200 OK` in the Description field.



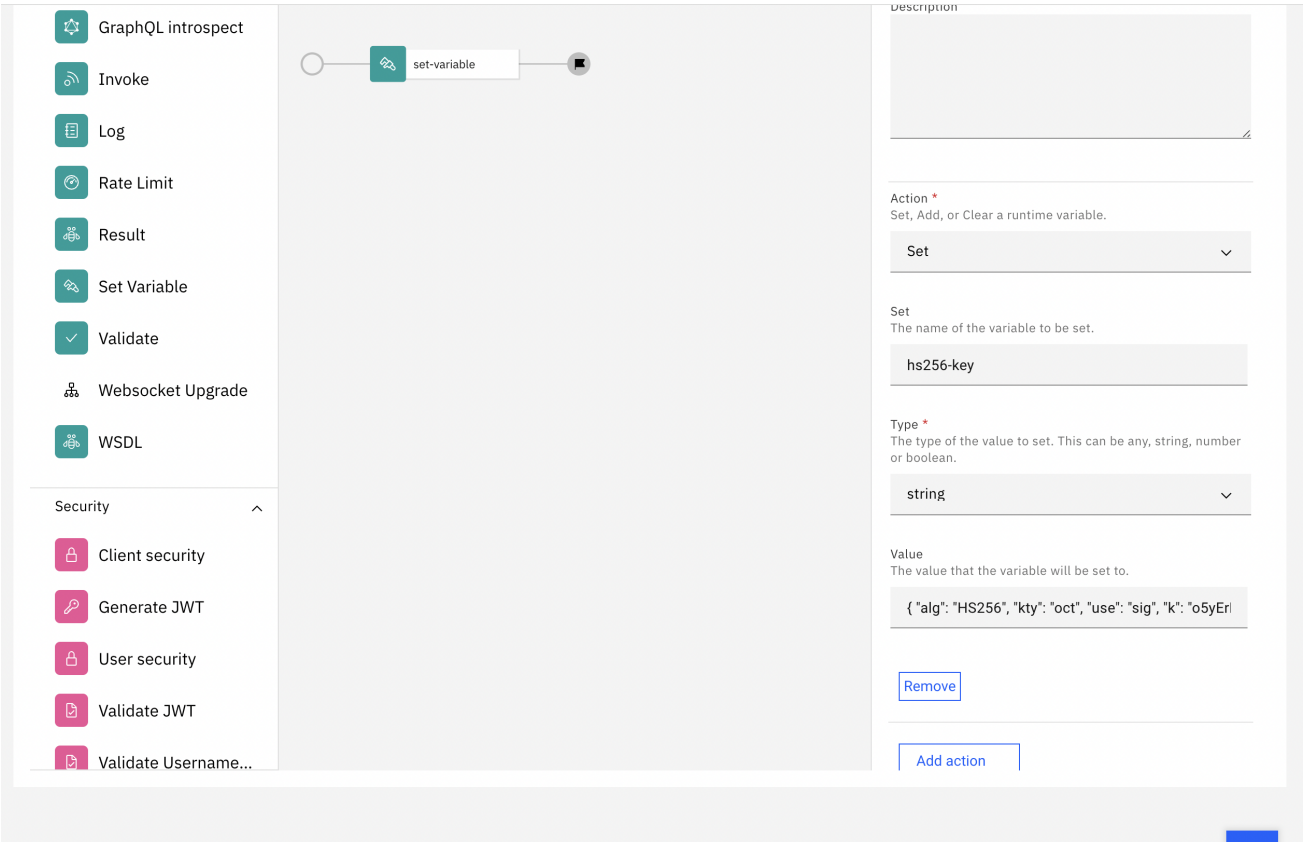
20. After you create the response, click Save.
21. Click Gateway.
22. Hover the mouse over the existing Proxy or Invoke action and click the trash can icon to delete it.



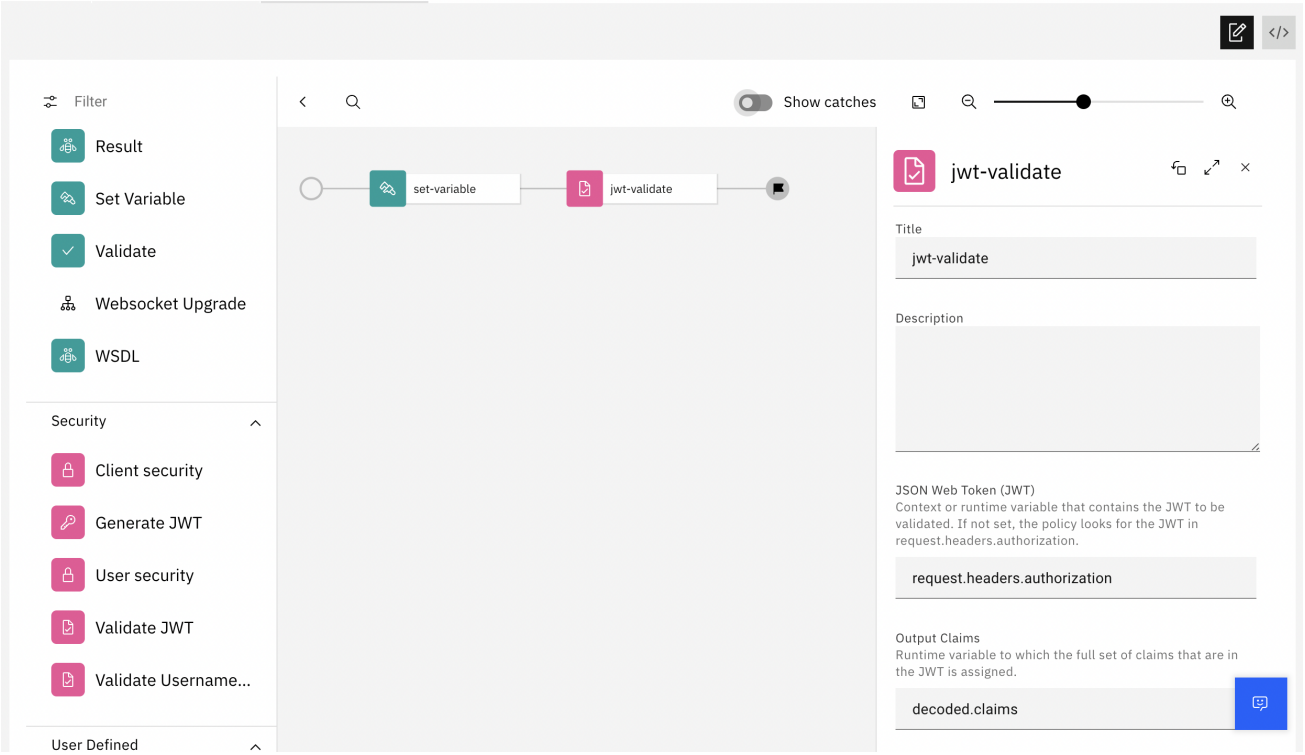
23. Drag the Set Variable action onto the processing flow line. A configuration panel automatically opens.
24. Click Add action.



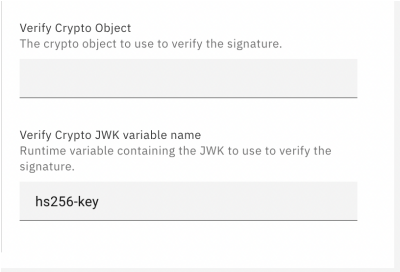
25. Enter `hs256-key` in the Set field.
26. Select `string` in the Type field.
27. Enter a JWK in the Value field. Here is an example. `{ "alg": "HS256", "kty": "oct", "use": "sig", "k": "o5yErLaE-dbgVpSw65Rq57OA9dHyaF66Q_Et5azPa-XUjbyP0w9iRWhR4kru09aFfQLXeIODIN4uhjElYKXt8n76jt0Pjkd2pqk4t9abRF6tnL19GV4pflfL6uvVKkP4weOh39tqHt4TmkBgF2P-gFhgssZpjwq6l82fz3dUhQ2nkzoLA_CnyDGLZLd7SZ1yv73uzfE2Ot813zmig8KTMEMWVcWSDvy61F06vs_6LURcq_IEEevUiubBxG5S2akNnWigfpbhWYjMI5M22FOCpdcDBt4L7K1-yHt95Siz0QUb0MNlT_X8F76wH7_A37GpKKJGqeaiNWmHkgWdE8QWDQ", "kid": "hs256-key" }`



28. Close the property panel. Click Save.
29. Drag the Validate JWT action onto the processing flow line after the set-variable icon. A configuration panel automatically opens.

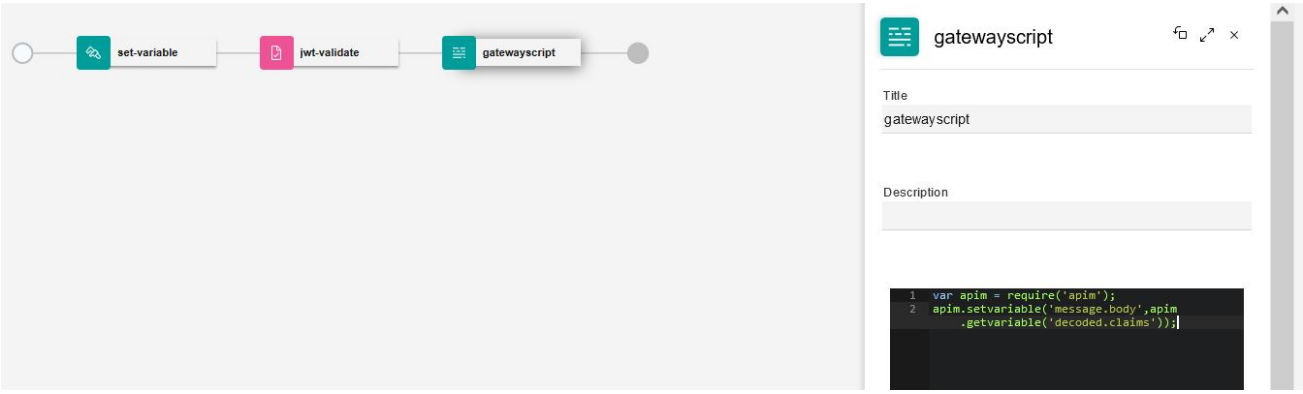


30. Enter `hs256-key` in the Verify Crypto JWK variable name field.

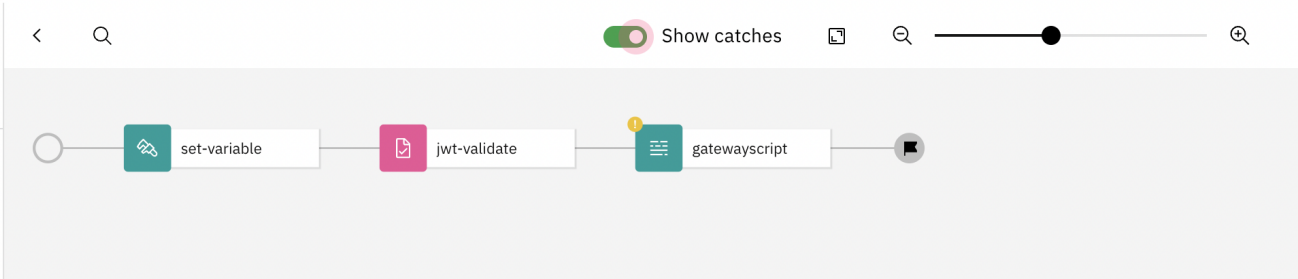


31. Close the property panel. Click Save.
32. Drag the GatewayScript action onto the processing flow line after the Validate JWT icon. A configuration panel automatically opens.
33. Enter the following code:

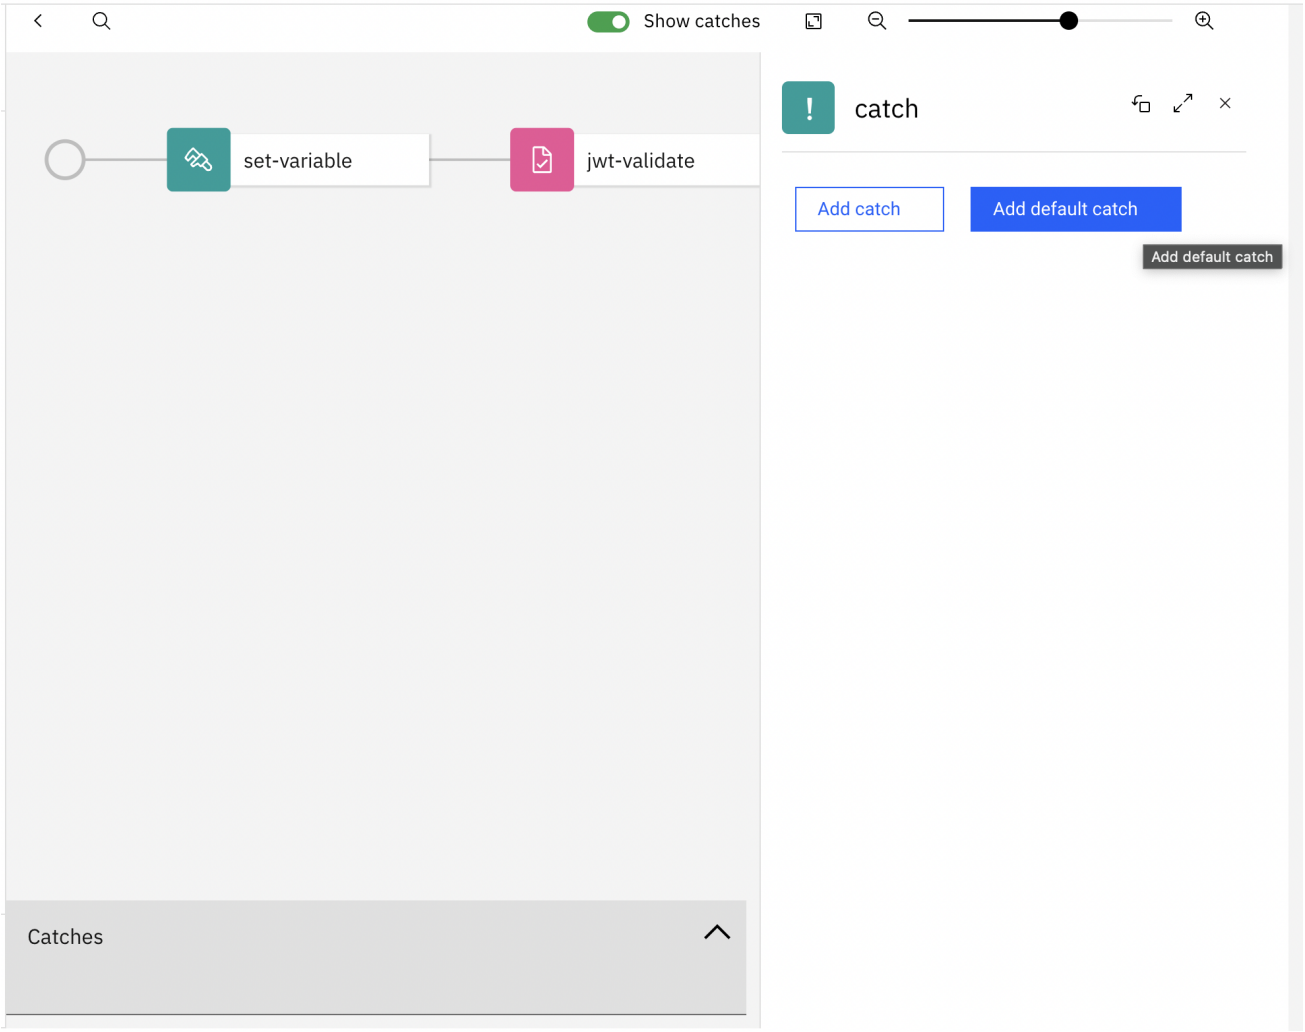
```
var apim = require('apim');
apim.setvariable('message.body',apim.getvariable('decoded.claims'));
```



34. Close the property panel. Click Save.
35. Ensure that the Show catches option is enabled so that the catch area is displayed.

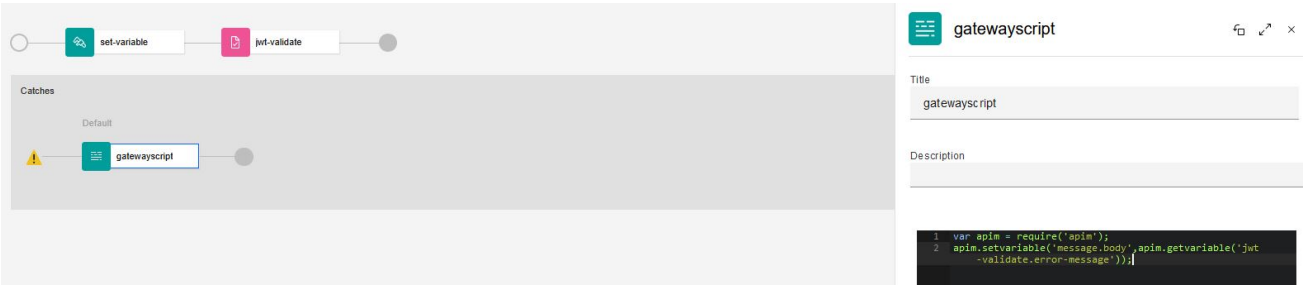


36. Click Catches. A property panel opens.
37. Click Add default catch.



38. Drag the GatewayScript policy action onto the catch flow line.
39. Enter the following code:

```
var apim = require('apim');
apim.setvariable('message.body',apim.getvariable('jwt-validate.error-message'));
```



40. Close the property panel. Click Save.

Testing the REST API

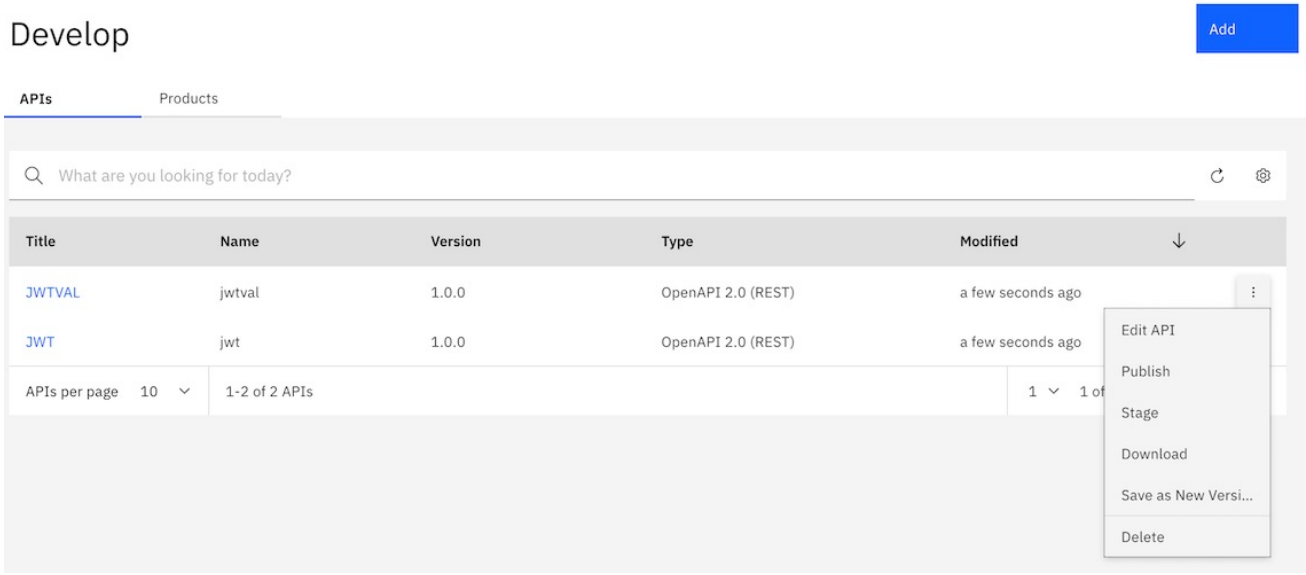
Note: Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.
To test the REST API, you need a valid JWT. You can obtain such a JWT by invoking the API created in the Tutorial: Generate a JSON Web Token (JWT). To test the REST API, complete the following steps:

1. Turn on the activation toggle to activate the API you created.
2. Click Test.
3. Enter `Bearer` followed by a space followed by a valid JWT generated with the same sign key in the Value field corresponding to the Authorization parameter. Note: If the Authorization key is missing from the parameters, confirm that the correct request path is selected. Select a request path that ends with **`/val`**, or manually append **`/val`** to the GET request.
4. Click Send.
5. The response contains branch data.

Manage your API definition

Now that your new API works correctly, you can manage this API. To see your immediate options, take the following steps.

1. Click the Develop icon on the navigation bar.
2. Click the Options icon alongside the Mapper API.



3. Select Download.

What you did in this tutorial

In this tutorial, you completed the following activities:

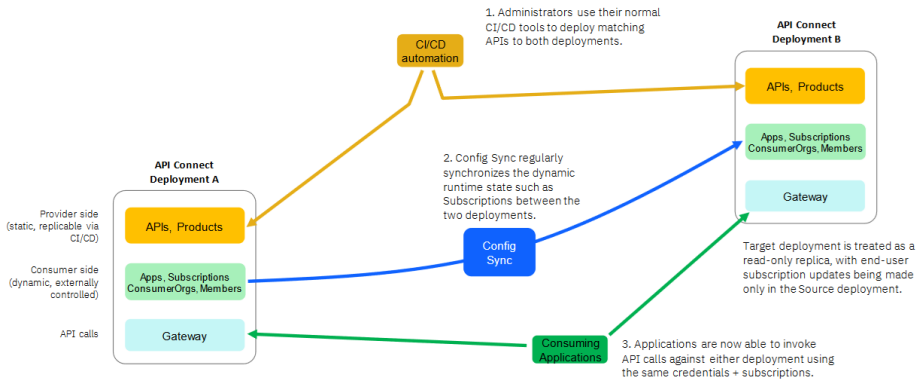
- Created a new API definition that validates a JSON Web Token (JWT).
- Tested the new API.

Using Config Sync to replicate catalog data

Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

API Connect Config Sync (apic-configsync) can be run either as a stand-alone binary with a Kubernetes cronjob, to facilitate the unidirectional replication of consumer-side data (consumer organizations, members, apps, subscriptions, credentials) and Product and API from a catalog in a source API Connect cluster to a corresponding catalog in a separate, target API Connect cluster.

The following image shows how you can use Config Sync to replicate consumer-side data from a source deployment to a target deployment:



Config Sync can be run as frequently as required, and detects the differences between the replicated resource types in the source and target catalogs so that it efficiently replicates only the new changes that have been made in the source instance.

Changes that are made in a target catalog can be synced back to the source by swapping the configuration, so that the original source catalog is the designated target and the original target is the designated source. This process is known as a *reverse sync*.

As shown in the following image, Config Sync helps to enable a range of hybrid cloud API topologies such as:

- Independent disaster recovery instances

- Software and SaaS hybrid scenarios
- Geo-replication
- Side-by-side version upgrade

Requirements

For API Connect Config Sync to run successfully, the following requirements must be satisfied:

Target cluster configuration
: The target API Connect cluster must be configured correctly, including:

  - Topology setup
  - Provider organization creation
  - Catalog creation

Replicating APIs and Products
: If you disable the product and API syncing using the **`SyncProductsAndAPIs`** environment variable, then you must manually replicate the APIs and products from the source catalog to the target catalog, either through manual procedures or CI/CD pipelines. For more information about API and Product syncing, see the SyncProductsAndAPIs section.

  Note: If you need to use Product and API sync feature then target API Connect cluster version must be equal or later than 10.0.8.3.

Target catalog settings
: The target catalog settings must be configured to match the configuration of the source catalog, including:

  - User registries
  - OAuth providers
  - TLS client profiles
  - Lifecycle approvals
  - Application lifecycle
  - Other relevant catalog settings

  If products and APIs syncing is enabled, you must set the **`catalog_settings.config_sync_target_catalog`** property to **`true`** on the target catalog. This can be done using the toolkit or REST API.

  To update the catalog settings using the toolkit, run the following command:

  ```
  ./apic catalog-settings:update -s <server_url> -o <org_name> -c <catalog_name> <catalog_setting_file>
  ```

  For example:

  ```
  ./apic catalog-settings:update -s https://api.example.com -o test_org -c test_catalog catalog_setting_file.txt
  ```

  The **`catalog_setting_file.txt`** should contain the following JSON:

  ```
  {
    "config_sync_target_catalog": true
  }
  ```

  Note: Login to the **`target cluster`** and run the command there, not in the source.

User registries and OAuth Providers

- Compatible onboarding user registries must be configured in the target catalog with the same name and type as in the source catalog. Ensure that the target configured must be same as the source.
- If this is not possible, use the USER_REGISTRY_NAME_MAPPING variable.
- All OAuth providers must be configured on the target catalog and spaces.
- All API user registries must be configured on the target catalog and spaces.
- All TLS client profiles must be configured on the target catalog and spaces.

Connectivity and permissions
: The Config Sync utility uses the API Connect Provider REST API, so you must have connectivity to both the source and target clusters with sufficient provider organization user permissions.

Reserved metadata key
: The **`metadata.source_id`** key is reserved for use by Config Sync

Resource mapping
: Config Sync uses the **`metadata`** field of a resource to track which resources in the source catalog map to which resources in the target catalog. In addition to using the **`metadata`** field, API Connect Config Sync also uses the **`name`** field of some resources to determine a match. This is typically done for resources that are not synchronized by the utility but are needed in the target catalog for the synchronization to be successful. Examples of such resources include:

  - User Registries

- Consumer Org Groups
- Roles
- Published Products (where both the `name` and `version` fields are used for product matching)

By using a combination of the `metadata` and `name` fields, Config Sync can accurately map resources between the source and target catalogs, ensuring a successful synchronization.

Tracking resource mappings

To track which resources in the source catalog map to which resources in the target catalog, Config Sync uses the `metadata` field of a particular resource. Specifically, when a new resource is created in the target catalog, the `metadata` field of that resource is set to contain a key named `source_id` with a value equal to the ID of the corresponding resource in the source catalog that is being synchronized.

This process enables Config Sync to maintain a record of the relationships between resources in the source and target catalogs, ensuring that changes are accurately propagated and that resources are correctly matched across catalogs.

Note: The first time Config Sync runs, it might take longer to complete than subsequent runs require (depending on the number of resources to synchronize). The first run of the utility creates all new resources in the target cluster; subsequent runs perform only synchronization of any data that was added, updated, or deleted since the last run of the utility.

Limitations

API Connect Config Sync has the following limitations:

- Config Sync does not back up data; it merely replicates the contents of a source catalog to a target catalog. You must still take periodic backups to ensure the safety of your data.
- A reverse sync can be performed only if the original source cluster and the original target cluster are at the same VRM (Version.Release.Milestone) level. For example, API Connect 10.0.8.1 and API Connect 10.0.8.0 are at the same VRM level even though they are at different fix pack levels. A reverse sync to a different version, release, or milestone is not supported.
- Source and target deployments operate independently of each other:
  - API rate limiting on Plans is counted independently in the source catalog and the target catalog.
  - OIDC tokens are not replicated. OIDC tokens that are generated in the source cluster are not valid within the target cluster.
  - Analytics data is tracked independently in the source cluster and the target cluster. Analytics data is not replicated or aggregated across clusters.
  - Developer Portal configuration is not replicated. If you want to enable consumer organization access in the target catalog, you must replicate your Developer Portal site for consistency (restore the site with UUID/URL update where needed).
- Config Sync operates on a single source-target catalog pair at a time.
  If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

Supported versions of API Connect

Config Sync can synchronize consumer-side resources across different versions of API Connect clusters. The target cluster version must always be greater or equal to the source cluster version.

Table 1 shows the supported version combinations of API Connect:

Table 1. Supported source and target version combinations of API Connect

Source version	Target Version	Release Stream
10.0.5+	10.0.5+	Previous LTS -> Previous LTS
10.0.5+	10.0.8+	Previous LTS -> Current SC2
10.0.8+	10.0.8+	Current SC2 -> Current SC2
10.0.8+	10.0.10.0	Current SC2 -> Current CD
10.0.10.0	10.0.10.0	Current CD -> Current CD

Consumption reporting

The analytics subsystem records the number of resources that are processed during a config sync. You can see the total number of resources that were processed for a config sync at provider organization and catalog scope in the consumption dashboard of the API Manager UI. To see the number of resources processed at the cloud scope, see the consumption dashboard in the Cloud Manager UI.

For users on call volume licensing, the amount of data that is synchronized is converted to API calls and is included in your call volume license.

- **Downloading and extracting the API Connect Config Sync utility**
  Download and extract the API Connect Config Sync utility.
- **Setting environment variables for Config Sync**
  Configure environment variables that can be used by the API Connect Config Sync utility.
- **Enabling encrypted LUR user data sync**
  Enable sensitive data (passwords) of members belonging to a LUR configured for a catalog to be synced between the source cluster and the target cluster.
- **Running Config Sync as a standalone binary**
  The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.
- **Running Config Sync as a cronjob on OpenShift**
  Running the apic-configsync utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.
- **Running Config Sync as a cronjob on Kubernetes**
  Running the apic-configsync utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.
- **Running Config Sync as a cronjob on VMware**
  Running the apic-configsync utility as a cronjob on VMware enables the utility to be run on a timed basis, such as every 10 minutes.

Downloading and extracting the API Connect Config Sync utility

Download and extract the API Connect Config Sync utility.

About this task

You can download Config Sync from one of the following locations:

- IBM Fix Central.
- The Cloud Manager or API Manager UI.

The Config Sync download is a compressed file called configsync.tgz, that contains the following artifacts:

- A binaries directory with subdirectories that contain the apic-configsync utility for each of the supported client platforms (Mac, Windows, and Linux x86).
- A helper_files directory that contains YAML files for configuring cronjobs if you want to run the utility on a schedule.
- An ibm-apic-configsync-image.tar.gz file that contains the Docker image for running the utility on a schedule in a Kubernetes cluster with a cronjob.

Procedure

1. Download the Config Sync compressed file and credentials.
   - V10.0.8.1: Download from the Cloud Manager or API Manager UI.
     - On the Welcome page, click the Download Clients tile.
     - Select the Config Sync tab.
     - Click the Download link under Step 1: Download Config Sync.
     - Click the Download link under Step 2: Download credentials.
   - V10.0.8.0: Download **`configsync`** from IBM Fix Central, and download the credentials from the API Manager UI.
     - Search for a file called **`configsync`** under the IBM API Connect product.
       Note: Fix Central returns the product files that you can upgrade to based on what you set in API Connect **`Installed Version`**. To find files for your current version, select a previous release. For example, if you want the **`configsync`** file from V10.0.8.1, set **`Installed Version`** to V10.0.8.0.
     - From the API Manager UI Welcome page, click the Download Toolkit tile. Select Toolkit credentials - Download to download the credentials file.
2. Extract the apic-configsync.tar.gz package by running the following command:

   ```
   tar xzf configsync.tgz
   ```

Setting environment variables for Config Sync

Configure environment variables that can be used by the API Connect Config Sync utility.

API Connect Config Sync consumes a set of configuration properties required to connect to and perform REST calls against the source and target API Connect clusters. The configuration properties are passed to the utility with environment variables.

The following environment variables must be set to the appropriate values for the source and target API Connect cluster:

```
# Properties for source catalog
export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
export SOURCE_ORG=sourceporg
export SOURCE_REALM=provider/default-idp-2
export SOURCE_ADMIN_USER=sourceadmin
export SOURCE_ADMIN_PASSWORD=sourceadminpassword
#export SOURCE_ADMIN_APIKEY=1010101010101010
export SOURCE_CATALOG=sourcecatalog
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111

# Properties for target catalog
export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
export TARGET_ORG=targetporg
export TARGET_REALM=provider/default-idp-2
export TARGET_ADMIN_USER=targetadmin
export TARGET_ADMIN_PASSWORD=targetadminpassword
#export TARGET_ADMIN_APIKEY=2020202020202020
export TARGET_CATALOG=targetcatalog
export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
```

Locating information for the environment variables

The following list explains how to obtain the setting for each of the environment variables.

`*_MGMT_SERVER`
: This property specifies the hostname and path that provides access to the REST API endpoint for your catalog. Locate **`toolkit.endpoint`** property in the toolkit **`credentials.json`** file that you downloaded in Downloading and extracting the API Connect Config Sync utility, and set the **`*_MGMT_SERVER`** variable to the value of the **`toolkit.endpoint`** property.
The value might look like the following example:

```
https://platform-api.hostname.com/api
```

`*_TOOLKIT_CREDENTIALS_CLIENTID, *_TOOLKIT_CREDENTIALS_CLIENTSECRET`

The toolkit credentials **clientID** and **clientSecret** are used to authenticate the utility to be able to make REST API calls against the API Connect cluster. Locate following properties in the toolkit **credentials.json** file that you downloaded in Downloading and extracting the API Connect Config Sync utility, and set the environment variables as shown:

- Set the ***_TOOLKIT_CREDENTIALS_CLIENTID** variable to the value of the **toolkit.client_id** property
- Set the ***_TOOLKIT_CREDENTIALS_CLIENTSECRET** variable to the value of the **toolkit.client_secret** property

***_ORG**

This is the short name of the provider organization in which your catalog is hosted. Set the ***_ORG** variable to the value of the provider organization's **Name** property. To locate the provider organization name, complete the following steps:

1. Log in to the API Manager.
2. From the Home tab, select Manage settings.
3. On the Settings page, click the Overview tab and locate the value of the **Name** property (not the **Title**).

***_REALM**

This property specifies the identity provider realm of the API Manager registry for your instance of API Connect. Set the ***_REALM** variable to the value of the realm name. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see ***_API_KEY** for details).
To obtain the realm name, run the following toolkit CLI command:

```
apic identity-providers:list --scope provider --server <mgmt_endpoint_url> --fields title,realm
```

where ***<mgmt_endpoint_url>*** is the API Manager URL with any segments (for example, **/manage**) removed from the end of the URL. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints.

The following example shows a response listing the available realms for a deployment:

```
apic identity-providers:list --scope provider --server <mgmt_endpoint_url> --fields title,realm

total_results: 2
results:
  - title: 'API Manager User Registry'
    realm: 'provider/default-idp-2'
  - title: 'Common Services User Registry'
    realm: 'provider/common-services'
```

In the example, the realm for the API Manager registry is **provider/default-idp-2**.

For more information on obtaining the realm name, see How to determine the identity provider.

***_CATALOG**

This property indicates the name of the Catalog that you want to synchronize. Set the ***_CATALOG** variable to the value of the catalog's **Name** property.
To locate the catalog name, complete the following steps:

1. Log in to the API Manager UI.
2. From the Home tab, select Manage catalogs.
3. Select the tile for the catalog you want to synchronize.
4. Click the Catalog settings tab.
5. On the Settings page, locate the value of the catalog's **Name** property (not the **Title**).

***_ADMIN_USER**

This property is the name of the user account under which you will authenticate to the catalog. Set the ***_ADMIN_USER** variable to the value of the username that the utility will log in with to perform the synchronization task. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see ***_API_KEY** for details).
In the source catalog, the user must be a Catalog Administrator or Organization Administrator with the ability to create consumer objects on behalf of the end users.
In the target catalog, the user must have authorization to update catalog settings and enable or disable the **hash_client_secret** property.

To confirm the username, complete the following steps:

1. Log in to the API Manager UI with the user account you will use to synchronize the catalog.
2. Click the username in the page header.
3. Select My account.
4. Locate the value of the Username property.

***_ADMIN_PASSWORD**

In most cases you will authenticate to the API Manager with the password associated to your username. Set the ***_ADMIN_PASSWORD** property to your password, being careful with any non-alphanumeric characters that may be in your password. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see ***_API_KEY** for details).
Attention: If you set the ***_ADMIN_PASSWORD** variable, then skip the ***_ADMIN_APIKEY** variable. Do not set both variables when synchronizing a particular catalog.

***_ADMIN_APIKEY**

In API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example API Connect Enterprise as a Service), you must authenticate using an API key instead of your password.
To locate your API key, complete the following steps:

1. Log in to the API Manager UI using your IBM ID.
2. In the page header, click and select My API Keys.
3. On the My API Keys page, click Add.
4. Set a title and description for your new API key and click Create.
5. Copy the new API key from the dialog box.

Attention: If you set the ***_ADMIN_APIKEY** variable, then skip the ***_ADMIN_PASSWORD** variable. Do not set both variables when synchronizing a particular catalog.

Setting the environment variables

- Mac and Linux x86:
  On Mac or Linux x86, you can either export the environment variables individually on the command line directly or create a script to export the environment variables and source that file from the command line, as in the following example:

  ```
  # Properties for source catalog
  export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
  export SOURCE_ORG=sourceporg
  export SOURCE_REALM=provider/default-idp-2
  export SOURCE_ADMIN_USER=sourceadmin
  export SOURCE_ADMIN_PASSWORD=sourceadminpassword
  #export SOURCE_ADMIN_APIKEY=1010101010101010
  export SOURCE_CATALOG=sourcecatalog
  export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
  export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111

  # Properties for target catalog
  export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
  export TARGET_ORG=targetporg
  export TARGET_REALM=provider/default-idp-2
  export TARGET_ADMIN_USER=targetadmin
  export TARGET_ADMIN_PASSWORD=targetadminpassword
  #export TARGET_ADMIN_APIKEY=2020202020202020
  export TARGET_CATALOG=targetcatalog
  export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
  export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
  ```

  In the example, notice that the command to set the ***_ADMIN_APIKEY** variable is commented out because the ***_ADMIN_PASSWORD** is used instead.

- Windows:
  On Windows, you can set each environment variable individually by opening a command window and running the following command for each variable:

  ```
  setx <variable_name> "<variable_value>"
  ```

  where:
  - ***<variable_name>*** is the name of the environment variable to set
  - ***<variable_value>*** is the value to set for the specified variable name

  Alternatively, you can create a batch file that uses the **setx** command to set the environment variables, as in the following example:

  ```
  REM Properties for source catalog
  setx SOURCE_MGMT_SERVER "https://yoursourcehostname.com/path"
  setx SOURCE_ORG "sourceporg"
  setx SOURCE_REALM "provider/default-idp-2"
  setx SOURCE_ADMIN_USER "sourceadmin"
  setx SOURCE_ADMIN_PASSWORD "sourceadminpassword"
  REM setx SOURCE_ADMIN_APIKEY "1010101010101010"
  setx SOURCE_CATALOG "sourcecatalog"
  setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTID "00000000-0000-0000-0000-000000000000"
  setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET "11111111-1111-1111-1111-111111111111"

  REM Properties for target catalog
  setx TARGET_MGMT_SERVER "https://yourtargethostname.com/path"
  setx TARGET_ORG "targetporg"
  setx TARGET_REALM "provider/default-idp-2"
  setx TARGET_ADMIN_USER "targetadmin"
  setx TARGET_ADMIN_PASSWORD "targetadminpassword"
  REM setx TARGET_ADMIN_APIKEY "2020202020202020"
  setx TARGET_CATALOG "targetcatalog"
  setx TARGET_TOOLKIT_CREDENTIALS_CLIENTID "22222222-2222-2222-2222-222222222222"
  setx TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET "33333333-3333-3333-3333-333333333333"
  ```

  In the example batch file, notice that the command to set the ***_ADMIN_APIKEY** variable is commented out because the ***_ADMIN_PASSWORD** is used instead.

Optional environment variables

USER_REGISTRY_NAME_MAPPING
: By default config sync requires that user registries in the target catalog have the same name and type as the user registries in the source catalog.

  If your source user registries have different names on your target, then you can use the **USER_REGISTRY_NAME_MAPPING** variable to map each source registry name to a target registry name.

  The format of **USER_REGISTRY_NAME_MAPPING** is as follows:

  ```
  USER_REGISTRY_NAME_MAPPING="source-ur1,target-url;source-ur2,target-ur2"
  ```

  Use a comma to separate source and target registry names.

  If you have multiple user registries to map, then use a semi-colon as a separator.

API_CACHE_REQUEST_PAGE_SIZE
: Use the environment variable to specify the number of APIs you want to fetch and cache in a single GET request . If you do not set this variable, the default page size of 100 is used.

SyncProductsAndAPIs
: Set the environment variable **SyncProductsAndAPIs** to `False`, if you want to disable the Product and API sync feature. By default, the Product and API sync feature is enabled.
  Note: Product and API is synced only when the target API Connect cluster are deployed on 10.0.8.2 or later.

Enabling encrypted LUR user data sync

Enable sensitive data (passwords) of members belonging to a LUR configured for a catalog to be synced between the source cluster and the target cluster.

About this task

An LUR (Local User Registry) can be configured with a JWKS (JSON Web Key Set) to enable the encryption and decryption of sensitive user data. The JWKS is added to the organization in the target API Connect cluster, which contains the LUR that is configured with the target catalog. The JWKS is then added to the LUR that is configured with the target catalog. Next, the public key of the JWKS is added to the corresponding LUR in the source cluster. Once configured, subsequent runs of the Config Sync will retrieve the encrypted user data from the source and sync it with the target.

Note: Encrypted user data is synced only when the both the source and target API Connect clusters are deployed on 10.0.8.0 or later.

Procedure

Configure a JWKS for the target LUR:

1. In the target deployment, log in to API Manager using the API Connect provider organization that owns the target catalog (where the LUR is defined).
2. Click > Crypto Material.
3. On the crypto page, look in the JWK Set section and click Create.
4. On the Create JWK Set page, either provide an existing JWK Set or generate a new one:
   - To use an existing set, complete the following steps:
     - Provide a name for the JWKS in the Key set title field.
     - Enter the values into the JWK private key and JWK public key fields.
       Note: Ensure that both the public and private keys include a **`kid`** property with the same **`uuid`** value; for example:

       ```
       "kid":"1facd4b7-4dac-409f-949c-9f0cb2f98689",
       ```

     - Save a copy of the keys:
       - You will use the JWK public key later in this task.
       - If you plan to perform a reverse sync (see What to do next) between the target catalog and the source catalog, you will use the JWK private key to complete that task.
     - Click Save.
   - To generate a JWKS, complete the following steps:
     - Provide a name for the JWKS in the Key set title field.
     - Click Generate to populate the JWK private key and JWK public key fields.
     - Save a copy of the keys:
       - You will use the JWK public key later in this task.
       - If you plan to perform a reverse sync (see What to do next) between the target catalog and the source catalog, you will use the JWK private key to complete that task.
     - Click Save.
5. On the Resources page, navigate to the Local User Registry that is configured with the target catalog by clicking User registries and then selecting the appropriate registry.
6. On the Edit local user registry page, locate the Additional Support section.
7. In the Key set for data import field, select the JWKS that you created for this LUR.
8. In the JWK public key for data export field, paste the JWK public key that you used for creating the JWK Set.
9. Click Save.

Provide the target LUR's JWK public key to the corresponding LUR in the source deployment:

10. In the source deployment, log in to API Manager using the API Connect provider organization that owns the source catalog (where the LUR is defined).
11. Click > User registries and then select the LUR that corresponds to the LUR you worked with in the target deployment.
12. In the JWK public key for data export field, paste the JWK public key that you used for creating the JWK Set.
13. Click Save.

Results

The LUR in your source catalog is now configured to encrypt sensitive user data, and the LUR in your target catalog is configured to both encrypt and decrypt the sensitive data.

The next time that you run Config Sync, the sensitive data (passwords) of users in the LUR will be synced from the source to the target to enable consumer org members to log into the target cluster using the same password.

What to do next

(Optional) Configure support for sensitive data with a reverse sync:

Changes made in a target catalog can be synced back to the source by swapping the configuration so that the original source catalog is the designated target and the original target is the designated source. This process is known as a *reverse sync*. If you want to enable the sensitive user data to be synced as part of a reverse sync scenario, create a new JWKS in the source API Connect deployment and use the same public/private key pair as the JWKS in the target deployment. Then, edit the LUR that is configured with the source catalog and select the JWKS in the Key set for data import field.

Running Config Sync as a standalone binary

The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

About this task

Running a standalone invocation of apic-configsync using one of the pre-built binaries is the most flexible option. For optimal performance, apic-configsync should run as close to the target cluster as possible.

Complete the following steps to configure environment variables and run the standalone binary.

Procedure

1. Download and extract the API Connect Config Sync package.
2. In the extracted package, navigate to the /binaries/*<platform>* directory that contains the appropriate version of the apic-configsync utility for your platform.
3. Define the environment variables for the source and target catalogs.
4. Run the utility with the following command:
   - Mac and Linux x86: `./apic-configsync`
   - Windows: `apic-configsync.exe`

Running Config Sync as a cronjob on OpenShift

Running the apic-configsync utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry.
  The examples in this topic use **skopeo** to copy the image to the target registry, but you could use equivalent **docker** or **podman** commands instead.
- Expose the OpenShift registry with **defaultRoute** by running the following command:

  ```
  oc patch configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}' --type=merge
  ```

  For more information, see Exposing the registry in the OpenShift documentation. It is not necessary to perform step 5 (the "podman login" step) in the instructions.
- Set the **REGISTRY_HOST** environment variable to the OpenShift registry by running the following command:

  ```
  REGISTRY_HOST=$(oc get route default-route -n openshift-image-registry --template='{{ .spec.host }}')
  ```

- Set the **APIC_PROJECT** environment variable to the namespace (project) where you intend to run the cronjob. For optimal performance, the cronjob should run within the same OpenShift environment as the target API Connect cluster.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on OpenShift or Cloud Pak for Integration. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same OpenShift environment as the target API Connect cluster.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

   ```
   tar xf ibm-apic-configsync-image.tar.gz
   ```

3. Copy the extracted Config Sync image to the target registry.
   For example, if you use skopeo, run the following command:

   ```
   skopeo copy --dest-tls-verify=false --dest-registry-token=$(oc whoami -t) dir:./ibm-apic-configsync/ibm-apic-configsync-<version>/<tag> docker://$REGISTRY_HOST/$APIC_PROJECT/ibm-apic-configsync-<version>:<tag>
   ```

   Replace ***<version>*** and ***<tag>*** with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

4. Define the environment variables for the source and target catalogs.
5. Create secrets to host configuration details for the source cluster and the target cluster.
   a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

   ```
   oc create secret --namespace $APIC_PROJECT generic source-catalog-details \
       --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
       --from-literal=SOURCE_ORG=$SOURCE_ORG \
       --from-literal=SOURCE_REALM=$SOURCE_REALM \
       --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
       --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
       --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
   ```

```
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

```
oc create secret --namespace $APIC_PROJECT generic target-catalog-details \
    --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
    --from-literal=TARGET_ORG=$TARGET_ORG \
    --from-literal=TARGET_REALM=$TARGET_REALM \
    --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
    --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
    --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

6. Create the cronjob:
   a. Open the **helper_files/configsync-cronjob-ocp.yaml** file located in the extracted API Connect Config Sync package.
   b. Modify the **schedule** property to specify how frequently the job will run.
   The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.
   c. Set the **concurrencyPolicy** to **Forbid**.
   Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.
   d. In the **image** property, replace the ***<APIC_PROJECT>*** variable with the namespace (project) where you will run the cronjob.
   e. Create the cronjob resource in the cluster by running the following command:

```
oc --namespace $APIC_PROJECT apply -f helper_files/configsync-cronjob-ocp.yaml
```

Running Config Sync as a cronjob on Kubernetes

Running the apic-configsync utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry.
  The examples in this topic use **skopeo** to copy the image to the target registry, but you could use equivalent **docker** or **podman** commands instead.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on Kubernetes. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same Kubernetes environment as the target API Connect cluster.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

```
tar xf ibm-apic-configsync-image.tar.gz
```

3. Copy the extracted Config Sync image to the target registry.
   For example, if you use skopeo, run the following command:

```
skopeo copy dir:./ibm-apic-configsync/ibm-apic-configsync-<version>/<tag> docker://<registry>/ibm-apic-configsync/ibm-apic-configsync-<version>:<tag>
```

   Replace ***<version>*** and ***<tag>*** with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

   Replace ***<registry>*** with the actual registry value for your image registry. Refer to the skopeo documentation on configuring credentials for your destination registry.

4. Define the environment variables for the source and target catalogs.
5. Create secrets to host configuration details for the source cluster and the target cluster.
   a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret --namespace <namespace> generic source-catalog-details \
    --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
    --from-literal=SOURCE_ORG=$SOURCE_ORG \
    --from-literal=SOURCE_REALM=$SOURCE_REALM \
    --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
    --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
    --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

   b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret --namespace <namespace> generic target-catalog-details \
    --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
    --from-literal=TARGET_ORG=$TARGET_ORG \
```

```
    --from-literal=TARGET_REALM=$TARGET_REALM \
    --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
    --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
    --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

6. Create the cronjob:
   a. Open the `helper_files/configsync-cronjob-k8s.yaml` file located in the extracted API Connect Config Sync package.
   b. Modify the `schedule` property to specify how frequently the job will run.
   The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.
   c. Set the `concurrencyPolicy` to `Forbid`.
   Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.
   d. In the `image` property, replace the *`<registry>`* variable with the actual registry value for your image registry.
   e. Create the cronjob resource in the cluster by running the following command:

```
kubectl --namespace <namespace> apply -f helper_files/configsync-cronjob-k8s.yaml
```

Running Config Sync as a cronjob on VMware

Running the apic-configsync utility as a cronjob on VMware enables the utility to be run on a timed basis, such as every 10 minutes.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on VMware. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run from the management subsystem virtual machines in the target API Connect cluster.

Ensure that your virtual machines have enough resources available (CPU/Memory) for the cronjob to run the apic-configsync utility.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Define the environment variables for the source and target catalogs.
3. For each node in the management subsystem:
   a. In the extracted apic-configsync.tar.gz package, locate the `ibm-apic-configsync-image.tar.gz` file.
   b. Upload the `ibm-apic-configsync-image.tar.gz` file using the following command:

```
scp ibm-apic-configsync-image.tar.gz apicadm@<hostname>:~
```

   where *`<hostname>`* is the hostname or IP address of the node.

   c. SSH into the node and become root with `sudo -i`.
   d. Switch into the registry directory with the following command:

```
cd /var/lib/apiconnect-subsystem/registry/
```

   e. Extract the image from the tar.gz file with the following command:

```
tar xf /home/apicadm/ibm-apic-configsync-image.tar.gz
```

   Extracting the file creates the following directory:

```
/var/lib/apiconnect-subsystem/registry/ibm-apic-configsync/ibm-apic-configsync-<version>/<tag>
```

   where *`<version>`* is the current version of the apic-configsync utility and *`<tag>`* is the tag of the built image.
   f. Restart the appliance-manager by running the following command:

```
systemctl restart appliance-manager
```

4. Create secrets to host configuration details for the source cluster and the target cluster.
   a. SSH into one of the nodes in the management subsystem and become root with `sudo -i`.
   b. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret generic source-catalog-details \
    --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
    --from-literal=SOURCE_ORG=$SOURCE_ORG \
    --from-literal=SOURCE_REALM=$SOURCE_REALM \
    --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
    --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
    --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

   c. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret generic target-catalog-details \
    --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
    --from-literal=TARGET_ORG=$TARGET_ORG \
    --from-literal=TARGET_REALM=$TARGET_REALM \
    --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
    --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
```

```
    --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

5. Create the cronjob:
   a. Open the **helper_files/configsync-cronjob-ova.yaml** file located in the extracted API Connect Config Sync package.
   b. Modify the **schedule** property to specify how frequently the job will run.
   The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.
   c. Set the **concurrencyPolicy** to **Forbid**.
   Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.
   d. Upload the **helper_files/configsync-cronjob-ova.yaml** file to one of the management nodes.
   To upload the file, run the following command:

   ```
   scp helper_files/configsync-cronjob-ova.yaml apicadm@<hostname>:~
   ```

   Replace ***<hostname>*** with the host name or IP of one of the nodes in the management subsystem.
   e. SSH into one of the nodes in the management subsystem and become root with **sudo -i**.
   f. Create the cronjob resource in the cluster by running the following command:

   ```
   kubectl apply -f /home/apicadm/configsync-cronjob-ova.yaml
   ```

Authoring policies

With the on-premise offering, you can control specific processing features in the Gateway server of IBM® API Connect by creating user-defined policies.

IBM API Connect enables organizations to easily promote business services as APIs to internal and external developer communities. API developers can rapidly create, proxy, assemble, and secure APIs through the API Designer user interface (UI). The API Designer assembly feature allows API developers to create complex REST or SOAP API operations that transform data, perform multiple service calls, aggregate data, and apply policies.

A policy is a piece of configuration that controls a specific aspect of processing in the IBM DataPower® Gateway server during the handling of an API invocation at run time. IBM API Connect provides a number of different types of policies, but you can also create user-defined policies to provide more processing control.

When would you need a user-defined policy?

A user-defined policy enables you to control extra processing features in the Gateway server, such as security, or routing of requests. The user-defined policies feature is available only with the on-premise offering of IBM API Connect.

Create a user-defined policy in IBM API Connect when you need to augment the actions or activities that are performed by the API gateway. For example, you might want to perform the following operations:

- Implement your own proprietary logic for dynamic routing of requests.
- Enforce extra security constraints to your API.
- Make accessible an extra capability that is provided in DataPower that is not yet accessible in the IBM API Connect policy catalog.

Note: For best results, do not try to update your existing user-defined policies, because those are already in use by your APIs. Instead, create a new version of the policy that you want to update, and then modify the API assembly to use the newer version of the policy.
See the following topics for more information about user-defined policies, and how to create and import them into IBM API Connect:

- **Authoring policies for the DataPower Gateway (v5 compatible)**
  A user-defined policy for the DataPower Gateway (v5 compatible) consists of a package that contains a YAML definition file that describes the policy, together with the policy implementation files. You import the package into one or more Catalogs in your IBM API Connect environment to make the policy available to APIs that are published to those Catalogs.

Authoring policies for the DataPower Gateway (v5 compatible)

A user-defined policy for the DataPower® Gateway (v5 compatible) consists of a package that contains a YAML definition file that describes the policy, together with the policy implementation files. You import the package into one or more Catalogs in your IBM® API Connect environment to make the policy available to APIs that are published to those Catalogs.

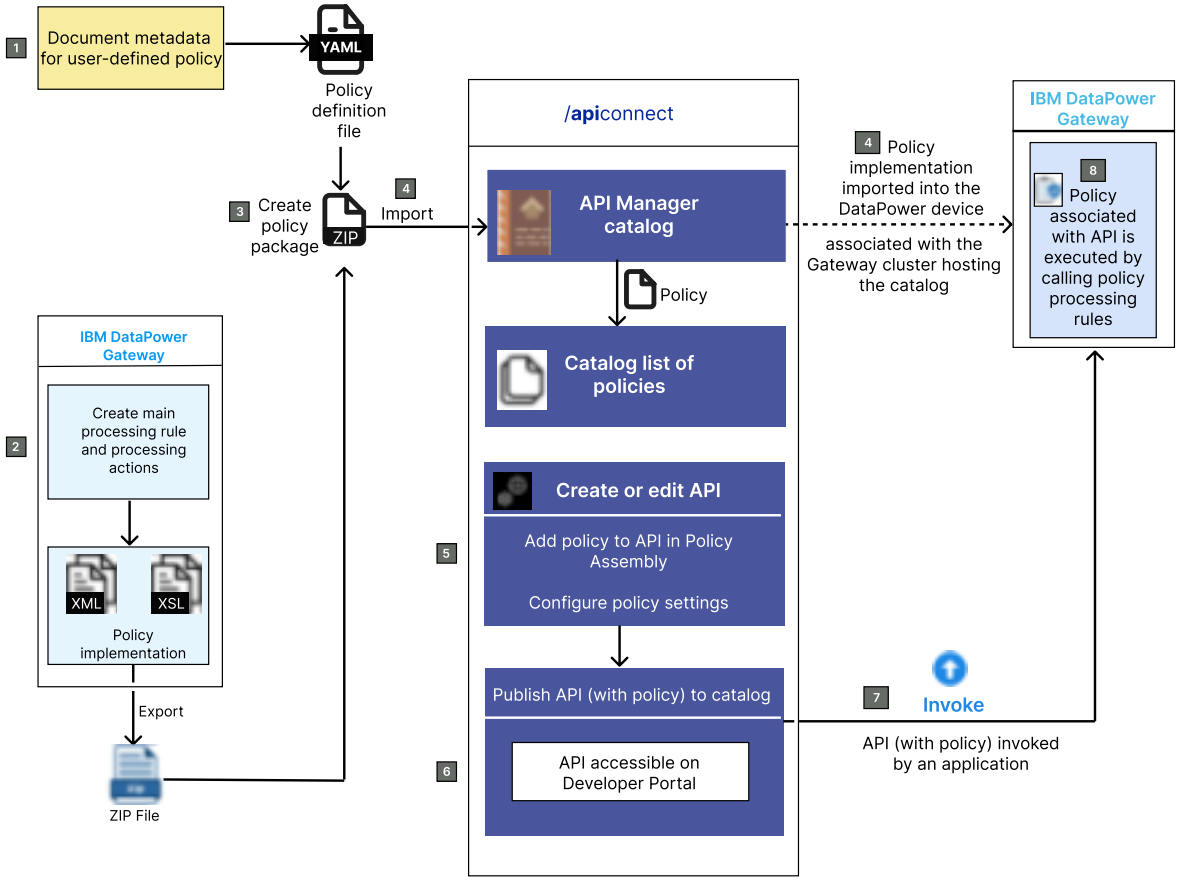
How do user-defined policies work?

A user-defined policy is implemented as a DataPower processing rule. After a policy is imported into an IBM API Connect Catalog, the policy is available to be placed into an assembly flow of an enforced API. When the API is published, and invoked by an application, the API Gateway executes all policies that are associated with this API. An

API Gateway that is running in DataPower calls the IBM DataPower Gateway processing rules that those policies implement.

The following diagram provides an overview of how to create and execute a user-defined policy in IBM API Connect.

Figure 1. The user-defined policy process



For details on how to define and deploy user-defined policies for the DataPower Gateway (v5 compatible), see the following subtopics:

- **Describing your policy**
  Describe your user-defined policy by creating a definition file in YAML format to document metadata about the policy.
- **Creating a new user-defined policy**
  Create a user-defined policy by configuring a policy definition file and its implementation, and then packaging the policy and importing it into IBM API Connect.
- **Packaging and importing your policies into IBM API Connect**
  Make your user-defined policy available to API developers by packaging it and importing it into an IBM API Connect Catalog.
- **Reference**
  Reference information for authoring policies in IBM API Connect.

DataPower Gateway (v5 compatible) only

Describing your policy

Describe your user-defined policy by creating a definition file in YAML format to document metadata about the policy.

About this task

A policy YAML file contains the following sections:

- A specification version.
- An information section.
- An attach section.
- A properties section.
- A gateways section.

You can create a policy YAML file by using any editor of your choice. Both .yaml and .yml file extensions are supported, but the use of the .yaml file extension is recommended by yaml.org.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Procedure

The following steps describe how to construct a policy YAML file.

1. Set the specification version by adding the following line to the beginning of the file: `policy: 1.0.0`.
2. Complete the information section with details about the policy by using the following syntax:

```
info:
  title: Title of policy
  name: shortnameofpolicy
  version: 1.0.0
  description: An example policy
  contact:
    name: name1
    url: url1
    email: email1
```

where:

- `title` is the title of the policy. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
- `name` is the short name for the policy and must contain only alphanumeric characters, the - (dash) character, and the _ (underscore) character (blank spaces are not supported). The name is case-sensitive, and should be 20 characters or less so that it can be displayed in the API Manager user interface. In the example, the name is shown as `<policy-name>`.
  Important: The policy short name must be different from the OpenAPI names of the built-in policies, otherwise it will cause a policy conflict in the API assembly definition. For a list of the OpenAPI built-in policy names, see execute. Also, consider including an appropriate unique prefix or suffix string in the short names of your user-defined policies to prevent possible name conflicts with future built-in policies.
  Note: The `name:` property must be identical to the Node.js module name.
- `version` is the version number of the policy. This is a reserved property.
  Tip: The *version.release.modification* version numbering scheme is recommended, for example *1.0.0*.
  Note: The `info.version` in policy.yaml must match the `version` indicated in package.json.
- `description` (optional) is a short description of the policy.
- `contact` (optional) is the contact information for the policy, where:
  - `name` (string) is the identifying name of the contact person or organization.
  - `url` (string) is the URL that points to the contact information.
  - `email` (string) is the email address of the contact person or organization.

3. Complete the attach section by specifying which type of API flow the policy can be attached to.

```
attach:
 - rest
 - soap
```

where:

- `rest` indicates that this policy can be attached to a REST API flow.
- `soap` indicates that this policy can be attached to a SOAP API flow.

The attach section must contain at least one API flow type. If a policy can be attached to both API flow types, they must both be indicated in the attach section.

4. Complete the properties section by defining a JSON schema (based on JSON Schema Specification Draft 4, but rendered in YAML format) that contains the list of properties the policy will declare as required input. These properties are presented to the API author at development time, when the properties can be configured or mapped to values as required.
   The JSON schema defines a root object that contains the following JSON properties:
   - `type`
   - `properties`
   - `required`

   The syntax and definition of these properties matches the JSON schema definition. The following code block shows an example of a simple schema that defines one required property (*a_property*):

```
properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    a_property:
    label: a label
    description: a description
    type: a type
  required:
    - a_property
```

   The root *type* of the schema must be an `object`, as shown in the example schema. You can define zero or more properties in the schema. Required properties are declared by using the `required` parameter, as shown in the example schema. The policy will not be accessible in the API Manager assembly editor, unless all the required properties have values. Each property is an object with the following items:
   - `label` is a short name for the property and is displayed in the Name column of the API Manager assembly editor.
   - `description` is a short description for the property and is displayed in the Description column of the API Manager assembly editor.
   - `type` must be one of the following primitives that are supported:
     - *integer*
     - *number*
     - *string*
     - *boolean* (this primitive is shown as a check box in the assembly editor)
     - *array*
   - `default` (optional) specifies a default value for the property.
   - `enum` (for properties with a `type` of *string*) is an array of valid values.
5. In your gateways section, specify that the policy is for the DataPower® Gateway.
   Enter the following code:

```
gateways:
  - datapower-gateway
```

6. Save the new policy as a YAML file using the value of the **name** property (in the **info** section) as the file's name.
   Required: To ensure a successful import, the YAML file must use the name specified in the policy's **name** property.

Results

You have created a user-defined policy definition YAML file that documents metadata about your policy.

Example

The following code block shows an example of a policy definition file that contains all the supported primitives. This policy must be saved as sampleimpl.yaml to ensure that it can be imported into API Connect.

```
policy: 1.0.0

info:
  title: Sample Policy
  name: sampleimpl
  version: 1.0.1
  description: This is a sample policy.
  contact:
    name: Steve Product Manager
    url: http://developer.acme.com/contacturl
    email: steve-product-manager@someemailservice.com

attach:
  - rest
  - soap

properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    samplestring:
      label: String Property
      description: Sample string property
      type: string
    sampleboolean:
      label: Boolean Property
      description: Sample boolean property
      type: boolean
    sampleinteger:

DataPower Gateway (v5 compatible) only

Implementing your policy

Create an implementation for your user-defined policy by using DataPower® processing rules and actions.

Before you begin

You must create a policy YAML file before you create an implementation. For more information, see Describing your policy.

You can create an implementation for your policy by using the usual tools available to IBM® DataPower Gateway developers. However, the DataPower user interface is typically the tool that is used to create processing rules and actions.
Note: You must be skilled in DataPower tooling and concepts, before you can create a policy implementation.
In order for your processing actions to work well under the API Gateway configuration, and also to enable the use of contextual information that is relevant to the processing actions, a library of functions and templates is available that you can use to assist you in writing the XSLT or GatewayScript transformations. This library provides the following mechanisms:

- Access to input property values (input from the assembly editor).
- Access to context values (the API Gateway runtime context).

- Access to the runtime payload message and media-type.
- Ability to modify the payload message.
- Ability to end the policy execution with an error.

About this task

You create an implementation for your user-defined policy in the IBM DataPower Gateway. The implementation must adhere to the following conventions:

1. You must create a main processing rule, and this rule will be the starting point for the policy. The rule name must start with the name of the policy (the value of the **`name`** property in the "info" section of the policy YAML file), followed by -main; for example *checkmembership-main*.
2. There are no restrictions on what actions the processing rule can execute, on condition that the rule adheres to the naming convention in point 1. and the instructions that are detailed in this topic.
3. The names of the processing actions and all other objects also must start with the name of the user-defined policy (the value of the **`name`** property in the "info" section of the policy YAML file).
4. If your processing rule runs transformation actions that use XSLT or GatewayScript files, these files must be stored in the following location: local://policy/*<policy-name>*.
5. If you have certificate and key files that must be stored in the cert: folder, the names of these files also must start with the name of the user-defined policy (as defined in the policy YAML file).
6. If your policy is using GatewayScript transformations, your policy code must require **`apim.custom.js`**, for example:

   ```
   var apic = require('local://isp/policy/apim.custom.js');
   ```

The following steps describe how to create an implementation for your user-defined policy:

- Create a main processing rule.
- Create one or more processing actions:
  - Configure access to input properties.
  - Configure access to the runtime context.
  - Configure access to the input payload.
  - Configure access to the HTTP headers.
  - Modify the payload in XSLT or gatewayscript.
  - Configure the implementation to produce error information.
  - Set variables.
- Export your policy implementation.

.

Procedure

1. Create a main processing rule that is called *<policy-name>*-main where *<policy-name>* is the name of your user-defined policy (the value of the **`name`** property in the "info" section of the policy YAML file).
   Note: You must specify the following processing rule settings:
   - Rule direction: Both Directions
   - Non-XML Processing: on
2. Create one or more processing actions.
   Each processing action should have a unique name and must start with the name of the user-defined policy (as defined in the policy YAML file).
   Note: Different processing actions in DataPower might require different releases of the DataPower firmware. When using the GatewayScript actions, the minimum DataPower firmware that should be used is version 7.2.0.
   The following processing actions are available:

   - Configure access to the input properties in XSLT (**`policyProperties`**), or in GatewayScript (**`apic.getPolicyProperty`**).
     If required by the properties that are defined in the policy YAML file, when the policy is attached to an API the API developer must enter the input settings or variables for a particular property. This function provides the mechanism to retrieve these input settings or variables at run time. For an example code snippet, see Access to input properties code snippet.

   - Configure access to the runtime context in XSLT (**`getContext`**), or in GatewayScript (**`apic.getContext`**).
     When an API is invoked, runtime information about the request can be accessed by using a user-defined policy, and this information is known as the runtime context. The function **`getContext`** provides the mechanism to access this runtime context. For an example code snippet, see Access to runtime context code snippet. For a complete list of context variables, see API Gateway context variables.

   - Configure access to the input payload in XSLT (**`payloadRead`**), or in GatewayScript (**`apic.readInput(callback)`**).
     Some policies require access to the input message or payload that is provided by the application. Accessing the input message or payload during an assembly flow can be difficult, as this information might change as the policies and the assembly steps run. This function provides a mechanism to get the correct input message or payload at the time of policy execution. For an example code snippet, see Access to input payload code snippet.

     This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.

     Note: The **`payloadType()`** function can be called to determine what type of payload (XML or JSONx) will be returned by the **`payloadRead()`** or the **`apic.readInput(callback)`** function.
   - Configure access to the HTTP headers in XSLT (**`getContext`**), or in GatewayScript (**`apic.getContext`**).
     The HTTP header information of a request can be retrieved from the request context. The HTTP header names are normalized to lowercase. The function **`getContext()`** provides the mechanism to access the HTTP header information. For an example code snippet, see Access to HTTP headers code snippet.

     Note: Access or modification of HTTP headers by using DataPower extensions, such as **`dp:set-request-header`**, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.
   - Modify the payload in XSLT or GatewayScript.
     When a policy implementation is required to change a payload message, you must configure the DataPower Transform Processing Action to set the Output context field to *OUTPUT* (referred to as the *OUTPUT* named context).

The output must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. To assist the API Gateway policy framework to accept the new or transformed message, call the **apim-output** template. For an example code snippet, see Modify the payload code snippet.

Note: The modify the payload processing action works only with a proxy task. An HTTP or web service task always overwrites the output of a policy implementation.

- Configure the implementation to produce error information.
  If you require your policy implementation to produce error information when there is a failure, you must configure the implementation by calling the error template. For an example code snippet, see Configure error information code snippet.

- Set variables.
  Use the **setVariable** template to set a runtime variable to a specified string value. This value can then be retrieved by using the function **getVariable()**, or by mapping the value into a step. For an example code snippet, see Set variables code snippet.

3. Export your policy implementation from DataPower.
   From the DataPower user interface, export the objects and files that are referenced by your main processing rule as a compressed file. No other objects or files should be exported. The following file list is an example configuration of an export from DataPower:

```
Archive: checkmembership.zip

11819    11-19-2014 22:53 dp-aux/basetypes.xml
3028207  11-19-2014 22:53 dp-aux/drMgmt.xml
6456     11-19-2014 22:53 dp-aux/map-dmz.xsl
7299     11-19-2014 22:53 dp-aux/management.xsl
23130    11-19-2014 22:53 dp-aux/SchemaUtil.xsl
216003   11-19-2014 22:53 dp-aux/clixform.xsl
5284     11-19-2014 22:53 local/policy/checkmembership/check.xsl
5061     11-19-2014 22:53 export.xml
```

   The example shows the exported configuration file (export.xml) that contains all the processing actions and DataPower objects, the referenced files, and the DataPower configuration schemas that are created by using the configuration export in the DataPower user interface.

Results

You have created an implementation for your user-defined policy and exported this implementation from the DataPower user interface.

What to do next

Create a user-defined policy package that can then be imported into IBM API Connect. For details, see Packaging and importing your policies into IBM API Connect.

Related concepts

- Authoring policies

Related information

- IBM DataPower Gateway

DataPower Gateway (v5 compatible) only

Packaging and importing your policies into IBM API Connect

Make your user-defined policy available to API developers by packaging it and importing it into an IBM® API Connect Catalog.

Before you begin

Before you can package a user-defined policy and import it into IBM API Connect, you must complete the following tasks:

1. Describe your policy in a YAML file.
2. Implement your policy by using DataPower processing rules and actions.

Procedure

To package and import your user-defined policy, complete the following steps:

1. Create a .zip file that contains the following folder structure:

```
<policy-name>.yaml
implementation/
              policy-name.zip
```

   where
   - *<policy-name>*.yaml is your policy definition file. The YAML file must use the name that is specified in its **name** property.
   - implementation/*policy-name*.zip is your policy implementation for a policy that is deployed to the DataPower Gateway. The policy implementation file contains the DataPower processing rules and actions that were exported from DataPower in step 2.

   The name of the .zip file must start with the name of the user-defined policy (as defined in the policy YAML file). If the implementation requires certificate and key files, these files must be added to the implementation directory.

   Note: Your package .zip file must contain a .zip policy implementation file.

2. Use the API Manager user interface to import your policy into a Catalog. For more information, see Importing a user-defined policy into a Catalog.
   Note:
   - You must import your user-defined policy into every Catalog in API Manager that you require your policy to run in.
   - For the policy to be displayed on the palette in the API assembly editor, you must import the user-defined policy into the Sandbox Catalog.

What to do next

Make your user-defined policy package accessible to the API Designer UI. To display user-defined policies in the API Designer UI, edit the .apiconnect/config file to point to the directory containing the policy.yaml file. You can edit the global config file (~/.apiconnect/config) or a project-specific config file (~/ProjectA/.apiconnect/config). Follow these steps:

1. Create one or more directories to hold your policy.yaml files that are accessible to Node.js, and copy the user-defined policy package into this directory. For example, create directories named /ProjectA/Policies and /ProjectB/Policies.
2. Extract the policy package so that the folder structure is visible, for example *policy*.yaml and implementation/*policy-name*.zip. The file containing the custom policies must be named policy.yaml.
3. Add the `userPolicies: [ ]` array object to the config file in ~/*ProjectA*/.apiconnect/ or ~/.apiconnect/, and edit the array object so it contains the absolute path to the director(ies) containing the policy.yaml file.
   Following is an example of an ~/.apiconnect/config file showing the userPolicies entry pointing to the directory containing the policy.yaml file:

```
apim_server: us.apiconnect.ibmcloud.com
us.apiconnect.ibmcloud.com.meta:
 formFactor: BLUEMIX_PUBLIC
 serverCapabilities:
    authTypes:
      - basic
      - token
 toolkit:
    version_recommended: 2.1.30
    version_minimum: 2.1.30
catalog: >-
  apic-catalog://us.apiconnect.ibmcloud.com/orgs/sampleorg-myspace2/catalogs/sb
app: >-
  apic-app://us.apiconnect.ibmcloud.com/orgs/sampleorg-myspace2/apps/acme-bank
userPolicies:
  - /ProjectA/Policies
```

   Note:
   - The `userPolicies: []` array object contains a list of absolute paths to the policy director(ies). The values can point to a parent location, for example `userPolicies: ["~/mypolicies"]`. Alternatively, each policy location can be specified in the array, for example `userPolicies: ["~/mypolicies/policya", ~/mypolicies/policyb"]`. However, do not use both of these approaches in the same directory. For example, do not create policies in a directory structure like this ~/mypolicies, ~/mypolicies/policya, and ~/mypolicies/policyb.
4. Open the API Designer UI. The user-defined policy is available on the policy assembly palette, and you can add the policy to your API definition.

- **Implementation code examples**
  Example code snippets to help the creation of a user-defined policy implementation.

DataPower Gateway (v5 compatible) only

Implementation code examples

Example code snippets to help the creation of a user-defined policy implementation.

Note: If you are using GatewayScript, you must include the following command:

```
var apic = require(./apim.custom.js);
```

where *apic* is the common name used for the GatewayScript examples in this topic. However, *apic* could be any given name of your choice, for example you could use:

```
var apim = require(./apim.custom.js);
```

and then you would start your calls with `apim`.

- Access to input properties code snippet
- Access to runtime context code snippet
- Access to input payload code snippet
- Access to HTTP headers code snippet
- Modify the payload code snippet
- Configure error information code snippet
- Set variables code snippet

Access to input properties code snippet

The following code block shows an example of how to access the input properties by using the XSLT `policyProperties()` function. The example defines a property that is named `a_property`, which is declared as an integer value, but is retrieved in XSLT as text.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="p" select="apim:policyProperties()" />
    <xsl:message>
      The value of my input property is
      <xsl:value-of select="$p/a_property" />
      <apigw:set-variable name="'propfound'" value="'true'"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getPolicyProperty(propertyName)
```

where ***propertyName*** is the name of the input property that you want to access. If the input property name is blank, the action will return all input properties.

Access to runtime context code snippet

The following code block shows an example of how to access the runtime context by using the XSLT `getContext()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="client-id" select="apim:getContext('client.app.id')" />
    <xsl:message>
      The calling application is
      <xsl:value-of select="$client-id" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getContext(varName)
```

where ***varName*** is the name of the context variable that you want to access.
For a complete list of context variables, see API Gateway context variables.

Access to input payload code snippet

The following code block shows an example of how to access the input payload by using the XSLT `payloadRead()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="input" select="apim:payloadRead()" />
    <xsl:message>
      The input payload is
      <xsl:copy-of select="$input" />
```

```
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.readInput(callback)
```

A callback is required because the actual payload read is asynchronous. The callback method is called when the payload is ready.
This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.
The following example shows how to use the `payloadType()` function to determine what type of payload (XML or JSONx) will be returned by the XSLT `payloadRead()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="payloadType" select="apim:payloadType()" />
    <xsl:message>
      <xsl:text>Payload type is [</xsl:text>
      <xsl:value-of select="$payloadType" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

Access to HTTP headers code snippet

The following code block shows an example of how to access the HTTP headers in XSLT by using the `getContext()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="content-type" select="apim:getContext('request.headers.content-type')" />
    <xsl:message>
      The request content type is
      <xsl:value-of select="$content-type" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getContext(request.headers.headerName)
```

where ***headerName*** maps to the name of the header you want to access.
Note: Access or modification of HTTP headers by using DataPower® extensions, such as `dp:set-request-header`, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.

Modify the payload code snippet

The output from a user-defined policy must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. The following code block shows an example of how to modify the payload in XSLT. To assist the API Gateway policy framework to accept the new or transformed message, call the `apim-output` template, as shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:jsonx="http://www.ibm.com/xmlns/prod/2009/jsonx"
  exclude-result-prefixes="apim"
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
```

```
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <!-- Creates a JSON document (empty object is for simplicity) -->
    <jsonx:object>
    </jsonx:object>

    <!-- Indicates the media type of the output being produced -->

    <xsl:call-template name="apim:output">
      <xsl:with-param name="mediaType" select="'application/json'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where `mediaType`:

- `'application/json'` is when the output is written in JSONx format.
- `'application/xml'` is when the output is written in XML format.

If you are using GatewayScript, you must call the function:

```
apic.output(mediaType)
```

where ***mediaType*** is:

- **application/json** is when the output is written in JSONx format.
- **application/xml** is when the output is written in XML format.

Specifying the media type allows the next steps in the assembly flow to understand how to process the new payload.

Tip: The output from a user-defined policy must be XML or JSONx. JSONx is an IBM standard format to represent JSON as XML. One way to convert output GatewayScript JSON data into JSONx, is to add a **Convert Query Params to XML** action to follow the GatewayScript action within the same policy rule. The **Convert Query Params to XML** action must have an **Input Conversion** with the **Default Encoding** set to **JSON**. The output from the GatewayScript action must be the input for the **Convert Query Params to XML** action for JSONx to be produced.

Configure error information code snippet

The following XSLT code block shows an example of how to configure the policy implementation to produce error information by calling the **apim-error** template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="apim"
  extension-element-prefixes="apim">

  <!-- Contains the APIM functions -->
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <!-- Indicates this policy has a failure and provides
       additional information for the client application -->
  <xsl:template match="/">
    <xsl:call-template name="apim:error">
      <xsl:with-param name="httpCode" select="'401'" />
      <xsl:with-param name="httpReasonPhrase" select="'Unauthorized'" />
      <xsl:with-param name="errorMessage" select="'Please select a Plan'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **errorMessage** is the suggested action for the user.

If you are using GatewayScript, you must call the template:

```
apic.error(name, httpCode, httpReasonPhrase, message)
```

where:

- **name** is the name of the error.
- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **message** is the suggested action for the user.

Set variables code snippet

The following XSLT code block shows an example of how to set a runtime variable to a specified string value by calling the **setVariable** template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="" select="'https://endpoint.host.com/data'" />
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'serviceEndpoint'" />
      <xsl:with-param name="value" select="$targetUrl" />
      <xsl:with-param name="action" select="'set'" />
    </xsl:call-template>
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$targetUrl" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$targetUrl}" response="xml" http-method="get"/>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **varName** is the name of the runtime variable that you want to set a value to.
- **value** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **value** as **$(request.headers.content-type)**.

If you are using GatewayScript, you must call the template:

```
apic.setvariable(varName, varValue, action)
```

where:

- **varName** is the name of the runtime variable that you want to set a value to, or that you want to add or clear.
- **varValue** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **varValue** as **request.headers.content-type**. This property is only required when **set** or **add** is specified as the action.
- **action** is the action that you want to apply to the variable. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

The following XSLT example shows how to retrieve the value of a runtime variable by using the **getVariable()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  exclude-result-prefixes="dp func apim"
  extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/> <!-- Use this import for XSLT 1.0.0 only (v5c Gateway) -->

  <xsl:template match="/">
    <xsl:variable name="varValue" select="apim:getVariable('serviceEndpoint')" />
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$varValue" />
      <xsl:text>]</xsl:text>
    </xsl:message>
    <dp:url-open target="{$varValue}" response="xml" http-method="get"/>
  </xsl:template>

</xsl:stylesheet>
```

where

- **varValue** is the name of the runtime variable that you want to retrieve a value for.

If you are using GatewayScript, you must call the function:

```
apic.getvariable(varName)
```

where ***varName*** is the name of the runtime variable that you want to retrieve a value for.

API Gateway only

Authoring policies for the DataPower API Gateway

A user-defined policy for the DataPower API Gateway consists of a package containing configuration details that define the actions of the policy. You publish the package to the DataPower API Gateway to make it available to APIs that are deployed there.

There are two types of user-defined policies, *Catalog scoped* user-defined policies and *global scoped* user-defined policies:

Catalog-scoped user-defined policies
: Catalog-scoped user-defined policies are available to APIs only in the Catalogs that you specify. Use a Catalog scoped user-defined policy if you want to limit the availability of your policy on a Catalog specific basis. The possible actions of a Catalog scoped user-defined policy are limited to the API Connect built-in assembly policies. For more information, see Defining, packaging, and publishing a catalog-scoped policy for the API Gateway.

Global-scoped user-defined policies
: Global-scoped user-defined policies are available to APIs in every Catalog in every provider organization. Use a global scoped user-defined policy in the following situations:

  - You want to make your policy available everywhere rather than limiting its availability to specific Catalogs.
  - Your policy uses a DataPower® implementation, where configuration changes are made directly on the DataPower API Gateway.

  Note: Global-scoped user-defined policies are not the same as global policies that you define with the toolkit CLI, as documented on Working with global policies. For more information, see Defining, packaging, and publishing a global-scoped policy for the API Gateway.

- **Defining, packaging, and publishing a catalog-scoped policy for the API Gateway**
  Create a catalog-scoped, user-defined policy that can be used in API assemblies within the catalog where the policy is published.
- **Defining, packaging, and publishing a global-scoped policy for the API Gateway**
  Create a global-scoped, user-defined policy that is available to APIs in any of the catalogs in any provider organization.

Defining, packaging, and publishing a catalog-scoped policy for the API Gateway

Create a catalog-scoped, user-defined policy that can be used in API assemblies within the catalog where the policy is published.

About this task

When a catalog-scoped policy is published, you can only use it in the API Assembler's Policy palette for APIs contained within the same catalog where the policy was published. Complete the following tasks to define, package, and publish the catalog-scoped policy.

Tip: During this task, you will create several zip files. On macOS, run the `zip` command on the command line with the following flags:

```
-x ".DS_Store" -x "__MACOSX"
```

Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

- **Structure of the catalog-scoped user-defined policy YAML file**
  Review the required structure of the YAML file that contains your catalog-scoped user-defined policy.

Step 1: Define a catalog-scoped policy for API Gateway

Use the DataPower Web GUI to define a new policy that can be used in API assemblies within the catalog where the policy is published.

Procedure

1. Log in to the DataPower Web GUI.
2. Create a new "test" domain and then switch to it.
   This test domain will be used as a "sandbox" to build and export the custom policies.
3. Navigate to Assembly Function and create a new object:
   a. Name the object ***<org-name>_<catalogname>***`_udp-`***<policyname>_<version>***.
      Example: "testorg_stagecatalog_udp-testpolicy_1.0.0". Use the same name for all of the objects that you create in this task.
      Note: This naming convention specifies the provider organization and catalog where the policy will be available, as well as the policy's name and version.
   b. Under the "Assembly" property, create a new Assembly.
   c. Under the new Assembly, create a new Rule.
   d. Under the new Rule, create a new API Action.
   e. Optionally add an implementation file for the new Action.

For example, an XSLT Action requires an XSL file. Create the file in the using the following path and name (where "udp" refers to user-defined policy:

local:///*<udp-name>*/*<udp-name>*.*<file-extension>*

f. Click Apply and then save all of the new objects.

4. Export the new user-defined policy.
   a. Navigate to the newly created Assembly Function.
   b. Click Export to export the new user-defined policy to a file named *<policyname>*_*<version>*.zip.
   c. Open the exported *<policyname>*_*<version>*.zip file and confirm that all referenced files are included.
   d. Delete the dp-aux folder from the zip.
   This optional folder requires a lot of storage space and might cause a problem when you package and publish the new policy in the next task.

Step 2: Package and publish a catalog-scoped policy for API Gateway

Decide how you want the new catalog-scoped policy to be managed, and then publish it to make it available to API assemblies within a particular catalog.

About this task

Be sure to complete Step 1: Define a catalog-scoped policy for API Gateway before attempting to package and publish the new policy.

There are two methods for packaging and publishing a user-defined policy, based on how you want the policy to be managed:

- Step 2, Option A: Package and publish a catalog-scoped policy directly in the DataPower configuration
- Step 2, Option B: Package and publish a catalog-scoped policy as a gateway extension that API Connect manages

Step 2, Option A: Package and publish a catalog-scoped policy directly in the DataPower configuration

Package and publish a catalog-scoped policy so it can be stored directly on the DataPower API Gateway.

About this task

When you store a catalog-scoped policy on the DataPower API Gateway, the policy exists in the gateway's startup domain configuration and will be unaffected by the API Manager lifecycle. If you want to store the catalog-scoped policy directly on DataPower, you do not need to package it for API Manager. Instead, complete the following steps.

Procedure

1. Import the custom policy created in Step 1: Define a catalog-scoped policy for API Gateway to the application domain for every DataPower node in the cluster.
2. Proceed to Step 3: Create and publish a policy.yaml file, where you will create a file that describes the new policy so that API Manager can support it.

Step 2, Option B: Package and publish a catalog-scoped policy as a gateway extension that API Connect manages

Package and publish a catalog-scoped policy as a gateway extension in API Connect.

Before you begin

The xml-manager must be enabled on the default domain of every gateway that will have a gateway-extension published to it.

About this task

When you publish a catalog-scoped policy as a gateway extension in API Connect, it is subject to the API Manager lifecycle. The individual assembly functions will not be added to the API Connect Gateway Service (only global-scoped policies are added to the service).

Procedure

1. Rename the *<policyname>*_*<version>*.zip file (that you created in Step 1: Define a catalog-scoped policy for API Gateway) to *<org-name>*_*<cat-name>*_*<policyname>*_*<version>*.zip.
   The new file name indicates the provider organization and the catalog where the policy will be used.

2. Create a gateway-extension manifest.json file as explained in Gateway extensions manifest.
   The manifest contains one or more entries. The following example contains a sample entry for the new catalog-scoped policy and references the new policy filename.

```
{
    "filename": "<org-name>_<cat-name>_<policyname>_<version>.zip",
    "deploy": "immediate",
    "type": "dp-import",
},
```

3. Create a new zip file called gateway-extension.zip that contains the following files:
   - manifest.json
   - *<org-name>*_*<cat-name>*_*<policyname>*_*<version>*.zip
4. Publish the new gateway extension using the toolkit CLI or the Cloud Manager UI:
   - API Connect toolkit CLI:
     Use the **apic gateway-extensions:create** command to publish the gateway extension (see toolkit CLI reference documentation).

   - Cloud Manager UI:
     Complete the following steps to publish the gateway extension from Cloud Manager:

     - Log in to Cloud Manager.

- Click Topology > ⋮ > Configure gateway extensions > Upload gateway-extension.zip file and upload your new gateway-extension.zip file.

5. Verify that the new catalog-scoped policy is available in the API Assembler's Policy palette.
   a. Log in to API Manager and open the Catalog where you published the new catalog-scoped policy.
   b. Create an API.
   c. Open the API Assembler page and view the Policy palette; verify that your new catalog-scoped policy displays and can be added to the API.

Step 3: Create and publish a policy.yaml file

Create a file that describes the properties of the catalog-scoped policy, and then publish it to make it accessible to API Manager.

Procedure

1. Create a YAML file that describes the new catalog-scoped policy.
   a. Create a file named *<policyname>*.yaml.
   b. Paste the following content into the new file:

```
attach:
- rest
- soap
policy: 1.0.0
info:
  title: <policyname>
  name: <policyname>
  version: 1.0.0
  description: <description-here>
properties:
  $schema: 'http://json-schema.org/draft-04/schema#'
  type: object
  properties:
    exampleProperty:
      label: Test Property
      description: Enter any value
      type: string
    exampleProperty2:
      label: Another Test Property
      description: Enter any value
      type: string
  required:
    - exampleProperty2
gateways:
- datapower-api-gateway
```

   c. Modify the content as needed to correctly describe your new catalog-scoped policy.
   For more information, see Structure of the catalog-scoped user-defined policy YAML file.

   d. Save and close the file.
2. Create a new zip file called *<policyname>*.zip that contains the new YAML file.
3. Publish the new policy using either the toolkit CLI or the API Manager:
   - API Connect toolkit CLI:
   Use the **apic policies:create** command to publish the gateway extension (see toolkit CLI reference documentation).

   - API Manager:
   Complete the following steps to publish the new policy:

     - Log in to API Manager.
     - Click Manage Catalogs > Select Catalog > Gateways > *selected_gateway* > ⋮ > View policies and upload your new policy.zip file.

4. Verify that the new catalog-scoped policy is available in the API Assembler's Policy palette.
   a. In API Manager, select the Catalog where you published the new catalog-scoped policy.
   b. Create an API.
   c. Click ⚙ (next to Save) and for the Target Catalog, select the catalog where you published the new policy.
   d. Save the API.
   e. Open the API Assembler page and view the Policy palette; verify that your new catalog-scoped policy displays and can be added to the API.

Structure of the catalog-scoped user-defined policy YAML file

Review the required structure of the YAML file that contains your catalog-scoped user-defined policy.

The .yaml file for a catalog-scoped user-defined policy contains the following sections:

- Specification version
- Information
- Attach
- Gateways
- Properties
- Assembly section

Specification version

Set the specification version by adding the following line to the beginning of the file:

```
policy: 1.0.0
```

Information

Complete the information section with details about the policy by using the following syntax:

```
info:
  title: Title of policy
  name: shortnameofpolicy
  version: 1.0.0
  description: An example policy
  contact:
    name: name1
    url: url1
    email: email1
```

where:

- `title` is the title of the policy. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
- `name` is the short name for the policy. Must be a single word, and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or less so that it can be displayed in the API Manager user interface.
  Important: The policy short name must be different from the OpenAPI names of the built-in policies, otherwise it will cause a policy conflict in the API assembly definition. For a list of the OpenAPI built-in policy names, see execute. Also, consider including an appropriate unique prefix or suffix string in the short names of your user-defined policy to prevent possible name conflicts with future built-in policies.
  Note: The `name:` property must be identical to the Node.js module name.
- `version` is the version number of the policy. This is a reserved property.
  Tip: The *version.release.modification* version numbering scheme is recommended, for example *1.0.0*.
  Note: The `info.version` in policy.yaml must match the `version` indicated in package.json.
- `description` (optional) is a short description of the policy.
- `contact` (optional) is the contact information for the policy, where:
  - `name` (string) is the identifying name of the contact person or organization.
  - `url` (string) is the URL that points to the contact information.
  - `email` (string) is the email address of the contact person or organization.

For example:

```
info:
  title: Custom Invoke Policy
  name: custom-invoke
  version: 1.0.0
  description: Invokes httpbin
  contact:
    name: IBM DataPower Samples
    url: 'https://github.com/ibm-datapower/'
    email: steve-product-manager@ibm.com
```

Attach

Complete the attach section by specifying which types of API flow the policy can be attached to.

- `rest` indicates that this policy can be attached to a REST API flow.
- `soap` indicates that this policy can be attached to a SOAP API flow.

The attach section must contain at least one API flow type. If a policy can be attached to both API flow types, they must both be indicated in the attach section.

For example:

```
attach:
  - rest
  - soap
```

Gateways

Specify the DataPower® API Gateway, as follows:

```
gateways:
  - datapower-api-gateway
```

Properties

Complete the properties section by defining a JSON schema (based on JSON Schema Specification Draft 4, but rendered in YAML format) that contains the list of properties the policy will declare as required input. These properties are presented to the API author at development time, when the properties can be configured or mapped to values as required. The JSON schema defines a root object that contains the following JSON properties:

- `type`
- `properties`
- `required`

The syntax and definition of these properties matches the JSON schema definition. The following code block shows an example of a simple schema that defines one required property (*a_property*):

```
properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
```

```
    a_property:
    label: a label
    description: a description
    type: a type
  required:
    - a_property
```

The root *type* of the schema must be an `object`, as shown in the example schema. You can define zero or more properties in the schema. Required properties are declared by using the `required` parameter, as shown in the example schema. The policy will not be accessible in the API Manager assembly editor, unless all the required properties have values. Each property is an object with the following items:

- `label` is a short name for the property and is displayed in the Name column of the API Manager assembly editor.
- `description` is a short description for the property and is displayed in the Description column of the API Manager assembly editor.
- `type` must be one of the following primitives that are supported:
  - *integer*
  - *number*
  - *string*
  - *boolean* (this primitive is shown as a check box in the assembly editor)
  - *array*
- `default` (optional) specifies a default value for the property.
- `enum` (for properties with a `type` of *string*) is an array of valid values.

For example:

```
properties:
  $schema: 'http://json-schema.org/draft-04/schema#'
  type: object
  properties:
    test:
      label: Test Property
      description: Enter any value
      type: string
  required:
    - test
```

Assembly section

The assembly section defines the assembly policy flow that will be activated when the user-defined policy is invoked. For example:

```
assembly:
  execute:
    - invoke:
        version: 2.0.0
        title: custom-invoke
        header-control:
          type: blacklist
          values: []
        parameter-control:
          type: whitelist
          values: []
        timeout: 60
        verb: keep
        cache-response: protocol
        cache-ttl: 900
        stop-on-error: []
        target-url: 'http://httpbin.org/headers'
```

You can determine the correct content of this section in either of the following ways:

- Define the assembly flow by using the graphical assembly editor in either the API Designer or API Designer user interface, then copy the `assembly:` section from the Source tab. For more information on defining an assembly flow in the user interface, see The Assemble view and API policies and logic constructs.
- Code the policies in the `execute:` subsection of the `assembly:` section by hand; for details, see execute.

The assembly section can contain only the API Connect built-in policies. However, you can include a gatewayscript policy that references native DataPower configuration.

Defining, packaging, and publishing a global-scoped policy for the API Gateway

Create a global-scoped, user-defined policy that is available to APIs in any of the catalogs in any provider organization.

About this task

When a global-scoped policy is published, you can use it in the API Assembler's Policy palette for APIs in any catalog belonging to any provider organization. Complete the following tasks to define, package, and publish the global-scoped policy.

Tip: During this task, you will create several zip files. On macOS, run the `zip` command on the command line with the following flags:

```
-x ".DS_Store" -x "__MACOSX"
```

Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

Step 1: Define a global-scoped policy for API Gateway

Use the DataPower Web GUI to define a new policy that can be used in API assemblies in all catalogs belonging to all provider organizations.

Procedure

1. Log in to the DataPower Web GUI.
2. Create a new "test" domain and then switch to it.
   This test domain will be used as a "sandbox" to build and export the custom policies.

3. Navigate to Assembly Function and create a new object:
   a. Name the object ***<policyname>_<version>***.
      Example: "testpolicy_1.0.0". Use the same name for all of the objects that you create in this task. Because the policy will be available in all provider organizations and catalogs, there is no need to specify that information in the object name.
   b. Under the "Assembly" property, create a new Assembly.
   c. Under the new Assembly, create a new Rule.
   d. Under the new Rule, create a new API Action.
   e. Optionally add an implementation file for the new Action.
      For example, an XSLT Action requires an XSL file. Create the file in the using the following path and name (where "udp" refers to user-defined policy:

      local:///*<udp-name>*/*<udp-name>*.*<file-extension>*

   f. Click Apply and then save all of the new objects.
4. Export the new user-defined policy.
   a. Navigate to the newly created Assembly Function.
   b. Click Export to export the new user-defined policy to a file named *<policyname>*_*<version>*.zip.
   c. Open the exported *<policyname>*_*<version>*.zip file and confirm that all referenced files are included.
   d. Delete the dp-aux folder from the zip.
      This optional folder requires a lot of storage space and might cause a problem when you package and publish the new policy in the next task.

Step 2: Package and publish a global-scoped policy for API Gateway

Decide how you want the new global-scoped policy to be managed, and then publish it to make it available to API assemblies.

About this task

Be sure to complete the steps in Step 1: Define a global-scoped policy for API Gateway before attempting to package and publish the new global-scoped policy. There are two methods for packaging and publishing a user-defined policy, based on how you want the policy to be managed:

- Step 2, Option A: Package and publish a global-scoped policy directly in the DataPower configuration
- Step 2, Option B: Package and publish a global-scoped policy as a gateway extension that API Connect manages

Step 2, Option A: Package and publish a global-scoped policy directly in the DataPower configuration

Package and publish a global-scoped policy so it can be stored directly on the DataPower API Gateway.

About this task

When you store a global-scoped policy on the DataPower API Gateway, the policy exists in the gateway's startup domain configuration and will be unaffected by the API Manager lifecycle.

Procedure

1. Import the *<policyname>*_*<version>*.zip file containing the new global-scoped policy to the application domain for every DataPower node in the cluster.
   Complete the following steps on every DataPower node in the cluster--if you omit a node, then the policy will not be available in the API Assembly's Policy palette.
   a. On the DataPower node, navigate to the API Connect Gateway Service object.
   b. Under the "User-defined policies" property, add a new Assembly Function by importing the *<policyname>*_*<version>*.zip file containing your new global-scoped policy.
   c. Click Apply, and then Save.
2. Verify that the new global-scoped policy is available in the API Assembler's Policy palette.
   a. Log in to API Manager.
   b. Create an API.
   c. Open the API Assembler page and view the Policy palette; verify that your new global-scoped policy displays and can be added to the API.

Step 2, Option B: Package and publish a global-scoped policy as a gateway extension that API Connect manages

Package and publish a global-scoped policy as a gateway extension in API Connect.

Before you begin

The xml-manager must be enabled on the default domain of every gateway that will have a gateway-extension published to it.

About this task

When you publish a global-scoped policy as a gateway extension in API Connect, it is subject to the API Manager lifecycle.

Procedure

1. Make a copy of the *<policyname>*_*<version>*.zip file containing your new global-scoped policy and remove the ***<version>*** number from the file name.
   This name change ensures that the relative path of the file meets the requirement to match the following regular expression: **`implementation\/[\w_-]+\.zip`**.
   You can retain the copy of the file with its original name for tracking purposes.

2. Create a local folder named implementation and store the renamed zip file in that folder.
3. Create a YAML file that describes the new global-scoped policy.
   a. Create a file named *<policyname>*.yaml.
   b. Paste the following content into the new file:

```
policy: 1.0.0
info:
  title: <policyname>
  name: <policyname>
  version: 1.0.0
  description: <description-here>
```

   Only the **policy** and **info** sections are needed in the *<policyname>*.yaml for this task.

   c. Save and close the file.
4. Create a new zip file called *<policyname>_<version>*.zip that contains the following files:
   - The implementation folder
   - *<policyname>*.yaml
5. Create a gateway-extension manifest.json file as explained in Gateway extensions manifest.
   The manifest contains one or more entries. The following example contains a sample entry for the new global-scoped policy and references the original policy *<policyname>_<version>*.zip file that you created in Step 1: Define a global-scoped policy for API Gateway:

```
        {
            "filename": "<policyname>_<version>.zip",
            "deploy": "immediate",
            "type": "user-defined-policy",
        },
```

6. Create a new zip file called gateway-extension.zip that contains the following files:
   - manifest.json
   - *<policyname>_<version>*.zip
     This is the file that you created in step 4 of this task (it contains the implementation folder and the *<policyname>*.yaml file).
7. Publish the new gateway extension using one of the following methods:
   - API Connect toolkit CLI:
     Use the **apic gateway-extensions:create** command to publish the gateway extension (see toolkit CLI reference documentation).
   - Cloud Manager UI:
     Complete the following steps to publish the gateway extension from Cloud Manager:
     - Log in to Cloud Manager.
     - Click Topology > ⋮ > Configure gateway extensions and upload your new gateway-extension.zip file.
8. Verify that the new global-scoped policy is available in the API Assembler's Policy palette.
   a. Log in to API Manager.
   b. Create an API.
   c. Open the API Assembler page and view the Policy palette; verify that your new global-scoped policy displays and can be added to the API.

Developer Portal: socialize your APIs

The Developer Portal serves as a comprehensive platform for facilitating API sharing with application developers.

In addition to allowing application developers to find and subscribe to APIs, the Developer Portal provides additional features including forums, blogs, comments, and ratings, together with an administrative interface for customizing the Developer Portal to your brand and theme. See the following topics for more information.

Using the Developer Portal
: As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.

Configuring the Developer Portal site
: Customize the look and feel of the Developer Portal site, and brand it for your organization.

Concepts in the Developer Portal
: Understand the various concepts and terminology that are referenced throughout the Developer Portal.

Getting started configuring the Developer Portal site
: A quick start guide to configuring your Developer Portal site.

Developer Portal tutorials
: Guided examples that take you through some of the most common user scenarios, as well as some of the more complex areas.

- **Using the Developer Portal**
  As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.
- **Configuring the Developer Portal site**
  Customize the look and feel of your Developer Portal site, and brand it for your organization.
- **Managing the Developer Portal by using the toolkit CLI**
  You can perform operations on your Developer Portal by using the API Connect toolkit CLI.
- **Troubleshooting guide for the Developer Portal**
  Use this guide to help you diagnose and resolve Developer Portal issues in IBM® API Connect. For example, why is the Developer Portal not connecting to the Management server, why is my site not created, and why can't I log in?

  Tutorials for using the Developer Portal.

Using the Developer Portal

As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.

The Developer Portal is a convenient place to share APIs with application developers. After a Developer Portal has been enabled through the API Manager, and one or more API Products have been published, application developers can browse and use the APIs. Typically, a Developer Portal is customized to fit the corporate branding and design requirements of a particular organization. For more information about configuring a Developer Portal site, see Configuring the Developer Portal site. However, when the Developer Portal is first enabled it can be used as is, for example for test and development purposes, or for internal use only.

The following topics provide information about the main API consumer concepts in the Developer Portal, and how an application developer can navigate the default site. However, bear in mind that the actual consumer experience might be very different depending on how the site is configured. For tutorials guiding you through enabling a Developer Portal site, and navigating and using APIs as an application developer, see Tutorial: Creating the Developer Portal and Tutorial: Creating Accounts and Applications on the Developer Portal.

- **Logging in as a consumer to the Developer Portal by using the CLI**
  Use the toolkit CLI to log in to the Developer Portal as a consumer.
- **Exploring APIs and Products in the Developer Portal**
  As an application developer, you can browse, test, and subscribe to APIs in the Developer Portal by exploring the available API Products.
- **Applications in the Developer Portal**
  You can view, edit, configure, and create applications in the Developer Portal.
- **Analytics in the Developer Portal**
  You can view analytics for APIs in the Developer Portal at the application and organization levels. This information is displayed in dashboard views that show the analytics metrics in the form of *visualizations* (represented as charts).
- **Consumer organizations in the Developer Portal**
  Consumer organizations provide a way of grouping application developers together. You can add, remove, and configure Consumer organizations in the Developer Portal.
- **User accounts, passwords, and support in the Developer Portal**
  You can change general elements such as user accounts and passwords in the Developer Portal.

Logging in as a consumer to the Developer Portal by using the CLI

Use the toolkit CLI to log in to the Developer Portal as a consumer.

Before you begin

To log in as a consumer, you must have created a developer account in the Developer Portal as explained in the following tutorial: Tutorial: Creating Accounts and Applications on the Developer Portal.

About this task

You can use the toolkit CLI to log in to the Developer Portal as a consumer to view it and test how it behaves for your customers.

Procedure

1. Set up the toolkit as explained in Installing the toolkit.
2. Determine the name of your identity provider.
   When you log in from the CLI, you must provide the name of the realm (identity provider) that hosts your API Connect user account. If you don't know the name of your account's realm, you can look it up by using the following command.

   In the CLI, run the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --server consumer_endpoint_api --mode consumer --catalog catalog_name_or_id --org
   <provider_org_name_or_id> --fields registry_type,realm
   ```

   Where:
   - `consumer_endpoint_api` is the endpoint of the consumer API.
   - `catalog_name_or_id` is the name or ID of your catalog.
   - `<provider_org_name_or_id>` is the name of ID of your provider organization.

   For example:

   ```
   apic identity-providers:list -s consumer.abce-ci-15608-master.abce.ibm.com -m consumer -c sandbox -o org --fields
   registry_type,realm
   total_results: 1
   results:
     - registry_type: 'lur'
       realm: 'consumer:4da2f1b9-05c1-4506-9e2d-951198d19ad3:faa5577d-625c-4fc8-8d19-26077c8aff95/sandbox-idp'
   ```

In the response, the realm consists of the following elements:

`consumer:<provider_org_name_or_id>:<catalog_name_or_id>/<catalog_identity_provider_name>`

For example, `consumer:myorg:mycatalog/sandbox-idp`.
Note that `<catalog_identity_provider_name>` is typically made up of `catalog_name-idp`, for example `sandbox-idp`.

3. In the toolkit CLI, run the following command to log in to the Developer Portal:
   Command syntax:

   ```
   apic login --mode consumer --server consumer_endpoint_api --username username --password password --realm realm
   ```

   Where:
   - `consumer_endpoint_api` is the endpoint of the consumer API.
   - `username` is your API Connect username.
   - `password` is the password that corresponds to your API Connect username.
   - `realm` is the user registry realm for the specified `<username>`.

   Example:

   ```
   apic login --mode consumer --server consumer.9a6e-88fa49bc.eu-gb.apiconnect.cloud.ibm.com -u my_username -p Blue123 -r
   consumer:frankenstein:om-portal/portal-idp

   Logged into consumer.9a6e-88fb51bc.eu-gb.apiconnect.cloud.ibm.com successfully
   ```

Exploring APIs and Products in the Developer Portal

As an application developer, you can browse, test, and subscribe to APIs in the Developer Portal by exploring the available API Products.

Browsing available APIs
: In API Connect API providers package their APIs into Products to offer one or more APIs to application developers. The providers then use Plans to control access to APIs and to manage API usage. Products are packages that contain both the APIs and the accompanying Plans.
From the Developer Portal home screen, click API Products to browse the available products. You can then select a Product to explore the available Plans and APIs further, including viewing API code snippets, and request and response examples.
Note:
Note: If you have an account on the Developer Portal, you can specify a default programming language for the code snippets to display in by editing the Code Snippet Language in your account settings.

Subscribing to a Plan
: A Plan is a collection of API operations or subsets of operations from one or more APIs. In order to subscribe to a Plan, you must have an account on the Developer Portal and have created an App. For more information, see User accounts, passwords, and support in the Developer Portal and Applications in the Developer Portal. Rate limits specify how many requests an App is allowed to make during a specified time interval. A Plan can have a shared rate limit for all the operations, or each operation can have a different rate limit. In addition, Plans can have multiple rate limits set per Plan and per operation, at second, minute, hour, day, and week time intervals. Plans can also have burst limits to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals.

  After you have identified the Plan that you want to use, click Subscribe and then select the App that you want to use with this Plan. If the Plan is not restricted, you can use it immediately. If the Plan is restricted, the subscription is shown as Pending Approval, and you cannot use the requested Plan until the administrator approves your request.

  You cannot subscribe to a monetized Plan without first adding your payment information to your Consumer organization. You can register your payment information by editing the Billing tab for your Consumer organization. Note: you must either be the Consumer organization owner, or have `Settings: Manage` permissions for your organization to be able to edit the billing information. Consumer organizations can have at most one payment method. You can delete your payment method and add a different method, for example if your credit card expires. If you change your subscription to a Plan that has a different pricing structure, the subscription billing system will add a prorated amount to the next invoice of your subscription billing cycle.

Testing an API
: You can test an API in the Developer Portal by using the interactive API document test tool. If the API operation that you want to test doesn't require a client ID, then you can use the test tool without the need to log in. For more information, see Testing an API by using the Developer Portal test tool.

Calling an API in your application
: When you have subscribed to a Plan and you begin coding your application, you must retrieve the operation URL in order to call the API. You can retrieve the operation URL from the API overview page. For more information, see Calling an API.

- **How to use a URL to navigate directly to a Product or API in the Developer Portal**
  You can navigate to a specific Product or API in the Developer Portal by using `x-ibm-name:version` in the URL.
- **Testing an API by using the Developer Portal test tool**
  You can test the behavior of an API without the need to write any code by using the Developer Portal test tool. You provide the necessary API parameters within the test tool and click Invoke to see the response.
- **Calling an API**
  When you have a selected a Plan and you begin coding your application, you must retrieve the operation URL to call the API.

How to use a URL to navigate directly to a Product or API in the Developer Portal

You can navigate to a specific Product or API in the Developer Portal by using `x-ibm-name:version` in the URL.

To find a Product or API in the Developer Portal you typically navigate there by searching in the UI, clicking on the relevant Product, and then selecting the API. However, if you know the `x-ibm-name:version` of your Product or API, you can insert that information into the URL to go there directly.

To navigate directly to a specific API, use the following URL syntax:

`portal.site.url/productselect/api_x-ibm-name:version`

For example:

`https://my.portal.com/myorg/sandbox/productselect/petstore-header-clientid:1.0.0`

To navigate directly to a specific Product, use the following URL syntax:

`portal.site.url``/product/`*`product_x-ibm-name:version`*

For example:

`https://my.portal.com/myorg/sandbox/product/my-product:1.0.0`

To navigate directly to a specific API within a specific Product, use the following URL syntax:

`portal.site.url``/product/`*`product_x-ibm-name:version`*`/api/`*`api_x-ibm-name:version`*

For example:

`https://my.portal.com/myorg/sandbox/product/my-product:1.0.0/api/petstore-header-clientid:1.0.0`

Testing an API by using the Developer Portal test tool

You can test the behavior of an API without the need to write any code by using the Developer Portal test tool. You provide the necessary API parameters within the test tool and click Invoke to see the response.

Before you begin

To use the Developer Portal test tool with an API that requires an App client ID, you must first complete the following tasks:

- Create an App. For more information, see Registering an application.
- Subscribe to a Plan that contains the API that you want to test. For more information, see Exploring APIs and Products in the Developer Portal.

About this task

The Developer Portal test tool is an interactive API document test tool. If the operation that you want to test does not require a client ID, then you can use Developer Portal test tool without the need to sign in. However, if the operation that you want to interact with requires a client ID, then you must sign in to the Developer Portal first.

Using the Developer Portal test tool is subject to the rate limit that is applied to an operation or Plan. For example, if an operation has a rate limit of 10 requests per minute and you invoke the operation, the number of requests that can be made is reduced to nine. The limitations are triggered every time that you click invoke within the minute interval. This caveat affects the quota of the App that is selected to use with the Developer Portal test tool, but it does not affect the quota of the other Apps that are using the same operation or Plan.

To test an API in the Developer Portal, the Allow this API to be tested check box must be selected in the API Manager. For more information, see Creating API definitions.

Restriction:

- There are security mechanisms that prevent you using the Developer Portal test tool to test an Implicit or Authorization Code grant type in an OAuth provider API. Other grant types in the same OAuth provider API **can** be tested. If your OAuth provider allows those actions to function correctly from the test tool, you can disable this option. For more information, see Disabling test tool restrictions.
- You cannot use the Developer Portal test tool with suspended applications.
- You can only test an unenforced API if `testable=true`, and if the existing API implements CORS and is using HTTPS.

Note: GraphQL APIs can be tested from the Developer Portal user interface. However, not all authentication methods are supported. You must use one of the following authentication methods:

- Unsecured
- Client ID, passed in the header
- Client ID and secret, passed in the header

Also, `cost` metrics are not supported, and rate limits specific to GraphQL are not listed in Product plans.

Procedure

1. To use the Developer Portal test tool with an API that does not require the client ID of an App, complete the following steps:
   a. Click API Products.
      All of the APIs that can be used by application developers are displayed.
   b. Click the name of the API that you want to test.
   c. Select an operation and then select Try It.
   d. Click Try this operation.
   e. Supply the values for required headers or parameters.
   f. If the operation is secured with Basic Authentication, supply the credentials.
   g. Click Send Request.
      The result is displayed in the Response Body field. You can continue to test different parameter values as necessary.
      Note:
      The first time that you click Try It, you might be presented with a security error. Copy the URL from the Request URL field, open it in a browser window, and accept the security certificate. You are not presented with the security error again.

      Also, for performance reasons, if the payload is large, more than 1500 DOM highlighted elements, you get the response, but it is not pretty printed.
2. To use the Developer Portal test tool with an API that does require the client ID of an App, complete the following steps:
   a. Sign in to the Developer Portal.

b. If you have not already done so, you must create an App so that you can test an API that requires a client ID. For more information, see Registering an application.
c. Ensure that your App is subscribed to the Plan that contains the API that you want to test. For more information, see Exploring APIs and Products in the Developer Portal.
d. Click API Products.
All of the APIs that can be used by application developers are displayed.
e. Click the *API* that you want to test.
f. Select the **`Provide credentials for Client ID (API Key)`** operation and then select Try It.
The API Key Identification window displays.
g. Use the Register an application in order to select a client ID drop-down list to select an App to test the API with.
h. Click Save credentials.
i. If a client secret is required, enter the value in the Client Secret field.
j. Find the operation that you want to test, then click Try It.
k. Supply the required parameters and values.
l. If the operation is secured with Basic Authentication, supply the credentials.
m. Click Send.
The result is displayed in the Response section. You can continue to test different field values as necessary.
Note: The first time that you click Invoke, you might be presented with a security error. Click the link that is provided to accept the security certificate. You are not presented with the security error again.

Related tasks

- Calling an API by using CORS

Calling an API

When you have a selected a Plan and you begin coding your application, you must retrieve the operation URL to call the API.

About this task

Be aware of the following points when you call APIs in IBM® API Connect:

- In the HTTP response message for status code 200 the reason phrase is replaced with OK.
- API error messages are displayed in English only.

Procedure

To retrieve the operation URL, complete the following steps:

1. Click API Products, then select a product.
2. Click the API that you want to work with.
The API overview page opens.
3. Select the operation you need and then copy the endpoint.
This is the URL that the application calls, and its structure is defined:

Type of API	URL
REST APIs	**`https://host/org/catalog/api/operation`**
SOAP APIs	**`https://host/org/catalog/api`** for all operations in the WSDL.

where:
   - *host* is the fully qualified host name of your gateway cluster.
   - *org* is the URL path of your organization.
   - *catalog* is the name of your Catalog.
   - *api* is the name of your API.
   - *operation* is the URL path of your operation.
4. Take note of any parameters, the request body, and the response body. Code your application to create the expected requests and handle the expected responses.

Depending on the Identify your application using setting for the API, you might have to provide a client ID, or client ID and client secret. To do this, complete the following steps:

5. To find the client ID, complete the following steps:
   a. Click Apps, then click the application name that you want to work with.
   b. Select the Show check box for Client ID.
   The client ID is displayed.
   c. Provide the client ID with the header parameter &client_id=
   For example, the URL used in the API might be:

   `https://host/org/catalog/api/quote?loanAmount=20000`

   but when you call it with a client ID of *1234*, change the URL to:

   `https://host/org/catalog/api/quote?loanAmount=20000&client_id=1234`

   Note: API Gateway only A client ID is generated automatically by API Connect when you register an application. However, if you specify a customized client ID, by using the CLI or REST API, then the length must not exceed 512 bytes, otherwise the gateway will reject the API request and return a **`401`** error.
6. The client secret is produced when you register an application. Provide the client secret with the query parameter &client_secret=. If you did not note the client secret when you registered the application, you must reset it; for information, see Managing applications.

The client ID, or client ID and secret can be logged along with the URL. Web servers usually log the URL in their access logs, which would give away the client secret. If you do not want to expose your client ID or secret in the URL, complete the following steps.

7. For the client ID, set the header, **`X-IBM-Client-Id`**, as part of the HTTP message that the application sends when it calls the API.
   An example URL statement might be:

   ```
   curl --header "X-IBM-Client-Id: 1234" https://host/org/catalog/api/quote?loanAmount=20000
   ```

   Note: API Gateway only A client ID is generated automatically by API Connect when you register an application. However, if you specify a customized client ID, by using the CLI or REST API, then the length must not exceed 512 bytes, otherwise the gateway will reject the API request and return a **`401`** error.
8. For the client secret, set the header, **`X-IBM-Client-Secret`**, as part of the HTTP message that the application sends when it calls the API.
   For example, the URL would be:

   ```
   https://host/org/catalog/api/quote?loanAmount=20000
   ```

   and set the following HTTP headers:

   ```
   X-IBM-Client-Id=1234
   X-IBM-Client-Secret=ABCD
   ```

What to do next

Monitor the API and application usage. For more information, see Managing applications.

- **Calling an API by using CORS**
  CORS (cross origin resource sharing) is a technique that allows calls to be made from code that is running in a browser to a third-party server (such as APIs running on an API Connect). These calls are, by default, not allowed as per the same origin security policy that is applied to the browser sandbox. Without CORS support, web developers are required to use more complex techniques such as server-side proxies.

Calling an API by using CORS

CORS (cross origin resource sharing) is a technique that allows calls to be made from code that is running in a browser to a third-party server (such as APIs running on an API Connect). These calls are, by default, not allowed as per the same origin security policy that is applied to the browser sandbox. Without CORS support, web developers are required to use more complex techniques such as server-side proxies.

About this task

Note: CORS support is available only on the DataPower® API Gateway.
API Connect Gateway servers support CORS to make it as easy as possible for web developers to use APIs within their web applications.
CORS is supported in the following browsers:

- Chrome 3+
- Firefox 3.5+
- Internet Explorer V11, or later
- Opera 12+
- Safari 4+

A CORS enabled browser automatically sends either a simple CORS request, consisting of the original request with the addition of the **`Origin`** header, or a preflight request followed by a simple CORS request.

An example CORS preflight request is as follows:

```
OPTIONS /org/env/api/resourceHTTP/1.1
User-Agent: useragent details
Access-Control-Request-Method: GET
Access-Control-Request-Headers: header names
Host: x.xx.xxx.xx
Origin: https://example.com
Accept: */*
```

You do not need to create CORS requests yourself, other than for testing or troubleshooting purposes.

A CORS response is received from the gateway; for example:

```
HTTP/1.1 200 OK
X-Backside-Transport: FAIL FAIL
Connection: Keep-Alive
Transfer-Encoding: chunked
Access-Control-Allow-Origin: https://example.com
Access-Control-Allow-Credentials: true
Access-Control-Allow-Headers:accept, accept-language, content-type, x-ibm-client-id
Access-Control-Allow-Methods: methods allowed on the resource
Vary: Origin
```

Applications in the Developer Portal

You can view, edit, configure, and create applications in the Developer Portal.

Before you can subscribe to a Plan that contains the API or APIs that you want to use, you must first register an application by creating an App. You can create more than one App, and these Apps can be edited and deleted as required.

To learn about applications in the Developer Portal, use the following topic links.

- **Registering an application**
  Before you can use an API, you must register your application to the Developer Portal.
- **Upgrading a Development application to Production status**
  If development application workflow is enabled for the Catalog associated with your Developer Portal, any new application that you register initially has Development status. When you have completed your application testing, you can request to upgrade your application to Production status.
- **Managing applications**
  You can show or reset a client ID for an application, verify or reset a client secret, and view the details of the APIs in the application. You can also unsubscribe from a Plan that the application is subscribed to.
- **Editing an application**
  You can edit applications in the Developer Portal. If a user has the correct permissions, they can edit the content of any application in their organization.
- **Deleting an application**
  You can delete applications in the Developer Portal.
- **Changing an application image**
  You can change the image for an application in the Developer Portal.
- **Verifying an application client secret**
  You can verify an application client secret in the Developer Portal

Registering an application

Before you can use an API, you must register your application to the Developer Portal.

About this task

When you register an application, you are provided with a client ID and client secret for the application. You must supply the client ID when you call an API that requires you to identify your application by using a client ID, or a client ID and client secret.

You can, optionally, add further client ID/client secret pairs to an application, any of which can be used to identify the application when calling an API.

Procedure

To register an application, complete the following steps:

1. Click Apps.
   The Apps page opens.
2. Click Create new app.
3. Optional: Specify a URL in the Application OAuth Redirect URL(s) field.
   You can specify multiple OAuth redirect URLs by clicking Add another item. If only one redirect URL is specified, and the application does not provide the `redirect_uri` in the OAuth request, then API Connect automatically uses the one redirect URL specified. However, if more than one redirect URL is specified, then the application must provide the `redirect_uri` in the OAuth request, or the OAuth request is rejected.
4. Click Submit.
   Your application is displayed.
5. The client secret is hidden; click the Show check boxes, make a note of your client secret because it is displayed only once.
   You must supply the client secret when you call an API that requires you to identify your application by using a client ID and client secret.
   Note: The client secret cannot be retrieved. If you forget it, you must reset it.
6. Optional: In the Certificate field, paste the public X509 certificate for your application, in PEM format.
   The Certificate field is available only if the APIs that have been published to the Developer Portal include at least one API that has been secured with TLS mutual authentication. You must complete this field if you want to call an API that has been secured with TLS mutual authentication. For more information, see Composing a REST API definition.

   These certificates are sent to the management server and to the gateway, and are used for certificate verification when the application calls an API that has been secured with TLS mutual authentication.

   Important: When you paste the certificate, ensure that it contains no line breaks, and that the `(-----BEGIN CERTIFICATE-----)` prefix and `(-----END CERTIFICATE----)` suffix are removed.
7. Optional: The client ID is hidden, to display the client ID for your application, click Subscriptions, then select the Show check box for Client ID.
   The client ID is displayed and can be hidden again by clearing the check box.
8. Optional: To verify your client secret, click Subscriptions, then click Verify, enter your client secret in the Secret field, then click Submit.
   You have confirmed whether your client secret is correct or incorrect.
9. To add an additional client ID and client secret to the application, complete the following steps:
   a. Click Subscriptions.
   b. Click Add alongside Credentials.
      The "Add new application credentials" window opens.
   c. Enter a name and an optional summary, and click Submit.
   d. Select the Show Client ID or Show Client Secret check box to display the client ID or client secret for the new credentials.
   e. To add a description to a set of client credentials, or to change the current description, click Update alongside the required credentials.
   f. To remove a set of client credentials from the application, click Delete alongside the required credentials.

   If you add additional credentials to an application, any of the associated client ID/client secret pairs can be used to identify the application when calling an API.
   Note: If you add two or more sets of client credentials to an application, OAuth tokens are not shared between them; each client credential set uses a different OAuth token.
10. To add an image, click Upload image from the application overflow menu.
    A new window opens; click Browse, select an image from your directory, and click Submit.
11. Optional: To change the URL that authenticated OAuth flows for this application should be redirected to, click Edit from the application overflow menu, then enter a URL in the Application OAuth Redirect URL(s) field.
12. Optional: To change the application name or description, click the Edit from the application overflow menu.

Results

Your application is registered.

What to do next

Select a Plan to use with your application, see Exploring APIs and Products in the Developer Portal.

Upgrading a Development application to Production status

If development application workflow is enabled for the Catalog associated with your Developer Portal, any new application that you register initially has Development status. When you have completed your application testing, you can request to upgrade your application to Production status.

Procedure

To request to upgrade a Development application to Production status, complete the following steps:

1. From the Developer Portal home page, click Apps.
2. Click the title of the application that you want to upgrade.
3. Click Upgrade to production, then click Request upgrade to confirm the upgrade request.

Results

An upgrade approval request is submitted. Your application continues to have Development status while the approval request is pending, and a Pending Upgrade label is displayed on the application details page. When the request is approved, you will receive a notification, and the application will move automatically to Production status.

If the request is rejected, the status of the application remains unchanged, and the Pending Upgrade label is removed.

Managing applications

You can show or reset a client ID for an application, verify or reset a client secret, and view the details of the APIs in the application. You can also unsubscribe from a Plan that the application is subscribed to.

About this task

On the application details page, you can display and reset a client ID and client secret. You might want to reset a client secret if it is compromised or you forget it. A client secret is only displayed once, so after you reveal it for the first time at a time of your choosing, you can use this window to verify that what you have is correct or reset it if necessary.

You can, optionally, add further client ID/client secret pairs to an application, any of which can be used to identify the application when calling an API.

Note: You can see the Add, Reset Credentials, and Reset API Secret options on the Applications page only if it is selected in the Configure the IBM API Developer Portal page under Applications. For more information, see Configuring the application settings.

Procedure

To manage an application, complete the following steps:

1. Click Apps.
   The Apps page opens.
2. Select the application that you want to work with from the displayed list.
3. Click Subscriptions.
4. The client ID is hidden; to display the client ID, select the Show check box. The client ID is displayed, and can be hidden again by clearing the Show check box.
5. To reset your client ID, click the options icon ⋮ and then click Reset Credentials.
   Warning: API calls made by the application with the existing client ID will fail.
6. If the client secret is compromised or you forget it, click the options icon ⋮ and then click Reset API Secret to generate a new value for the client secret.
7. If you are unsure whether the value that you have for the client secret is correct, you can click Verify, enter the value, and click Submit to confirm whether or not it is correct.
8. To add an additional client ID and client secret to the application, complete the following steps:
   a. Click Subscriptions.
   b. Click Add alongside Credentials.
      The "Add new application credentials" window opens.
   c. Enter a name and an optional summary, and click Submit.
   d. Select the Show Client ID or Show Client Secret check box to display the client ID or client secret for the new credentials.
   e. To add a description to a set of client credentials, or to change the current description, click Update alongside the required credentials.

f. To remove a set of client credentials from the application, click Delete alongside the required credentials.
If you add additional credentials to an application, any of the associated client ID/client secret pairs can be used to identify the application when calling an API.
Note: If you add two or more sets of client credentials to an application, OAuth tokens are not shared between them; each client credential set uses a different OAuth token.
9. To view more details about an individual API, click the API name.
The operations are listed.
10. To unsubscribe from a Plan, click Unsubscribe alongside the Plan name.

Editing an application

You can edit applications in the Developer Portal. If a user has the correct permissions, they can edit the content of any application in their organization.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the target application.
3. Click Edit from the application overflow menu.
4. Make any required changes, then click Submit.

Deleting an application

You can delete applications in the Developer Portal.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the required application.
3. Click Delete from the application overflow menu.
4. Click Delete again to confirm.

Changing an application image

You can change the image for an application in the Developer Portal.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the required application.
3. Click Upload image from the application overflow menu.
4. Browse for the target image, then click Submit.
You can remove the image by clicking Remove.

Verifying an application client secret

You can verify an application client secret in the Developer Portal

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the target application.
3. Click Subscriptions.
4. Click Verify for the client secret.
5. Enter your secret string and click Submit.
You receive a notification saying whether or not the secret that you entered is correct.

Analytics in the Developer Portal

You can view analytics for APIs in the Developer Portal at the application and organization levels. This information is displayed in dashboard views that show the analytics metrics in the form of *visualizations* (represented as charts).

Restriction:

- If the Catalog that is associated with this Developer Portal has two or more gateway services enabled then, for analytics data to be available, the gateway services must all be associated with the **same** analytics service. If the set of associated analytics services for the gateway services includes two or more different analytics services then the Developer Portal does **not** display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see Associating an analytics service with a gateway service.
- If the visualizations in your dashboard views display no data, show data only for a time period in the past, or the Dashboard tab does not show up, a possible reason might be that access to analytics data within API Connect has been switched off. Contact your API provider for confirmation.
- What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings. For more information, see Configuring analytics in the developer portal.

Use the following topic links to learn how to access the various analytics available to you in the Developer Portal:

- **Application analytics in the Developer Portal**
  From the Developer Portal, you can view interactive analytics information about all of the APIs used by an application.
- **Organization analytics in the Developer Portal**
  From the Developer Portal, you can view interactive analytic information about all of the APIs within an organization.

Application analytics in the Developer Portal

From the Developer Portal, you can view interactive analytics information about all of the APIs used by an application.

About this task

All members of the consumer organization can view analytics information relating to APIs used by an application.

Note: What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings. For more information, see Configuring analytics in the developer portal.

Procedure

1. Click Apps from the Developer Portal dashboard.
2. Click the name of the application for which you want to view analytics information.
   From the Dashboard tab, you can see your application analytics including, API Stats, Total Calls, and Total Errors.

Organization analytics in the Developer Portal

From the Developer Portal, you can view interactive analytic information about all of the APIs within an organization.

About this task

All members of the consumer organization can view analytics information relating to the APIs that are used within an organization.

Note: What API consumer analytics are displayed in the Developer Portal depends on the visibility configuration settings. For more information, see Configuring analytics in the developer portal.

Procedure

1. Click your userName from the Developer Portal dashboard.
2. From the drop-down menu, select My organization.
3. Click the Analytics tab.
   From the Analytics tab, you can see your organization analytics including, API Stats, Total Calls, and Total Errors.

Consumer organizations in the Developer Portal

Consumer organizations provide a way of grouping application developers together. You can add, remove, and configure Consumer organizations in the Developer Portal.

Developer Portal users must be a member of at least one Consumer organization. A Consumer organization can have multiple members and multiple applications. Members must register an application before they can subscribe to an API. A Consumer organization owns all the applications that are created within it. The members do not own any applications. As long as there is one member of a Consumer organization, all applications continue unchanged.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.
To learn more about Consumer organizations in the Developer Portal, see the following topics.

- **Adding a Consumer organization from within the Developer Portal**
  You can create a new Consumer organization from within your user account in the Developer Portal. The new Consumer organization appears also in the API

Manager UI after it is created.

- **Editing the name of a Consumer organization**
  You can edit the name of your Consumer organization from within the Developer Portal.
- **Switching Consumer organizations**
  You can switch from one Consumer organization to another in the Developer Portal.
- **Adding users to a Consumer organization**
  If the API Provider organization administrator has granted you permission to collaborate, you can invite users to join your Consumer organization. Those organization members can then access the Developer Portal and use the APIs that have been made available to the Consumer organization.
- **Removing a user from a Consumer organization**
  You can remove a developer from a Consumer organization in the Developer Portal.
- **Changing the ownership of a Consumer organization**
  You can change the ownership of a Consumer organization in the Developer Portal.
- **Deleting a Consumer organization**
  You can delete a Consumer organization in the Developer Portal.

Adding a Consumer organization from within the Developer Portal

You can create a new Consumer organization from within your user account in the Developer Portal. The new Consumer organization appears also in the API Manager UI after it is created.

Procedure

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page.
3. Select Create organization from the drop-down menu.
4. In the Organization Title field, type the name of the new Consumer organization, then click Submit.

Results

Your new Consumer organization is created, and you can switch to it by clicking on its name in the Organization drop-down menu on the home page.

Editing the name of a Consumer organization

You can edit the name of your Consumer organization from within the Developer Portal.

Procedure

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page, and click My organization.
3. In the Manage tab, click the vertical ellipsis Manage organization icon, and click Edit organization.
4. Enter the new name for your Consumer organization in the Organization Title field, and then click Submit.
   You changed the name of your Consumer organization.

Switching Consumer organizations

You can switch from one Consumer organization to another in the Developer Portal.

Procedure

1. If you are a member of more than one Consumer organization, click the menu of Consumer organizations in the Developer Portal home page.
2. Select the Consumer organization that you want to switch to, and ensure that any applications you register are registered to the correct catalog.

Adding users to a Consumer organization

If the API Provider organization administrator has granted you permission to collaborate, you can invite users to join your Consumer organization. Those organization members can then access the Developer Portal and use the APIs that have been made available to the Consumer organization.

About this task

Depending on the permissions enabled by the Provider organization administrator, members can view applications and application activity, create and edit applications, manage client keys and subscribe to API Plans, or perform all activities.
Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any

attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.

Procedure

To invite users to join your Consumer organization, complete the following steps.

Note: The ability to invite users is only visible if the API Provider organization administrator has granted you permission to collaborate.

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page, and click My organization.
   The organization page is displayed.
3. On the Manage tab, select Invite.
4. Enter the email address of the new user in the Email field.
5. Under the Assign Roles heading, use the radio buttons to select a role for the new user, the roles are:
   - **Administrator**-- Can administer the Consumer organization, including invite new members, and can create, and edit applications, manage client keys, and subscribe to API Plans.
   - **Developer**-- Can create and edit applications, manage client keys, and subscribe to API Plans.
   - **Viewer**-- Can only view applications and application activity.

   For full details of the permissions that are assigned to the Developer Portal roles, see API Connect user roles.
6. Click Submit.
   An invitation is sent to the new user.

Results

The user is added to the Consumer organization list of members, and they are sent an email inviting them to join the organization. The user must click the link that is provided in the email to activate their account, and complete the setup.

Removing a user from a Consumer organization

You can remove a developer from a Consumer organization in the Developer Portal.

Before you begin

You must be the owner of your Consumer organization and have previously added the developer you wish to remove from the organization.
Note that removing a user from a Consumer organization does not delete their user account, it only removes them from that organization.

Procedure

1. Click your user name in the Developer Portal home page.
2. Click My organization in the menu.
3. Click Remove user for the user you want to remove.

Changing the ownership of a Consumer organization

You can change the ownership of a Consumer organization in the Developer Portal.

Before you begin

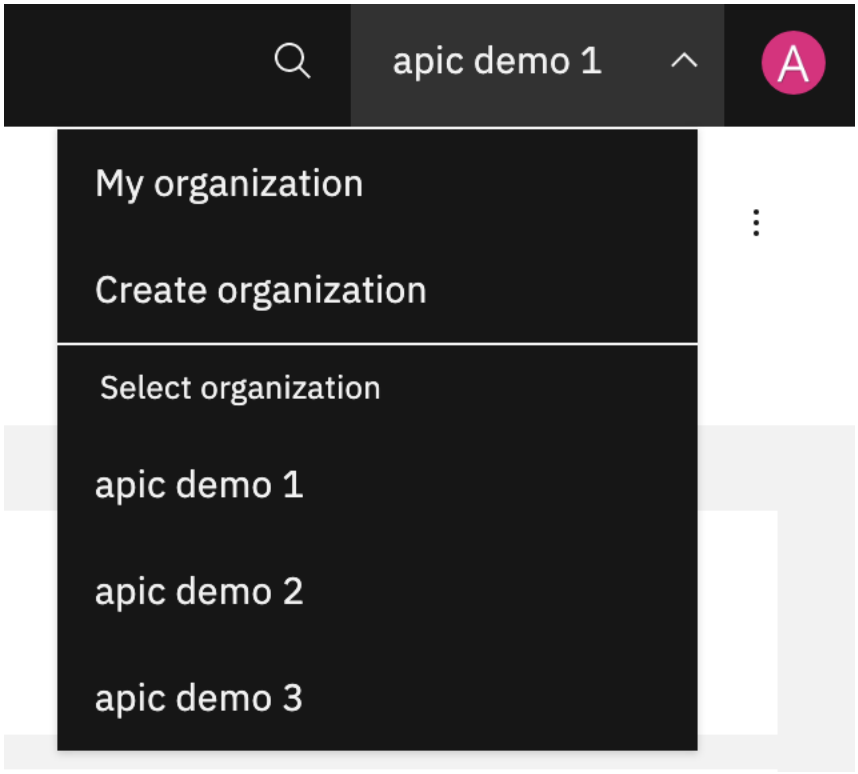
You can change the ownership of a Consumer organization only if you are the owner of that organization. The user that you transfer ownership to must already be a member of the organization. To have an account on a Developer Portal, you must be a member of at least one Consumer organization.

About this task

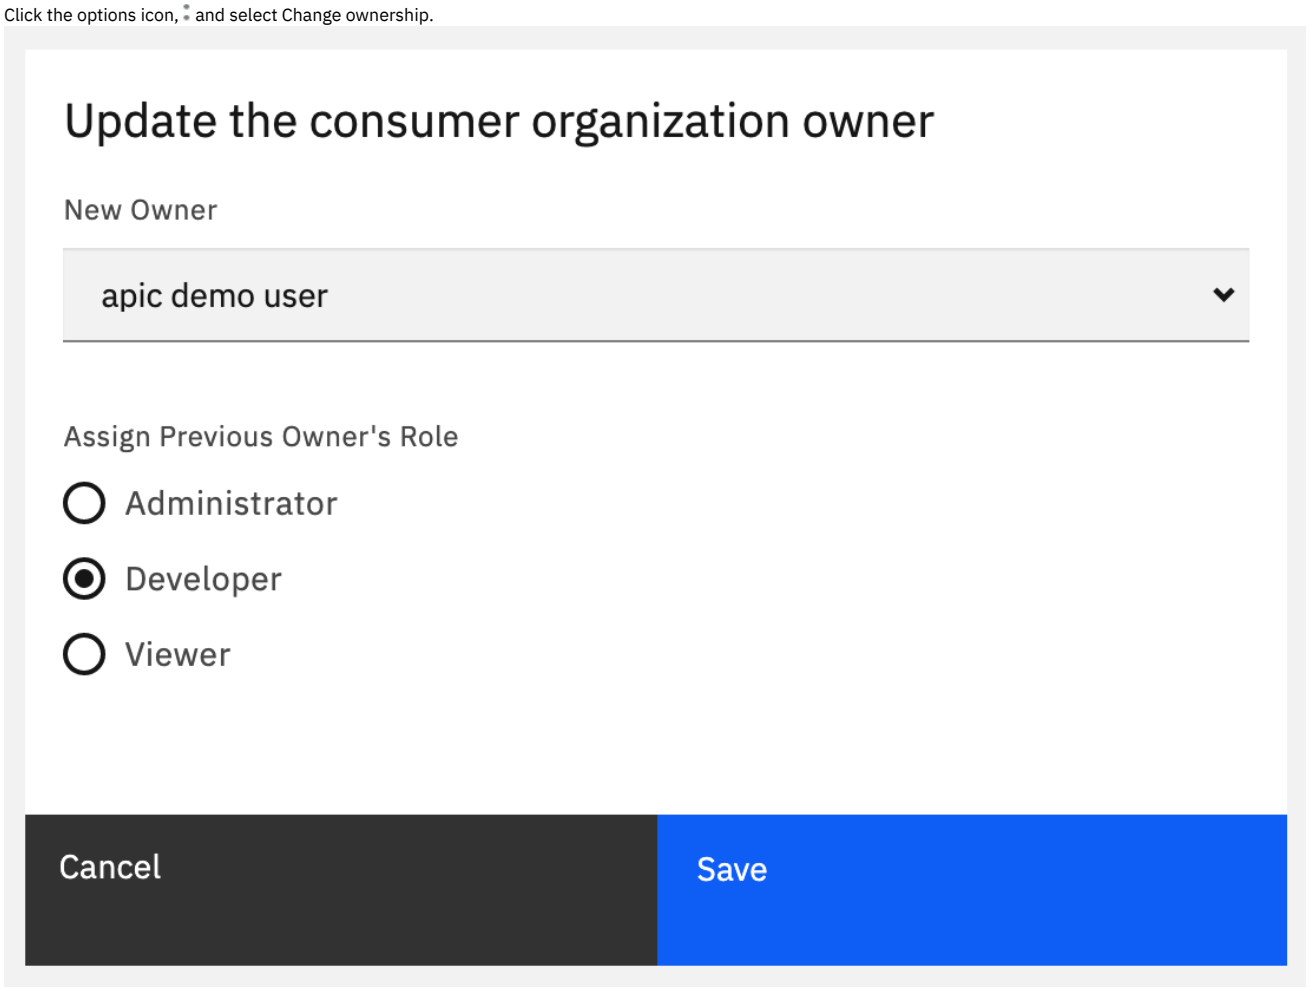
Transferring the ownership of a Consumer organization to another organization member, changes your role in that organization to App Developer.

Procedure

1. Click your Organization name in the Developer Portal home page, and select the organization whose owner you want to change by using the drop-down arrow.



2. Click your Organization name in the Developer Portal home page, and select My organization.
3. Click the options icon, ⋮ and select Change ownership.



4. Select the **`New Owner`** by using the drop-down arrow.
5. Use the radio buttons to **`Assign Previous Owner's Role`**, then click Submit.

Results

You successfully transferred ownership of a Consumer organization in the Developer Portal.

Deleting a Consumer organization

You can delete a Consumer organization in the Developer Portal.

Before you begin

You can delete a Consumer organization only if you are the owner of that organization. To have an account on a Developer Portal, you must be a member of at least one Consumer organization. Therefore, if you are a member of only one Consumer organization, to delete that organization you must first either join or create another Consumer organization, or you can delete your whole developer account. For more information, see Deleting your developer account.

About this task

Deleting a Consumer organization in the Developer Portal permanently removes access to the organization, and all of its applications and subscriptions, for all members of the organization. Consider carefully the impact on any members of your Consumer organizations before you delete the organization. Any users that were members of only the deleted organization, must create a new Consumer organization when they next logon to the Developer Portal.
Important: When an organization is deleted, it cannot be reactivated. You might want to consider changing the ownership of a Consumer organization, rather than deleting it. For more information, see Changing the ownership of a Consumer organization.

Procedure
